# 1.0 INTRODUCTION

The Jordan Cove Energy Project (JCEP) proposes to construct and operate the South Dunes Power Plant (SDPP), located in Coos Bay, Oregon, at the former Weyerhaeuser North Bend containerboard mill site. The mill was demolished in 2003 and the site is currently being used as an industrial waste landfill. Prior to the commencement of construction on the SDPP, the landfill will be closed and pre-construction activities will be conducted, including the placement of clean sand fill to approximately 46 feet in elevation on the majority of the site. Impacts to habitat and wildlife as result of these activities are discussed in this Exhibit.

The site of the proposed SDPP is located on the North Spit of Coos Bay, adjacent to Jordan Cove. Coos Bay/North Bend is the largest urban area located in the Coast Range Ecoregion, and is a center for the fisheries, forestry and transportation industries (ODFW 2006). Within the Coast Range Ecoregion, Coos Bay is located in the Coastal Lowlands, which are characterized by beaches, dunes and marine terraces below 400 feet in elevation (Thorson et al. 2003).

## 1.1 DEFINITION OF TERMS

The following terms are outlined in detail to provide context for the information presented in Exhibit Q. Figures 1, 2 and 3 of Exhibit C illustrate the site boundary and analysis area in closer detail.

### 1.1.1 Site Boundary

The Energy Facility Siting Council (EFSC) site boundary is defined as the area encompassing the temporary and permanent direct impact footprint of the project. The site boundary consists of 137.86 acres, and includes the area of the former mill site, along with all temporary laydown and staging areas, utility corridor, heavy haul road, and barge berth.

### 1.1.2 Analysis Area

The analysis area for state and federally listed species and associated habitat includes the area within the site boundary as well as a five-mile buffer in all directions.

## 1.2 EXHIBIT OVERVIEW

Exhibit Q identifies and evaluates state and federally threatened and endangered plant and animal species, in addition to federally listed critical habitat, that may be affected by the construction and operation of the proposed SDPP. Candidate and proposed species have been included in this analysis as they have the potential for listing during the application process. Potential impacts to threatened and endangered species and existing conditions from pre-construction activities at the site will be analyzed.

Exceptions to fill areas within the site boundary are shown in Exhibit P on Figures P-2 and P-3 and include narrow areas of dune forest other native habitats, some more weedy habitats, and Department of State Lands (DSL) jurisdictional wetlands and estuarine habitat. Please refer to Exhibit J for a discussion of jurisdictional wetlands, estuarine habitat and associated permits.

## 2.0 THREATENED AND ENDANGERED PLANT AND ANIMAL SPECIES

**OAR 345-021-0010(1)(q)** *Information about threatened and endangered plant and animal species that may be affected by the proposed facility, providing evidence to support a finding by the Council as required by OAR 345-022-0070.*

**OAR 345-021-0010(q)(A)** *Based on appropriate literature and field study, identification of all threatened or endangered species listed under ORS 496.172(2), ORS 564.105(2) or 16 USC §1533 that may be affected by the proposed facility.*

The State of Oregon and the federal government maintain separate lists of threatened and endangered species. Under Oregon Revised Statutes (ORS) 496.171-496.192, the Fish and Wildlife Commission, through the Oregon Department of Fish and Wildlife (ODFW), maintains the list of native wildlife species in Oregon that are threatened or endangered, according to criteria set forth by rules for the Wildlife Diversity Plan under OAR 635-100-0105. Plant listings are handled through the Oregon Department of Agriculture (ODA). Most invertebrates are handled through the U.S. Fish and Wildlife Service (USFWS) and the Oregon Biodiversity Information Center (ORBIC). Under federal law, the USFWS and National Marine Fisheries Service (NMFS) share responsibility for implementing the federal Endangered Species Act (ESA). In general, the USFWS has oversight over terrestrial and freshwater species, and NMFS over marine and anadromous species.

Twenty-three state listed species and 26 federally listed species occur, or have the potential to occur, in the analysis area evaluated for Exhibit Q. Figure Q-1 shows the analysis area for threatened and endangered plant and animal species, including the EFSC site boundary and the five-mile analysis area buffer. The assessment of impacts to listed species includes species within the SDPP site boundary and the larger analysis area

The construction, operation and retirement of the SDPP may affect, but is not likely to adversely impact, 18 state listed and 21 federally listed species and/or their designated critical habitat. Impact determinations, as well as a summary of justification for these determinations, are provided in Table Q-1 below.

**Table Q-1. State and Federal Threatened and Endangered Species Effects Analysis in the SDPP Analysis Area**

| ***Species*** | ***State Status***[1] | ***Federal Status***[2] | ***Effect***[3] | ***Potential to Occur***[4] | ***Justification***[5] |
|---|---|---|---|---|---|
| **Plants** | | | | | |
| Pink sand verbena *Abronia umbellata ssp. breviflora* | E | SOC | No Effect | Low | Habitat for the species may be found within the analysis area. Based on areas surveyed, however, the species is absent inside the site boundary, and suitable habitat would not be affected by the project. |
| Point Reyes bird's-beak *Chloropyron maritimum ssp* | E | SOC | NLAA | Present | Multiple occurrences were detected along the shoreline of Jordan Cove below the highest measured tide. Appropriate conservation and mitigation measures will be developed and implemented through consultation with the ODA to ensure that Point Reyes bird's-beak and potential suitable habitat for the species will not be impacted. |
| Silvery phacelia *Phacelia argentea* | T | SOC | No Effect | Low | Habitat for the species may be found within the analysis area. Based on areas surveyed, however, the species is absent within the site boundary and suitable habitat would not be affected by the project. |
| Western lily *Lilium occidentale* | E | E | NLAA | Low | The species has not been found in the SDPP site boundary found during focused surveys, and the areas to be impacted by the SDPP are not expected to include western lily habitat. |
| Wolf's evening primrose *Oenothera wolfii* | T | SOC | No Effect | Unlikely | Based on areas surveyed and lack of documented species in Coos County, the species is absent from the analysis area and would not be affected by the project. |
| **Amphibians and Reptiles** | | | | | |
| Green sea turtle *Chelonia mydas* | E | T | NLAA | Low | Shipping and barge traffic would be traveling at slow speeds within the analysis area (10 knots or less) |

[1] ORBIC July 2013, ODA 2013, ODFW 2013
[2] USFWS 9/11/13, NMFS 8/21/13
[3] SHN 2014 and JCEP/PCGP Draft Biological Assessment April 2014
[4] SHN 2014
[5] SHN 2014 (all species) and JCEP/PCGP Draft Biological Assessment April 2014 (federal species)

| ***Species*** | ***State Status***[1] | ***Federal Status***[2] | ***Effect***[3] | ***Potential to Occur***[4] | ***Justification***[5] |
|---|---|---|---|---|---|
| Leatherback sea turtle *Dermochelys coriacea* | E | E | NLAA | Low | making the potential for ship-strike extremely low. Ship noise would be detectable but would not permanent or temporarily impair hearing. |
| Loggerhead sea turtle *Caretta caretta* | T | E | NLAA | Low | |
| Olive Ridley sea turtle *Lepidochelys olivacea* | No Listing | T | NLAA | Low | |
| **Birds** | | | | | |
| Brown pelican *Pelecanus occidentalis* | E | Delisted | NLAA | Moderate (nearshore waters, foraging, non-breeding) | Incremental noise and human activities associated with the project are not likely to directly affect the brown pelican in the project area due to the pelicans' acclimation to current human-generated sounds and facilities in the bay area. Overhead transmission lines located inland will have bird flight diverters installed, and collisions are not anticipated during the pelican's flight path along Coos Bay. |
| Marbled murrelet (MAMU) *Brachyramphus marmoratus* | T | T | NLAA | Low (overhead, transient, possible foraging) | Suitable nesting habitat does not occur within the project footprint or within a range that could potentially affect the species by construction of the SDPP. Exposure to incremental noise by transient and foraging MAMUs in the analysis area is not expected to cause behavioral effects. Overhead transmission lines located inland will have bird flight diverters installed, and collisions are not anticipated. |
| Northern spotted owl *Strix occidentalis caurina* | T | T | No Effect | Unlikely | No suitable habitat occurs within the project vicinity that will be affected by construction, operation or retirement of the SDPP and the species is unlikely to be encountered in the analysis area. |
| Short-tailed albatross[(6)] *Phoebastria (Diomedea) albatrus* | No Listing | E | NLAA | Low (foraging off the coast) | The species is not expected other than possibly foraging off the coast. Shipping/barge traffic would be traveling at slow speeds within the analysis area (10 knots or less) making the potential for ship-strike extremely low. |

[6] Pacific Coast population

| ***Species*** | ***State Status***[1] | ***Federal Status***[2] | ***Effect***[3] | ***Potential to Occur***[4] | ***Justification***[5] |
|---|---|---|---|---|---|
| Streaked horned lark<br>*Eremophila alpestris strigata* | SC | T | NLAA | Low<br>(foraging along the shoreline) | Based on areas surveyed, the species is absent, and no suitable habitat occurs in or near the SDPP site boundary. Suitable habitat could occur on the north spit in the analysis area and while an occasional individual may show up on a sandflat to forage, the species would likely keep a distance and avoid close interactions with areas of human activity. Overhead transmission lines located inland will have bird flight diverters installed and collisions are not anticipated. |
| Western snowy plover<br>*Charadrius alexandrinus nivosus* | T | T | NLAA | Low<br>(foraging along the shoreline) | The primary nesting areas on the North Spit used by the western snowy plover are more than 4.5 miles from the Site boundary. Noise at nesting areas and critical habitat would not be above ambient levels. Avoidance and conservation measures will be in place to decrease the possibility of adverse effects to the species due to attraction of predators to the vicinity. |
| **Fish** | | | | | |
| Coho salmon [7]<br>*Onchorhynchus kisutch* | SC | T | NLAA | Nearshore waters<br>(foraging/migrating) | For all three species: The SDPP does not require water intake, and no entrainment or impingement would occur. Storm water from the SDPP site will be managed under Best Management Practices and either |
| Eulachon [8]<br>*Thaleichthys pacificus* | No Listing | T | NLAA | Nearshore waters<br>(foraging/migrating) | |

[7] Oregon Coast Evolutionarily Significant Unit (ESU)
[8] Southern Distinct Population Segment (DPS)

| *Species* | *State Status*[1] | *Federal Status*[2] | *Effect*[3] | *Potential to Occur*[4] | *Justification*[5] |
|---|---|---|---|---|---|
| Green sturgeon [(9)]<br>*Acipenser medirostris* | No Listing | T | NLAA | Nearshore waters (foraging) | (1) retained on site for infiltration in vegetated bioswales and ponds constructed to treat stormwater, or (2) collected in a separate system for treatment and discharge under the National Pollutant Discharge Elimination System ("NPDES") Individual Permit. Construction Stormwater will be managed under the revised NPDES Stormwater Construction General Permit No. 1200-C program managed by Oregon Department of Environmental Quality (ODEQ) for the Environmental Protection Agency (EPA). The permit regulates stormwater runoff to surface waters from construction activities that disturb one or more acres in Oregon. During operations on-site stormwater from impervious surfaces will be collected for infiltration on-site in bio-swales and ponds. Stormwater that comes in contact with industrial process, roof areas, maintenance areas, or chemical or petroleum storage areas will be collected in a separate stormwater system for treatment and discharge under the JCEP Individual NPDES permit to the ocean outfall as described in the SDPP Storm Water Management Plan developed in the 401 Certificate. All water quality criteria will be addressed through consultation with the ODEQ, ODFW, and NMFS during approval of the NPDES Individual permit and the Storm Water Management Plan required for the 401 Water Quality Certification. Potential impacts and mitigation, if necessary, will also be addressed during formal ESA consultation with NMFS for the overall JCEP LNG project that includes the construction, operation and retirement of the SDPP. |
| **Terrestrial Mammals** | | | | | |

[9] Southern Distinct Population Segment

| ***Species*** | ***State Status***[1] | ***Federal Status***[2] | ***Effect***[3] | ***Potential to Occur***[4] | ***Justification***[5] |
|---|---|---|---|---|---|
| Fisher<br>*Pekania pennanti*<br>(previously called *Martes pennanti)* | SC | C | NLAA | Unlikely | No fisher was observed during focused wildlife surveys of the area and there are no records of its presence. Moderate habitat for this species was found in the forested hillsides west of the facility; however, it is assumed that there is too much disturbance and that the forest is too immature and fragmented for the site to be used by fishers. |
| Gray wolf<br>*Eschrichtius robustus* | E | E | No Effect | Unlikely | Current ODFW tracking and distribution data available documents the gray wolf as occurring in four counties in Eastern Oregon. In the unlikely occurrence of a gray wolf within the SDPP analysis area, the species would likely keep a distance and avoid close interactions with areas of human activity. |
| **Marine Mammals** | | | | | |
| Blue whale<br>*Balaenoptera musculus* | E | E | NLAA | Coastal waters | For all eight species: limited barge traffic delivering construction materials for the SDPP would be traveling at slow speeds (10 knots or less as detailed in the Ship Strike Avoidance Measures for Whales for the JCEP) making the potential for ship-strike extremely low. Ship noise would be detectable and could exceed NMFS interim noise exposure criteria for Level B non-pulse noise but would not cause injury. This traffic for the SDPP would be temporary and occur during the construction phase of the project. There will be approximately 38 trips for construction of the SDPP over a period of 3 years, on average this will be about 13 trips per year.[10] |
| Fin whale<br>*Balaenoptera physalus* | E | E | NLAA | Coastal waters | |
| Gray whale<br>*Eschrichtius robustus* | E | Delisted | NLAA | Coastal waters | |
| Humpback whale<br>*Megaptera novaeangliae* | E | E | NLAA | Coastal waters | |
| Orcas [(11)]<br>*Orcinus orca* | No Listing | E | NLAA | Coos Bay (rare), coastal waters | |
| North Pacific right whale<br>*Eubalaena glacialis* | E | E | NLAA | Coastal waters | |
| Sei whale<br>*Balaenoptera borealis* | E | E | NLAA | Coastal waters | |
| Sperm whale<br>*Physeter macrocephalus* | E | E | NLAA | Coastal waters | |

[10] The following trips are estimated for the SDPP: 12 trips for the heat recovery steam generator, 6 trips for large process modules, and 20 trips for aggregate and road materials.
[11] Eastern North Pacific Southern Resident Stock

SC = Sensitive-Critical
SOC = Species of Concern

**Effect Determination:**
NLLA = May Affect, Not Likely to Adversely Affect
LAA = Likely to Adversely Affect

## 2.1 METHODOLOGY USED TO IDENTIFY THREATENED AND ENDANGERED SPECIES

### 2.1.1 Agency Consultation

Information about potential effects to listed species from the construction, operation and retirement of the SDPP is based on coordination and consultation, as applicable, with the following agencies and data resources: ODFW, ODA, USFWS and NMFS and ORBIC.

At the state level, consultation was conducted with the ODA for state-listed plant species and the ODFW for fish and wildlife species. State regulations pertaining to the protection of botanical resources are limited to ORS 564 and OAR Chapter 603, Division 73. State threatened and endangered plant species that could be present within the site boundary have no legal protective status in Oregon, as they would occur on private land, and Oregon regulations only apply on non-federal public lands (state, county, city, etc.). However, all lands below the highest measured tide are considered “waters of the state” under the jurisdiction of the Oregon DSL and are therefore protected.

For state-listed fish and wildlife species, consultation was conducted with the ODFW under the Oregon ESA (ORS 496, 506, and 509) and the Oregon Fish and Wildlife Habitat Mitigation Policy (OAR 345-022-0060) to ensure conservation of fish and wildlife resources, and to develop a fish and wildlife habitat mitigation plan, as appropriate.

### 2.1.2 Literature Review

Current state and federal threatened and endangered species lists were obtained for Coos County,[12] as well as an ORBIC list of rare, threatened, and endangered plants and animals within five miles of the site boundary.[13] In addition, the ORBIC list of Rare, Threatened, and Endangered Species of Oregon was reviewed for species that occur within the coastal range or are known to occur in Coos County (ORBIC 2013). The appropriate literature and field studies were used for each identified species to determine the nature, extent, locations, and timing of potential occurrences in the analysis area.

The species lists consulted are included as appendices for Exhibit Q, with the exception of the ORBIC data, which is site-specific and confidential per the data use agreement signed with ORBIC. The list of species included in Table Q-1 reflects the ORBIC data acquired, along with species known to occur, or with the potential to occur, from threatened and endangered species lists provided by the ODFW, ODA, USFWS, and NMFS. Additional state-sensitive species, federal species of concern, and other special-status species are addressed in Exhibit P.

## 2.2 FIELD SURVEYS

Site evaluations and surveys for listed species known to be present or potentially present within the general JCEP site boundary were conducted during the appropriate season for individual listed species as part of larger surveys for fish, wildlife, and vegetation in 2005, 2006, 2012 and

[12] USFWS 9/11/13, NMFS 8/21/13.
[13] Per ORBIC, the data provided is confidential for the specific purposes of the project and not to be distributed.

2013 (see Appendices P-2 through P-5).[14] The surveys conducted were designed to identify potential threatened and endangered species and associated habitat that may be affected by the construction, operation, and retirement of the SDPP.

### 2.2.1 Plants

Plant surveys for threatened and endangered species in or near the SDPP site boundary were conducted by SHN Consulting Engineers & Geologists, Inc. (SHN) from 2005-2006[15] and again in 2012 and 2013.[16] The survey methodology is described in the August 2013 Botanical Resources Assessment Report provided in Appendix P-3 (SHN 2013). More focused surveys were conducted in July and August 2013, which is a floristically appropriate time to identify the plant species of concern. A literature search for each species was also conducted to determine habitat requirements and current range information.[17]

Currently, there are 59 plant species that are administratively protected in the State of Oregon. Of these 59 species, 29 are listed as endangered and 28 are listed as threatened. Two species have been federally listed, but Oregon Administrative Rules have not yet been updated to grant the state protection conferred by federal listing (ODA 2013). In addition to threatened and endangered plant species, Oregon has 77 candidate species (ODA 2013).

Five listed plant species were identified as having the potential to occur in the SDPP analysis area.[18] Of the five listed species, the western lily is the only federally-listed species. The four state-listed species identified were the pink sand verbena (*Abronia umbellata* ssp. *breviflora*), Point Reyes bird's-beak (*Chloropyron maritimum* ssp. *Palustre*), silvery phacelia (*Phacelia argentea*), western lily (*Lilium occidentale*), and Wolf's evening primrose (*Oenothera wolfii*). Only one state-listed species – the Point Reyes bird's-beak – has been observed adjacent to the SDPP site boundary along the Jordan Cove shoreline (SHN 2013), along with documented occurrences along other Coos Bay shorelines (ORBIC 2013).

### 2.2.2 Wildlife

Wildlife surveys were conducted in 2005, 2006 and 2012. For the 2005 and 2006 wildlife surveys, LBJ Enterprises (LBJ) biologists visited the JCEP site on 15 separate occasions for one to two days each from late June 2005 to early November 2006. Rigorous surveys were conducted from late July 2005 to mid-April 2006. LBJ designed their survey methodology based on a preliminary site reconnaissance visit in June 2005, and coordinated with relevant agency personnel from the ODFW, USFWS and Bureau of Land Management (BLM). They designed and utilized a variety of survey techniques to document or assess the potential for occurrence of listed and other sensitive wildlife species (amphibians, reptiles, birds and mammals).

In 2012, surveys and associated research were conducted by SHN to reassess and update the LBJ surveys conducted in 2005 and 2006, and to determine whether any changes in conditions had

[14] LBJ Enterprises 2005-2006, SHN 2005, 2013, ABA 2006
[15] SHN Botanical Resources Assessment Report August 2006; SHN Addendum No. 1 August 2006; SHN Addendum No. 2 October 2006
[16] Botanical Resources Assessment Report August 2013
[17] Botanical Resources Assessment Reports are attached as appendices and the literature reviewed is included in the reference section of each.
[18] SHN Botanical Resources Assessment Report August 2006; SHN Addendum No. 1 August 2006; SHN Addendum No. 2 October 2006; SHN Botanical Resources Assessment Report August 2013

occurred at the project site. The surveys included the addition of sites within and adjacent to the SDPP site boundary to address changes in the proposed JCEP footprint. SHN biologists conducted field surveys from October 9-12, 2012 and consulted with the ODFW prior to conducting the surveys. During the course of the surveys conducted by SHN, biologists identified significant terrestrial biological resources, including significant habitats, state-listed species, and federally-listed species (SHN 2012). Wildlife survey reports produced by LBJ and SHN are included in Appendices P-2 and P-4.

#### 2.2.2.1 Birds

Six special status bird species have been identified within the analysis area: the brown pelican, marbled murrelet, northern spotted owl, short-tailed albatross, streaked-horned lark and western snowy plover (ORBIC 2013). The brown pelican is listed as endangered by the State of Oregon. The marbled murrelet, northern spotted owl, streaked-horned lark and western snowy plover are federally listed as threatened, while the short-tailed albatross is federally listed as endangered.

#### 2.2.2.2 Mammals

Two listed mammal species also are included in this exhibit. The fisher is a federal candidate species and the gray wolf population west of highways 395, 78 and 95 is federally listed as endangered.

#### 2.2.2.3 Fish

Three listed fish species have previously been observed in Coos Bay and have the potential to occur in the analysis area – the Oregon Coast ESU of Coho salmon, the southern distinct population segment (DPS) of Pacific eulachon, and the southern DPS of green sturgeon (ORBIC 2013). Alice Berg & Associates, LLC (ABA) produced a Fisheries Report in October 2006 describing the habitat subsystems that occur in Coos Bay, fish and invertebrate species known to occur, and habitat assessments for those species (see Appendix P-5).

#### 2.2.2.4 Marine Mammals

Eight listed whales have been identified as occurring, or having the potential to occur, in the analysis area for the SDPP. Of these eight species, only orcas have been observed entering Coos Bay on rare occasions. While the remaining seven whale species may occasionally occur along the Pacific Coast within the analysis area, their potential to occur within Coos Bay and be affected by the construction, operation or retirement of the SDPP is discountable and does not warrant further analysis (SHN 2013). However, extensive analysis of potential impacts to whales has been conducted for the JCEP LNG project, and JCEP will undergo formal consultation with NMFS for compliance with the federal ESA and the Marine Mammal Protection Act (MMPA).

# 3.0 NATURE, EXTENT, LOCATIONS, AND TIMING OF SPECIES OCCURRENCE

**OAR 345-021-0010(1)(q)(B).** *For each species identified under (A), a description of the nature, extent, locations and timing of its occurrence in the analysis area and how the facility might adversely affect it.*

The SDPP site, as a previously developed and extensively disturbed industrial site, has a low potential for the occurrence of threatened and endangered plant and animal species within the site boundary. The potential for impacts to listed species that are either known to occur, or have the potential to occur, within the five-mile analysis area is discussed below. The discussion focuses on species habitat requirements and existing conditions.

## 3.1 PLANTS

The five plant species with the potential to occur in the SDPP analysis area are discussed below. Surveys conducted at the SDPP site and adjoining areas that might be affected by the SDPP have not found threatened or endangered plant species, with the exception of the state endangered Point Reyes bird's-beak, observed outside the SDPP project footprint on state land along the shoreline (SHN 2006, 2013).

### 3.1.1 Pink Sand Verbena (State Endangered, Federal Species of Concern)

The pink sand verbena (*Abronia umbellata* ssp. *breviflora*) is the only pinkish-purple-flowered coastal *Abronia* species in Oregon. The historic range of pink sand verbena occurs from California to British Columbia, Canada. Its present range is predominantly from to Point Reyes National Seashore in Marin County, California to Cape Blanco in Curry Country, Oregon. The species does, however, sporadically occur along Oregon's northern and central coast. In the northern portion of its range, most populations occur on broad beaches and/or near the mouths of creeks and rivers. The species usually occurs on beaches in fine sand between the high-tide line and the driftwood zone, and in areas of active sand movement below the foredune. Associated species include sea rocket (*Cakile maritina*), silver burweed (*Ambrosia chamissonis*), European beachgrass (*Ammophila arenaria*), beach silvertop (*Glehnia littoralis*), and yellow sand verbena (*Abronia latifolia*).[19]

There is a successful population of pink sand verbena that was introduced to the North Spit within the western snowy plover habitat restoration area, approximately 2.6 miles away from the SDPP site boundary.[20] Not all species observed were flowering. Pink sand verbena is not likely to occur within the SDPP site boundary due to its distance from the coast (approximately 1.3 miles from its westernmost point). Botanical surveys conducted by SHN in 2006 and 2012, followed by surveys in 2013 in previously un-surveyed portions of the SDPP site, did not result in the detection of any pink sand verbena (SHN 2006, 2013).

[19] ODA website 2013
[20] SHN 2006, 2013; ODA website 2013; USFWS website 2013

Based on areas surveyed, pink sand verbena is absent from the project site and the construction, operation and retirement of the SDPP would not directly affect the species, or its potential habitat. Thus, impacts to pink sand verbena are not anticipated from construction, operation, or retirement of the SDPP.

### 3.1.2 Point Reyes Bird's-Beak (State Endangered, Federal Species of Concern)

Point Reyes bird's-beak (*Chloropyron maritimum* ssp. *Palustre*, formerly *Cordylanthus maritimus* ssp. *palustris*) is an annual gray-green and purple-tinged herbaceous species with pinkish to purplish red flowers that grows 4 to 16 inches tall and has few branched stems. The species flowers from June to October. Also referred to as salt marsh bird's beak, it occurs in coastal salt marshes, typically within the zone that is periodically or frequently inundated by high tides. Point Reyes bird's-beak habitat requirements are specific: approximately 7.5 to 8.5 feet above mean lower low water, sandy soils with soil salinity of 34 to 55 parts per thousand, and less than 30 percent bare soil in summer. Associated species include those that are tolerant of high salinity levels such as salt grass (*Distichlis spicata*), pickleweed (*Salicornia virginica*), fleshy jaumea (*Jaumea carnosa*), sea lavender/western marsh rosemary (*Limonium californicum*), and dodder (*Cuscuta salina*). Point Reyes bird's-beak occurs along the Pacific Coast from Tillamook County, Oregon south to Santa Clara County, California. In Oregon, the species is restricted to Netarts Bay, Yaquina Bay and Coos Bay, with the majority of known occurrences located in Coos Bay.[21]

Occurrences documented by ORBIC include multiple sites along the Coos Bay shoreline (ORBIC 2013) within the analysis area (Figure Q-2). These sites include each side of the bay closer to the harbor entrance; along the western and eastern shore of Jordan Cove; north and south of the Trans Pacific Parkway causeway bridge on the western side of Haynes Inlet; up to the west side of U.S. Highway 101 along Haynes Inlet; in the marsh on the east side of the airport; at multiple locations along Pony Slough across the bay; and on a dredge spoil island east of the Coquille Indian Tribe casino in Coos Bay (ORBIC 2013). In general, all detections occurred near the high tide line in open light with inundated moist sandy soil.

Focused botanical surveys were conducted during July and August of 2013 by SHN during the appropriate blooming period to document occurrences of Point Reyes bird's-beak in or near the JCEP project footprint. Multiple occurrences were detected along the shoreline of Jordan Cove, near Wetland J, and on the shoreline east of the SDPP site boundary, as shown in Figure Q-2. The habitat where Point Reyes bird's-beak was detected was below the highest measured tide, with pickleweed as the dominant associate species (SHN 2013). All detections were low lying and averaged 4-6 inches in height. Detections ranged from small patches of 3 to 9 individual plants, to large patches with an estimated 500 to 1,000 individuals.

All detections of Point Reyes bird's-beak were mapped by SHN surveyors using a Trimble R82 real time kinematic global positioning system accurate to within 0.1 foot. The surveys documented the relative abundances of the Point Reyes bird's-beak occurring within the SDPP site boundary and adjacent lands within the analysis area on the North Spit, and provided a

[21] SHN 2006, 2013; ODA website 2013; USFWS website 2013

qualitative and quantitative assessment of the populations, including information on numbers of individuals comprising the populations. Populations around the SDPP showed no obvious signs of disease or predation, or suspected negative impacts from past land actions.

The primary threat to Point Reyes bird's-beak is habitat loss due to development. The species is also threatened by off-road vehicle use, water pollution, and habitat alteration due to invasion by non-native dense-flowered cordgrass (*Spartina densiflora*),[22] which has not been observed along the SDPP shoreline.

It is not anticipated that populations of Point Reyes bird's beak outside of the site boundary would be affected by the construction, operation, or retirement of the SDPP. Within the site boundary, activities such as the construction of the power plant facility and associated infrastructure could potentially impact the species through erosion and sedimentation and encroachment on suitable habitat. The species is not anticipated to be significantly impacted by SDPP construction activities, however, because appropriate best management practices (BMPs) and mitigation measures will be implemented to ensure the species is preserved and protected. Avoidance and minimization measures are described in further detail in Section Q.6, and may include temporary and permanent erosion controls, fencing and the establishment of buffers to separate Point Reyes bird's beak populations from construction activities and a noxious weed control program. Appropriate mitigation measures will be developed and implemented through ongoing consultation with the ODA to ensure that suitable habitat for the Point Reyes bird's-beak will not be impacted by construction of the SDPP.

