Premature death

Because leading causes of death vary by age, mortality rates by cause alone do not reflect the full societal impact of premature death. Estimating years of potential life lost (YPLL) is a way of quantifying the cost of early death by measuring the number of years between age at death and a standard age such as 75 years.

FIGURE 1

Leading causes of years of potential life lost (YPLL) before age 75, Oregon, 2017

Source: Oregon Death Certificate Data

During 2017, 251,628 years of potential life were lost before age 75 years among Oregon residents. The average potential years of life lost were 63% higher for deaths among males than among females (155,852 vs. 95,721).

Injury (both unintentional and intentional combined) ranks third among causes of death, but first among causes of YPLL. While injuries accounted for 8.5% of all Oregon resident deaths in 2017, they accounted for 27.0% of total YPLL (Figure 1).

Among racial/ethnic groups, the YPLL rate for American Indians and African Americans is 41% and 33% higher than whites, respectively. The rates for the Hispanic, multiple-race and Asian populations are 50%, 55% and 59% lower, respectively, when compared to the white population (Figure 2).

About the Data: Data source is Oregon Death Certificate Data. Data are based on the underlying cause of death listed on Oregon death certificate. Years of potential life lost for each Oregon death is calculated by subtracting the age at death from 75 years. For example, a person who dies at age 20 years would contribute 55 years to total YPLL, whereas a person who dies at age 80 would contribute nothing to YPLL.