### 3.1.3 Silvery Phacelia (State Threatened, Federal Species of Concern)

Silvery phacelia (*Phacelia argentea*) is a hairy, fleshy perennial herb with thick leaves that are coated in long, straight, silvery hairs. It occupies open sand above the high tide line, open and partly stabilized sand dunes farther inland and coastal bluffs. It flowers from late May to early August. Silvery phacelia occurs in Coos and Curry Counties along the Oregon coast and in Del Norte County in California, from the vicinity of Bandon, Oregon south to Crescent City, California. The majority of occurrences are in Oregon.[23]

Suitable habitat for silvery phacelia exists in the analysis area and at the SDPP site in locations with active or semi-stabilized dune land and upper beach habitat where European beachgrass and red fescue-salt rush herbaceous vegetation associations occur. This habitat is considered moderate to highly suitable for supporting an occurrence of silvery phacelia. Focused surveys were conducted by SHN in 2013 in areas identified as suitable habitat that may be impacted by project activities within the JCEP project vicinity, including the SDPP site, and did not detect silvery phacelia (SHN 2013).

No silvery phacelia were detected during surveys conducted for the project. There are no anticipated impacts to suitable habitat for silvery phacelia during the construction, operation, or retirement of the SDPP, and, thus, no impacts to the species are expected.

---

[22] ODA website 2013
[23] SHN 2006, 2013; ODA website 2013; USFWS website 2013

### 3.1.4 Western Lily (State Endangered, Federal Endangered)

The western lily (*Lilium occidentale*) is one of the rarest plants on the west coast. It is a member of the perennial lily family (Liliaceae) and grows up to five feet tall with nodding red, sometimes deep orange, flowers. The species was federally listed as endangered in 1994 (USFWS 1994) and a final recovery plan was released in 1998 (USFWS 1998). Western lily inhabits 31 small, widely separated populations in freshwater marshes and swamps, coastal scrub and prairie, and openings in Sitka spruce dominated coastal coniferous forest along the coast of southern Oregon and northern California. It occurs within four miles of the coast, and is generally found on marine terraces 0 - 300 feet above mean sea level. The western lily is considered a bog plant and grows in areas with perched water tables which are associated with one or two soil types.[24]

The wetlands where western lilies occur are not traditional wetlands but are areas where the marsh is flooded in the winter and is typically very dry in the summer. The species emerges in Oregon in late March or early April and flowers in late June or July. Species typically associated with western lily include Sitka spruce (*Picea sitchensis*), Pacific reed grass (*Calamagrostis nutkaensis*), willows, false lily-of-the-valley (*Maianthemum dilatatum*), and evergreen huckleberry (*Vaccinium ovatum*). The closest known western lily occurrence to the site boundary is approximately 5.2 miles northeast at Hauser Bog (ORBIC 2013) and there are no records of the western lily north of Hauser Bog along the Oregon coast.

Seasonally timed focused surveys following USFWS protocol were conducted for the western lily by SHN from July 8-11, 2013 in areas identified as potential habitat for the species throughout the JCEP project area (Figure Q-2) and including the SDPP site (SHN 2013). The surveys yielded no detections of the species. In addition, no western lilies were observed at any time during SHN's site visits for the project. Complete information on the areas surveyed and findings are included in the August 2013 SHN Botanical Resources Assessment Report included in Appendix P-3.

The SDPP project is not likely to adversely affect the western lily. The species has not been found during focused surveys conducted for the JCEP project and the areas to be impacted by the SDPP are not expected to include western lily habitat. [25]

### 3.1.5 Wolf's Evening Primrose (State Threatened, Federal Species of Concern)

Wolf's evening primrose (*Oenothera wolfii*) is a rare species of flowering plant in the evening primrose family. It was removed by the USFWS as an ESA candidate species in1996 (61 FR 7597-7613) but continues to be listed as a federal Species of Concern, in addition to being listed by the state as threatened. It occurs in well-drained sandy soils in coastal strands, roadsides, and coastal bluffs. Wolf's evening primrose is associated with a high disturbance regime, and several occurrences in California are located along roadsides with sandy soil. Wolf's evening primrose is typically associated with low elevation coastal habitats, but there have been reported

[24] SHN 2006, 2013; ODA website 2013; USFWS website 2013 (unless otherwise noted)
[25] SHN 2013

occurrences in lower montane coniferous forest in California at elevations greater than 2,500 feet above mean sea level.[26]

The current range of Wolf's evening primrose is from Curry County in southern Oregon to the northern California coast. The closest known occurrence to the SDPP site is in Port Orford, Oregon (ORBIC 2013). The species was included in all botanical surveys conducted by SHN and is included in this analysis because suitable habitat exists within the analysis area and the SDPP footprint.

Despite the presence of suitable habitat, surveys conducted for the SDPP did not detect wolf's evening primrose and the closest known occurrence of the species is located approximately 60 miles to the south in Port Orford. Thus, the project is not anticipated to adversely affect the species (SHN 2013).

## 3.2 AMPHIBIANS AND REPTILES

No threatened or endangered amphibian species are known to occur, or anticipated to occur, within the SDPP analysis area.[27] Although the Oregon spotted frog was federally listed as threatened in August, 2014, this species does not occur, nor does it have the potential to occur within the site boundary or analysis area. No impacts to this species or potential critical habitat are anticipated, as the closest known populations of Oregon spotted frogs are located in Jackson and Klamath counties to the east (Appendix Q-8).[28]

Sea turtles are the only listed reptile species with the potential to occur in the analysis area.

### 3.2.1 Sea Turtles

Sea turtles are not known to nest on the Oregon coast, although they may occasionally be found in the Exclusive Economic Zone (EEZ), which extends from 12-200 nautical miles offshore.[29] Threatened and endangered sea turtles that have the potential to occasionally occur in the analysis area are listed below, followed by potential impact analysis for all sea turtles that may be encountered. General information, including distribution range for each species on the west coast, is provided below and was accessed through the NMFS website unless otherwise noted.[30] Potential effects to sea turtles within the analysis area are presented as a group analysis at the end of this section.

### 3.2.2 Green Sea Turtle (State Endangered, Federal Threatened)

Green sea turtles (*Chelonia mydas*) typically are found in warm tropical waters and, to a lesser extent, subtropical waters. Many facets of the green turtle's life history and ecology remain unknown, including details of its residence in, and use of, the U.S. Pacific Coast. The Pacific green sea turtle nests on tropical beaches in Hawaii and other islands of the Pacific, while the East Pacific green turtle is a separate population of the same species, nesting primarily on the

[26] SHN 2006, 2013; ODA website 2013; USFWS website 2013
[27] LBJ 2006; SHN 2006, 2012
[28] JCEP Draft Biological Assessment 2014, pages ES-6, 4-312 through 4-313
[29] NMFS website 2013
[30] http://www.nmfs.noaa.gov/pr/species/turtles/

coast of Mexico and in the Galapagos Islands. The species was listed as threatened under the federal ESA in 1978 (43 FR 32800), with the exception of the Florida and Mexico breeding populations. Except during breeding migrations, they tend to be found in shallow waters such as those inside reefs, bays, and inlets. The turtles are attracted to lagoons and shoals with an abundance of marine grass and algae. Green turtles have strong nesting site fidelity and migrate long distances between feeding grounds and nesting beaches. There is no known nesting by green turtles on the U.S. Pacific Coast.

Green turtles have been sighted from Baja California to southern Alaska, but most commonly occur from San Diego south. The northernmost resident population is a small population of approximately 30 turtles in San Diego Bay, reported in 1990 in the waters warmed by the effluent of a power plant. Green sea turtles primarily use three types of habitat: oceanic beaches for nesting, convergence zones in the open ocean, and benthic feeding grounds in coastal areas. No critical habitat for this species is located on the U.S. Pacific Coast. They are likely infrequent visitors to the Oregon coast, but may occasionally be found in the EEZ portion of the analysis area for the SDPP.

### 3.2.3 Leatherback Sea Turtle (State Endangered, Federal Endangered)

Leatherback sea turtles (*Dermochelys coriacea*) are the largest, most migratory sea turtle species, with the widest range of all extant sea turtles. Adult leatherback turtles are capable of tolerating a wide range of water temperatures and have been sighted as far north as the Gulf of Alaska. The species was federally listed as endangered in 1970 (35 FR 8491) and critical habitat was designated for the species by NMFS in 2012 along the Oregon and Washington coasts from Cape Blanco to Cape Flattery (77 FR 4170). Critical habitat includes nearshore waters within the analysis area for the SDPP.

Nesting occurs on sandy tropical beaches and no known nesting locations occur on the U.S. Pacific Coast. Their presence in the EEZ off the Pacific coast is unknown, although they are expected to occur within this zone. Peak numbers of leatherback turtles occur from July to September in neritic (coastal) zones, when intermittent decreases in upwelling allow surface water temperatures to increase. They aggregate in warm, highly productive coastal areas to forage on prey.

NMFS has defined nine geographic areas along the west coast from Washington to Northern California that are occupied by leatherback turtles. Area 2 is considered a principal foraging area for leatherbacks and includes nearshore waters from Cape Blanco, Oregon, to Cape Flattery, Washington, extending offshore to 2,000 meters in depth. They feed on a variety of moon jellies and brown sea nettles that are present in high densities associated with the Columbia River plume and Heceta Bank to the north.

### 3.2.4 Loggerhead Sea Turtle (State Threatened, Federal Endangered)

Loggerhead sea turtles (*Caretta caretta*) occupy three different ecosystems during their lives—the terrestrial zone, the oceanic zone, and the neritic zone. Loggerhead sea turtles are circumglobal in distribution, occurring throughout the temperate and tropical regions of the Atlantic, Pacific, and Indian Oceans. They are the most abundant species of sea turtle found in

U.S. coastal waters. There are nine distinct population segments (DPS) for loggerhead turtles under the federal ESA, with the North Pacific Ocean DPS (including the Oregon coast) listed as endangered in 2011 (76 FR 58868). Occasional sightings are reported along the coasts of Washington and Oregon, but most records are of juveniles off the coast of California. They are thought to spend much of their time in continental shelf waters closer to the shoreline looking for food.

Critical habitat was proposed for the North Pacific Ocean DPS; however, NMFS determined on July 18, 2013 that there are no areas meeting the definition of "critical habitat" for the DPS (78 FR 43005). Loggerhead sea turtles could potentially be encountered within the SDPP analysis area along the Pacific coast.

### 3.2.5 Olive Ridley Sea Turtle (No State Listing, Federal Threatened)

Olive Ridley sea turtles (*Lepidochelys olivacea*) occur within the tropical regions of the Pacific, Atlantic, and Indian Oceans. They are primarily pelagic sea turtles and have been observed as far as 2,400 miles from shore, but occasionally inhabit coastal areas. The species was federally listed as threatened in 1978 (43 FR 32800), except for the Mexican Pacific coast breeding populations, which were listed as endangered. Critical habitat has not been designated for this species.

Olive Ridley sea turtles undertake an annual migration from open ocean foraging grounds to coastal breeding and nesting grounds. Important nesting areas include the west coast of Mexico and Central America. Olive Ridley sea turtle populations have declined from former times, but are still the most abundant nesting turtle on the Pacific Coast. This species does not nest in the United States, but during feeding migrations may disperse into waters off the U.S. Pacific Coast as far north as Oregon. Although unlikely, Olive Ridley sea turtles could potentially be encountered within the SDPP analysis area along the Pacific Coast.

### 3.2.6 Sea Turtle Impacts

Sea turtles are generally found in warmer waters and occur only occasionally off the Oregon coast during migrations and foraging. There is no known nesting of any of the four species described above on the U.S. Pacific coast. Any potential effects to sea turtles would be related to offshore vessel traffic for the barge berth during construction, including ship strikes, underwater noise, and spills and releases at sea. Although they can be injured or killed when struck by a vessel, especially by an engaged propeller, such strikes are considered to be highly unlikely, given the limited number of barge trips estimated for the SDPP project, and the rarity of sea turtle occurrences in Coos Bay. Sea turtles can detect sound, and their hearing is most sensitive to lower frequencies within the same range of the low frequencies generated by vessels, therefore enabling sea turtles to avoid collisions. The noise produced by vessel traffic en route to Coos Bay is not expected to cause temporary or permanent threshold shifts in turtles' hearing given the limited number of barge trips and the limited occurrence of sea turtles in the analysis area. Any petroleum products released by vessels would include engine oil, lubricating oils, diesel fuel and/or gasoline. The background rate of spills off the Oregon coast by fishing vessels, recreation vessels, and other vessel types is generally low, and this frequency is expected to continue into the foreseeable future (Appendix Q-8).[31] Given the low population numbers and limited occurrence of sea turtles in Oregon coastal waters, it is considered unlikely that sea turtles would be affected by the SDPP project, and potential effects are judged to be insignificant.[32]

## 3.3 BIRDS

Five bird species listed as threatened or endangered occur, or have the potential to occur, in the analysis area and are discussed in the following paragraphs.

### 3.3.1 Brown Pelican (State Endangered, Federal Delisted)

The brown pelican (*Pelecanus occidentalis*), sometimes referred to as the California brown pelican, is found in nearshore waters, in large bays and river mouths, and on beaches and spits. These birds are rarely seen inland or more than 40 miles from shore, feeding mostly in shallow estuarine waters. Pelicans make extensive use of sand spits, offshore sand bars and islets for nocturnal roosting and daily loafing, especially by non-breeders and during the non-nesting season. They are most likely to be encountered in the coastal nearshore waters out to 0.3 mile.

In Coos Bay, brown pelicans are commonly known to occur from river mile (RM) 6 to the open ocean and are considered a common post-breeding migrant on the North Spit. They arrive from the south along the Oregon coast in April and become abundant by August and September. Although most brown pelicans have migrated to the south by December, small numbers now over winter most years in the Coos Bay area.

Coos Bay is considered foraging and roosting habitat for the brown pelican, with roosting occurring on the north side of the bay on the sunken jetty close to the bay mouth, on the sand spit of the North Spit, and on dredge spoil islands around RM 3 to 4. Onshore fish cleaning stations, often associated with boat ramps, may also attract brown pelicans to feed on offal. Coos Bay, adjacent to the SDPP site boundary, provides excellent habitat for this species. The species was recorded foraging near the SDPP site boundary more than 500 feet from the shore and loafing daily across the bay in moderate numbers during surveys conducted by SHN in October 2012. The species was also observed until early September during surveys conducted in 2005 and 2006 by LBJ. The analysis area provides no nesting habitat for the brown pelican. Nesting sites within the Coos Bay estuary have not been documented, and the species is not believed to breed in or near the project vicinity.[33]

It is likely that the brown pelican would be present within Coos Bay over the period of SDPP construction, operation, and retirement; however, no adverse impacts to brown pelican roosting and feeding habits are expected. The incremental noise, human activities, and low-level facility lighting associated with the SDPP are not likely to directly affect the brown pelican in the project area due to the pelicans' acclimation to current human-generated sounds and facilities already occupying the area.

[31] JCEP Draft Biological Assessment 2014, page 4-21
[32] JCEP Resource Report 3 2013; SHN 2013
[33] LBJ Enterprises 2006; SHN 2012, 2013; JCEP RR3 2013

Oil, gasoline or diesel spills are not likely to adversely impact the brown pelican since the background rate of spills by fishing, recreational and other vessels in Oregon is generally low and expected to continue to be low in the future (Appendix Q-8). Additionally, the current number of barge trips related to construction of the SDPP is estimated to be 38trips. All barges entering the bay will be pushed by tug boats with fuel capacities ranging from approximately 12,000 to 250,000 gallons (Ocean Class 2014, Tug Boat Sizes 2014). Tug boat contractors will have spill prevention and emergency response plans in place, and will be responsible for reporting any spills to the appropriate agencies. In addition to spill prevention and response plans maintained by vessel operators, a Geographic Response Plan (GRP) for Coos Bay has been developed by the ODEQ, United States Coast Guard (USCG) and EPA that prioritizes resources to be protected in the event of a spill, and allows for immediate and proper action (ODEQ 2004). All vessel operators in Coos Bay would follow the procedures outlined in the GRP in the event of a spill.

Overhead transmission lines located inland will have bird flight diverters installed, and collisions are not anticipated as pelicans fly along the bay. Pelicans appear unaffected by industrial activity already taking place in and around the bay, and no impact to this species is anticipated from construction, operation or retirement of the SDPP. [34]

### 3.3.2 Marbled Murrelet (State Threatened, Federal Threatened)

The marbled murrelet (*Brachyramphus marmoratus*) is a small, robin-sized, diving seabird that has a very short neck. It spends the majority of its time on the ocean roosting and feeding, but comes inland up to 50 miles to nest in forest stands with old growth characteristics. It was listed as threatened under the ESA in 1992 in Washington, Oregon, and California (57 FR 45328-45337). The Final Rule cited loss and modification of nesting habitats, mostly by commercial timber harvest of late successional and old-growth forests, as the principal threat to the species, along with effects of coastal oil spills and gill-net fishing operations off the Washington coast. In addition, critical habitat was designated for the marble murrelet in 1996 (61 FR 26256-26320). Following a series of proposed revisions in 2006 and 2008, a final rule on revised critical habitat was issued in 2011 (76 FR 61599-61621).[35]

Marbled murrelets nest from Alaska to Monterey Bay, California primarily in coastal old-growth forests that are characterized by large conifer trees, multi-storied stands, and moderate-to-high canopy coverage. The sexually mature adult murrelet generally lays a single egg on a mossy limb of an old-growth conifer tree. Not all adults nest every year. Both sexes incubate the egg in alternating 24-hour shifts until the young fledge from the nest in about 28 days and appear to fly directly to the sea upon leaving the nest. Nesting adults make daily foraging trips to shallow, protected, nearshore coastal waters, feeding mostly on small fish but sometimes on euphausiids. When at sea, marbled murrelets are rarely found more than a few miles out from the shore.[32]

The USFWS consults on projects within 0.25 miles of critical habitat for effects from construction with heavy equipment and within one mile for more-complex projects (Tuerler, personal communication). The USFWS is primarily concerned about removal of MAMU habitat

[34] JCEP RR3 2013
[35] USFWS species profile website, accessed 2013 and 2014, unless otherwise noted

and impacting the land, or the ability of the land, to grow trees. It is concerned also about possible predation to the species due to predators attracted to potential habitat in the vicinity by human activities (Tuerler, personal communication).

Based on guidance provided by the USFWS (Tuerler, personal communication), potential marbled murrelet nesting habitat does not occur within the SDPP analysis area. Although no individuals were observed during wildlife surveys conducted within the vicinity of the SDPP, it is considered possible that murrelets could fly over the bay within the analysis area and, perhaps, over the SDPP site while in transit between terrestrial nesting habitat and offshore feeding sites.[36] As the project will not affect nesting habitat or marine foraging habitat, the flyways used by murrelets in between these areas are the only areas within the analysis area where murrelets have the potential to be impacted by project activities.

There are two components of marbled murrelet habitat that are biologically important: terrestrial nesting habitat and associated stands, and marine foraging habitat. The closest documented marbled murrelet nests occur in designated critical habitat in the Elliott State Forest northeast of Coos Bay in the Oregon Coast Range, over 8 miles northeast of the SDPP site boundary and outside the analysis area (ORBIC 2013).

The species is considered an uncommon, year-round, offshore resident on the North Spit (LBJ 2006) and one to four murrelets are observed most years during the annual Coos Bay Christmas bird count (LBJ, 2006). The foraging habitat and potential for obstruction of marbled murrelet fly paths are discussed in the paragraphs that follow.

Marbled murrelets that forage offshore or in Coos Bay could be directly affected by: [37]

- Underwater noise generated during construction
- Disturbance during feeding by barge traffic
- Collisions with aboveground transmission lines within the SDPP site during daily flights to and from foraging areas.

The Draft BA for the JCEP (Appendix Q-8) used USFWS guidelines in the effects analysis for foraging marbled murrelets and concluded that the species is not expected to be exposed to ship noise that would cause harm, although they would likely detect noise from barges transiting the EEZ. Since murrelets forage in shallow offshore areas, they would not be expected to be exposed to high levels of shipping noise, but could potentially be exposed to noise from tugboats guiding barges into Coos Bay and to the barge berth. Although tug boat noise levels could reach 160 dB within 15 meters of the boat, exposure to that noise level is not expected to cause potential behavioral effects given the number of estimated barge trips and predicted murrelet densities in the analysis area (Appendix Q-8).[38] In addition, no underwater noise from pile driving is expected to impact diving murrelets in the analysis area because pile driving related to the construction of the barge berth would be land-based rather than being conducted in the

[36] LBJ 2006, SHN 2012
[37] JCEP/PCGP Draft BA April 2014 (Section 4, pages 132-137)
[38] JCEP Draft Biological Assessment 2014

water.[39] Risk of impacts to marbled murrelets from oil spills is similar to that of brown pelicans. The low background rate of spills in Oregon, minimal number of barge trips, fuel capacity of tug boats and existing prevention and emergency management measures in place suggest that the risk of an oil spill is low and marbled murrelets will not be adversely impacted.

Marbled murrelets may be susceptible to power line collisions due to their rapid flight speeds, which average 65 miles per hour when flying to the sea, and 55 miles per hour on returning landward flights. Murrelets fly at an average of 807 feet above ground level, although the lowest flight height reported was 203 feet. However, less than 0.1 percent of all individuals observed flew below transmission line heights. Therefore, flight height data for marbled murrelets suggest that flights would be above the top shield wires of the power poles (between 81 and 126 feet tall). Installation of bird flight diverters on the power transmission lines, as previously discussed, will also decrease potential adverse impacts to the marbled murrelets from transmission lines (Appendix Q-8).[40]

Minimal impact to foraging murrelets is anticipated from the construction, operation, or retirement of the SDPP. Although murrelets may occasionally fly over the analysis area and SDPP site, none were observed during site surveys and no nesting habitat is located within the analysis area (LBJ 2006, SHN 2013). Thus, no timing restrictions are currently in place to reduce noise impacts from construction of the SDPP during the marbled murrelet critical breeding season (approximately April 1 through August 15).

### 3.3.3 Northern Spotted Owl (State Threatened, Federal Threatened)

The northern spotted owl (*Strix occidentalis caurina*) was federally listed as threatened in 1990 by the USFWS (55 FR 26114-26194). The Final Rule cited declining populations due to loss and adverse modification of suitable habitat from timber harvest and natural catastrophes such as wild fire and windthrow, as well as inadequate regulatory mechanisms to protect the owl or its habitat (USFWS 1990).

The northern spotted owl is dependent on old-growth components in coniferous forests, and is extremely rare on the immediate coast of Oregon and in coastal Coos County. In Oregon, the owl is found in low- and mid-elevation coniferous forests in the Coast, Siskiyou, and Cascade mountain ranges, including many spotted owl habitat areas in the forests inland of Coos Bay. The nearest documented occurrence of a spotted owl nest to the SDPP site boundary is just inside the five-mile radius of the analysis area in the Kentuck Creek drainage (ORBIC 2013). The northern spotted owl is absent from the BLM North Spit wildlife list and is unlikely to be encountered in any of the terrestrial or aquatic habitat in or near the SDPP due to a lack of suitable habitat (BLM 2006).[41]

No spotted owls were observed during wildlife surveys at the site, nor will any mature or old-growth forest be affected by construction, operation or retirement of the SDPP. Consequently, no adverse effects to the northern spotted owl are anticipated as a result of the project.

[39] JCEP Draft Biological Assessment 2014, pages 4-132 to 4-134
[40] JCEP/ Draft Biological Assessment 2014, pages 4-135 to 4-136
[41] USFWS species profile website, accessed 2013 and 2014, unless otherwise noted

### 3.3.4 Short-Tailed Albatross (State No Listing, Federal Endangered)

The short-tailed albatross (*Phoebastria albatrus*) is the largest pelagic seabird in the North Pacific. Its long, narrow wings are adapted to soaring low over the ocean. It is best distinguished from other albatrosses by its large, bubblegum-pink bill. The short-tailed albatross was federally listed as endangered throughout its range in 2000 (65 FR 46643-46654). Critical habitat has not been designated for this species given the great distances it travels over the ocean. A recovery plan was finalized for the species by the USFWS in 2009 (74 FR 23739-23741).

Historically, millions of short-tailed albatrosses bred in the western North Pacific on several islands south of the main islands of Japan. Only two Japanese breeding colonies remain active today. Single nests occasionally occur on Midway Island, west of Hawaii. Eggs hatch in late December through early January, and chicks remain near the nest for about 5 months, fledging in June. After breeding, short-tailed albatrosses move to feeding areas, with juveniles remaining at sea up to 10 years before returning to nest. The species is distributed widely throughout its historical foraging range of the temperate and subarctic North Pacific Ocean, is often found close to the U.S. coast, and has been known to forage up to 1,988 miles from its breeding ground.[42]

The short-tailed albatross population is estimated at 1,200. Of these, the total number of breeding-age birds is thought to be approximately 600. The worldwide population of short-tailed albatrosses continues to be in danger of extinction throughout its range due to natural environmental threats, small population size, and the small number of breeding colonies. Longline fishing, plastics pollution, oil contamination, and airplane strikes are considered threats to the conservation and recovery of the species. Short-tailed albatross have been noted to occur off the Oregon coast (LBJ 2006; SHN 2012); the closest observation to Coos Bay being recorded approximately 75 miles to the north, off the coast of Yachats in 2010 (ORBIC 2013).

Short-tailed albatrosses spend much of their time feeding in nutrient-rich waters of ocean upwelling, which often occur at continental shelf breaks. The short-tailed albatross would not occur in Coos Bay adjacent to the SDPP site, but could occur in the analysis area along the Pacific Ocean, approximately 1.3 miles west of the SDPP site boundary.

Within the analysis area, effects to the short-tailed albatross would be associated with barge traffic transecting the EEZ perpendicularly as they approach and depart from Coos Bay. Shipping traffic would be traveling at slow speeds (10 knots or less), making the potential for ship-strikes extremely low. Risk of oil spills impacting the short-tailed albatross is similar to that for brown pelicans and marbled murrelets. None of the factors that threaten the short-tailed albatross would result from any component of the proposed SDPP project; thus, adverse impacts to this species are not anticipated as part of the project.

### 3.3.5 Streaked Horned Lark (State Sensitive-Critical, Federal Threatened)

The streaked horned lark (*Eremophilia alpestris strigata*) was listed as a threatened species under the federal ESA in October, 2013 (78 FR 61451-61503). In addition to the listing, critical habitat was proposed for seven counties in Washington and 11 counties in Oregon, but did not

[42] USFWS species profile website, accessed 2013 and 2014, unless otherwise noted

include Coos County. The closest county with critical habitat is Lane County to the north. The population of streaked horned larks remaining in the world is estimated between 500 and 1,000 individuals, and preliminary genetic analysis suggests that the remaining birds have little genetic diversity. The remaining populations are vulnerable to all of the threats small populations commonly face such as environmental and demographic variability and the loss of genetic variability.

The streaked horned lark is a rare subspecies of the horned lark. It migrates between Oregon and Washington, with breeding populations found in the Puget Sound lowlands, Columbia River/coastal Washington, and the Willamette Valley in Oregon from late March to early August. Some individuals winter in California and occur along the Oregon coast during migration, while a few winter on the coast. The species occurs in bare and sparsely vegetated habitats such as coastal dunes, beaches, gravel roads, airport runways, grazed pastures, and dry mudflats; however, it does not occur on rolling or steep areas at these sites. Where deflation plains occur, streaked horned larks are often found behind the foredune. Larks also occur where dredge spoils have been deposited, or in areas where there is accretion (deposition) of sand causing beach areas to become wider, provided the sites are sparsely vegetated and are immediately adjacent to water. [43] For the species to inhabit sites that aren't adjacent to water, the area of expanse has to be quite large, likely 300 acres or greater, although further studies are needed (Pearson, personal communication).

During winter surveys conducted in 2004 and 2005 by the Washington Department of Fish and Wildlife (WDFW), streaked horned larks were found on the Washington coast on dune and beach habitat adjacent to open water with few or no trees and shrubs. On the lower Columbia River, they were primarily found on sparsely vegetated dredge spoils (Pearson and Altman 2005). The streaked horned lark has been documented by BLM on the North Spit and may over winter on the southern Oregon coast (BLM 2006). It spends the winter in large groups of mixed subspecies of horned larks in the Willamette Valley, and in smaller flocks along the lower Columbia River and Washington Coast (Pearson and Altman 2005).

When new unvegetated land is created by dredge spoils and sand accretion, it is not used by larks for the first year or two after deposition. Once the site becomes sparsely vegetated, it can be quickly colonized by larks, especially on fill where there is no off-road vehicle traffic. There is a fairly narrow window of time when habitat is sparsely vegetated and suitable for larks. As sandy habitats on the coast continue to be colonized by beach grasses, streaked horned larks do not use these habitats for breeding or over-wintering once the site becomes densely vegetated. Similarly, fill colonized by Scotch broom (*Cytisus scoparus*) or horsetail (*Equisetum* spp.) is not used by the species (Pearson and Altman 2005).

A focused field evaluation within the SDPP site boundary was conducted by SHN staff on April 23, 2013 to assess the presence of suitable habitat for streaked horned larks. One small area of approximately 75 by 150 feet was noted at the SDPP site; however, it is surrounded by the footprint of the former industrial mill site and is not adjacent to open water. Along the utility corridor and access road between the SDPP and JCEP sites, sparsely vegetated portions of

[43] USFWS species profile website, accessed 2013 and 2014, unless otherwise noted

rolling and, at times, steep, dunes were noted. Again, these sites were not adjacent to open water. Based on a literature review and personal communication with Dr. Scott Pearson of the WDFW, potential suitable habitat within the SDPP site boundary was discounted.[44]

The proposed SDPP project will result in the disturbance of a small amount of low grassland habitat and conversion of bare ground areas to a filled site. Construction and operation activities occurring near habitat used by streaked horned larks migrating through or over-wintering in Coos Bay could potentially affect foraging activities, causing the birds to relocate or alter their behavior to spend more time on the alert and less time foraging.

Although industrial development has reduced habitat available to breeding and wintering larks, potential adverse effects to streaked horned lark populations from construction, operation, and retirement of the SDPP are anticipated to be negligible.[45] In consultation with Dr. Scott Pearson, it was determined that suitable habitat is likely not present near the SDPP site due to the lack of open water immediately adjacent to the few locations where sparsely vegetated lark habitat potentially exists. In addition, encroachment by European beachgrass and other noxious weed species further reduces the suitability of potential lark habitat, especially given the large amounts of more suitable habitat on the North Spit and along the coast that remain relatively undisturbed by human influence (Pearson, personal communication).

In addition to a lack of suitable habitat, bird surveys conducted to date did not identify the presence of streaked horned larks within the SDPP vicinity. While fill placed on the SDPP site could become suitable habitat for the streaked horned lark, disturbance at the site from construction, operation and retirement activities will prevent it from becoming vegetated and developing into suitable habitat. An occasional individual may show up to forage; however, the ensuing development within the site boundary is likely to preclude the continued use by individuals in the project vicinity. Other more suitable habitat is available on the North Spit, including the critical habitat established for the western snowy plover. While streaked horned larks may be encountered within the SDPP analysis area, they likely would keep a distance and avoid close interactions with areas of human activity. No adverse impacts to the streaked horned lark population are anticipated from the construction, operation, or retirement of the SDPP.[46]

### 3.3.6 Western Snowy Plover (State Threatened, Federal Threatened)

The western snowy plover (*Charadrius alexandrinus nivosus*) is a small shorebird approximately six inches long with a thin, dark bill. The extent of the Pacific Coast breeding population includes Oregon, with coastal populations typically consisting of resident and migratory birds. The North Spit of Coos Bay supports the most-productive snowy plover population segment on the Oregon coast.

The Pacific Coast population of the western snowy plover has been listed as a threatened species under the federal ESA since 1993 (58 FR 12864). In addition to being listed as threatened under the ESA, critical habitat was designated for the Pacific Coast population in 2000. The most

[45] JCEP Resource Report 3, May 2013
[46] JCEP Resource Report 3, May 2013

recent revised designation of critical habitat was in 2012 and includes 273 acres on the North Spit of Coos Bay, primarily along the ocean sand beach (77 FR 36727-36869). A recovery plan for the species was finalized by the USFWS in 2007. Objectives in the recovery plan include achieving well-distributed increases in numbers and productivity of breeding adult birds, and providing for long-term protection of breeding and wintering plovers and their habitat. In 2010, the USFWS, along with other federal agencies and the State of Oregon, signed off on a statewide Habitat Conservation Plan (HCP). Consequently, the Oregon Parks and Recreation Department (OPRD) is required to submit an annual report to USFWS documenting management actions from the previous year, which includes snowy plover population data, snowy plover take occurrences, recreational use enforcement issues, and anticipated management efforts for the following year.[47]

The southwestern portion of the North Spit is designated as critical habitat for the western snowy plover from the ocean beach at Horsfall to the Coos Bay north jetty, and includes all federal lands at the south end of the spit (USFWS 2012). The SDPP site boundary is approximately 1.3 miles from the northern extent of the critical habitat, and more than 4.5 miles from primary nesting areas. The closest known snowy plover nest is more than three miles from the SDPP site (ORBIC 2013). Nesting in Oregon may occur as early as mid-March, with peak nest initiation occurring from mid-April through mid-July.

On the coast, the western snowy plover inhabits sand beaches almost exclusively. It is unlikely that this species would nest in or around the SDPP site boundary due to the lack of primary habitat for the species, as its typical coastal nesting habitat is at the upper edge beaches, below the foredunes. It also nests on bare spits at small estuary mouths and, on the North Spit, is most prevalent on restored sand habitat east of the foredune.

The western snowy plover hatch rate at the North Spit in 2012 was the highest on the coast and the highest since predator management was implemented in 2002. In 2012, the site continued to be the most productive in Oregon, with 58 broods (nine more than in 2011) and an overall brood success rate of 59 percent (Lauten et al 2012). The hatch rate in 2013 was considerably lower than the previous two years, and similar to 2010 when the lowest ever rate was recorded for the site (Lauten et al 2013). There were 29 total broods in 2013, nearly half the number recorded in 2012, and the overall fledging success rate was the lowest ever recorded for the site. Due to the relatively low number of fledglings, the productivity index was the lowest ever recorded for the site and well below the post-predator management average (Lauten et al 2013).

In the past, predation by corvids (crows, ravens, jays, magpies, etc.) has been the main cause of known nest failure noted in distribution and reproductive success reports prepared for ORBIC. In 2013, however, 15 nests were confirmed on the North Spit as being depredated by northern harriers (*Circus cyaneus)*, a medium-sized hawk, through video evidence or tracks at the nest site. Corvid activity was very low to non-existent all summer and harrier depredation is suspected for most if not all of the known depredations at the site. Wildlife Services removed two harriers toward the end of the nesting season, and it is hoped their removal will result in future benefits and better nest success in 2014 (Lauten et al 2013). Other threats to western

[47] USFWS species profile website, accessed 2013 and 2014, unless otherwise noted

snowy plovers include the introduction of European beachgrass that encroaches on available nesting and foraging habitat, and disturbance from humans, dogs, and off-highway-vehicles in important foraging and nesting areas.

Current management activities and use restrictions within the North Spit Recreation Management Area relative to the snowy plover population include predator management, symbolic fencing, habitat restoration, public outreach and education by BLM staff, monitoring of snowy plover populations, and seasonal recreational use restrictions. Beginning annually on March 15th, signs and ropes are used to inform the public of sensitive western snowy plover nesting areas and to direct the public to non-sensitive areas where recreational activities are permitted. At these marked beach areas, beachgoers still have access to the wet sand portion of the beach to enjoy passive recreational activities such as walking and horseback riding. All recreational activities within the dry sand areas, however, are prohibited. Access restrictions are in effect through September 15th, but may be lifted early if there is no more nesting by July 15th.[48]

There does not appear to be any suitable plover nesting habitat within the SDPP project area and no plovers were detected during field surveys from 2005 to the present. While an occasional individual may use the sandflats adjacent to Jordan Cove for foraging, breeding is unlikely (LBJ 2006, SHN 2012).

When the SDPP site is filled with sand, potential snowy plover habitat could be temporarily created; however, given the level of disturbance at the site from construction, operational and retirement activities, it is unlikely that snowy plovers would utilize fill areas.

The SDPP project does not add elements other than increased human activity that are likely to attract snowy plover predators identified along the Oregon coast, including corvids, harriers, and mammals such as the red fox, raccoon, striped skunk, black rat, and feral cat. Increased nest predation of western snowy plovers within the SDPP analysis area is possible, particularly if predators are attracted to construction sites by garbage or discarded food. An increase in the numbers of these predators could be detrimental to the continued recovery of snowy plover populations. However, the distance to the closest documented plover nest makes increased nest predation as a result of SDPP activities unlikely.

No threats to the western snowy plover are anticipated from the construction, operation, and retirement of the SDPP due to the lack of nesting habitat in or near the site boundary. Efforts will also be made to discourage nesting activity after fill is placed on the SDPP site. Additionally, no impacts are anticipated from collisions with transmission lines in the utility corridor, as bird flight diverters will be installed on the power lines, which have been shown to reduce collisions, increase behavioral avoidance, and decrease bird mortality (Appendix Q-8).[49] Implementation of additional mitigation measures for the project, discussed in detail in Section 7.0, will address predator species such as corvids, harriers, and mammals that may be drawn to the site by human activity.

[48] JCEP Resource Report 3, May 2013
[49] JCEP Draft Biological Assessment 2014

## 3.4 MAMMALS

### 3.4.1 Fisher (State Sensitive-Critical, Federal Candidate Species)

The fisher (*Martes pennanti)* is a large weasel that inhabits forests with high canopy closure, large trees and snags, large woody debris, large hardwoods, and multiple canopy layers. Fishers are known to have very large home ranges and to wander widely. They avoid areas lacking overhead canopy cover and disturbance by humans. Fishers also occupy and reproduce in some managed forest landscapes and forest stands not classified as late-successional that provide some of the habitat elements important to the species.

The fisher was nearly extirpated from Oregon by logging and trapping and is now very rare. Reintroductions have been attempted in several inland counties, and there have been recent sightings in the mountains east and west of the Willamette Valley. The BLM Coos Bay District wildlife sightings database contains several fisher observations in Coos County, but none of these sightings was in the vicinity of the North Spit or the SDPP site boundary. The closest sighting to the SDPP site was in 1991, when an adult fisher was seen near Daniels Creek, approximately 10 miles southeast of the site boundary. The presence of the fisher on the North Spit is unlikely given the rarity of the species and the lack of large, well-connected tracts of mature forest with continuous canopies. Most forested areas on the North Spit are interspersed with areas of open sand and fishers are reluctant to cross openings greater than 25 meters (BLM 2006). Furthermore, fishers on the North Spit would be separated from Coast Range populations by Highway 101, human development, and fragmentation of mature forests.[50]

Although the species has the potential to occur on the North Spit (BLM 2006) and porcupines, one of the fisher’s preferred prey species, are present in the SDPP area, there are no records of its presence and no fishers were observed during focused wildlife surveys of the area.[51] Moderate habitat for this species was found in the forested hillsides west of the facility; however, this habitat is likely too disturbed and the forest too immature and fragmented for the site to be suitable for fishers (LBJ 2006). Because of the lack of observation of fishers in the SDPP site vicinity and the lack of suitable habitat in the vicinity of the site boundary, no impacts to the fisher are expected from construction, operation, or retirement of the SDPP.

### 3.4.2 Gray Wolf (State Endangered, Federal Endangered)

Gray wolves (*Canis lupus*) in Oregon are listed statewide as endangered under the Oregon ESA, and wolves occurring west of Oregon Highways 395,78 and 95 continue to be federally protected as endangered under the ESA since 1978 (43 FR 9607-9615). The USFWS is in the process of evaluating the classification status of gray wolves and has proposed to delist the populations currently listed as endangered in the contiguous U.S. (79 FR 7627-7629). If delisted, the endangered status of the Mexican wolf (same species) would be maintained by listing it as a subspecies (*Canis lupus baileyi*). In the federally listed portion of Oregon, the ODFW implements an Oregon Wolf Conservation and Management Plan (OWP).

[50] ODFW and USFWS websites, accessed 2013, unless otherwise noted
[51] LBJ 2006, SHN 2012

Wolves occurring in Oregon today are part of the Northern Rocky Mountain wolf population. They are descendants of wolves originally captured in Canada and released in Yellowstone National Park and Idaho in the mid-1990s. Wolf numbers fluctuate throughout the year as wolves disperse, pups are born, and new packs are formed. The Oregon wolf population is officially documented at the end of each year. On December 31, 2013, the Oregon population was estimated at 64 wolves. The majority of documented wolves occur in Wallowa, Umatilla, Union, and Baker counties in northeast Oregon. The closest areas of known wolf activity are in Jackson, Klamath and Douglas counties, well southeast of Coos Bay. .[52]

It is very unlikely that the gray wolf would occur within the SDPP analysis area, given current tracking and distribution data available. Construction, operation, and retirement of the SDPP are not anticipated to have any impact to the gray wolf, and the gray wolf does not warrant further evaluation at this time.

## 3.5 FISH

Three federally-listed anadromous fish species spend a portion of their life cycle within the estuarine environment of Coos Bay – the Oregon Coast ESU of Coho salmon, southern DPS green sturgeon, and southern DPS Pacific eulachon, each of which are listed as threatened under the ESA. These three species have not warranted listing as threatened or endangered by the State of Oregon. Based on various ODFW seining surveys, use of the Coos Bay system by Pacific eulachon and green sturgeon is sporadic, and there is very little habitat available for Coho salmon in the immediate project area, except as they traverse the area on their migrations to and from the ocean (Mike Gray, personal communication).

### 3.5.1 Oregon Coast Coho Salmon (State Sensitive-Critical, Federal Threatened)

The Oregon Coast ESU of Coho salmon (*Oncorhynchus kisutch*) is one of several anadromous salmonid species that utilize Coos Bay as juvenile rearing habitat and during migrations to and from the ocean between marine and freshwater environments. In 2008, NMFS listed the naturally spawning populations of Oregon Coast Coho salmon as a federal threatened species under the ESA (73 FR 7816). The Coos Bay watershed, including the bay itself, was included as critical habitat. The Southern Oregon/Northern California ESU of Coho salmon is also listed as a federally threatened species; however the northernmost extent of critical habitat for this ESU is the Elk River, which is located more than 50 miles southeast of the project site near Cape Blanco, OR.

Essential physical and biological features , or primary constituent elements (PCEs), of estuaries include whether an area is free of obstruction, water quality and salinity conditions supporting juvenile and adult physiological transitions between freshwater and saltwater, natural cover, and foraging opportunities. The Coos Bay estuary adjacent to the SDPP site has one or more PCEs within the acceptable range of values required to support the biological processes for which Coho salmon use the habitat. Coho salmon adults and smolts would migrate through this area

[52] ODFW, BLM and USFWS websites, accessed 2013

and use the area to make the physiological transition between marine and freshwater environments.[53]

The SDPP does not require water intake and no entrainment or impingement of fish would occur as a result of the project. Stormwater runoff from impervious surfaces at the SDPP site could contain trace metals such as copper and zinc, which are of concern to aquatic organisms. To avoid any impacts to fish from trace metals, non-contact storm water will infiltrate through bioswales, retention ponds and approximately 30 feet of sand fill before entering into the water table. Contact stormwater will be treated prior to being discharged through the Port's ocean outfall. All stormwater will be treated or managed to meet DEQ requirements under modified NPDES Permit no. 101499 (Appendix E-4) and a DEQ-approved Conceptual Stormwater Management Plan (Appendix I-4).

Impacts to Coho salmon from lighting of the barge berth are anticipated to be insignificant. A Proposed Site Lighting Plan has been developed to minimize impacts from lighting to the maximum extent possible (Appendix R-7). Perimeter lighting will be illuminated in accordance with U.S. Coast Guard security requirements, but will utilize low-emission light fixtures and shielding of the illumination source to limit light emissions to specific areas. Whenever possible, light fixtures will be illuminated only when required for safety and security and will otherwise be turned off. Lighting specification drawings are also provided in Appendix R-7, which illustrate the limited spatial extent of illumination from planned lighting at the site.

Potential significant impacts to Coho salmon are further addressed in Section 7.

### 3.5.2 Pacific Eulachon (No State Listing, Federal Threatened)

Pacific eulachon (*Thaleichthys pacificus*) is a small, anadromous fish from the eastern Pacific Ocean that is commonly known as smelt, candlefish, or hooligan. In North America, they range from northern California into the southeastern Bering Sea. In 2010, the southern DPS of Pacific eulachon was listed as threatened under the ESA (75 FR 13012), followed by the designation of critical habitat in 2011 (76 FR 65323). The range of the southern DPS extends from Nass River, British Columbia to Mad River, California. While this range includes Coos Bay and its upper reaches, critical habitat was not designated in the Coos Bay system.

Eulachon are plankton-feeders, chiefly feeding on crustaceans such as copepods and euphausiids. They typically spend three to five years in saltwater before returning to freshwater to spawn. Spawning runs can be erratic, appearing in some years but not others (NMFS 2006). They do not feed while in freshwater and remain there only a few weeks to spawn.

There is currently little information available about Pacific eulachon presence in Coos Bay. Should they occur, adults would begin moving through the bay as early as December, and spawning typically occurs from January to mid-May, peaking in February to mid-March. When present, Pacific eulachon may utilize both shallow and deep water habitats within the estuary as they migrate to spawning grounds. They will spawn only in the lower reaches of rivers and major tributaries (i.e. the Coos River), as they require moving water and large substrate to

[53] NMFS website, accessed 2013; JCEP Resource Report 3, May 2013

spawn. Eggs are fertilized in the water column, sink, and adhere to the river bottom typically in areas of gravel and coarse sand. Eulachon eggs hatch in 20 to 40 days, with incubation time dependent on water temperature. Shortly after hatching, the larvae are carried downstream and dispersed by estuarine and ocean currents. When the larvae reach juvenile size, they disperse to the ocean as soon as they are able. Juveniles may migrate out of Coos Bay as early as February to as late as almost mid-summer (Chuck Wheeler, personal communication). Adult eulachon do not always die after spawning and could return to the ocean. [54]

Potential impacts to Pacific eulachon could occur during seasonal migrations by adults to spawn in inland rivers and outmigrations of larvae and juveniles after hatching. Pacific eulachon do not feed in freshwater, and their presence in Coos Bay is likely to be brief and limited (JCEP 2013). Given the number of other deep and shallow water habitats available along the bay transit route, there is a low likelihood that there would be a significant impact from the SDPP on spawning runs of eulachon in Coos Bay.

The likelihood of effects to larval and juvenile stages of eulachon as they outmigrate through the Coos Bay estuary is likewise anticipated to be minimal. As the larvae are carried by currents and tides, they would pass through the waters adjacent to the SDPP relatively quickly and would not spend any substantial length of time in the area. Once the larvae have grown to juvenile size, they naturally disperse to the ocean as soon as they are able. Thus, any juveniles occurring near the site would be migratory in nature.

Impacts to Pacific eulachon from lighting of the barge berth are anticipated to be minimal. A Proposed Site Lighting Plan has been developed to minimize impacts from lighting to the maximum extent possible (Appendix R-7). Perimeter lighting will be illuminated in accordance with U.S. Coast Guard security requirements, but will utilize low-emission light fixtures and shielding of the illumination source to limit light emissions to specific areas. Whenever possible, light fixtures will be illuminated only when required for safety and security and will otherwise be turned off. Lighting specification drawings are also provided in Appendix R-7, which illustrate the limited spatial extent of illumination from planned lighting at the site. As Pacific eulachon presence in Coos Bay is brief and limited, and mitigation measures will be taken to minimize the illumination of aquatic areas, no adverse impacts to Pacific eulachon from lighting are anticipated.

The risk of impacts to larval eulachon from oil spills is also anticipated to be low. The presence of all stages of Pacific eulachon that are likely to be in Coos Bay is minimal, the background rate of oil spill in Oregon is low, and the anticipated number of barge trips associated with the project will be approximately 38 trips over 42 months, which would suggest that the overall risk to Pacific eulachon from oil spills is negligible. In the unlikely event of a spill, vessel operators would follow the guidelines outlined in the Coos Bay GRP (ODEQ 2004) to prioritize the protection of resources in the bay. Consequently, no adverse effects to eulachon are anticipated from the construction, operation, and retirement of the SDPP.[55]

[54] NMFS website, accessed 2013; JCEP Resource Report 3, May 2013
[55] JCEP Resource Report 3, May 2013

### 3.5.3 Green Sturgeon (No State Listing, Federal Threatened)

Green sturgeon (*Acipenser medirostris*) are long-lived, slow-growing fish and are the most marine-oriented of the sturgeon species. They are believed to spend the majority of their lives foraging in nearshore oceanic waters, bays, and estuaries ranging from nearshore waters in Baja California to those in Canada. They utilize both freshwater and saltwater habitat, and spawn in deep pools or holes in large, turbulent, freshwater river mainstems.

There are two DPS defined for green sturgeon—the Northern DPS and the Southern DPS. The Northern DPS is a federal species of concern (SOC) with spawning populations in the Klamath and Rogue rivers. The Southern DPS was federally listed as threatened in 2006 (71 FR 17757) and includes all spawning populations of green sturgeon south of the Eel River in California. The principal factor in the decline of the southern DPS is the reduction of their spawning area in California. Critical habitat for the Southern DPS was designated in 2009 and includes Coos Bay (74 FR 52300). The species has not warranted protective listing status by the State of Oregon.[56]

The distribution of green sturgeon ranges from the U.S.-Mexico border to the Bering Sea in Alaska. Southern DPS green sturgeon are reported to congregate in coastal waters and estuaries and are known to occupy Coos Bay. Because Coos Bay is not their natal stream, Southern DPS green sturgeon are likely to be present outside of the spawning season from June through October. While in Coos Bay, they likely seek out the deepest habitats to rest during low tides and feed on invertebrates in shallow water during high tides. Both Southern and Northern DPS green sturgeon may occur in Coos Bay; however, if a green sturgeon spawns in Oregon, it is not considered part of the southern DPS and not considered threatened under the ESA.[57]

Southern DPS green sturgeon occurring in the analysis area are expected to reside primarily in the deeper waters of the bay, depending on the time of day, tidal cycle, and activity (Mike Gray, personal communication). Thus, project-induced impacts from stormwater are discountable given the migratory nature and distribution range of the species. While larval and juvenile sturgeon have some sensitivity to the copper and zinc concentrations (Vardy 2013) that may be associated with stormwater discharge, only adult and sub-adult Southern DPS green sturgeon occur in Coos Bay. Also, all stormwater discharged from the SDPP site will be treated or management to meet DEQ requirements for modified NPDES Permit no. 101499. Thus, adverse impacts to Southern DPS green sturgeon from stormwater discharge is considered unlikely.

Construction of the barge berth will reduce a small portion of shallow water habitat for green sturgeon prey species such as ghost shrimp and clams, which could indirectly impact green sturgeon. However, there is extensive shallow water habitat available for foraging throughout the bay.

Lighting of the barge berth area also has the potential to impact green sturgeon, and as such, measures will be taken to minimize the amount of light that reaches the aquatic areas around the barge berth. A Proposed Site Lighting Plan has been developed to minimize impacts from lighting to the maximum extent possible (Appendix R-7). Perimeter lighting will be illuminated

[56] NMFS website, accessed 2013, unless otherwise noted
[57] Mike Gray, ODFW, personal communication, 2013

in accordance with U.S. Coast Guard security requirements, but will utilize low-emission light fixtures and shielding of the illumination source to limit light emissions to specific areas. Whenever possible, light fixtures will be illuminated only when required for safety and security and will otherwise be turned off. Lighting specification drawings are also provided in Appendix R-7, which illustrate the limited spatial extent of illumination from planned lighting at the site.

The risk of impacts to green sturgeon from oil spills is also anticipated to be low. Larval and juvenile green sturgeon – the life stages most vulnerable to oil spills – generally do not occur in Coos Bay. Additionally, the background rate of oil spill in Oregon is low (JCEP 2013), and the anticipated number of barge trips associated with the project will be approximately 38 trips over 42 months, which would suggest that the overall risk to green sturgeon from oil spills is negligible. In the unlikely event of a spill, vessel operators would follow the guidelines outlined in the Coos Bay GRP (ODEQ 2004) to prioritize the protection of resources in the bay. Consequently, adverse effects to green sturgeon from the construction of the barge berth are not anticipated.

## 3.6 MARINE MAMMALS

The estuarine and open ocean habitats of the analysis area support a variety of marine mammal species. Of these species, the harbor seal, Steller sea lion, gray whale and orca would potentially enter into Coos Bay. The harbor seal is not a state or federally listed species, and the Steller sea lion was federally delisted in 2013 and is not listed by the state of Oregon. Although the gray whale was federally delisted in 1994, it remains listed as endangered by the state of Oregon. Lastly, the Southern Resident DPS of orcas are federally listed as endangered. Thus, the only state and/or federally listed marine mammals with the potential to occur in Coos Bay are the gray whale and the orca, which are discussed in more detail below.

### 3.6.1 Southern Resident Orcas (No State Listing, Federal Endangered)

Orcas (*Orcinus orca*) are wide-ranging predators of the open ocean that have a worldwide distribution, although they are most common found in subarctic, temperate, and subantarctic waters. Along the North Pacific coast, resident orcas occur from Oregon and Washington to the Bering Sea. Their distribution is correlated to food supplies, and they feed primarily on fish (salmon, cod, and herring). [58] Southern resident orcas are typically found in the inland waterways of Washington and British Columbia during the spring, summer and fall, but are occasionally observed in Oregon and as far south as central California in the winter. Orcas occasionally enter bays in pursuit of salmon and have on occasion been observed inside Coos Bay, although such sightings have not been formally recorded with NMFS.

The southern resident DPS of orcas was federally listed as endangered in 2005 (70 FR 69903). Critical habitat was subsequently designated in 2006, and encompasses the inland waters of northern Washington, including Haro Straight, the San Juan Islands and Puget Sound (71 FR 69054). [59]

[58] Center for Whale Research, www.whaleresarch.com, last accessed June 25, 2014.
[59] NMFS website, accessed 2013; JCEP Resource Report 3

Orca presence in Coos Bay or along the Pacific Coast within the analysis area may occasional occur, but given the rarity of these occurrences, vessel traffic related to construction of the SDPP is unlikely to impact the species. Although orcas can be injured or killed when struck by a vessel, such strikes are considered to be highly unlikely given the limited number of vessel visits to the barge berth and the reduced speeds at which barges will be travelling through the analysis area (JCEP 2013). Additionally, orcas can detect the sound of vessels, enabling them to avoid collisions.

The risk of oil spills adversely impacting the southern resident DPS is also low. Any petroleum products released by vessels would consist of engine oil, lubricating oils, diesel fuel and/or gasoline. However, the background rate of spills off the Oregon coast by fishing vessels, recreation vessels, and other vessel types is generally low, and this frequency is expected to continue into the foreseeable future. Therefore, it is considered unlikely that orcas would be affected by the SDPP project, and potential effects to southern resident orcas are judged to be insignificant.[60]

### 3.6.2 Gray Whales (State Endangered, Federal No Listing)

Gray whales are found mainly in the shallow coastal waters of the North Pacific Ocean. Two isolated geographic distributions of gray whales are found in the North Pacific – the Eastern North Pacific stock, which is found along the west coast of North America, and the Western North Pacific stock, which is found along the coast of eastern Asia.

The Eastern North Pacific stock spends the summer months feeding primarily in the northern Bering and Chukchi Seas in Alaska, although some whales will remain farther south, feeding in the waters along the west coast from southeast Alaska to California, including Oregon. In the fall and winter, gray whales migrate from their summer feeding grounds to winter breeding grounds and calving areas off the coast of Baja California, Mexico. The height of the winter gray whale migration in Oregon typically occurs between late December and early January. From mid-February to May, the Eastern North Pacific stock migrates back north along the U.S. west coast. Females with calves typically migrate north beginning in April, and travel closer to the shore. Additionally, there is a population of approximately 200 resident gray whales that live almost year-round in Oregon.[61]

Both the Eastern and Western North Pacific stocks of gray whales were federally listed as endangered in 1970 (35 FR 18319). The Eastern North Pacific stock was delisted from the ESA in 1994, while the Western North Pacific stock remains listed as endangered (59 FR 31094). The Eastern North Pacific stock remains listed as endangered in Oregon, and therefore warrants discussion as part of this exhibit.

While gray whales typically reside in shallow coastal waters, they may occasionally enter bays and estuaries. Local reports have documented gray whales entering Coos Bay in 2000 and 2009, and a gray whale calf was beached in July, 2014 at Bastendorff Beach, approximately one mile

[60] JCEP/PCGP Draft BA, April 2014 (Section 4, Pages 21, 36-45)
[61] NMFS website, ODFW website; accessed 2014.

south of the entrance to Coos Bay.[62] While whales have been known to enter Coos Bay, these occurrences are rare.

The risk of oil spills adversely impacting gray whales is low, given the rarity of whale occurrences in the bay and the low rate of oil spills off the Oregon coast.[63] Similarly, the risk of vessel strikes to gray whales is also low, given the limited number of barge trips projected and the speed at which the barges will be travelling. Consequently, the risk of adverse impacts to gray whales as a result of the construction, operation and retirement of the SDPP site are not anticipated.

[63] JCEP/PCGP Draft BA, April 2014 (Section 4, Pages 21, 36-45)

# 4.0 MEASURES PROPOSED TO AVOID OR REDUCE ADVERSE IMPACTS TO SPECIES

**OAR 345-021-0010(1)(q)(C)** *For each species identified under (A), a description of measures proposed by the applicant, if any, to avoid or reduce adverse impact.*

As a result of avoidance, minimization and mitigation measures proposed for the SDPP project, no significant adverse impacts to threatened and endangered species are anticipated during the construction, operation and retirement of the facility. The majority of the SDPP facility will be constructed on previously developed land to avoid and minimize as many impacts as possible to potential suitable habitat for wildlife species. No threatened or endangered plant or animal species were observed within the site boundary during field surveys. A number of threatened and endangered plant and animal species do occur within the project analysis area, and measures will be taken to avoid impacts to habitat or species that may be present by implementing best management practices (BMPs).

The Conceptual Erosion and Sediment Control Plan and Conceptual Stormwater Management Plan (Appendix I-4) will be implemented to prevent erosion, sedimentation, stormwater and water quality impacts within the site boundary and to adjacent habitats. BMPs outlined in these plans include:

- Prior to construction activities, the limits of grading, clearing and grubbing will be clearly marked with stakes and fencing to minimize the extent of disturbance
- Temporary seeding will be conducted to re-establish vegetative cover in previously disturbed areas to prevent erosion of exposed soils. Compost or peat layers will be placed on disturbed areas to absorb wind and rain forces and to develop a growing medium for vegetation
- Dust will be controlled by reducing vehicle speeds, irrigating, applying dust palliatives, installing sand fences and placing compost or peat layers on disturbed areas
- Sediment fences will be installed to pond and filter stormwater upstream of the fence and promote the settlement of soil particles
- Compost berms will be constructed to filter stormwater runoff to prevent sediment from leaving the site
- Exposed slopes in disturbed areas will be covered with a rolled erosion control fabric to prevent wind or water erosion prior to the establishment of vegetation. Peat and processed woody materials will be used to develop a seed bed on top of the fabric and subsequently planted with American dune grass to provide permanent revegetation and stabilize slopes.

As outlined in the Wildlife Habitat Mitigation Plan (Appendix P-6), exotic and invasive species control measures will be implemented to reduce invasions by non-native species at the site throughout the life of the project. Restoration and revegetation of project areas with native species will also be conducted. The project will follow noxious weed management BMPs including the following methods:

- Pre-construction surveys will be conducted to identify noxious species listed by the ODA that persist despite previous and recent control efforts
- Ongoing weed control at the site will be conducted by mechanical or manual means to prevent the spread of noxious weed species throughout the site. Herbicides may also be used in combination with other weed control methods
- Herbicides will not be used within 100 feet of a wetland or waterbody, unless allowed by the appropriate agency. Treatment buffers will be applied to noxious weed infestations in sensitive areas to avoid impacts to non-target species
- Restoration of treatment areas will be conducted using a native seed mix that conforms to BLM policy

Any discharges of stormwater or wastewater to Coos Bay will be treated or managed in accordance with the modified NPDES Permit no. 101499 and a DEQ-approved Conceptual Stormwater Management Plan (Appendix E-4). Additionally, a Stormwater Pollution Prevention Plan, including Spill Prevention and Response Procedures, will be implemented during construction in accordance with the EPA's National Stormwater Program General Permit requirements.

Transmission lines will be constructed within an existing utility corridor to avoid impacts to surrounding habitat. The transmission lines will be outfitted with bird flight diverters to reduce the risk of potential bird collisions. Additionally, in order to prevent electrocution of birds, transmission lines have been designed so that the distance between conductors, and between conductors and grounded hardware, is greater than the wingspan of any raptor. Birds are electrocuted when they contact two energized conductors or an energized conductor and grounded hardware. Among avian species, raptors are at greatest risk of electrocution because of their large wingspans and tendency to perch on power poles.

Potential impacts to estuarine species and habitat as a result of the construction of the barge berth and access triangle will be reduced by implementing BMPs and avoidance and minimization measures. As outlined in the DSL removal fill permit application (Appendix J-2), the barge berth area will be temporarily filled so that pile driving can be conducted on dry land, thereby avoiding noise impacts to aquatic species. Open Cell sheet piles will hold the fill material in place and turbidity curtains will be placed around the bill to prevent turbidity impacts from pile driving activities. Dredging of the access triangle will be conducted used a cutter-head suction dredge to minimize turbidity and noise impacts to aquatic species. All fill removal and dredging activities will take place during the ODFW in-water work window from October 1 to February 15.

All unavoidable impacts to upland habitat and non-jurisdictional wetlands at the SDPP site will be mitigated under the Wildlife Habitat Mitigation Plan (Appendix P-6). Impacts to jurisdictional wetlands and estuarine habitat will be mitigated under the Compensatory Wetland Mitigation Plan as part of the DSL removal fill permit application (Appendix J-2).

In addition to the above measures, species-specific conservation measures will be implemented for the Point Reyes bird's beak and western snowy plover. In consultation with the ODA, mitigation measures will be developed and implemented to ensure that impacts to Point Reyes bird's beak are avoided or minimized to the maximum extent possible. In consultation with the ODFW and USFWS, a western snowy plover mitigation plan will be developed and implemented to avoid or minimize potential impacts, including measures to discourage predators from entering the project area.

## 5.0 COMPLIANCE WITH ODA PROTECTION AND CONSERVATION PROGRAMS FOR LISTED PLANT SPECIES

**OAR 345-021-0010(1)(q)(D)** *For each plant species identified under (A), a description of how the proposed facility, including any mitigation measures, complies with the protection and conservation program, if any, that the Oregon Department of Agriculture has adopted under ORS 564.105(3).*

The Point Reyes bird's beak is the only state or federally listed plant species that was identified as occurring within the project analysis area during focused field surveys. The ODA has not developed a conservation, recovery, or protection plan for the Point Reyes bird's-beak; therefore, this species is addressed in Section Q.6.

# 6.0 SIGNIFICANT POTENTIAL IMPACTS TO LISTED PLANT SPECIES AND CRITICAL HABITAT

**OAR 345-021-0010(1)(q)(E)** *For each plant species identified under paragraph (A), if the Oregon Department of Agriculture has not adopted a protection and conservation program under ORS 564.105(3), a description of significant potential impacts of the proposed facility on the continued existence of the species and on the critical habitat of such species and evidence that the proposed facility, including any mitigation measures, is not likely to cause a significant reduction in the likelihood of survival or recovery of the species.*

The Point Reyes bird's-beak is the only state or federally listed plant species that has been detected during focused botanical surveys conducted for the overall JCEP (SHN, 2006, 2013). Point Reyes bird's-beak occurrences were recorded below the highest measured tide outside and below the SDPP site boundary (SHN 2006, 2013). Four additional plant species (pink sand verbena, silvery phacelia, western lily, and Wolf's evening primrose) listed as threatened or endangered, and determined to have the potential to occur, are not anticipated to be affected by the SDPP, as they were not detecting during field surveys and minimal suitable habitat is present at the site. No additional pre-construction surveys are recommended at this time for plant species other than the Point Reyes bird's-beak.

## 6.1 POINT REYES BIRD'S-BEAK

As required by the ODA under OAR 603-073-0090(5)(d)(A)(E), reasonable efforts will be made to ensure that the construction, operation and retirement of the SDPP will not significantly impact the continued existence of Point Reyes birds-beak or critical habitat near the site boundary.

The ODA has not developed a conservation, recovery, or protection plan for the Point Reyes bird's-beak. Preliminary consultation was conducted with the ODA regarding the occurrences documented along the Jordan Cove shoreline that have the potential to be affected by the project. Coordination and consultation with the ODA will be ongoing to ensure that the avoidance, minimization and mitigation measures proposed to protect the species during construction, operation, and retirement of the SDPP will ensure the likelihood of survival of the species. This will include reasonable measures taken to minimize any potential significant adverse impacts to Point Reyes bird's-beak, including brightly colored fencing to separate the populations from construction activities and to ensure there is an adequate buffer between fill placement and construction activities. In addition, avoidance and minimization measures such as erosion and sedimentation control, stormwater runoff management (Appendix I-4) and a noxious weed management program (Appendix P-6) will be implemented to minimize water quality impacts to the adjacent shoreline, prevent erosion and sedimentation in around the Point Reyes bird's beak population, and to reduce the introduction of invasive plants to the project area. All actions will be designed to be consistent with conserving and protecting Point Reyes bird's-beak populations.

In addition to the measures above, a conservation and mitigation plan that includes monitoring will be developed and approved by the ODA prior to implementation of any ground disturbing actions for the project to ensure the project is not likely to cause a significant reduction in the likelihood of survival or recovery of the species.

# 7.0 SIGNIFICANT POTENTIAL IMPACTS TO LISTED ANIMAL SPECIES AND CRITICAL HABITAT

**OAR 345-021-0010(1)(q)(F)** *For each animal species identified under (A), a description of significant potential impacts of the proposed facility on the continued existence of such species and on the critical habitat of such species and evidence that the proposed facility, including any mitigation measures, is not likely to cause a significant reduction in the likelihood of survival or recovery of the species.*

No threatened or endangered wildlife species were detected within the SDPP site boundary during focused wildlife surveys, nor did these surveys identify suitable terrestrial habitat for state or federally listed wildlife species.[64] Listed species, as well as suitable habitat, were identified within the analysis area; however, significant potential impacts to these species and habitats are not expected as a result of the SDPP project. Should listed species occur within the project vicinity or be displaced by project activities, suitable habitat is available adjacent to the site boundary and elsewhere in the analysis area that can be utilized.

## 7.1 WESTERN SNOWY PLOVER

Although western snowy plovers were not observed during wildlife surveys and there is no critical habitat located within the site boundary, activities associated with the construction, operation and retirement of the SDPP facility have the potential to attract plover predators to the area. The ODFW and USFWS have previously raised concerns that increased human presence and disturbance from project activities may attract predators such as crows, ravens, red foxes and raccoons that could impact western snowy plover populations on the North Spit. In response to these concerns, measures will be taken to avoid or minimize impacts to western snowy plovers, including the implementation of BMPs and an education and outreach program (JCEP 2013). BMPs will include:

- Staff training on western snowy plover regulations, recreational use restrictions and conservation measures such as litter control, avoidance of nesting and foraging areas and staying on established roads and trails.
- Environmental training for operational personnel to comply with existing management policies in place on the North Spit.
- Posting printed educational materials at the project site for the life of the project and posting interpretive signs, educational materials and kiosks at the SDPP or other approved locations.
- Funding a Wildlife Services position dedicated to snowy plover predator monitoring and control during construction of the SDPP.
- Keeping the site clear of construction debris, food waste and garbage that could attract predators to the site.

[64] LBJ 2006, SHN 2012

- Providing animal-proof receptacles in eating areas, parking lots and other appropriate locations.
- Monitoring of structures at the site to discourage use by avian predators and removal of any nests found at the site.

As a result of implementing the mitigation measures outlined above, significant potential impacts to western snowy plovers on the North Spit from increased predator presence are not anticipated. In the event that a clearly demonstrable and sustained decrease in snowy plover productivity is detected by ongoing monitoring, the project will coordinate with the USFWS, ORBIC, Oregon Wildlife Services, BLM, OPRD, ODFW, and other interested parties to identify adaptive management strategies, as appropriate, to help reverse any such trend.

## 7.2 OREGON COAST ESU OF COHO SALMON

Stormwater discharge to Coos Bay has been identified as a potential pollution source for metals that could impact Coho salmon. There is concern that elevated metals concentrations, copper in particular, may disrupt fish behavior or damage sensory capabilities in salmonids (Hecht et al. 2007). These impacts could in turn cause migration delays or increased susceptibility to predation in Coho salmon (Phippen, personal communication).

To minimize impacts from metals to Coho salmon and other fish species in Coos Bay, non-contact stormwater runoff from the SDPP site will infiltrate into the ground through bioswales and infiltration ponds designed for the bioretention of stormwater pollutants. As outlined in the modified NPDES Permit no. 101499 application, stormwater will infiltrate through approximately 30 feet of unsaturated sand fill before entering the underlying water table aquifer (Appendix E-4). Similar systems have been shown to remove more than 90 percent of copper from stormwater after three hours of retention time (Davis et al. 2003). Contact stormwater will be collected on-site and managed or treated before being discharged through the Port's ocean outfall. All stormwater discharges to Coos Bay will be in accordance with modified NPDES Permit No. 101499 (Appendix E-4) and a DEQ-approved Conceptual Stormwater Management Plan (Appendix I-4). Consequently, the discharge of stormwater is not anticipated to result in a change in background metals concentrations in Coos Bay, nor significantly impact the continued existence of Coho salmon, other threatened or endangered fish species or critical habitat in Coos Bay.

Potential significant impacts to Coho salmon could also result from the construction of the barge berth and access triangle. Localized turbidity and sedimentation impacts from barge berth construction and dredging of the access triangle could include trauma to gill structures, loss of foraging potential due to reduced light, and effects on salmonid physiology, behavior and habitat leading to a reduction in fitness and survival (Bash et al. 2001). Effects on foraging and predation vary, however. Some salmonid and Pollock species have been reported to continue to consume prey during periods or turbidity, while species that prey upon salmonids reduced consumption of juveniles during periods of elevated turbidity (De Robertis et al. 2003).

While the severity of impacts to fish from turbidity and sedimentation may vary, measures to reduce these impacts will be implemented regardless during construction of the barge berth and dredging of the access triangle. The installation of Open Cell sheet pile membrane walls during construction of the barge berth will isolate construction activities and result in only minor and localized levels of turbidity. A turbidity curtain will also be employed to further reduce impacts to surrounding species and habitat (Appendix J-2). Dredging of the access triangle will be performed primarily with a cutter-head suction dredge, which minimizes both turbidity and noise. Water quality monitoring will be conducted throughout construction activities to ensure compliance with federal and state standards (Appendix J-2). Most importantly, all in-water work will be conducted during the ODFW-approved in-water work window from October 1st through February 15th to avoid vulnerable fish life stages including migration, spawning and rearing (ODFW 2008).

Noise impacts are also a concern during construction of the barge berth and dredging of the access channel. Typical construction activities such as pile driving have the potential to impact fish and marine mammals in the vicinity. In order to avoid or minimize noise impacts, all pile driving will be conducted in the dry using land-based mobile cranes. The barge berth area will be back filled with sand to create a dry environment and pile driving will occur in areas of fill, which will act as a sound buffer and minimize noise impacts to aquatic species (Appendix J-2). As such, noise generated from pile driving in temporary fill areas is not expected to exceed NOAA’s current in-water acoustic threshold of 160 dB for behavioral disruption from impulsive noise (NOAA 2013).

# 8.0 PROPOSED MONITORING PROGRAM FOR IMPACTS TO THREATENED AND ENDANGERED SPECIES

**OAR 345-021-0010(1)(q)(G)** *The applicant's proposed monitoring program, if any, for impacts to threatened and endangered species.*

The proposed SDPP will be sited on previously developed land zoned as industrial and no state or federally listed species are known to reside within the site boundary. Consequently, no adverse impacts are anticipated to known populations of listed species during construction or operation of the SDPP. To further ensure there are no impacts to threatened and endangered species, habitat requirements, monitoring and mitigation measures will be implemented for the project. A Wildlife Habitat Mitigation Plan (Appendix P-6) has been developed in accordance with the ODFW Fish and Wildlife Habitat Mitigation Policy (OAR 635-415-0000 through 0025), which outlines both the mitigation and monitoring measures that will be implemented for the JCEP (Appendix Q-13).

The monitoring measures outlined in the Wildlife Habitat Mitigation Plan are designed to ensure that the goals and standards of the ODFW's Habitat Mitigation Recommendations are met, as outlined in OAR 635-415-0025. The monitoring plan for the habitat mitigation sites proposes a monitoring period of five years, with the first year of monitoring beginning upon substantial completion of mitigation construction and implementation.

Mitigation objectives and performance standards have been established for each site to ensure successful mitigation. Objectives and performance standards are described in detail in Appendix P-6 and are presented below.

## 8.1 AS-BUILT SURVEY

In the first year of monitoring, an as-built survey will be conducted to document that the appropriate contours have been attained where grading is proposed and plantings were installed as designed. An as-built report will be prepared, which will include the as-built survey, photos, and a brief synopsis of work completed, including any design changes.

## 8.2 PHOTO DOCUMENTATION

Photo locations will be established within the Panhandle, North Bank and Lagoon sites to document conditions at the sites every year for the first five years post-mitigation. Supplemental photos will be taken as appropriate to document any problem areas or enhancement actions.

## 8.3 MITIGATION OBJECTIVES AND PERFORMANCE STANDARDS

A number of mitigation objectives and performance standards have been identified to assess the success of mitigation at all project mitigation sites. Long-term monitoring and site management will be conducted at the mitigation sites to determine whether performance standards have met the mitigation objectives.

**Objective 1:** Permanent preservation of parcel.

**Performance Standard 1.1:** A legal protection instrument is in place in the form of a conservation easement.

**Objective 2:** The portion of the parcel preserved for mitigation purposes is demonstrably managed for conservation for the life of the project.

**Performance Standard 2.1:** A land manager will be endowed to monitor and maintain the parcels, demonstrate that an ecological uplift has been provided at each site, provide monitoring reports for the first five years after implementation of proposed mitigation measures, and maintain the sites throughout the life of the project.

**Performance Standard 2.2:** A long-term maintenance plan will be in place prior to the issuance of a Notice to Proceed for construction of the JCEP.

**Objective 3:** An ecological uplift has been provided at each mitigation site.

***Panhandle Site***

**Performance Standard 3.1**: Ecological uplift (in the form of Scotch broom removal over a minimum of 5.8 acres) has been completed and is reflected in monitoring reports for five years.

***North Bank Site***

**Performance Standard 3.2:** Ecological uplift (forestry activities designed to encourage succession to mature forest within a minimum of 71.2 acres) has been completed for five years based on annual monitoring reports.

***Lagoon Site***

**Performance Standard 3.3:** Ecological uplift (in the form of Scotch broom and Himalayan blackberry removal within a minimum of 10.2 acres, and construction of an educational kiosk) has been completed and maintained for five years based on annual monitoring reports.

**Performance Standard 3.4:** Placement and compaction of sand to an approximate depth of six feet has been completed and maintained over an area of at least 1.9 acres to provide at least 95% open sand cover for five years based on annual monitoring reports.

In addition to the monitoring activities outlined above, long-term maintenance will be conducted at the mitigation sites, which may include garbage and debris removal, installation of protective signage and other deterrents in the event that vandalism or other inappropriate activities are found to occur at any of the sites.

## 8.4 CONTINGENCY PLAN

Contingency plans will be developed by the endowed land manager and coordinated with ODFW should mitigation not meet performance standards. The nature of the contingency plan will depend on the problems that arise and would likely be related to weed control and potential vandalism or effects from natural disasters.

## 8.5 SPECIES-SPECIFIC MONITORING

In addition to monitoring plans developed for the habitat mitigation sites, species-specific monitoring for threatened and endangered species will also be conducted. As described in detail in Section 7.0, western snowy plover impact minimization measures will be implemented through the establishment of BMPs and an educational outreach program (JCEP 2013). BMPs related to species monitoring will include:

- Funding of a Wildlife Services position dedicated to snowy plover predator monitoring and control during the 39-month construction period.
- Monitoring of structures associated with the project to discourage use by avian predators. Frequent inspection of these areas will be conducted to ensure that nests are not being constructed; any nests found will be removed immediately.
- Monitoring of dredged material placement areas to ensure that no snowy plover denning is occurring in the hillocks.

Monitoring will also be conducted during in-water work for the construction of the barge berth and dredging of the access triangle to ensure that impacts to Coho salmon and other fish species are minimized. Water quality monitoring will be conducted to confirm that turbidity levels comply with state and federal standards (Appendix J-2). In addition, the project will comply with the requirements of the modified NPDES Permit No. 101499 to minimize impacts to Coho salmon from stormwater discharge to Coos Bay (Appendix E-4).

Notes:
The Point Reyes Bird's-Beak (PRBB) is state listed as endangered and federally listed as a species of concern under the Endangered Species Act. SHN biologists conducted focused plant surveys for the PRBB on July 10 and 17, 2013 along the entire South Dunes Power Plant shoreline. During the July 17 survey, PRBB occurrences were mapped by SHN surveyors using a Trimble R82 real time kinematic (rtk) GPS accurate to within 0.1 ft. The PRBB was detected in substantial numbers at numerous sites.

The Western Lily (WELI) is state and federally listed as endangered. SHN biologists conducted focused plant surveys for the WELI from July 8-11, 2013. It was not detected in any of the surveys.

Notes | To Do

Green Sturgeon

Mike said he wouldn't occurrences of green sturgeon in Coos Bay rare. They do occur in Coos Bay. It's a little confusing because they classify a Southern DPS which is federally listed as threatened, but the Northern DPS could also occur. In addition to green sturgeon, quite a few white sturgeon occur. Neither greens or whites have shown any evidence to reproduce in Coos Bay but they do occur here. Most anglers don't encounter green sturgeon much and they are fairly easily to distinguish by their coloration and the shape of their snout makes it fairly easy to distinguish the two.

Green sturgeon spend more time in the ocean, as they have less tolerance for freshwater, but they do come in and out of the bay. White sturgeon are able to tolerate freshwater more and go upriver. In the Columbia River, white sturgeon are found clear up in the Snake River in Idaho. Green sturgeon are strictly in estuaries and the ocean and are not known to run up into freshwater at all.

There is no evidence at all that either green or white sturgeon spawn in Coos Bay. Coos Bay gets only the medium to larger sized sturgeon, which means they're coming from somewhere else. They're a very long-lived species; likely past 100 years old for white sturgeon. It takes approximately 15 years before they're even mature enough to spawn, which is why they can be vulnerable.

Evidence from tagging studies show the fish move around quite a bit. Columbia River whites have been found in Oregon coastal estuaries and as far north as BC and the general understanding is Coos Bay is probably getting white sturgeon from the Columbia River. Whites are probably from spawning areas in the Columbia and possibly the Rogue River.

There is a sturgeon research team out of Clackamas that came down several years ago and did sturgeon tagging up and down the coast. Tom Rien, manager, fisheries research biologist and ODFW manager for the Columbia River Coordination Program (Clackamas), is the project leader for the sturgeon research team. He might also be working with NMFS regarding the eulachon listing. He is a good contact for more specific information related to green sturgeon in Coos Bay from this tagging program. The team conducted either 3 or 4 seasons of sturgeon sampling along the coast, including Coos Bay. In addition, creel sampler staff that check recreational anglers while fishing in Coos Bay record any sturgeon caught.

Where the green sturgeon that enter Coos Bay spawn is not clear. (However, according to Chuck Wheeler of NMFS, if they don't spawn in the Southern DPS they aren't considered threatened.)

ODFW estuary seining that occurs is primarily related to salmonid movement through the estuary. Occasionally they pick up a sturgeon; not so much from seining by from infrequent gillnet sampling.

The Coos River going up to where it forks to the South Coos and Millicoma, the stretch of river below the forks is pretty common for bank angling primarily targeting white sturgeon.

Eulachon

There was a basin report written back in 1990 that refers to eulachon as an occasional visitor to Coos Bay but not having a strong run (Coos Basin report). There hasn't been any sampling that tracks their population numbers. Occasionally eulachon will occur in seining conducted by the ODFW that primarily targets salmonids. Starting in the mid to late 1970s, seining has been conducted annually. ODFW is working with the Coos Watershed Association to get the data into a database that would be available for query for the public. Currently, seining data is not available other than in handwritten sheets.

| Contact: Chris Claire, Habitat Protection Biologist, ODFW | | Job Name: Coos Bay WWTP No. 2 |
| Address: Charleston Field Office | | Logged By: Barb Gimlin |
| Subject: Potential affects to fisheries | | |

Notes

ODFW biologists act in a technical role as a resource advisory for DEQ, DSL, and, to a lesser extent, the USACE (due to the federal nexus and their coordination with NMFS instead). Chris is familiar with the new site for Wastewater Treatment Plant (WWTP) No. 2 and has walked along the channelized drainage on the north and northwest portions of the site with ODOT representatives. ODOT is planning on replacing the culvert for the drainage channel when they redo Empire Boulevard. He thought there is also another culvert located upstream of the site.

Chris stated if the project is going to improve the water quality of the effluent released at the outfall, ODFW is very excited about that and is a huge supporter of such actions. Although it likely isn't practical for the project due to lack of available space, ODFW is very excited about running all outfalls through a small wetland created for post water quality treatment before it gets to a primary production area (i.e., Coos Bay). Nonetheless, he is comfortable with moving forward with the planned use of the existing outfall for improved treatment of the effluent discharged for the new facility.

Impacts related to how stormwater is treated have become a big issue for water quality and fisheries management. He will be sending me a recent article in Washington State about fish dying in an area where every time it rained about half the coho salmon would die. There has been a renewed and very energetic focus on runoff that affects streams and waterways. Resource agencies are now looking at hydrocarbons and other pollutants such as bacteria and fine sediment that come off impervious surfaces during stormwater runoff, with flashiness in particular a problem. Municipal stormwater drainage in Salem and Portland is enough to affect the Willamette River. Locally, there are problems with stormwater oozing off timber lots. There are a lot of potential impacts to water quality from residues that are semi-toxic and it creates a whole new level of perceived government regulation than in previous years.

Mitigation that can be used in new construction projects includes the use nontoxic, permeable concrete for parking lots, driveways, roads, or paths so that water doesn't accumulate or runoff. Permeable surfaces allow water to percolate into the ground below, reducing runoff and filtering solids and pollutants. In Coos Bay, Sol Coast Consulting and Design, LLC, is a local firm that subcontracts to assist with impervious surface management (see: http://solcoast.com/storm-water-management/). The idea is to keep stormwater from running off the site into streams or Coos Bay. Chris said one option for the WWTP No. 2 project may be to pave one road or section that will receive the most traffic, and for the other sections use permeable concrete with collection galleries (3 or 4) that go into flower beds. Then you won't have stormwater runoff and every time it rains you wouldn't have these big releases of stormwater.

Chris mentioned Coos Bay is one of the only bays in the state that has made the commercial shellfish industry productive again. Water quality was exceeding the limits, but they have since cleaned it up.

Chris is available for technical meetings on site and mentioned it is favorable to have a concise running record of feedback from ODFW in the project record. ODFW provides technical assistance regarding stormwater runoff, including overflow management, to help manage release of pollutants. In addition, the shellfish industry doesn't want e coli or artificial nutrients in the bay.

(continued)

Drainage channel: I also asked Chris about the drainage channel and if actions to remove any of the thick riparian vegetation are allowed. He said if it its native woody vegetation, those plants don't encroach on an active stream. The riparian buffer strip helps to manage stormwater at the site and helps to shade the stream. If it has been determined there is a safety issue, ODFW recommends taking a brushhog to cut the vegetation down to approximately 6 feet tall. If any of the species are invasive (i.e., Himalayan blackberries), they can be removed and the state rules are very flexible. Of note, the county planning rules don't apply in city limits. The channel can be used as a positive aspect of the site. For example, if the City continues to maintain the riparian area, it will help to provide shade for the small stream, prevent erosion from leaving the site, and will maintain ecological function at some level despite the stream running through an urbanized area.

| Contact Name: Scott Pearson, WDFW Biologist | | Logged By: | Barbara Gimlin |
| Subject: Streaked Horned Lark (ESA Proposed as Threatened) | | | Environmental Planner |

| Notes | To Do |
|---|---|
| Scott Pearson is considered an expert regarding the streaked horned lark and has published various reports, including the *Range-wide Streaked Horned lark Assessment and Preliminary Conservation Strategy* with Bob Altman in September 2005 for the Washington Department of Fish and Wildlife, Wildlife Program Science Division.<br><br>Most of Scott's work has been in Washington and in Oregon it has been in the Willamette Valley primarily. Scott has asked the snowy plover folks who monitor the North Spit to let him know if they ever encounter a streaked horned lark [Dave Lauten, deweysage@frontier.com, and Kathleen (Kathy) Castellein].<br><br>Scott said it's possible they could breed on the Oregon coast as they breed along the Washington coast. He wouldn't be surprised at all, as it seems the habitat is ideal-- particularly in areas where there are western snowy plovers, along with the habitat restoration that has occurred. Portions of the North Spit are well-suited for lark habitat. When asked if they could possibly share the same habitat with plovers, he said he found a nest of a lark within 5 meters of a plover in Washington and they use very similar habitat. He noted plovers use more extreme open habitats, whereas the lark needs some vegetation.<br><br>In the sparsely vegetated dune and beach habitats where larks are found, they do not find larks in rolling or steep areas. Where deflation plains occur, larks are often behind the foredune. They also occur where dredge spoils have been deposited or in areas where there is accretion (deposition) of sand causing beach areas to become wider (i.e., due to waves, tides, or currents).<br><br>Streaked horned larks will use small sites when they're immediately adjacent to water (habitat goes right to the open water) and it doesn't always have to be marine. Islands occurring along the Columbia River provide ideal habitat and larks occur on a number of those islands. For sites not adjacent to water, the area of expanse has to be quite large, likely 300 acres or greater, although further studies are needed. Scott is not sure how small such sites would go, but they tend to be pretty big.<br><br>Scott recommended the following additional contacts for more information related the potential of streaked horned larks to occur within the Project vicinity:<br><br>Martin Nugent, diversity division, ODFW, martin.nugent@state.or.us.<br><br>Bob Altman, American Bird Conservancy, baltman@abcbirds.org. Bob co-authored the September 2005 *Range-wide Streaked Horned Lark Assessment and Prelininary Conservation Strategy* with Scott. He also recently published the article *Historical and Current Distribution and Populations of Bird Species in Prairie-Oak Habitats in the Pacific Northwest*, Northwest Science, Issue 85, Vol. 2, 2011.<br><br>Randy Moore, randy.moore@oregonstate.edu, teaches at Oregon State; has done a lot of work in the Willamette Valley but may have been on the coast. | |

| Contact: | Ken Phippen, Branch Chief, Oregon Coast Habitat Branch Chief, NMFS, Roseburg Office<br>Ken.Phippen@noaa.gov | | | Logged By: | Barb Gimlin |
| Subject: | City of Coos Bay Wastewater Treatment Plant No. 2 | | | | |

Notes

I called Ken Phippen, Branch Chief for the Oregon Coast Habitat Branch of the National Marine Fisheries Service (NMFS), as a follow-up after briefly discussing the proposed upgrade and expansion by the City of Coos Bay for Wastewater Treatment Plant No. 2 with Jeff Young, NMFS Fisheries Biologist, on September 10. Jeff recommended I contact Ken, as projects are not assigned so much by county as by workload. Jeff also mentioned that due to stormwater and wastewater water quality baseline issues that NMFS has been working on, the project may require formal consultation under Section 7 consultation under the Endangered Species Act.

Ken said things have changed in the last two to three years due to further findings regarding impacts from stormwater constituents. A big issue is copper that is embedded in brake pad materials and released into stormwater from vehicles. NMFS has always talked about petroleum products as sources of pollution, but now on top of that there is copper (from brake pads) and zinc (from other vehicle parts). Copper research in Seattle over the past five years has determined that even in very minute amounts it gets suspended in the water column. When fish basically breathe it in, it blocks the receptors in their skin and affects their normal behavior. An example is when a predator comes by. In normal behavior, pheromones or other such means signal the fish that, "Hey, there's a predator, go hide". Experiments have been conducted with copper concentrations in aquariums with juvenile coho salmon. In water without copper, the juveniles head straight to the bottom when a predator is added. With copper in the water, juveniles don't pick up on the predator(s) and swim around oblivious to the danger, therefore making them easy targets as prey. Ken used this as an example of the bad side effects of copper in stormwater.

Ken said NMFS has stepped up pretty intensively their approach towards stormwater and getting it treated in the last three years. Analysis for copper is carried all the way out to the ocean from inland areas, as once it goes into the system, it stays there.

Regarding use of the existing outfall for the new facility, Ken said if there is an effort being made to upgrade a plant, "all that is great". However, there are still compounds in the effluent that NMFS would want to take a look at and there may be other components in the effluent that may have adverse effects. In addition, while running wastewater from the paved areas through the wastewater collection system (as proposed) may be adequate, further analysis is needed to ensure there is adequate filtration for heavy metal, including copper and zinc.

Ken recommended that I send him a notification by email regarding the project and he will assign a fisheries biologist to the project that will assist in the review and in the development of a Biological Assessment (BA), which he also recommended. Ken said the project will likely require formal consultation to ensure NMFS has a chance to respond with a Biological Opinion to ensure potential adverse effects from the project are mitigated to the maximum extent possible. Jim Muck will likely be the biologist assigned.

| Contact Name: Chuck Wheeler, Fisheries Biologist, Oregon Coast Branch, Oregon State Habitat Office, NMFS | | | Logged By: Barb Gimlin |
| Subject: Eulachon and Green Sturgeon in Coos Bay | | | |

| Notes | To Do |
|---|---|

Chuck provided the following information about eulachon and green sturgeon (both listed as threatened under the ESA) in Coos Bay:

Eulachon

Eulachon spawn in the first part of rivers, i.e., the Coos River or other larger tributaries, but not in the bay. Adults begin moving through the bay as early as December. To spawn, they need moving water and large substrate. That's not going to occur in the estuary, but will occur upstream in the Coos River or other large tributaries feeding into the bay. Spawning typically occurs from January to mid-May, with the peak in February to mid-March. Eggs hatch in 30-40 days and the larvae immediately wash downstream to estuarine and ocean areas where they feed on phytoplankton and zooplankton. When the larvae reach juvenile size, they disperse to the ocean as soon as able. Juveniles may be migrating out as early as February to almost mid-summer. Adult eulachon don't always die after spawning so they could return to the ocean. There is currently little information available about eulachon movement in Coos Bay and its nearshore marine areas.

Green Sturgeon

The green sturgeon population that is listed as threatened is the population that spawns in California (Sacramento River). The Sacramento River has a lot of issues, which is why the species is threatened. If they spawn in Oregon, they are not threatened. Southern DPS green sturgeon. Green sturgeon are routinely found in Washington State estuaries, hence the likelihood of their occurrence also along the Oregon Coast. From the monitoring that has occurred, they typically occur in estuaries from June to October. Sturgeon typically occur in deep water resting and then come into shallow areas for feeding.

******

Not much is known about either species outside of the general biology for each fish.

# APPENDIX Q-2

ODFW 2012 Threatened and Endangered Species List

## Threatened, Endangered, and Candidate Fish and Wildlife Species in Oregon

The State of Oregon and the federal government maintain separate lists of threatened and endangered (T&E) species. These are species whose status is such that they are at some degree of risk of becoming extinct.

Under State law (ORS 496.171-496.192) the Fish and Wildlife Commission through ODFW maintains the list of native wildlife species in Oregon that have been determined to be either “threatened” or “endangered” according to criteria set forth by rule (OAR 635-100-0105).

Plant listings are handled through the Oregon Department of Agriculture.

Most invertebrate listings are handled through the Oregon Natural Heritage Program.

Under federal law the U.S. Fish and Wildlife Service and National Oceanic and Atmospheric Administration share responsibility for implementing the federal Endangered Species Act of 1973 (Public Law 93-205, 16 U.S.C. § 1531), as amended. In general, USFWS has oversight for land and freshwater species and NOAA for marine and anadromous species. In addition to information about species already listed, the USFWS-Oregon Field Office maintains a list of Species of Concern.

Additional information about the federal programs in place in Oregon can be found at the following websites:
• U.S. Fish and Wildlife-Oregon (http://www.fws.gov/oregonfwo)
• Northwest Region of NOAA-Fisheries (http://www.nwr.nmfs.noaa.gov)

# CONTENTS

Extinction is a natural process. Today, however, plant and animal species are disappearing world-wide at an accelerated pace. Based on current trends, half of the species on earth will be extinct within the next 100 years. The major reasons for this are human caused changes to the environment, which continue to increase - in Oregon and throughout the world.

Once lost, a species can never be recovered, and there is no way of knowing how useful it may have been. We do know that human beings and many of their industries depend on plant and animal products. About 50% of all pharmaceuticals have a natural component as an active ingredient, yet less than one percent of the world's species have been chemically analyzed and tested. Many insects and plants contain undescribed and highly functional compounds.

*Limnanthes pumila* subsp. *grandiflora*, or wooly meadow-foam, a rare plant that grows in southwest Oregon, has been found to produce a hybrid with the more common member of the genus, *Limnanthes alba*. This hybrid grows well in the poorly drained soils of the Willamette Valley and produces a valuable oil used for soaps, plastic and rubber production. In addition, the new hybrid meadow-foam does not require the field burning necessary for other crops. This species, and many other Oregon natives, will be lost without intervention. The purpose of this publication is to provide land managers, owners and interested parties with a list of those species in Oregon which are in greatest jeopardy.

**Oregon State Endangered Species Programs**

In 1987, the Oregon Legislature passed an Endangered Species Act which gave the Oregon Department of Agriculture (ODA) responsibility and jurisdiction over threatened and endangered plants, and reaffirmed the Oregon Department of Fish and Wildlife's (ODFW) responsibility for threatened and endangered fish and wildlife. Both of these agencies have entered into cooperative (Section 6) agreements with the United States Fish and Wildlife Service (USFWS) for the purpose of carrying out research and conservation programs for animals and plants under the auspices of the federal Endangered Species Act. Oregon Parks and Recreation Department (OPRD) has a similar agreement with USFWS for invertebrates. More information on the state endangered species programs can be found at the beginning of the animal and plant sections of this booklet.

**Oregon Biodiversity Information Center**

The Oregon Biodiversity Information Center (ORBIC) is part of the Institute for Natural Resources (INR) located at Portland State University (PSU). ORBIC maintains extensive databases of Oregon biodiversity, concentrating on rare and endangered plants, animals and ecosystems.

ORBIC is managed by PSU, but has been a cooperative project, with significant support from Oregon Parks and Recreation, the Department of State Lands, The Nature Conservancy in Oregon, U.S. Fish and Wildlife Service (USFWS), the Bureau of Land Management (BLM), the U.S. Forest Service (USFS) and Oregon State University. Biologists working for these agencies, together with the state's herbaria and museums, provide most of the information that comprise ORBIC's databases. ORBIC also manages the state Natural Areas Program, for OPRD, as well as their Section 6 invertebrate program. ORBIC is also affiliated with the Natural Heritage U.S. network with information being coordinated by the NatureServe organization.

This booklet has been compiled using the most current information available on the distribution and abundance of plants and animals native to Oregon. Although based on a large volume of information, it is by no means complete. Much is known about some species, very little about others. ORBIC welcomes additional information or recommendations regarding any of the taxa listed herein. Such information, as well as data requests, should be directed to:

Oregon Biodiversity Information Center
Institute for Natural Resources
Portland State University
Mail Stop: INR
PO Box 751
Portland, Oregon 97207-0751

Or, send an e-mail to *inrdata@pdx.edu*.

On-line versions of the booklet can be found at *http://orbic.pdx.edu*.

**Outline**

This booklet is divided into animal and plant (including fungi) sections. The sections begin with a description of the animal and plant programs in the state and are followed by the main list of animals and plants. For animals, the list is first divided into major groups (fish, amphibians, reptiles, mammals, birds, and invertebrates) and then arranged alphabetically by scientific name. Invertebrates are further divided by class and order. The plant list is first divided into four groups (vascular plants, non-vascular plants, lichens and fungi) and then alphabetized by scientific name. The information for each taxa includes the scientific and common names with authorities for plants, county, ecoregion, and adjacent state distribution information; the state and federal status; and the NatureServe/Heritage Network Global and State ranks, as well as the ORBIC list. Distribution abbreviations are listed and explained below.

**Criteria and Definitions**

Inclusion of any given taxon on these lists is based on several specific criteria. The most important factors are the total number of known, extant populations in Oregon and world-wide, and the degree to which they are potentially or actively threatened with destruction. Other criteria include the number of known populations considered to be securely protected, the size of the various populations, and the ability of the taxon to persist at known sites. The taxonomic distinctness of each species also has been considered. Hybrids or questionable, undescribed species have not been included, although undescribed taxa recognized by the scientific community in Oregon are included.

Taxonomic experts who were consulted are listed in the Acknowledgments section. All of these criteria are considered in the development of NatureServe/ Heritage Network species ranks as well.

Definitions and explanations of the various ranks and federal and state status are included on page 4, and summarized on the back inside cover along with a list of abbreviations. A number of definitions and criteria specific to animals (wintering or breeding ranks in birds) are discussed in detail at the beginning of the animal section of this booklet.

## DISTRIBUTION INFORMATION

**Distribution Information**

The distribution information included on the lists represents both the current and historic, documented distribution of the taxa.

The information is in the following format: Ecoregion; State (and/or Canadian Province); and County. Out-of-state distribution information is complete for plant and animal taxa on ORBIC List 1 (which are usually Oregon or regional endemics). For all other taxa, all adjacent states or the closest state with occurrences will be listed; a plus (+) signifies that the taxa is found in additional states. Taxa with no other states noted are Oregon endemics. For the most part, the Ecoregion, County and State distribution is based on both historic and current information. Any additional input on distribution will be incorporated in future updates of this publication.

**Ecoregions**

The map on the following page divides the state into nine distinct regions based on geologic and vegetative patterns. The map and the regions are based on EPA's Level 3 ecoregions. The Ecoregions are: CR = Coast Range, WV = Willamette Valley, KM = Klamath Mountains, WC = West Cascade Range and Crest, EC = East Cascade Range, BM = Blue Mountains, BR = Northern Basin and Range, CB = Columbia Basin, and ME=Marine & Estuarine.

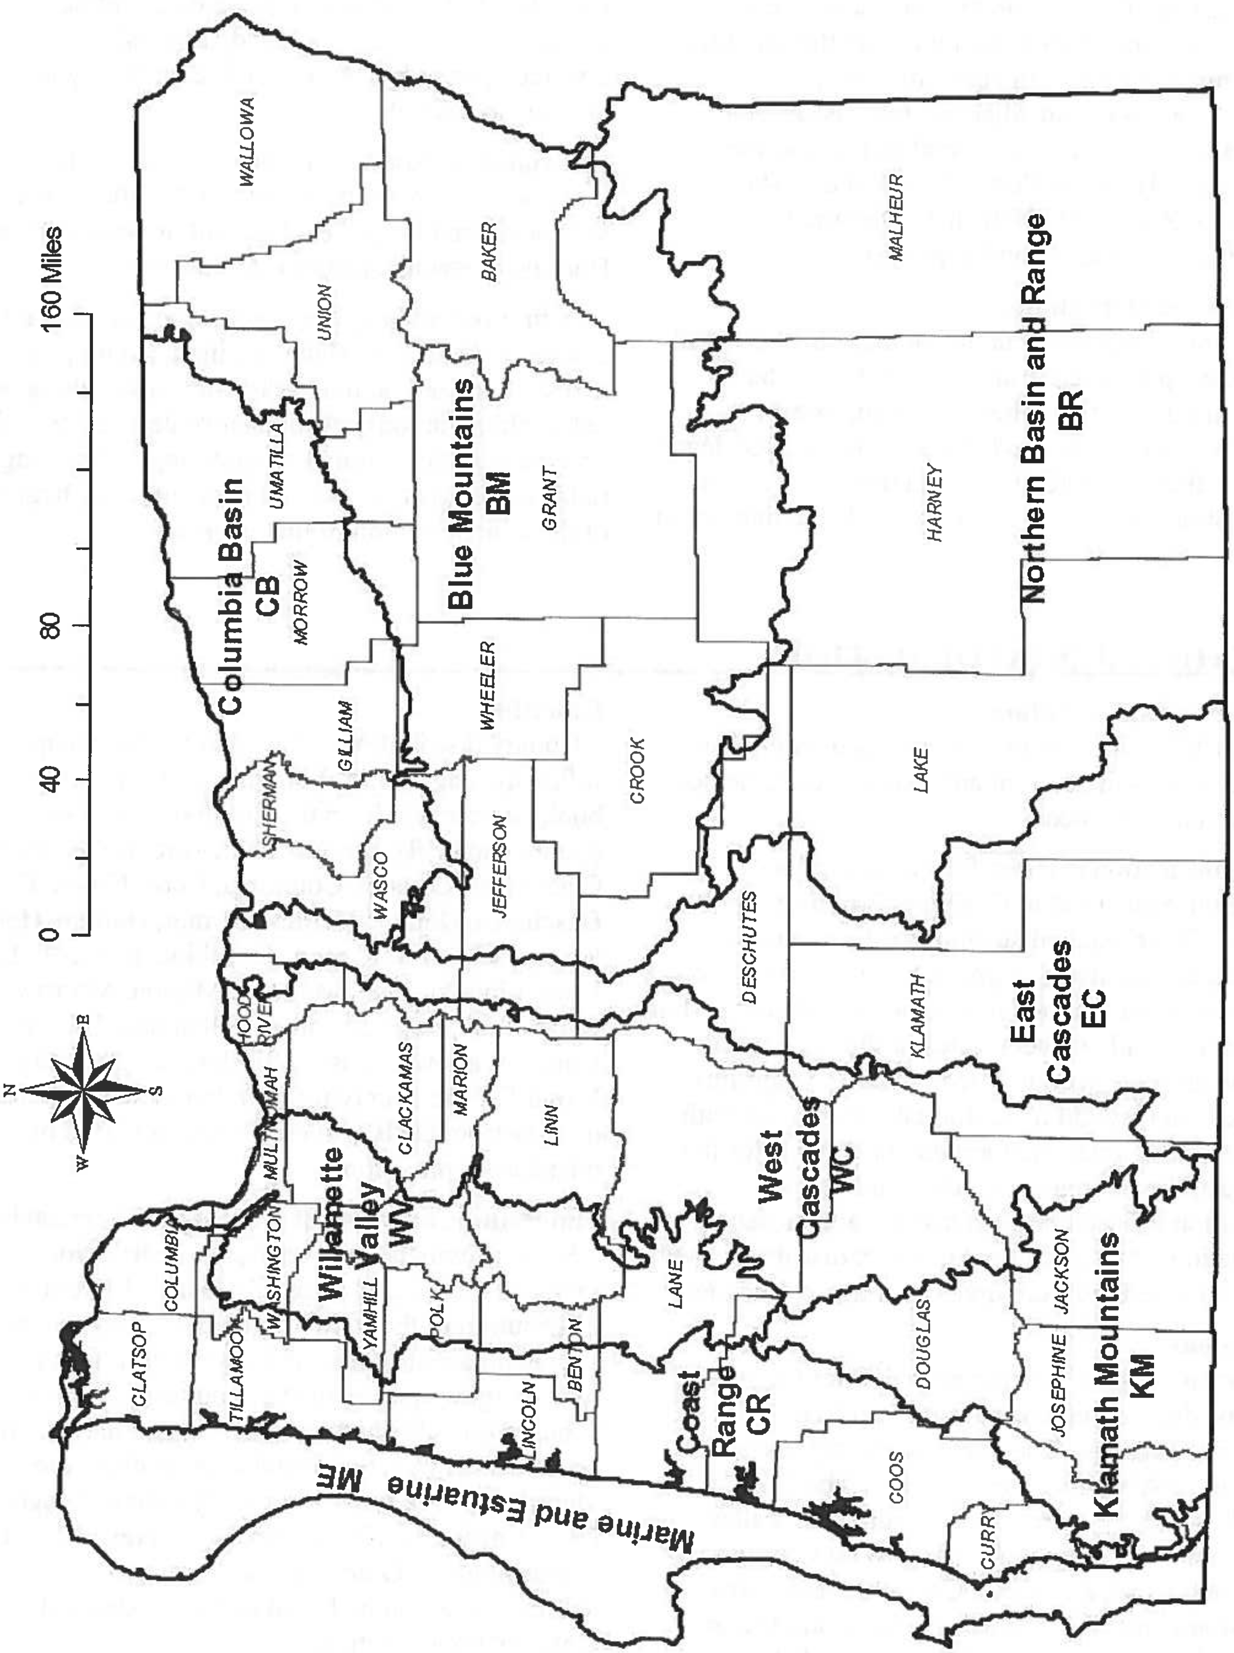
**Counties**

County distribution is keyed to the base map on the following page. The abbreviations used in the booklet are made from the first four letters of each county name. The county names are: Baker, Benton, Clackamas, Clatsop, Columbia, Coos, Crook, Curry, Deschutes, Douglas, Gilliam, Grant, Harney, Hood River, Jackson, Jefferson, Josephine, Klamath, Lake, Lane, Lincoln, Linn, Malheur, Marion, Morrow, Multnomah, Polk, Sherman, Tillamook, Umatilla, Union, Wallowa, Wasco, Washington, Wheeler, and Yamhill. The county information included is based on data from ORBIC files. Please notify us of mistakes or omissions.

**States and Canadian Provinces and Territories**

State, provincial, and territorial distribution is included on the lists primarily to alert biologists to the distribution of these rare, threatened, and endangered taxa in adjacent states. The distribution for the more wide ranging species in states not adjacent to Oregon is based on published information and may not be complete. Two-letter postal abbreviations are used to identify these regions. States adjacent to Oregon are: CA = California, ID = Idaho, NV = Nevada, and WA = Washington. Other state and province abbreviations can be found in the "Codes and Abbreviations" section.

## OREGON MAP WITH ECOREGIONS AND COUNTIES



## DEFINITIONS

**Endangered** taxa are those which are in danger of becoming extinct within the foreseeable future throughout all or a significant portion of their range.

**Threatened** taxa are those likely to become endangered within the foreseeable future.

**LE** = Listed Endangered. Taxa listed by the USFWS or the National Marine Fisheries Service (NOAA Fisheries) as Endangered under the Endangered Species Act (ESA), or by the ODA or ODFW under the Oregon Endangered Species Act of 1987 (OESA).

**LT** = Listed Threatened. Taxa listed by the USFWS, NOAA Fisheries, ODA, or ODFW as Threatened.

**PE** = Proposed Endangered. Taxa proposed by the USFWS or NOAA Fisheries to be listed as Endangered under the ESA or by ODFW or ODA under the OESA.

**PT** = Proposed Threatened. Taxa proposed by the USFWS or NOAA Fisheries to be listed as Threatened under the ESA or by ODFW or ODA under the OESA.

**C** = Candidate. Taxa for which NOAA Fisheries or USFWS have sufficient information to support a proposal to list under the ESA, or which is a candidate for listing by the ODA under the OESA.

**SOC** = Species of Concern. Taxa which the USFWS is reviewing for consideration as Candidates for listing under the ESA.

**PS** = Partial Status. Taxa for which some but not all infraspecific taxa have status.

### Lists Following Animal and Plant Sections

In addition to the main lists summarizing information on animals and plants, this booklet includes the agency lists compiled from the most recent information available:

- Federal and State, listed and proposed animals (USFWS, NOAA Fisheries, ODFW)
- Federal candidate (USFWS, NOAA Fisheries) and species of concern (USFWS) animals
- State sensitive animals (ODFW)
- Federal listed, proposed and candidate plants, and species of concern (USFWS)
- State listed and candidate plants (ODA)

The criteria for the ORBIC lists are as follows:

**List 1** contains taxa that are threatened with extinction or presumed to be extinct throughout their entire range.

**List 2** contains taxa that are threatened with extirpation or presumed to be extirpated from the state of Oregon. These are often peripheral or disjunct species which are of concern when considering species diversity within Oregon's borders. They can be very significant when protecting the genetic diversity of a taxon. ORBIC regards extreme rarity as a significant threat and has included species which are very rare in Oregon on this list.

**List 3** contains taxa for which more information is needed before status can be determined, but which may be threatened or endangered in Oregon or throughout their range.

**List 4** contains taxa which are of conservation concern but are not currently threatened or endangered. This includes taxa which are very rare but are currently secure, as well as taxa which are declining in numbers or habitat but are still too common to be proposed as threatened or endangered. While these taxa may not currently need the same active management attention as threatened or endangered taxa, they do require continued monitoring.

**Drops and Name Changes** contains taxa deleted or had their names changed from the previous edition (October 2010).

### NatureServe/Natural Heritage Network Ranks

ORBIC participates in an international system for ranking rare, threatened and endangered species throughout the world. The system was developed by The Nature Conservancy and is now maintained by NatureServe in cooperation with Heritage Programs and Conservation Data Centers in all fifty states (plus the Navajo Nation, Tennessee Valley Authority, Puerto Rico and the Virgin Islands), all of Canada except for two territories, and many Latin American countries.

**Rank Definitions**

The ranking is a 1-5 scale, based primarily on the number of known occurrences, but also including threats, sensitivity, area occupied, and other biological factors. In this booklet, the ranks occupy two lines. The top line is the Global Rank and begins with a "G". If the taxon has a trinomial (a subspecies, variety or recognized race), this is followed by a "T" rank indicator. The second line is the State Rank and begins with the letter "S". The ranks are summarized below (see page 6 for migratory bird ranks):

1 = Critically imperiled because of extreme rarity or because it is somehow especially vulnerable to extinction or extirpation, typically with 5 or fewer occurrences.
2 = Imperiled because of rarity or because other factors demonstrably make it very vulnerable to extinction (extirpation), typically with 6-20 occurrences.
3 = Rare, uncommon or threatened, but not immediately imperiled, typically with 21-100 occurrences.
4 = Not rare and apparently secure, but with cause for long-term concern, usually with more than 100 occurrences.
5 = Demonstrably widespread, abundant, and secure.
H = Historical Occurrence, formerly part of the native biota with the implied expectation that it may be rediscovered.
X = Presumed extirpated or extinct.
U = Unknown rank.
NR = Not yet ranked.

**Rank Qualifiers**

Q = Questionable taxonomy. Global ranks sometimes have a "Q" at the end. This indicates that there are questions related to the taxonomic validity of the taxon.
? = Inexact Numeric Rank. Taxa that can be ranked, but for which the rank is not certain. Ranks with a "?" indicate that the rank is probably correct, but that either documentation is lacking or there is still some uncertainty. Such ranks are always provisional.
Range Ranks = Ranks with more than one value. These can be G1G2, G1G3, etc. These indicate that the predicted final rank would be within the range, but with no indication of preference among the possibilities.

More details on the Heritage Ranking system and more definitions can be found at the NatureServe web site: *http://www.natureserve.org/explorer/ranking.htm*

## SPECIAL ANIMALS

Information on Oregon's rare, threatened and endangered animal species is presented here in two formats. The first is a list summarizing the distribution, federal and state status, and Heritage Network rank of the species as described on pages 4 and 5. The second format breaks the species into lists based on their status.

In both formats, the special animals are divided into major groups (fish, amphibians, reptiles, birds, mammals, invertebrates), then listed alphabetically by scientific name. The invertebrate summary list is unique in being further subdivided into class and order.

The animals included in this booklet are those rare, threatened and endangered vertebrate and invertebrate species that are native to Oregon and have (or have had) sustained breeding populations within the state. Open-ocean mammals or sea turtles which generally occur offshore and do not breed in Oregon are not included in this book. Wintering bird species and those which occur on an accidental or occasional basis present special problems which are described below.

### Animal Species Tracked

ORBIC strives to serve as a clearinghouse of information regarding site-specific locations of rare, threatened and endangered species in Oregon. The goal is to obtain and computerize information for all locations of all state and federally listed animal species. Location data is also computerized for other animal species that are rare (of limited abundance or restricted distribution), threatened, endangered or otherwise vulnerable in Oregon, based on the NatureServe/Natural Heritage Network ranks. Locations for a species are tracked only if it is possible to track all sites in the state.

Ranking decisions are made based on the best available information. Comments on ranks or on the inclusion or exclusion of taxa are welcome. Funds are not currently available to track all species of concern and all ODFW Sensitive Species, although ORBIC tracks as many of these as possible.

ORBIC maintains computerized information for all animal species on ORBIC Lists 1 and 2. There are several accidental or occasional breeding birds that are not tracked, even though they rank out highly. Since most of these species are well outside their normal range, effort is better spent on species which are part of Oregon's usual fauna. Additionally, ORBIC maintains manual files and observation data for all animal species in this booklet.

ORBIC encourages everyone to send in any information, reports or observations for the special animal species listed. A form for providing animal data is available at *http://orbic.pdx.edu/documents/animalform.pdf* Information need not be limited to this format to be considered for submission.

## Animal Lists and Wildlife State Ranks

### Fish

All vertebrate taxa in this booklet have published or soon to be published valid names, except for some fish taxa. These fish are represented on the lists by their Evolutionarily Significant Unit (ESU) designation. The ESU designations are defined by NOAA Fisheries under their ESA responsibility. ORBIC tracks and ranks all listed, proposed and candidate ESUs for anadromous fish. For listed or proposed anadromous fish, spawning and rearing areas are mapped as well as, but separately from, migratory corridors. As a result, there are a few listed salmon tracked which may never have spawned in Oregon, but which travel through the waters of the state. ODFW evaluates and manages anadromous and freshwater fish populations within areas defined as Species Management Units (SMU). For salmonids, these areas generally align with ESUs identified by NOAA. In cases of a sensitive fish species which has no NOAA-identified ESU, we track the SMU as identified by ODFW.

### Birds

Avian species are usually placed on the ORBIC Lists based on breeding populations. Some species may be common in winter or migration but rare as breeders in Oregon. In these instances it is only the breeding populations that are of concern (e.g. horned grebe, bufflehead). Species that occur in Oregon in migration or as winter residents only are generally not considered here, except for especially sensitive species with critical staging or wintering locations in Oregon (e.g. Aleutian Canada goose, California brown pelican). There are several bird species that have nested in Oregon on occasion (semipalmated plover, black-chinned sparrow) but are not yet considered established breeders. For now these species are not included on the list, pending more accurate determination of their breeding status. Species of accidental occurrence are not included either.

The NatureServe/ORBIC state ranks for migratory species (mainly birds) require further explanation. State ranks for long-distance migrants are separated by the breeding and nonbreeding components of the population. State ranks followed by a 'B' refer to breeding populations, while ranks followed by an 'N' refer to a nonbreeding (often wintering) population. Thus a state rank of S1B, S2N indicates that the breeding portion of the population is extremely rare and the wintering portion is slightly more common. If a species occurs in the state only during the breeding season it will only have an S#B rank. Similarly, if a species only occurs in Oregon during the nonbreeding season it will have an S#N rank. Species which are not long-distance migrants are ranked without the B or N modifier.

### Invertebrates

Compilation of the invertebrate lists has been especially challenging. Little is known about the status and distribution of most invertebrate taxa found in Oregon, especially those which appear to be rare, threatened or otherwise vulnerable. Most invertebrate groups are under-collected and under-observed. As a result state ranks may not accurately reflect the true population status for some species. Currently ORBIC assigns these species a state ranking number but the "?" modifier is occasionally used to indicate species that may be rarely collected as opposed to truly rare.

The Natural Areas Program of the Oregon Parks and Recreation Department has been granted limited authority to assist in conserving invertebrates through a cooperative agreement with the USFWS via Section 6 of the Endangered Species Act. ORBIC provides staff to help manage this program. It is hoped that with the cooperation of conservation organizations, state agencies and federal agencies, additional information can be gathered to help understand and conserve rare, threatened and endangered invertebrates in Oregon.

## Oregon Department of Fish and Wildlife's Threatened, Endangered and Sensitive Species Program – ODFW

Martin Nugent, Threatened, Endangered and Sensitive Species Coordinator
Eric Rickerson, Assistant Administrator, Wildlife Division

The Oregon Department of Fish and Wildlife (ODFW) maintains a list of threatened and endangered species under the authority of ORS 496.172, the Oregon Endangered Species Act, 1987. The list included in this booklet reflects ODFW's revisions as of October 2013. There are currently 32 taxa on the list. The list includes 12 marine animals (i.e. whales, sea turtles, pelagic birds) that are not included in this book. The Act requires state agencies to develop programs for the management and protection of endangered species, and requires agencies to comply with guidelines adopted by the Oregon Fish and Wildlife Commission for threatened species. The Oregon Fish and Wildlife Commission has adopted administrative rules, OAR 635-100-100 to 130, which clarify the Act and provide criteria for listing, delisting and protection of listed species.

Oregon Department of Fish and Wildlife maintains a Sensitive Species list in accordance with OAR 635-100-0040 which is designed to provide a positive, proactive approach to species conservation. The Sensitive Species list focuses fish and wildlife management and research activities on species that need conservation attention. Although the intent of the Sensitive Species list is to prevent species from declining to the point of qualifying as threatened or endangered, this list is not used as a "candidate" list for species to be considered for listing under the Oregon Threatened and Endangered Species rules. The Sensitive Species list serves as an early warning system for biologists, land managers, policy makers, and the public. It helps ensure that conservation actions are prioritized, cost-efficient, and effective. The sensitive species list is updated by ODFW every five years. The sensitive species list was last revised in 2008.

"Sensitive species" are those naturally-reproducing fish and wildlife species, subspecies, or populations which are facing one or more threats to their populations and/or habitats. Implementation of appropriate conservation measures to address the threats may prevent them from declining to the point of qualifying for threatened or endangered status.

Sensitive species categories are defined as follows:

**"Critical"** sensitive species (SC) are imperiled with extirpation from a specific geographic area of the state because of small population sizes, habitat loss or degradation, and/or immediate threats. Critical species may decline to point of qualifying for threatened or endangered status if conservation actions are not taken.

**"Vulnerable"** sensitive species (SV) are facing one or more threats to their populations and/or habitats. Vulnerable species are not currently imperiled with extirpation from a specific geographic area or the state but could become so with continued or increased threats to populations and/or habitats.

All efforts towards management and protection of threatened, endangered and sensitive species in Oregon will be coordinated with other state and federal agencies and private conservation organizations. The current threatened and endangered species list is available on ODFW's website at: *http://www.dfw.state.or.us/wildlife/diversity/species/threatened_endangered_species.asp*. The sensitive species list is available at: *http://www.dfw.state.or.us/wildlife/diversity/species/sensitive_species.asp*

Copies of the Oregon Endangered Species Act or administrative rules, or the Sensitive Species rule, or lists of the threatened and endangered or sensitive species may also be requested from the department by writing to:

# FEDERAL ENDANGERED SPECIES ACT STATUS*

## Animals Listed as Endangered

### Fish

*Catostomus microps* - Modoc sucker
*Chasmistes brevirostris* - Shortnose sucker
*Deltistes luxatus* - Lost River sucker
*Gila boraxobius* - Borax Lake chub
*Oncorhynchus nerka* - Sockeye salmon (Snake River ESU)

### Birds

*Gymnogyps californianus* - California condor (extirpated)

### Mammals

*Canis lupus* - Gray wolf (Western Oregon)
*Odocoileus virginianus leucurus* - Columbian white-tailed deer (Columbia River population)

### Invertebrates

*Icaricia icarioides fenderi* - Fender's blue butterfly

## Animals Listed as Threatened

### Fish

*Acipenser medirostris* -- Green sturgeon (Southern DPS)
*Catostomus warnerensis* - Warner sucker
*Gila bicolor ssp.* - Hutton tui chub
*Oncorhynchus clarki henshawi* - Lahontan cutthroat trout
*Oncorhynchus keta* - Chum salmon (Columbia River ESU)
*Oncorhynchus kisutch* - Coho salmon (Lower Columbia River/SW Washington Coast ESU)
*Oncorhynchus kisutch* - Coho salmon (Southern Oregon/Northern California Coasts ESU)
*Oncorhynchus kisutch* - Coho salmon (Oregon Coast ESU)
*Oncorhynchus mykiss* - Steelhead (Snake River Basin ESU)
*Oncorhynchus mykiss* - Steelhead (Lower Columbia River ESU, summer run)
*Oncorhynchus mykiss* - Steelhead (Lower Columbia River ESU, winter run)
*Oncorhynchus mykiss* - Steelhead (Middle Columbia River ESU, summer run)
*Oncorhynchus mykiss* - Steelhead (Middle Columbia River ESU, winter run)
*Oncorhynchus mykiss* - Steelhead (Upper Willamette River ESU, winter run)
*Oncorhynchus tshawytscha* - Chinook salmon (Snake River ESU, fall run)
*Oncorhynchus tshawytscha* - Chinook salmon (Lower Columbia River ESU, spring run)
*Oncorhynchus tshawytscha* - Chinook salmon (Lower Columbia River ESU, fall run)
*Oncorhynchus tshawytscha* - Chinook salmon (Upper Willamette River ESU, spring run)
*Oncorhynchus tshawytscha* - Chinook salmon (Snake River ESU, spring/summer run)
*Oregonichthys crameri* - Oregon chub
*Rhinichthys osculus ssp.* - Foskett Spring speckled dace
*Salvelinus confluentus* - Bull trout (Klamath River population)
*Salvelinus confluentus* - Bull trout (Columbia River population)
*Salvelinus confluentus* - Bull trout (Deschutes SMU)
*Salvelinus confluentus* - Bull trout (Grande Ronde SMU)
*Salvelinus confluentus* - Bull trout (Hells Canyon SMU)
*Salvelinus confluentus* - Bull trout (Hood River SMU)
*Salvelinus confluentus* - Bull trout (Imnaha SMU)
*Salvelinus confluentus* - Bull trout (John Day SMU)
*Salvelinus confluentus* - Bull trout (Malheur SMU)
*Salvelinus confluentus* - Bull trout (Odell Lake SMU)
*Salvelinus confluentus* - Bull trout (Umatilla SMU)
*Salvelinus confluentus* - Bull trout (Willamette SMU)
*Thaleichthys pacificus* - Eulachon

### Birds

*Brachyramphus marmoratus* - Marbled murrelet
*Charadrius nivosus nivosus* - Western snowy plover (coastal population)
*Strix occidentalis caurina* - Northern spotted owl

### Mammals

*Eumetopias jubatus* - Northern sea lion
*Lynx canadensis* - Canada lynx
*Ursus arctos horribilis* - Grizzly bear (extirpated)

### Invertebrates

*Branchinecta lynchi* - Vernal pool fairy shrimp
*Speyeria zerene hippolyta* - Oregon silverspot butterfly

## Animals Proposed for Listing as Endangered

### Invertebrates

*Euphydryas editha taylori* - Taylor's checkerspot butterfly

## Animals Proposed for Listing as Threatened

### Birds

*Eremophila alpestris strigata* - Streaked horned lark

### Mammals

*Gulo gulo* - Wolverine

## Candidate Animals for Listing

### Amphibians

*Rana luteiventris* - Columbia spotted frog
*Rana pretiosa* - Oregon spotted frog

### Birds

*Centrocercus urophasianus* -- Greater sage-grouse
*Coccyzus americanus* - Yellow-billed cuckoo

### Mammals

*Arborimus longicaudus* -- Red tree vole (North Oregon Coast)
*Pekania (Martes) pennanti* - Fisher
*Urocitellus washingtoni* - Washington ground squirrel

### Invertebrates

*Polites mardon* - Mardon skipper (butterfly

*Does not include sea turtles, whales, or accidental species

## USFWS SPECIES OF CONCERN

### Fish

*Acipenser medirostris* - Green sturgeon (Northern DPS)
*Catostomus occidentalis lacusanserinus* - Goose Lake sucker
*Catostomus rimiculus* - Jenny Creek sucker
*Catostomus snyderi* - Klamath largescale sucker
*Cottus bendirei* - Malheur mottled sculpin
*Cottus marginatus* - Margined sculpin
*Cottus tenuis* - Slender sculpin
*Entosphenus tridentatus*- Pacific lamprey
*Entosphenus tridentatus* ssp. - Goose Lake lamprey
*Gila alvordensis* - Alvord chub
*Gila bicolor eurysoma* - Sheldon tui chub
*Gila bicolor oregonensis* - Oregon Lakes tui chub
*Gila bicolor* ssp. - Summer Basin tui chub
*Gila bicolor* ssp. - Catlow tui chub
*Lampetra ayresi* - River lamprey
*Lavinia symmetricus mitrulus* - Pit roach
*Oncorhynchus clarki* - Coastal cutthroat trout (OR Coast ESU)
*Oncorhynchus clarki* - Coastal cutthroat trout (Upper Willamette River ESU)
*Oncorhynchus clarki* - Coastal cutthroat trout (Southwestern WA/Columbia River ESU)
*Oncorhynchus clarki* - Coastal cutthroat trout (Southern Oregon/California Coasts ESU)
*Oncorhynchus clarki lewisi* - Westslope cutthroat trout
*Oncorhynchus mykiss* - Steelhead (OR Coast ESU, summer run)
*Oncorhynchus mykiss* - Steelhead (OR Coast ESU, winter run)
*Oncorhynchus mykiss gairdneri (= O, m. gibbsi)* - Inland Columbia Basin/Great Basin redband trout
*Oncorhynchus mykiss* - Catlow Valley redband trout
*Oncorhynchus mykiss* - Warner Valley redband trout
*Oncorhynchus mykiss* - Goose Lake redband trout
*Oregonichthys kalawatseti* - Umpqua chub
*Rhinichthys cataractae* ssp. - Millicoma dace

### Amphibians

*Ascaphus montanus* -- Rocky Mountain tailed frog
*Ascaphus truei* - Coastal tailed frog
*Batrachoseps wrighti* - Oregon slender salamander
*Plethodon elongatus* - Del Norte salamander
*Plethodon larselli* - Larch Mountain salamander
*Plethodon stormi* - Siskiyou Mountains salamander
*Rana aurora* - Northern red-legged frog
*Rana boylii* - Foothill yellow-legged frog
*Rana cascadae* - Cascades frog
*Rhyacotriton variegatus* - Southern torrent salamander

### Reptiles

*Actinemys marmorata*– Western pond turtle
*Lampropeltis getula* - Common kingsnake
*Lampropeltis zonata* - California mountain kingsnake
*Sceloporus graciosus graciosus* - Northern sagebrush lizard

### Birds

*Accipiter gentilis* - Northern goshawk
*Agelaius tricolor* - Tricolored blackbird
*Athene cunicularia hypugaea* - Western burrowing owl
*Bartramia longicauda* - Upland sandpiper
*Buteo regalis* - Ferruginous hawk
*Chlidonias niger* - Black tern
*Contopus cooperi* - Olive-sided flycatcher
*Coturnicops noveboracensis* - Yellow rail
*Empidonax traillii adastus* - Willow flycatcher
*Haematopus bachmani* – Black oystercatcher
*Histrionicus histrionicus* - Harlequin duck
*Icteria virens* - Yellow-breasted chat
*Melanerpes formicivorus* - Acorn woodpecker
*Melanerpes lewis* - Lewis's woodpecker
*Oreortyx pictus* - Mountain quail
*Patagioenas fasciata* - Band-tailed pigeon
*Picoides albolarvatus* - White-headed woodpecker
*Plegadis chihi* - White-faced ibis
*Pooecetes gramineus affinis* - Oregon vesper sparrow
*Progne subis* - Purple martin
*Tympanuchus phasianellus columbianus* - Columbian sharp-tailed grouse

### Mammals

*Antrozous pallidus* - Pallid bat
*Arborimus albipes* - White-footed vole
*Brachylagus idahoensis* - Pygmy rabbit
*Corynorhinus townsendii* - Townsend's big-eared bat
*Euderma maculatum* - Spotted bat
*Lasionycteris noctivagans* - Silver-haired bat
*Myotis ciliolabrum* - Western small-footed myotis
*Myotis evotis* - Long-eared myotis
*Myotis thysanodes* - Fringed myotis
*Myotis volans* - Long-legged myotis
*Myotis yumanensis* - Yuma myotis
*Sorex preblei* - Preble's shrew
*Thomomys bottae detumidus* - Pistol River pocket gopher
*Thomomys bulbivorus* - Camas pocket gopher
*Thomomys mazama helleri* - Gold Beach pocket gopher

### Invertebrates

*Acetropis americana* - American grass bug
*Agapetus denningi* - Denning's agapetus caddisfly
*Agonum belleri* - Beller's ground beetle
*Allomyia scotti* - Scott's apatanian caddisfly
*Anodonta californiensis* - California floater (mussel)
*Apatania tavala* - Cascades apatanian caddisfly
*Apochthonius malheuri* - Malheur pseudoscorpion
*Bombus franklini* - Franklin's bumblebee
*Chloealtis aspasma* - Siskiyou short-horned grasshopper
*Cryptochia neosa* -- Blue Mountains cryptochian caddisfly
*Driloleirus macelfreshi* - Oregon giant earthworm
*Eobrachycentrus gelidae* - Mt. Hood brachycentrid caddisfly
*Farula davisi* - Green Springs Mountain farulan caddisfly
*Farula jewetti* - Mt. Hood farulan caddisfly
*Farula reapiri* - Tombstone Prairie farulan caddisfly
*Fluminicola fuscus* - Columbia pebblesnail or spire snail
*Goeracea oregona* - Sagehen Creek goeracean caddisfly
*Gomphus lynnae* - Lynn's clubtail dragonfly
*Homoplectra schuhi* - Schuh's homoplectran caddisfly
*Kenkia rhynchida* - A flatworm (planarian)
*Lepidostoma astaneum* - Goeden's lepidostoman caddisfly
*Littorina subrotundata* - Newcomb's littorine snail
*Monadenia fidelis minor* - Oregon snail (Dalles sideband)
*Nebria gebleri siskiyouensis* - Siskiyou gazelle beetle
*Neothremma andersoni* - Columbia Gorge caddisfly
*Oligophlebodes mostbento* - Tombstone Prairie caddisfly
*Pisidium ultramontanum* - Montane peaclam
*Plebeius saepiolus littoralis* - Insular blue butterfly
*Pterostichus rothi* - Roth's blind ground beetle
*Rhyacophila colonus* - O'Brien rhyacophilan caddisfly
*Rhyacophila haddocki* - Haddock's rhyacophilan caddisfly
*Rhyacophila unipunctata* - One-spot rhyacophilan caddisfly
*Stygobromus hubbsi* - Malheur Cave amphipod
*Zapada wahkeena* - Wahkeena Falls flightless stonefly

## STATE ENDANGERED SPECIES ACT STATUS

### Animals Listed as Endangered

#### Fish

*Chasmistes brevirostris* - Shortnose sucker
*Deltistes luxatus* - Lost River sucker
*Gila boraxobius* - Borax Lake chub
*Oncorhynchus kisutch* - Coho salmon (Lower Columbia River/SW Washington Coast ESU)

#### Birds

*Pelecanus occidentalis californicus* - California brown pelican

#### Mammals

*Canis lupus* - Gray wolf
*Urocitellus washingtoni* - Washington ground squirrel

### Animals Listed as Threatened

#### Fish

*Catostomus warnerensis* - Warner sucker
*Gila bicolor* ssp. - Hutton tui chub
*Oncorhynchus clarki henshawi* - Lahontan cutthroat trout
*Oncorhynchus tshawytscha* - Chinook salmon (Snake River ESU, fall run)
*Oncorhynchus tshawytscha* - Chinook salmon (Snake River ESU, spring/summer run)
*Rhinichthys osculus* ssp. - Foskett Spring speckled dace

#### Birds

*Brachyramphus marmoratus* - Marbled murrelet
*Charadrius nivosus nivosus* - Western snowy plover
*Strix occidentalis caurina* - Northern spotted owl

#### Mammals

*Enhydra lutris* - Sea otter
*Gulo gulo* - Wolverine
*Vulpes macrotis* - Kit fox

## ODFW SENSITIVE SPECIES LIST

#### Fish

*Catostomus microps* - Modoc sucker (C)
*Catostomus occidentalis lacusanserinus* - Goose Lake sucker (V)
*Entosphenus minimus* – Miller Lake lamprey (V)
*Entosphenus tridentatus* - Pacific lamprey (V)
*Gila alvordensis* - Alvord chub (V)
*Gila bicolor* ssp. - Summer Basin tui chub (C)
*Lampetra richardsonii* – Western brook lamprey (V)
*Oncorhynchus clarki* - Coastal cutthroat trout (Southwestern Washington/Columbia River ESU) (V)
*Oncorhynchus clarki lewisi* - Westslope cutthroat trout (C)
*Oncorhynchus keta* - Chum salmon (Columbia River ESU) (C)
*Oncorhynchus keta* - Chum salmon (Pacific Coast ESU) (C)
*Oncorhynchus kisutch* - Coho salmon (Southern Oregon/Northern California Coasts ESU) (V)
*Oncorhynchus kisutch* - Coho salmon (Oregon Coast ESU) (V)
*Oncorhynchus mykiss gairdneri* - Inland Columbia Basin redband trout (V)
*Oncorhynchus mykiss* - Steelhead (Snake River Basin ESU) (V)
*Oncorhynchus mykiss* - Steelhead (Klamath Mountains Province ESU, summer run) (V/C)
*Oncorhynchus mykiss* - Steelhead (Lower Columbia River ESU, summer run) (C)
*Oncorhynchus mykiss* - Steelhead (Lower Columbia River ESU, winter run) (C)
*Oncorhynchus mykiss* - Steelhead (Middle Columbia River ESU, summer run) (C)
*Oncorhynchus mykiss* - Steelhead (Oregon Coast ESU, summer run) (V)
*Oncorhynchus mykiss* - Steelhead (Oregon Coast ESU, winter run) (V)
*Oncorhynchus mykiss* - Steelhead (Upper Willamette River ESU, winter run) (V)
*Oncorhynchus mykiss* - Catlow Valley redband trout (C)
*Oncorhynchus mykiss* - Chewaucan redband trout (V)
*Oncorhynchus mykiss* - Fort Rock redband trout (C)
*Oncorhynchus mykiss* - Goose Lake redband trout (C)
*Oncorhynchus mykiss* - Klamath Basin redband trout (V)
*Oncorhynchus mykiss* - Malheur Lakes redband trout (V)
*Oncorhynchus mykiss* - Warner Valley redband trout (C)
*Oncorhynchus tshawytscha* - Chinook salmon (Lower Columbia River ESU, spring run) (C)
*Oncorhynchus tshawytscha* - Chinook salmon (Lower Columbia River ESU, fall run) (C)
*Oncorhynchus tshawytscha* - Chinook salmon (Middle Columbia River ESU, spring run) (V)
*Oncorhynchus tshawytscha* - Chinook salmon (Middle Columbia River ESU, fall run) (V)
*Oncorhynchus tshawytscha* - Chinook salmon (Oregon Coast ESU, spring run) (C)
*Oncorhynchus tshawytscha* - Chinook salmon (Southern Oregon/Northern California Coast ESU, fall run) (V)
*Oncorhynchus tshawytscha* - Chinook salmon (Southern Oregon/Northern California Coast ESU, spring run) (V)
*Oncorhynchus tshawytscha* - Chinook salmon (Upper Willamette River ESU, spring run) (C)
*Oregonichthys crameri* - Oregon chub (C)
*Oregonichthys kalawatseti* - Umpqua chub (C)
*Rhinichthys cataractae* ssp. - Millicoma dace (V)
*Salvelinus confluentus* - Bull trout (Klamath River population) (C)
*Salvelinus confluentus* - Bull trout (Deschutes SMU) (V)
*Salvelinus confluentus* - Bull trout (Grande Ronde SMU) (C)
*Salvelinus confluentus* - Bull trout (Hells Canyon SMU) (C)
*Salvelinus confluentus* - Bull trout (Hood River SMU) (C)
*Salvelinus confluentus* - Bull trout (Imnaha SMU) (C)
*Salvelinus confluentus* - Bull trout (John Day SMU) (C)
*Salvelinus confluentus* - Bull trout (Malheur SMU) (C)
*Salvelinus confluentus* - Bull trout (Odell Lake SMU) (C)
*Salvelinus confluentus* - Bull trout (Umatilla SMU) (C)
*Salvelinus confluentus* - Bull trout (Willamette SMU) (C)

#### Amphibians

*Anaxyrus boreas* - Western toad (V)
*Aneides ferreus* - Clouded salamander (V)
*Aneides flavipunctatus* - Black salamander (V)
*Ascaphus montanus* - Rocky Mountain tailed frog (V)
*Ascaphus truei* - Coastal tailed frog (V)
*Batrachoseps wrighti* - Oregon slender salamander (V)
*Dicamptodon copei* - Cope's giant salamander (V)
*Lithobates pipiens* - Northern leopard frog (C)
*Plethodon elongatus* - Del Norte salamander (V)
*Plethodon larselli* - Larch Mountain salamander (V)
*Plethodon stormi* - Siskiyou Mountains salamander (V)

*Rana aurora* - Northern red-legged frog (V)
*Rana boylii* - Foothill yellow-legged frog (C/V)
*Rana cascadae* - Cascades frog (V)
*Rana luteiventris* - Columbia spotted frog (C/V)
*Rana pretiosa* - Oregon spotted frog (C)
*Rhyacotriton cascadae* - Cascade torrent salamander (V)
*Rhyacotriton kezeri* - Columbia torrent salamander (V)
*Rhyacotriton variegatus* - Southern torrent salamander (V)

**Reptiles**

*Actinemys marmorata* - Western pond turtle (C)
*Chrysemys picta* - Painted turtle (C)
*Crotalus viridis* - Western rattlesnake (C)
*Lampropeltis getula* - Common kingsnake (V)
*Lampropeltis zonata* - California mountain kingsnake (V)
*Sceloporus graciosus graciosus* - Northern sagebrush lizard (V)

**Birds**

*Accipiter gentilis* - Northern goshawk (V)
*Ammodramus savannarum* - Grasshopper sparrow (V)
*Artemisiospiza belli* - Sage sparrow (C)
*Athene cunicularia hypugaea* - Western burrowing owl (C/V)
*Bartramia longicauda* - Upland sandpiper (C)
*Buteo regalis* - Ferruginous hawk (C/V)
*Buteo swainsoni* - Swainson's hawk (V)
*Centrocercus urophasianus* - Greater sage-grouse (V)
*Cerorhinca monocerata* - Rhinoceros auklet (V)
*Chordeiles minor* - Common nighthawk (C)
*Coccyzus americanus* - Yellow-billed cuckoo (C)
*Contopus cooperi* - Olive-sided flycatcher (V)
*Coturnicops noveboracensis* - Yellow rail (C)
*Dolichonyx oryzivorus* - Bobolink (V)
*Dryocopus pileatus* - Pileated woodpecker (V)
*Egretta thula* - Snowy egret (V)
*Empidonax traillii adastus* - Willow flycatcher (V)
*Empidonax traillii brewsteri* - Little willow flycatcher (V)
*Eremophila alpestris strigata* - Streaked horned lark (C)
*Falcipennis canadensis* - Spruce grouse (V)
*Falco peregrinus anatum* - American peregrine falcon (V)
*Falco peregrinus tundrius* - Arctic peregrine falcon (V)
*Fratercula cirrhata* - Tufted puffin (V)
*Grus canadensis tabida* - Greater sandhill crane (V)
*Haliaeetus leucocephalus* - Bald eagle (V)
*Haematopus bachmani* - Black oystercatcher (V)
*Icteria virens* - Yellow-breasted chat (C)
*Lanius ludovicianus* - Loggerhead shrike (V)
*Larus pipixcan* - Franklin's gull (V)
*Melanerpes formicivorus* - Acorn woodpecker (V)
*Melanerpes lewis* - Lewis's woodpecker (C)
*Numenius americanus* - Long-billed curlew (V)
*Oreortyx pictus* - Mountain quail (V)
*Otus flammeolus* - Flammulated owl (V)
*Pelecanus erythrorhynchos* - American white pelican (V)
*Picoides albolarvatus* - White-headed woodpecker (C)
*Picoides arcticus* - Black-backed woodpecker (V)
*Picoides dorsalis* - American three-toed woodpecker (V)
*Podiceps grisegena* - Red-necked grebe (C)
*Pooecetes gramineus affinis* - Oregon vesper sparrow (C)
*Progne subis* - Purple martin (C)
*Ptychoramphus aleuticus* - Cassin's auklet (V)
*Sialia mexicana* - Western bluebird (V)
*Sitta carolinensis aculeata* - Slender-billed nuthatch (V)
*Strix nebulosa* - Great gray owl (V)
*Sturnella neglecta* - Western meadowlark (C)
*Tympanuchus phasianellus columbianus* - Columbian sharp-tailed grouse (C)

**Mammals**

*Antrozous pallidus* - Pallid bat (V)
*Arborimus longicaudus* - Red tree vole (V)
*Bassariscus astutus* - Ringtail (V)
*Brachylagus idahoensis* - Pygmy rabbit (V)
*Corynorhinus townsendii* - Townsend's big-eared bat (C)
*Euderma maculatum* - Spotted bat (V)
*Lasionycteris noctivagans* - Silver-haired bat (V)
*Lasiurus cinereus* - Hoary bat (V)
*Lepus californicus* - Black-tailed jack rabbit (V)
*Lepus townsendii* - White-tailed jackrabbit (V)
*Martes caurina* - Pacific marten (V)
*Myotis californicus* - California myotis (V)
*Myotis thysanodes* - Fringed myotis (V)
*Myotis volans* - Long-legged myotis (V)
*Odocoileus virginianus leucurus* - Columbian white-tailed deer (V)
*Pekania pennanti* - Fisher (C)
*Sciurus griseus* - Western gray squirrel (V)

C = Critical V = Vulnerable

## DROPS AND NAME CHANGES since October 2010 list

**Fish**

| | |
|---|---|
| *Lampetra lethophaga* (Pit-Klamath brook lamprey) | Name change, now called *Entosphenus lethophagus* |
| *Lampetra minima* (Miller Lake lamprey) | Name change, now called *Entosphenus minimus* |
| *Lampetra tridentata* (Pacific lamprey) | Name change, now called *Entosphenus tridentatus* |
| *Lampetra tridentata* ssp. (Goose Lake lamprey) | Name change, now called *Entosphenus tridentatus* ssp. |

**Reptiles**

| | |
|---|---|
| *Actinemys marmorata* (Pacific pond turtle) | Common name change, now called Western pond turtle |

**Birds**

| | |
|---|---|
| *Amphispiza belli* (Sage sparrow) | Name change, now called *Artemisiospiza belli* |
| *Charadrius alexandrinus nivosus* (Western snowy plover) | Name change, now called *Charadrius nivosus nivosus* |
| *Ixobrychus exilis hesperis* (Western least bittern) | Name change, now called *Ixobrychus exilis* (Least bittern) |

**Mammals**

| | |
|---|---|
| *Martes americana* (American marten) | Name change, now called *Martes caurina* (Pacific marten) |
| *Martes pennanti* (Fisher) | Name change, now called *Pekania pennanti* |

**Invertebrates**

| | |
|---|---|
| *Bembidion nigricoeruleum* (A carabid beetle) | Dropped, too common |
| *Deroceras hesperium* (Evening fieldslug) | Dropped, part of more common *D. laeve* |
| *Euphydryas gillettii* (Gillette's checkerspot) | Common name correction, Gillett's checkerspot |
| *Gliabates sp. nov.* (Cascades axetail slug) | Name change, now called *Carinacauda stormi* |

### Nomenclature

Ongoing research has resulted in a number of recent changes which have been included in this version of the booklet. Whenever possible, for vascular plants we have used names and authorities provided by the Oregon Flora Project at the Oregon State University Herbarium. More information on this project is included on page 41.

### Lists

This plant list is an update of the 2010 edition of this publication. All status changes for specific taxa reflect new information obtained since then.

Species that have been dropped from the list or have had name changes are not included within the main body of the lists. These are listed separately in the "Drops and Name Changes" section on page 106. If you do not see a species name that had been in the 2010 edition of the booklet, please refer to that section.

The lists are arranged alphabetically by scientific name. Descriptions of the categories and lists can be found in the Introduction on page 1. State distribution is included for all vascular plant taxa in this edition. Distribution information for the non-vascular plants and fungi is not complete.

At the end of the main list, taxa are listed again by status. These include: a) the USFWS Federal Listed, Candidate and Species of Concern, b) the ODA State Listed and Candidate taxa, c) List 1, d) List 2, e) List 3, and f) List 4.

**List 1** contains taxa which are endangered or threatened throughout their range or which are presumed extinct. The status of taxa on this list represents its status throughout its range. Species which have been extirpated from Oregon are included with an -ex after the List number (e.g. 1-ex). Taxa known or thought to be extinct throughout their range have an -X following the list number (e.g. 1-X).

**List 2** contains taxa which are threatened, endangered or possibly extirpated from Oregon, but are stable or more common elsewhere. Taxa extirpated from Oregon are included with an -ex after the List number (e.g. 2-ex).

**List 3** contains taxa for which more information is needed before status can be determined, but which may be threatened or endangered in Oregon or throughout their range.

**List 4** contains taxa of concern which are not currently threatened or endangered. This list includes taxa which are very rare but are currently secure, as well as taxa which are declining in numbers or habitat but are still too common to be proposed as threatened or endangered.

### Other Information

ORBIC recognizes that fungi are not plants and should be recognized as a distinct kingdom. However, for this booklet they are included with the plants. As in previous editions, information on the fungi in the lists is not as complete as other groups of species. As a result, most remain on the Review List (List 3).

New information on these species has been summarized from recent work, which included extensive herbaria searches and fieldwork from federal agency biologists as well as from OSU faculty and staff. Most of this work was a result of the efforts by the USFS and BLM in implementing the Survey and Manage program of the Northwest Forest Plan. The heritage ranks are the best determination of a species' status, but due to their limited inventory, heritage ranks for fungi are generally less certain than for other vascular and non-vascular species. We hope their inclusion here will stimulate more research and survey, since many of these taxa may be among Oregon's rarest.

ORBIC is interested in obtaining and databasing information for all locations of taxa on Lists 1 and 2. Manual files are maintained for locations of those on List 3 and 4. It is critical that additional information be obtained for List 3 taxa so accurate status determinations can be made. The submission of additional information on status or occurrences of any species included on these lists would be appreciated. Distribution information is based on historical and current reports and is included to aid in searches and to increase knowledge of these taxa.

## State Endangered Plant Protection

Native Plant Conservation Program
Oregon Department of Agriculture (ODA)
Department of Botany and Plant Pathology
2082 Cordley Hall, Oregon State University
Corvallis, OR 97331-2902

Dr. Robert Meinke, Program Lead (OSU Graduate Faculty, Adjunct)
- (541) 737-2317
Kelly Amsberry, Plant Conservation Research Coordinator (OSU Research Associate)
- (541) 737-4333
Rebecca Currin, Conservation Planning and Regulatory Specialist (OSU Research Associate)
- (541) 737-4135
Jordan Brown, Staff Plant Conservation Biologist
- (541) 737-2346 (OSU Research Associate)
Dr. Stephen Meyers, Consulting Systematist (Oregon Flora Project, OSU)
- (541) 737-4338
Matt Groberg, Graduate Student (Botany Program, OSU)

In 1987, Oregon legislators passed Senate Bill 533 (unofficially the "Oregon Endangered Species Act") at the urging of the Native Plant Society of Oregon and others in the state's botanical community. This bill, and its accompanying statutes (ORS 564.100 through 564.135), directed the state Department of Agriculture (ODA) to conserve and protect those native plant species facing the greatest threats to their survival. The resulting Endangered Species Program (now integrated into the Native Plant Conservation Program in ODA's Plant Division) was initiated in 1988. Currently, there are 60 plant species listed as threatened or endangered in the State of Oregon.

The Native Plant Conservation Program works with governmental agencies, non-governmental organizations, universities, businesses, and individuals to conserve Oregon's rich natural heritage of native plant diversity. This is achieved through two avenues: research and regulation. The research conducted by program staff focuses on taxonomic questions, reproductive biology, disturbance ecology, and population augmentation and creation, providing data in support of listing or delisting species. Such biologically-based projects are critical to the development of accurate status determinations for many rare plants, including formally listed species, candidate taxa, and species of concern.

On the regulatory side, ODA is responsible for setting the guidelines on listing, reclassification, and delisting plant species as threatened or endangered. In addition, the program is charged with developing and administering a permit system which regulates commercial and research actions involving state-listed plant species. Any person or organization planning to study, collect, cultivate, transplant, reintroduce, or otherwise work with or impact a listed species (for commercial or research purposes) must first apply in advance for a written permit from ODA. If the application is approved, the permittee then provides an annual summary describing completed or ongoing activities for each listed species (see OAR 603-073-0100 and -0110). Regular permits are currently issued free of charge, though ODA may request reasonable reimbursement from applicants for any costs incurred by the department during follow-up permit reviews, report evaluations, or for special services. Contact Bob Meinke or Rebecca Currin if you have any questions regarding permits.

With the exception of the state's ability to regulate the import, export, and commercial trafficking of threatened and endangered plants, Oregon's conservation authority regarding state-listed plants presently extends only to non-federal public lands (state, city, county, public schools and utilities, etc.). Although the statutes do not require private or federal land owners to safeguard species protected under state law, ODA is willing to cooperate with the owners or managers of such lands in conservation efforts if they request assistance. Since 1988, ODA has collaborated with federal agencies such as the Forest Service and BLM (as well as with private organizations and individuals) on over 150 plant conservation research and recovery projects.

ODA has also adopted administrative rules (OAR 603-73-001 through 603-73-0090) that describe departmental procedures for the state listing, reclassification, or de-listing of plant species as threatened or endangered; how to go about petitioning ODA for the listing or delisting of a species; and the regulations and programs designed to assist and direct state land management agencies in their important roles involving native plant protection. If you are interested in learning how state agencies are required to protect listed plant species, or wish to review other laws and regulations governing threatened and endangered plant management in Oregon, you may download the complete rules at: *http://arcweb.sos.state.or.us/pages/rules/oars_600/oar_603/603_073.html*

Alternatively, you may write to ODA and ask for a copy of the endangered plant species administrative rules (please cite OAR 603-73-001 through 603-73-0110). Address your request to:
Native Plant Conservation Program
Plant Division
Oregon Department of Agriculture
635 Capitol Street NE
Salem, OR 97301-2532

For more information about the Native Plant Conservation Program, please see the program's website at:

## Native Plant Society of Oregon (NPSO)
### Plant Protection and Education Programs

NPSO has had a long history of working to increase the knowledge and protection of rare plants in Oregon. From involvement in the original Oregon Rare and Endangered Plant Project (1972-1982), to writing and passage of the Oregon Endangered Species Act of 1987, NPSO members have been at the forefront of plant conservation in our state.

In addition to sponsoring and supporting endangered species legislation, NPSO carries on its own rare plant protection program. Members in 13 chapters across the state monitor rare plants in each area, and report findings to our state R&E chair. This information is then incorporated into ORBIC's databases. In addition, each chapter has an active schedule of programs, workshops, and field trips. Our monthly *Bulletin,* and annual journal, *Kalmiopsis* feature articles on Oregon R&E species. New members are always welcome. Please visit our website below for more information about NPSO's Rare & Endangered Plant Program. For information contact us at:

Native Plant Society of Oregon
P.O. Box 902
Eugene, OR 97440-0902

## Oregon Flora Project

The goal of the Oregon Flora Project (OFP) is to provide the public with comprehensive information on the vascular plants growing without cultivation in Oregon. The major components of the Oregon Flora Project are a checklist, flora, photo gallery, and atlas of plant distribution. Information is accessible to the public through the OFP website, *http://www.oregonflora.org*. The OFP is housed in the Botany & Plant Pathology Dept. of Oregon State University and is closely associated with the OSU Herbarium. The work is accomplished by scores of participants, many of whom are volunteers.

The **Oregon Vascular Plant Checklist** is a standardized, documented reference for Oregon vascular plants which allows users to effectively communicate taxonomic concepts across diverse datasets. It serves as the foundation of the OFP by providing a nomenclatural framework for use in all aspects of the Project. The Checklist itemizes all native and exotic species, subspecies, and varieties (taxa) confirmed to grow in Oregon without cultivation, either currently or historically. There are currently 4,540 accepted taxa in the most recent version of the Checklist, Version 1.3, which was published online in August 2013. Each taxon entry lists the accepted scientific name, synonyms, common name, plant origin (native or exotic), location of a voucher specimen, and key bibliographic references. Names are also cross-referenced to nine key floras and field guides that cover portions of the state.

The **Oregon Vascular Plant Atlas** is an online, interactive mapping tool that creates distribution maps of any combination of plant taxa. There are >550,000 mappable records derived from herbarium specimens (from 39 herbaria) and unvouchered observations (from images, species lists, research, and survey projects). Details about each plant occurrence (excluding sensitive plant localities) are available and can be downloaded in spreadsheet format. The Atlas can be accessed at
*http://www.oregonflora.org/atlas.php*

The writing of ***The Flora of Oregon*** is in progress. Development is under the direction of Dr. Stephen Meyers, OFP lead taxonomist. As of August 2013, manuscripts for 34% of the flora are complete. Each genus will be represented by a full illustration, and taxa with multiple species will have drawings for every 4(-5) species. The *Flora* will be paper published as a two-volume manual and will include identification keys, illustrations, and detailed species descriptions; the target publication date is 2015. The digital *Flora* will additionally feature a multiple entry key and links to supporting OFP data.

The **Oregon Flora Photo Gallery** is an online resource presenting multiple images of Oregon plants. There are field photographs depicting flowers as well as a plant's habitat, general habit, and details of key characters. An image of a representative herbarium specimen for each taxon is also included. Currently there are more than 26,700 searchable images representing ~99% of the taxa in the flora. The OFP is pleased to accept contributed digital images of plants that are accompanied by an identification and locality data.

Digital presentation of Oregon Flora Project data that is accessible and useful to a broad spectrum of users is a key element of the OFP mission. Information is continuously being updated and curated by OFP staff. A restructured website will be released in late 2013 to add new features and streamline data presentation.

Six staff members (totaling 4.1 FTE), student workers, and volunteers comprise the OFP team. An 11-member advisory board supports the OFP mission, as does a Native Plant Society of Oregon liaison. Collectively, participants' backgrounds encompass plant taxonomy, ecology, horticulture, cartography, GIS, software development, and statistics. To date, thousands of volunteer hours have been donated by hundreds of professionals and amateurs alike.

Since its inception in 1994, approximately 50% of the OFP's funding has come from donations made by individuals, plant-oriented organizations, and the sponsorship of the Native Plant Society of Oregon. Competitive awards cover the balance of expenses, with principal funding from the Bureau of Land Management and the John & Betty Soreng Environmental Fund of the Oregon Community Foundation. Grants from small foundations, societies, and corporations have provided seed money for a number of project activities and have indirectly supported the compilation of primary data. The OFP continues to search for funding opportunities to help accomplish project goals in a timely manner.

To access the resources described, and learn more about the OFP, visit our web site at *http://www.oregonflora.org*. You can also view the online version of the *Oregon Flora Newsletter*, which is published twice yearly.

# FEDERAL ENDANGERED SPECIES ACT STATUS

**Plants Listed as Endangered**

*Arabis macdonaldiana*
*Astragalus applegatei*
*Erigeron decumbens*
*Fritillaria gentneri*
*Lilium occidentale*
*Limnanthes pumila* ssp. *grandiflora*
*Lomatium bradshawii*
*Lomatium cookii*
*Plagiobothrys hirtus*
*Stephanomeria malheurensis*

**Plants Listed as Threatened**

*Castilleja levisecta*
*Howellia aquatilis*
*Lupinus oreganus*
*Mirabilis macfarlanei*
*Sidalcea nelsoniana*
*Silene spaldingii*
*Thelypodium howellii* ssp. *spectabilis*

**Candidate Plants for Listing**

*Artemisia campestris* var. *wormskioldii*
*Calochortus persistens*
*Pinus albicaulis*

**Species of Concern**

*Abronia umbellata* ssp. *breviflora*
*Achnatherum hendersonii*
*Achnatherum wallowaensis*
*Agrostis hendersonii*
*Agrostis howellii*
*Allium dictuon*
*Allium robinsonii*
*Amsinckia carinata*
*Anemone oregana* var. *felix*
*Arabis hastatula*
*Arabis koehleri* var. *koehleri*
*Arabis modesta*
*Arabis suffrutescens* var. *horizontalis*
*Arctostaphylos hispidula*
*Artemisia ludoviciana* ssp. *estesii*
*Astragalus collinus* var. *laurentii*
*Astragalus mulfordiae*
*Astragalus tegetarioides*
*Bensoniella oregana*
*Botrychium ascendens*
*Botrychium campestre*
*Botrychium crenulatum*
*Botrychium montanum*
*Botrychium paradoxum*
*Botrychium pedunculosum*
*Calochortus coxii*
*Calochortus greenei*
*Calochortus howellii*
*Calochortus longebarbatus* var. *peckii*
*Calochortus macrocarpus* var. *maculosus*
*Calochortus nitidus*
*Calochortus umpquaensis*
*Camissonia pygmaea*
*Cardamine pattersonii*
*Carex idahoa*
*Castilleja chambersii*
*Castilleja fraterna*
*Castilleja mendocinensis*
*Castilleja rubida*
*Castilleja rupicola*
*Caulanthus major* var. *nevadensis*
*Collomia renacta*
*Cordylanthus maritimus* ssp. *palustris*
*Corydalis aquae-gelidae*
*Cupressus bakeri*
*Cymopterus acaulis* var. *greeleyorum*
*Cypripedium fasciculatum*
*Delphinium leucophaeum*
*Delphinium oreganum*
*Delphinium pavonaceum*
*Dicentra pauciflora*
*Dodecatheon austrofrigidum*
*Epilobium oreganum*
*Epilobium siskiyouense*
*Erigeron cervinus*
*Erigeron engelmannii* var. *davisii*
*Erigeron howellii*
*Erigeron oreganus*
*Eriogonum chrysops*
*Eriogonum crosbyae*
*Eriogonum cusickii*
*Eriogonum prociduum*
*Eriogonum umbellatum* var. *glaberrimum*
*Erysimum menziesii* ssp. *concinnum*
*Erythronium elegans*
*Eucephalus vialis*
*Filipendula occidentalis*
*Fritillaria purdyi*
*Galium serpenticum* ssp. *warnerense*
*Gentiana plurisetosa*
*Gentiana setigera*
*Gilia millefoliata*
*Gratiola heterosepala*
*Hackelia cronquistii*
*Hastingsia bracteosa* var. *atropurpurea*
*Hastingsia bracteosa* var. *bracteosa*
*Horkelia congesta* ssp. *congesta*
*Horkelia hendersonii*
*Hymenoxys lemmonii*
*Ivesia rhypara* var. *rhypara*
*Ivesia rhypara* var. *shellyi*
*Kalmiopsis fragrans*
*Lasthenia ornduffii*
*Lathyrus holochlorus*
*Lepidium davisii*
*Leptodactylon pungens* ssp. *hazeliae*
*Lilium kelloggii*
*Limbella fryei* (moss)
*Limnanthes floccosa* ssp. *bellingeriana*
*Limnanthes floccosa* ssp. *pumila*
*Lomatium erythrocarpum*
*Lomatium greenmanii*
*Lomatium ochocense*
*Lomatium suksdorfii*
*Luina serpentina*
*Lupinus lepidus* var. *ashlandensis*
*Lupinus lepidus* var. *cusickii*
*Meconella oregana*
*Mentzelia mollis*
*Mentzelia packardiae*
*Microseris laciniata* ssp. *detlingii*
*Mimulus evanescens*
*Mimulus hymenophyllus*
*Monardella purpurea*
*Myosurus sessilis*
*Oenothera wolfii*
*Packera hesperia*
*Penstemon barrettiae*
*Penstemon glaucinus*
*Penstemon peckii*
*Perideridia erythrorhiza*
*Phacelia argentea*
*Phacelia inundata*
*Phacelia leonis*
*Phacelia lutea* var. *mackenzieorum*
*Phacelia minutissima*
*Plagiobothrys figuratus* ssp. *corallicarpus*
*Plagiobothrys salsus*
*Pleuropogon oregonus*
*Poa unilateralis*
*Pogogyne floribunda*
*Polyctenium williamsiae*
*Pyrrocoma radiata*
*Ranunculus triternatus*
*Rubus bartonianus*
*Saxifraga hitchcockiana*
*Senecio ertterae*
*Sericocarpus rigidus*
*Sidalcea hendersonii*
*Sidalcea hirtipes*
*Sidalcea malachroides*
*Sidalcea malviflora* ssp. *patula*
*Silene douglasii* var. *oraria*
*Sisyrinchium hitchcockii*
*Sisyrinchium sarmentosum*
*Sophora leachiana*
*Stanleya confertiflora*
*Sullivantia oregana*
*Tauschia howellii*
*Texosporium sancti-jacobi* (lichen)
*Thelypodium brachycarpum*
*Thelypodium eucosmum*
*Thelypodium howellii* ssp. *howellii*
*Trifolium douglasii*
*Trifolium leibergii*
*Trifolium owyheense*
*Triteleia hendersonii* var. *leachiae*
*Viola primulifolia* ssp. *occidentalis*
*Zigadenus fontanus*

**Plants Listed as Endangered**

*Abronia umbellata* ssp. *breviflora*
*Arabis macdonaldiana*
*Artemisia campestris* var. *wormskioldii*
*Astragalus applegatei*
*Astragalus mulfordiae*
*Calochortus coxii*
*Calochortus indecorus*
*Calochortus umpquaensis*
*Castilleja levisecta*
*Chloropyron maritimum* ssp. *palustre*
*Delphinium leucophaeum*
*Delphinium pavonaceum*
*Erigeron decumbens*
*Fritillaria gentneri*
*Ivesia rhypara* var. *rhypara*
*Lilium occidentale*
*Limnanthes pumila* ssp. *grandiflora*
*Lomatium bradshawii*
*Lomatium cookii*
*Lomatium erythrocarpum*
*Lupinus lepidus var. cusickii*
*Mentzelia mollis*
*Mirabilis macfarlanei*
*Plagiobothrys hirtus*
*Plagiobothrys lamprocarpus*
*Pyrrocoma radiata*
*Silene spaldingii*
*Stephanomeria malheurensis*
*Thelypodium howellii* ssp. *spectabilis*
*Trifolium owyheense*

**Plants Listed as Threatened**

*Amsinckia carinata*
*Astragalus collinus* var. *laurentii*
*Astragalus cusickii* var. *sterilis*
*Astragalus diaphanus* var. *diurnus*
*Astragalus peckii*
*Astragalus tyghensis*
*Botrychium pumicola*
*Calochortus howellii*
*Eriogonum chrysops*
*Eriogonum crosbyae* var. *crosbyae*
*Eriogonum crosbyae* var. *mystrium*
*Erythronium elegans*
*Eucephalus vialis*
*Gratiola heterosepala*
*Hackelia cronquistii*
*Hastingsia bracteosa* var. *bracteosa*
*Hastingsia bracteosa* var. *atropurpurea*
*Howellia aquatilis*
*Lepidium davisii*
*Limnanthes pumila* ssp. *pumila*
*Lomatium greenmanii*
*Lupinus oreganus*
*Mentzelia packardiae*
*Microseris howellii*
*Oenothera wolfii*
*Phacelia argentea*
*Pleuropogon oregonus*
*Sericocarpus rigidus*
*Sidalcea nelsoniana*
*Silene douglasii* var. *oraria*
*Thelypodium eucosmum*

**State Candidate Taxa**

*Achnatherum hendersonii*
*Agrostis howellii*
*Arabis koehleri* var. *koehleri*
*Asarum wagneri*
*Astragalus tegetarioides*
*Bensoniella oregana*
*Boechera horizontalis*
*Bolandra oregana*
*Botrychium ascendens*
*Botrychium crenulatum*
*Botrychium paradoxum*
*Botrychium pedunculosum*
*Calochortus greenei*
*Calochortus longebarbatus* var. *peckii*
*Calochortus persistens*
*Camassia howellii*
*Cardamine nuttallii* var. *gemmata*
*Cardamine pattersonii*
*Caulanthus major* var. *nevadensis*
*Cimicifuga elata* var. *alpestris*
*Cimicifuga elata* var. *elata*
*Collomia renacta*
*Corydalis aquae-gelidae*
*Cypripedium fasciculatum*
*Delphinium oreganum*
*Draba howellii*
*Epilobium oreganum*
*Epilobium siskiyouense*
*Eremothera pygmaea*
*Erigeron howellii*
*Erigeron oreganus*
*Eriogonum cusickii*
*Eriogonum prociduum*
*Filipendula occidentalis*
*Frasera umpquaensis*
*Gentiana setigera*
*Hackelia diffusa* var. *diffusa*
*Horkelia congesta* ssp. *congesta*
*Lasthenia ornduffii*
*Limbella fryei* (moss)
*Limnanthes alba* var. *gracilis*
*Limnanthes floccosa* ssp. *bellingeriana*
*Lomatium suksdorfii*
*Luina serpentina*
*Lupinus lepidus* var. *ashlandensis*
*Meconella oregano*
*Micranthes hitchcockiana*
*Mimulus evanescens*
*Mimulus hymenophyllus*
*Mimulus jungermannioides*
*Mimulus patulus*
*Montia howellii*
*Myosurus sessilis*
*Packera hesperia*
*Penstemon barrettiae*
*Perideridia erythrorhiza*
*Phacelia minutissima*
*Plagiobothrys figuratus* ssp. *corallicarpus*
*Ranunculus austrooreganus*
*Rorippa columbiae*
*Rubus bartonianus*
*Sedum moranii*
*Sedum oblanceolatum*
*Senecio ertterae*
*Sidalcea campestris*
*Sidalcea hirtipes*
*Sidalcea malviflora* ssp. *patula*
*Sisyrinchium sarmentosum*
*Sophora leachiana*
*Streptanthus howellii*
*Sullivantia oregana*
*Tauschia howellii*
*Trifolium leibergii*
*Triteleia hendersonii* var. *leachiae*
*Viola primulifolia* ssp. *occidentalis*

## DROPS AND NAME CHANGES since October 2010 list

**Vascular Plants**

| | |
|---|---|
| *Achnatherum wallowaensis* | Name change, now called *Achnatherum wallowense* |
| *Arabis davidsonii* | Name change, now called *Boechera davidsonii* |
| *Arabis hastatula* | Name change, now called *Boechera hastatula* |
| *Arabis sparsiflora* var. *atrorubens* | Name change, now called *Boechera atrorubens* |
| *Arabis suffrutescens* var. *horizontalis* | Name change, now called *Boechera horizontalis* |
| *Asplenium trichomanes-ramosum* | Name change, now called *Asplenium viride* |
| *Callitriche hermaphroditica* | Dropped, taxonomic issues, synonym of *Callitriche fassettii* |
| *Camissonia boothii* ssp. *boothii* | Name change, now called *Eremothera boothii* ssp. *boothii* |
| *Camissonia graciliflora* | Name change, now called *Tetrapteron graciliflorum* |
| *Camissonia ovata* | Name change, now called *Taraxia ovata* |
| *Camissonia palmeri* | Name change, now called *Tetrapteron palmeri* |
| *Camissonia pygmaea* | Name change, now called *Eremothera pygmaea* |
| *Cardamine nuttallii* var. covilleana | Dropped, taxonomic issues, synonym of *C. nuttallii* var. *nuttallii* |
| *Cardamine nuttallii* var. dissecta | Dropped, taxonomic issues, synonym of *C. nuttallii* var. *nuttallii* |
| *Cochlearia officinalis* | Dropped, not documented from the state; ours *C. groenlandica* |
| *Cordylanthus maritimus* ssp. *palustre* | Name change, now called *Chloropyron maritimum* ssp. *palustre* |
| *Cupressus bakeri* | Name change, *Hesperocyparis bakeri* |
| *Delphinium bicolor* | Dropped, not documented from the state |
| *Draba lemmonii* var. *cyclomorpha* | Name change, *Draba cyclomorpha* |
| *Epilobium latifolium* | Name change, *Chamerion latifolium* |
| *Ericameria discoidea* var. *discoidea* | Name change, now called *Ericameria discoidea* |
| *Erigeron engelmannii* var. *davisii* | Name change, now called *Erigeron davisii* |
| *Erysimum menziesii* ssp. *concinnum* | Name change, now called *Erysimum concinnum* |
| *Gentianopsis holopetala* | Dropped, not documented from the state |
| *Gilia salticola* | Dropped, not documented from the state |
| *Gilia sinistra* ssp. *sinistra* | Name change, now called *Navarretia sinistra* ssp. *sinistra* |
| *Hymenoxys lemmonii* | Dropped, not documented from the state; ours *H. cooperi* var. *canescens* |
| *Juncus hemiendytus* var. *hemiendytus* | Dropped, too common |
| *Lesquerella douglasii* | Name change, now called *Physaria douglasii* ssp. *douglasii* |
| *Lesquerella kingii* ssp. *diversifolia* | Name change, now called *Physaria kingii* ssp. *diversifolia* |
| *Limnanthes gracilis* ssp. *gracilis* | Name change, now called *Limnanthes alba* ssp. *gracilis* |
| *Limnanthes floccosa* ssp. *grandiflora* | Name change, now called *Limnanthes pumila* ssp. *grandiflora* |
| *Limnanthes floccosa* ssp. *pumila* | Name change, now called *Limnanthes pumila* ssp. *pumila* |
| *Lupinus sulphureus* ssp. *kincaidii* | Name change, now called *Lupinus oreganus* |
| *Luzula arcuata* ssp. *unalaschcensis* | Dropped, not documented from the state |
| *Melica californica* | Dropped, not documented from the state |
| *Pellaea mucronata* ssp. *mucronata* | Dropped, not documented from the state |
| *Poa interior* | Dropped, not documented from the state |
| *Poa unilateralis* | See *P. unilateralis* ssp. *pachypholis* and *P. unilateralis* ssp. *unilateralis* |
| *Populus angustifolia* | Dropped, not documented from the state |
| *Potamogeton filiformis* | Name change, now called *Stuckenia filiformis* ssp. *alpinus* and *Stuckenia filiformis* ssp. *occidentalis* |
| *Potamogeton pusillus* ssp. *tenuissimus* | Name change, now called *Potamogeton berchtoldii* |
| *Potamogeton striatus* | Name change, now called *Stuckenia striata* |
| *Potamogeton vaginatus* | Dropped, not documented from the state |
| *Ranunculus verecundus* | Dropped, taxonomic issues |
| *Salix orestera* | Dropped, not documented from the state |
| *Saxifraga hitchcockiana* | Name change, now called *Micranthes hitchcockiana* |
| *Senecio porteri* | Name change, now called *Packera porteri* |
| *Scirpus heterochaetus* | Name change, now called *Schoenoplectus heterochaetus* |
| *Silene serpentinicola* | Name change, now called *Silene hookeri* ssp. *serpentinicola* |
| *Thlaspi montanum* var. *siskiyouense* | Name change, now called *Noccaea fendleri* ssp. *siskiyouense* |

**Fungi**

| | |
|---|---|
| *Balsamia alba* | Dropped, too common |
| *Cortinarius "barlowensis"* | Being described, *Cortinarius barlowensis* |
| *Gomphus kauffmanii* | Dropped, too common |
| *Hygrophorus caeruleus* | Dropped, too common |
| *Leucogaster citrinus* | Dropped, too common |
| *Ramaria concolor* forma *tsugina* | Name change, now called *Ramaria tsugina* |
| *Ramaria rubella* var. *blanda* | Name change, now called *Ramaria rubella* forma *blanda* |
| *Ramaria spinulosa* var. *diminutiva* | Dropped, not documented from the state |

## DROPS AND NAME CHANGES (continued)

| | |
|---|---|
| **Lichens** | |
| *Bryoria spiralifera* | Dropped, too common |
| *Chaenotheca subroscida* | Dropped, too common |
| *Erioderma sorediatum* | Dropped, too common |
| *Heterodermia leucomela* | Dropped, too common |
| *Hypogymnia duplicata* | Dropped, too common |
| *Lecanora pringlei* | Dropped, too common |
| *Leptogium teretiusculum* | Dropped, too common |
| *Ochrolechia subplicans* var. *subplicans* | Name change, now called *Ochrolechia subplicans* ssp. *subplicans* |
| *Sulcaria badia* | Dropped, too common |
| *Usnea "lambii"* | Officially described, *Usnea lambii* |
| *Usnea subgracilis* | Name change, now called *Usnea schadenbergiana* |
| **Liverworts** | |
| *Chiloscyphus gemmiparus* | Name change, now called *Rivulariella gemmipara* |
| *Diplophyllum plicatum* | Dropped, too common |
| *Herbertus aduncus* | Name change, now called *Herbertus aduncus* ssp. *aduncus* |
| *Tritomaria exsectiformis* | Dropped, too common |
| **Mosses** | |
| *Codriophorus depressus* | Name change, now called *Racomitrium depressum* |
| *Codriophorus ryszardii* | Name change, now called *Racomitrium ryszardii* |
| *Schistostega pennata* | Dropped, too common |

## ACKNOWLEDGMENTS

### ANIMALS

Revisions to the current edition included status changes made by ODFW, USFWS and NOAA Fisheries. Our thanks to these agencies for their continued efforts to protect and study Oregon's fauna. Dana Ross kindly allowed use of his photo for the cover of this book. Our appreciation goes, as always, to the many vertebrate and invertebrate biologists who contributed directly or indirectly and whose comments and criticisms were incorporated into this booklet. In 2013, the following biologists contributed to this effort: Jocelyn Akins, Chris Allen, Bob Altman, Keith Aubry, Barb Bresson, Charlie Bruce, Tom Burke, Bruce Bury, James Capurso, Brett Carre, John Fleckenstein, Sarah Foltz Jordan, Geoff Hammerson, Andrea Hanson, Tyler Hicks, Betsy Howell, Richard Hoyer, Rob Huff, Carol Hughes, Sarina Jepsen, James LaBonte, Christopher Marshall, Kim Nelson, Robert Nichols, Martin Nugent, Deanna Olson, Mark Penninger, Iral Ragenovich, Katherine Ramsey, Jason Reilly, Dana Ross, Randy Scarlett, Nicole Sears, Terry Smith, Robin Snider, Alan St. John, Richard Vacirca, Tom Valente, Steve Valley, Kelli Van Norman, and Tiffany Young.

### PLANTS AND FUNGI

Many of the changes made since the last edition of this booklet in 2010 resulted from the Rare and Endangered Plant Conference held at Oregon State University, Corvallis, Oregon in October 2012. We thank all conference participants and others who have contributed to this project. Many of the improvements in the information included in this booklet are a result of efforts by the professional botanists of the Oregon Department of Agriculture, the U.S. Forest Service and the Bureau of Land Management, and the amateur and professional botanists of the Native Plant Society of Oregon.

Michael Castellano (USFS) compiled the original list of fungi, to which additions have been recommended by agency and university mycologists, and the Oregon Mycological Society. Early contributors included Efren Cazares, Janet Lindgren, Randy Molina, Lorelei Norvell, Judy Roger, James Trappe, and Nancy Weber.

Special thanks go to Stephen Meyers at Oregon State University, who serves as the Taxonomic Director for the Oregon Flora Project and the arbiter for ORBIC and for this publication. We also would like to continue to recognize the years of help and support from Ken and Henny Chambers and from Peter Zika, in providing us with taxonomic guidance and assistance.

Primary sources of expertise for this edition include:

Carex: Carex Working Group – Richard Brainerd, Nick Otting, and Barbara Wilson. Previous Carex Working Group participants and contributors included Manuela Huso, Keli Kuykendall, Danna Lytjen, Bruce Newhouse, and Peter Zika.

Ferns: Ed Alverson, Frank Lang, David Wagner and Peter Zika.

Liverworts: John Christy, Amanda Hardman, Richard Helliwell, Scot Loring, Daphne Stone, Duncan Thomas, Chris Wagner, and David Wagner.

Marine Algae: David and Dianne Bilderback, Gayle Hansen

Mosses: John Christy, Clint Emerson, Ron Exeter, Doug Goldenberg, Amanda Hardman, Judith Harpel, Richard Helliwell, David Kofranek, Jenny Lippert, Scot Loring, Cheshire Mayrsohn, Bruce Newhouse, Wayne Rolle, Daphne Stone, Duncan Thomas, Chris Wagner, David Wagner and Rob Weiss.

Fungi: Johanna Fickenscher, Doug Goldenberg, Clint Emerson, Ron Exeter, Jenny Lippert, Scot Loring, Kelli Van Norman, Darci Rivers-Pankratz, and Darlene Southworth.

Lichens: Clint Emerson, Ron Exeter, Doug Glavich, Doug Goldenberg, Richard Helliwell, Jenny Lippert, Scot Loring, Bruce McCune, Bruce Newhouse, Keith Saylor, Steve Sheehy, Daphne Stone, Rob Taylor, and Rob Weiss.

**FEDERAL STATUS**

| | |
|---|---|
| LE | Listed as an Endangered Species |
| LT | Listed as a Threatened Species |
| PE | Proposed as an Endangered Species |
| PT | Proposed as a Threatened Species |
| C | Candidate for Listing as Threatened or Endangered |
| SOC | Species of Concern - Taxa for which additional information is needed to support a proposal to list under the ESA |

**STATE STATUS – ANIMALS**

| | |
|---|---|
| LE | Listed as an Endangered Species |
| LT | Listed as a Threatened Species |
| PE | Proposed as an Endangered Species |
| PT | Proposed as a Threatened Species |
| SC | Sensitive - Critical |
| SV | Sensitive - Vulnerable |

**STATE STATUS – PLANTS**

| | |
|---|---|
| LE | Listed as an Endangered Species |
| LT | Listed as a Threatened Species |
| PE | Proposed as an Endangered Species |
| PT | Proposed as a Threatened Species |
| C | Candidate for Listing as Threatened or Endangered |

**ECOREGIONS**

| | |
|---|---|
| BM | Blue Mountains (includes High Lava Plains) |
| BR | Northern Basin and Range (includes Owyhee Uplands) |
| CB | Columbia Basin |
| CR | Coast Range |
| EC | East Cascades |
| KM | Klamath Mountains |
| ME | Marine and Estuarine |
| WC | West Cascades and Crest |
| WV | Willamette Valley |

**STATES AND PROVINCES**

| | | | |
|---|---|---|---|
| AB | Alberta | NV | Nevada |
| AK | Alaska | NJ | New Jersey |
| AZ | Arizona | NM | New Mexico |
| AR | Arkansas | NY | New York |
| BC | British Columbia | NC | North Carolina |
| CA | California | NT | NW Territories |
| CO | Colorado | NS | Nova Scotia |
| HI | Hawaii | ON | Ontario |
| ID | Idaho | QC | Quebec |
| KS | Kansas | SK | Saskatchewan |
| LA | Louisiana | TN | Tennessee |
| MB | Manitoba | UT | Utah |
| MA | Massachusetts | WA | Washington |
| MS | Mississippi | WI | Wisconsin |
| MT | Montana | WY | Wyoming |

**NATURAL HERITAGE RANKS**

| | |
|---|---|
| G1 | Critically imperiled throughout its range |
| G2 | Imperiled throughout its range |
| G3 | Rare, threatened or uncommon throughout its range |
| G4 | Not rare, apparently secure throughout its range |
| G5 | Widespread, abundant and secure throughout its range |
| S1 | Critically imperiled in Oregon |
| S2 | Imperiled in Oregon |
| S3 | Rare, threatened or uncommon in Oregon |
| S4 | Not rare, apparently secure in Oregon |
| S5 | Widespread, abundant and secure in Oregon |
| T | Rank for a subspecies, variety, or race |
| Q | Taxonomic questions |
| H | Historic, formerly part of the native biota with the implied expectation that it may be rediscovered |
| X | Presumed extirpated or extinct |
| U | Unknown rank |
| NR | Not yet ranked |
| B | Rank of the breeding population (migratory birds) |
| N | Rank of the wintering population (migratory birds) |

**MISCELLANEOUS**

| | |
|---|---|
| ESA | Endangered Species Act |
| EPA | Environmental Protection Agency |
| FED | Federal |
| NOAA | National Oceanic and Atmospheric Administration |
| ODA | Oregon Department of Agriculture |
| ODFW | Oregon Department of Fish and Wildlife |
| OESA | Oregon Endangered Species Act |
| ORBIC | Oregon Biodiversity Information Center |
| sp. nov. | species novum (new species) - in the process of being described in the literature |
| ssp. | subspecies |
| ssp. nov. | subspecies novum (new subspecies) - in the process of being described in the literature |
| TNC | The Nature Conservancy |
| USFS | United States Forest Service |
| USFWS | United States Fish and Wildlife Service |
| var. | variety |
| + | taxon occurs in additional states |

**ORBIC LISTS**

| | |
|---|---|
| 1 | Threatened or Endangered Throughout Range |
| 2 | Threatened, Endangered or Extirpated from Oregon, but Secure or Abundant Elsewhere |
| 3 | Review |

# APPENDIX Q-4

NMFS 2013 Threatened and Endangered Species List

# Endangered and Threatened Marine Species under NMFS' Jurisdiction

(E = **"endangered"**; T = **"threatened"**; F = **"foreign"**; n/a = not applicable*****)

## Endangered and Threatened Marine Mammals (29 listed "species")

Manatees and sea otters are also listed under the ESA, but fall under jurisdiction of U.S. Fish and Wildlife Service.

| Species | Year Listed | Status | Critical Habitat* | Recovery Plan* |
|---|---|---|---|---|
| **Cetaceans** | | | | |
| **dolphin, Chinese River / baiji** (*Lipotes vexillifer*) | 1989 | E (F) | n/a | n/a |
| **dolphin, Indus River** (*Platanista minor*) | 1991 | E (F) | n/a | n/a |
| **porpoise, Gulf of California harbor / vaquita** (*Phocoena sinus*) | 1985 | E (F) | n/a | n/a |
| **whale, beluga** (1 listed DPS) *(Delphinapterus leucas)* | | | | |
| o Cook Inlet | 2008 | E | **final** | in process |
| **whale, blue** (*Balaenoptera musculus*) | 1970 | E | n/a | **final** |
| **whale, bowhead** (*Balaena mysticetus*) | 1970 | E | n/a | n/a |
| **whale, false killer** (1 listed DPS) (*Pseudorca crassidens*) | | | | |
| o Main Hawaiian Islands Insular | 2012 | E | no | no |
| **whale, fin** (*Balaenoptera physalus*) | 1970 | E | n/a | **final** |
| **whale, gray** (1 listed DPS) (*Eschrichtius robustus*) | | | | |
| o Western North Pacific | 1970 | E (F) | n/a | n/a |
| **whale, humpback** (*Megaptera novaeangliae*) | 1970 | E | n/a | **final** |
| **whale, killer** (1 listed DPS) (*Orcinus orca*) | | | | |
| o Southern Resident » **under review for delisting** | 2005 | E | **final** | **final** |
| **whale, North Atlantic right** (*Eubalaena glacialis*)<br>*original listing as "northern right whale" -* | 2008<br>1970 | E<br>E | **final** | **final** |
| **whale, North Pacific** | 2008 | E | **final** | no |

| | | | | |
|---|---|---|---|---|
| (*Eubalaena japonica*)<br><br>*original listing as "northern right whale" -* | <br><br>1970 | <br><br>E | | |
| **whale, sei**<br>(*Balaenoptera borealis*) | 1970 | E | n/a | **final** |
| **whale, Southern right whale**<br>(*Eubalaena australis*) | 1970 | E (F) | n/a | n/a |

| o Ladoga<br>(*Phoca hispida ladogensis*) | 2012 | E (F) | no | no |
| **seal, Mediterranean monk**<br>(*Monachus monachus)* | 1970 | E (F) | n/a | n/a |
| **seal, Saimaa**<br>(*Phoca hispida saimensis*) | 1993 | E (F) | n/a | n/a |
| **seal, spotted** (1 listed DPS)<br>*(Phoca largha)* | | | | |
| o Southern | 2010 | T (F) | n/a | n/a |

*** NOTE:** Critical habitat and recovery plans are not required for foreign species; critical habitat is also not required for species listed prior to the 1978 ESA amendments that added critical habitat provisions. Bowhead whales are also exempt from recovery planning.

---

(E = **"endangered"**; T = **"threatened"**; F = **"foreign"**; n/a = not applicable*****)

## Endangered and Threatened Sea Turtles (16 listed "species")

Recovery plans for marine turtles are developed and implemented by NMFS and USFWS; the plans have been written separately for turtles in the Atlantic and Pacific oceans (and East Pacific for the green turtle) rather than for each listed species.

| Species | Year Listed | Status | Critical Habitat* | Recovery Plan* |
|---|---|---|---|---|
| green turtle (2 listed populations**)<br>(*Chelonia mydas*) | | | | |
| o Florida & Mexico's Pacific coast breeding colonies | 1978 | E | final | final |
| o all other areas<br>» Hawaii population under review to delist | 1978 | T | final | final |
| hawksbill turtle<br>(*Eretmochelys imbricata*) | 1970 | E | final | final |
| Kemp's ridley turtle<br>(*Lepidochelys kempii*) | 1970 | E | n/a | final |
| leatherback turtle<br>(*Dermochelys coriacea*) | 1970 | E | final | final |
| loggerhead turtle (9 listed DPSs)<br>(*Caretta caretta*)<br>*original listing - 1978* | | | no | final |
| o Mediterranean Sea | 2011 | E (F) | n/a | n/a |
| o North Indian Ocean | 2011 | E (F) | n/a | n/a |
| o North Pacific Ocean | 2011 | E | no | final |
| o Northeast Atlantic Ocean | 2011 | E (F) | n/a | n/a |
| o Northwest Atlantic Ocean | 2011 | T | no | final |
| o South Atlantic Ocean | 2011 | T (F) | n/a | n/a |
| o South Pacific Ocean | 2011 | E (F) | n/a | n/a |
| o Southeast Indo-Pacific Ocean | 2011 | T (F) | n/a | n/a |
| o Southwest Indian Ocean | 2011 | T (F) | n/a | n/a |
| olive ridley turtle (2 listed populations**)<br>(*Lepidochelys olivacea*) | | | | |
| o Mexico's Pacific coast breeding colonies | 1978 | E | n/a | final |
| o all other areas | 1978 | T | n/a | final |

*** NOTE:** Critical habitat and recovery plans are not required for foreign species; critical habitat is also not required for species listed prior to the 1978 ESA amendments that added critical habitat provisions.
****** These populations were listed before the 1978 ESA amendments that restricted population listings to "distinct population segments" of vertebrate species.

---

(E = **"endangered"**; T = **"threatened"**; F = **"foreign"**; n/a = not applicable*****)

## Endangered and Threatened Marine and Anadromous Fish (44 listed "species")

| Species | Year Listed | Status | Critical Habitat* | Recovery Plan* |
|---|---|---|---|---|
| **bocaccio** (1 listed DPS)<br>(*Sebastes paucispinis*) | | | | |
| o Puget Sound/ Georgia Basin | 2010 | E | no | no |
| **eulachon, Pacific / smelt** (1 listed DPS)<br>(*Thaleichthys pacificus*) | | | | |
| o Southern DPS | 2010 | T | **final** | no |

| o California Central Valley | 1998** | T | **final** | **draft** |

*** NOTE:** Critical habitat and recovery plans are not required for foreign species; critical habitat is also not required for species listed prior to the 1978 ESA amendments that added critical habitat provisions.
****** All Pacific salmonid listings were revisited in 2005 and 2006. Only the salmonids whose status changed as a result of the review will show the revised date; for all others, only the original listing date is shown. For more information on the listing history, please click on the link for each ESU/DPS.

---

(E = **"endangered"**; T = **"threatened"**; F = **"foreign"**; n/a = not applicable*)

## Endangered and Threatened Marine Invertebrates (4 listed "species")

| Species | Year Listed | Status | Critical Habitat* | Recovery Plan* |
|---|---|---|---|---|
| **abalone, black**<br>*(Haliotis cracherodii)* | 2009 | E | **final** | no |
| **abalone, white**<br>(*Haliotis sorenseni*) | 2001 | E | **not prudent** | **final** |
| **coral, elkhorn**<br>*(Acropora palmata)* | 2006 | T* | **final** | in process |
| **coral, staghorn**<br>*(Acropora cervicornis)* | 2006 | T* | **final** | in process |

* These corals are **proposed to be reclassified from threatened to endangered**.

---

(E = **"endangered"**; T = **"threatened"**; F = **"foreign"**; n/a = not applicable*)

## Endangered and Threatened Marine Plants (1 listed "species")

| Species | Year Listed | Status | Critical Habitat* | Recovery Plan* |
|---|---|---|---|---|
| **Johnson's seagrass** (*Halophila johnsonii*) | 1999 | T | **final** | **final** |

*** NOTE:** Critical habitat and recovery plans are not required for foreign species; critical habitat is also not required for species listed prior to the 1978 ESA amendments that added critical habitat provisions.

---

(E = **"endangered"**; T = **"threatened"**; F = **"foreign"**; n/a = not applicable*)

## Candidates for Listing (18 candidate "species")

| Species | Year | *Federal Register* notice |
|---|---|---|
| **Fishes** | | |
| **alewife** *(Alosa pseudoharengus)* | 2011 | **76 FR 67652** |

# APPENDIX Q-5

USFWS 2013 Threatened and Endangered Species List

**FEDERALLY LISTED, PROPOSED, CANDIDATE SPECIES**
**AND SPECIES OF CONCERN**
**UNDER THE JURISDICTION OF THE FISH AND WILDLIFE SERVICE**
**WHICH MAY OCCUR WITHIN COOS COUNTY, OREGON**

# LISTED SPECIES

## Birds

| | | |
|---|---|---|
| Marbled murrelet | *Brachyramphus marmoratus* | CH T |
| Western snowy (coastal) plover | *Charadrius alexandrinus nivosus* | CH T |
| Short-tailed albatross | *Phoebastria albatrus* | E |
| Northern spotted owl | *Strix occidentalis caurina* | CH T |

## Reptiles and Amphibians

***Marine:***

| | | |
|---|---|---|
| Loggerhead sea turtle | *Caretta caretta* | E |
| Green sea turtle | *Chelonia mydas* | T |
| Leatherback sea turtle | *Dermochelys coriacea* | E |
| Olive (=Pacific) ridley sea turtle | *Lepidochelys olivacea* | T |

## Plants

| | | |
|---|---|---|
| Western lily | *Lilium occidentale* | E |

# PROPOSED SPECIES

## None

| | |
|---|---|
| No Proposed Endangered Species | PE |
| No Proposed Threatened Species | PT |

# SPECIES OF CONCERN

## Mammals

| | |
|---|---|
| White-footed vole | *Arborimus albipes* |
| Townsend's western big-eared bat | *Corynorhinus townsendii townsendii* |
| Silver-haired bat | *Lasionycteris noctivagans* |
| Long-eared myotis bat | *Myotis evotis* |
| Fringed myotis bat | *Myotis thysanodes* |
| Long-legged myotis bat | *Myotis volans* |
| Yuma myotis bat | *Myotis yumanensis* |

## Birds

| | |
|---|---|
| Northern goshawk | *Accipiter gentilis* |
| Upland sandpiper | *Bartramia longicauda* |
| Olive-sided flycatcher | *Contopus cooperi* |
| Black oystercatcher | *Haematopus bachmani* |
| Harlequin duck | *Histrionicus histrionicus* |
| Yellow-breasted chat | *Icteria virens* |
| Acorn woodpecker | *Melanerpes formicivorus* |
| Lewis' woodpecker | *Melanerpes lewis* |
| Mountain quail | *Oreortyx pictus* |
| Band-tailed pigeon | *Patagioenas fasciata* |
| Oregon vesper sparrow | *Pooecetes gramineus affinis* |

| | |
|---|---|
| Purple martin | *Progne subis* |

### Reptiles and Amphibians

| | |
|---|---|
| Northern Pacific pond turtle | *Actinemys marmorata marmorata* |
| Coastal tailed frog | *Ascaphus truei* |
| Del Norte salamander | *Plethodon elongatus* |
| Northern red-legged frog | *Rana aurora aurora* |
| Foothill yellow-legged frog | *Rana boylii* |
| Southern torrent (seep) salamander | *Rhyacotriton variegatus* |

### Fish

| | |
|---|---|
| River lamprey | *Lampetra ayresi* |
| Pacific lamprey | *Lampetra tridentata* |
| Coastal cutthroat trout | *Oncorhynchus clarki ssp* |
| Millicoma dace | *Rhinichthys cataractae ssp.* |

### Invertebrates

***Snails:***

| | |
|---|---|
| Newcomb's littorine snail | *Algamorda newcombiana* |

***Clams:***

| | |
|---|---|
| California floater mussel | *Anodonta californiensis* |

### Plants

| | |
|---|---|
| Pink sand-verbena | *Abronia umbellata ssp. breviflora* |
| Bensoniella | *Bensoniella oregona* |
| Pt. Reyes bird's-beak | *Cordylanthus maritimus ssp. palustris* |
| Frye's Limbella | *Limbella fryei* |
| Silvery phacelia | *Phacelia argentea* |
| Coast checkermallow | *Sidalcea malviflora ssp. patula* |
| Leach's brodiaea | *Triteleia hendersonii var. leachiae* |

## DELISTED SPECIES

### Birds

| | |
|---|---|
| Aleutian Canada goose | *Branta canadensis leucopareia* |
| American Peregrine falcon | *Falco peregrinus anatum* |
| Bald eagle | *Haliaeetus leucocephalus* |
| Brown pelican | *Pelecanus occidentalis* |

### Definitions:

Listed Species: An endangered species is one that is in danger of extinction throughout all or a significant portion of its range. A threatened species is one that is likely to become endangered in the foreseeable future.

Proposed Species: Taxa for which the Fish and Wildlife Service or National Marine Fisheries Service has published a proposal to list as endangered or threatened in the Federal Register.

Candidate Species: Taxa for which the Fish and Wildlife Service has sufficient biological information to support a proposal to list as endangered or threatened.

# FEDERALLY LISTED, PROPOSED, CANDIDATE SPECIES AND SPECIES OF CONCERN UNDER THE JURISDICTION OF THE FISH AND WILDLIFE SERVICE WHICH MAY OCCUR WITHIN COOS COUNTY, OREGON

Species of Concern: Taxa whose conservation status is of concern to the U.S. Fish and Wildlife Service (many previously known as Category 2 candidates), but for which further information is still needed. Such species receive no legal protection and use of the term does not necessarily imply that a species will eventually be proposed for listing.

Delisted Species: A species that has been removed from the Federal list of endangered and threatened wildlife and plants.

## Key:

| | |
|---|---|
| E | Endangered |
| T | Threatened |
| CH | Critical Habitat has been designated for this species |
| PE | Proposed Endangered |
| PT | Proposed Threatened |
| PCH | Critical Habitat has been proposed for this species |

## Notes:

**Marine & Anadromous Species:** Please consult the National Marine Fisheries Service (NMFS) (http://www.nmfs.noaa.gov/pr/species/) for marine and anadromous species. The National Marine Fisheries Service (NMFS) manages mostly marine and anadromous species, while the U.S. Fish and Wildlife Service manages the remainder of the listed species, mostly terrestrial and freshwater species.

**Marine Turtle Conservation and Management**: All six species of sea turtles occurring in the U.S. are protected under the Endangered Species Act of 1973. In 1977, NOAA Fisheries and the U.S. Fish and Wildlife Service signed a Memorandum of Understanding to jointly administer the Endangered Species Act with respect to marine turtles. NOAA Fisheries has the lead responsibility for the conservation and recovery of sea turtles in the marine environment and the U.S. Fish and Wildlife Service has the lead for the conservation and recovery of sea turtles on nesting beaches. For more information, see the NOAA Fisheries webpage on sea turtles http://www.nmfs.noaa.gov/pr/species/turtles/.

**Gray Wolf**: In 2008, the Service published a final rule that established a distinct population segment of the gray wolf (*Canis lupis*) in the northern Rocky Mountains (which includes a portion of Eastern Oregon, east of the centerline of Highway 395 and Highway 78 north of Burns Junction and that portion of Oregon east of the centerline of Highway 95 south of Burns Junction). Any wolves found west of this line in Oregon belong to the conterminous USA population [see 73 FR 10514]. On May 5, 2011, the Fish and Wildlife Service published a final rule – as directed by legislative language in the Fiscal Year 2011 appropriations bill – reinstating the Service's 2009 decision to delist biologically recovered gray wolf populations in the Northern Rocky Mountains. Gray wolves in Oregon are State-listed as endangered, regardless of location.

**Approved:** Steve Thompson

Manager, California/Nevada Operations Office,
U.S. Fish and Wildlife Service

**Date:** 8/13/2007

## PRIMARY AUTHORS

This final recovery plan was prepared by Kelly Hornaday, Ina Pisani, and Betty Warne of our Sacramento Fish and Wildlife Office. Ruth Pratt of the Sacramento Fish and Wildlife Office coordinated preparation of the draft recovery plan and acted as Recovery Team Manager.

We gratefully acknowledge the efforts of the Pacific Coast Western Snowy Plover Recovery Team in preparing this recovery plan. Special acknowledgment is also given to Nadav Nur, Point Reyes Bird Observatory, Stinson Beach, California, for his work on the population viability analysis.

## DISCLAIMER

Recovery plans delineate reasonable actions that are believed to be required to recover and/or protect listed species. We, the U.S. Fish and Wildlife Service, publish recovery plans, sometimes preparing them with the assistance of recovery teams, contractors, State agencies, and others. Recovery teams serve as independent advisors to the U.S. Fish and Wildlife Service. Objectives of the recovery plan will be attained and necessary funds made available subject to budgetary and other constraints affecting the parties involved, as well as the need to address other priorities. Recovery plans do not obligate other parties to undertake specific actions, and may not represent the views or the official positions or approval of any individuals or agencies involved in the recovery plan formulation other than our own. They represent our official position **only** after they have been signed by the Director, Regional Director, or Operations Manager as **approved**. Approved recovery plans are subject to modification as dictated by new findings, changes in species status, and the completion of recovery actions.

**Literature Citation Should Read As Follows:**
U.S. Fish and Wildlife Service. 2007. Recovery Plan for the Pacific Coast Population of the Western Snowy Plover (*Charadrius alexandrinus nivosus*). In 2 volumes. Sacramento, California. xiv + 751 pages.

An electronic version of this recovery plan also will be made available at http://www.fws.gov/cno/es/recoveryplans.html and http://endangered.fws.gov/recovery/index.html#plans

## ACKNOWLEDGMENTS

The following U.S. Fish and Wildlife Service staff provided valuable review and comments on the recovery plan: John Grettenberger and Martha Jensen, Western Washington Office, Lacey, Washington; Carrie Phillips, Elizabeth Kelly, and Fred Seavey, Newport Fish and Wildlife Office, Newport, Oregon; Jim Watkins, Arcata Fish and Wildlife Office, Arcata, California; Kevin Clark and Gjon Hazard, Carlsbad Fish and Wildlife Office, Carlsbad, California; Steve Henry, Steve Kirkland, and David Pereksta, Ventura Fish and Wildlife Office; Diane Elam, California/Nevada Operations Office, Sacramento, California; and Grant Canterbury, Pacific Regional Office, Portland, Oregon. Robert Mesta, Bureau of Land Management Region 2 Office, Tucson, Arizona also provided valuable review and comments on the recovery plan.

Jennifer Bain, Valary Bloom, Don Hankins, Larry Host, Harry McQuillen, Caroline Prose, Caralee Stevens, Glen Tarr, Kim Turner, Betty Warne, and Dan Welsh of the Sacramento Fish and Wildlife Office, Sacramento, California also assisted in preparation of the final recovery plan.

Maps of snowy plover sites in Appendix L were prepared by Brian Cordone, Cheryl Hickam, and Joni Mitchell, Sacramento Fish and Wildlife Office, Sacramento, California.

The cover illustrations for the front cover and Appendix K are used courtesy of Carleton R. Eyster, Santa Cruz, California.

# EXECUTIVE SUMMARY

**CURRENT SPECIES STATUS:** The Pacific coast population of the western snowy plover (*Charadrius alexandrinus nivosus*) (western snowy plover) is federally listed as threatened. The current Pacific coast breeding population extends from Damon Point, Washington, south to Bahia Magdalena, Baja California, Mexico (including both Pacific and Gulf of California coasts). The western snowy plover winters mainly in coastal areas from southern Washington to Central America.

**HABITAT REQUIREMENTS AND LIMITING FACTORS:** The Pacific coast population of the western snowy plover breeds primarily above the high tide line on coastal beaches, sand spits, dune-backed beaches, sparsely-vegetated dunes, beaches at creek and river mouths, and salt pans at lagoons and estuaries. Less common nesting habitats include bluff-backed beaches, dredged material disposal sites, salt pond levees, dry salt ponds, and river bars. In winter, western snowy plovers are found on many of the beaches used for nesting as well as on beaches where they do not nest, in man-made salt ponds, and on estuarine sand and mud flats.

Habitat degradation caused by human disturbance, urban development, introduced beachgrass (*Ammophila* spp.), and expanding predator populations have resulted in a decline in active nesting areas and in the size of the breeding and wintering populations.

**RECOVERY OBJECTIVE**: The primary objective of this recovery plan is to remove the Pacific coast population of the western snowy plover from the *List of Endangered and Threatened Wildlife and Plants* by: (1) increasing population numbers distributed across the range of the Pacific coast population of the western snowy plover; (2) conducting intensive ongoing management for the species and its habitat and developing mechanisms to ensure management in perpetuity; and (3) monitoring western snowy plover populations and threats to determine success of recovery actions and refine management actions.

**RECOVERY PRIORITY**: 3C, per criteria published by Federal Register Notice (U.S. Fish and Wildlife Service 1983).

**RECOVERY CRITERIA**: The Pacific coast population of the western snowy plover will be considered for delisting when the following criteria have been met:

1. An average of 3,000 breeding adults has been maintained for 10 years, distributed among 6 recovery units as follows: Washington and Oregon, 250 breeding adults; Del Norte to Mendocino Counties, California, 150 breeding adults; San Francisco Bay, California, 500 breeding adults; Sonoma to Monterey Counties, California, 400 breeding adults; San Luis Obispo to Ventura Counties, California, 1,200 breeding adults; and Los Angeles to San Diego Counties, California, 500 breeding adults. This criterion also includes implementing monitoring of site-specific threats, incorporation of management activities into management plans to ameliorate or eliminate those threats, completion of research necessary to modify management and monitoring actions, and development of a post-delisting monitoring plan.

2. A yearly average productivity of at least one (1.0) fledged chick per male has been maintained in each recovery unit in the last 5 years prior to delisting.

3. Mechanisms have been developed and implemented to assure long-term protection and management of breeding, wintering, and migration areas to maintain the subpopulation sizes and average productivity specified in Criteria 1 and 2. These mechanisms include establishment of recovery unit working groups, development and implementation of participation plans, development and implementation of management plans for Federal and State lands, protection and management of private lands, and public outreach and education.

**ACTIONS NEEDED:**

1. Monitor breeding and wintering populations and habitats of the Pacific coast population of the western snowy plover to determine progress of recovery actions to maximize survival and productivity.

2. Manage breeding and wintering habitat of the Pacific coast population of the western snowy plover to ameliorate or eliminate threats and maximize survival and productivity.

3. Develop mechanisms for long-term management and protection of western snowy plovers and their breeding and wintering habitat.

4. Conduct scientific investigations that facilitate the recovery of the western snowy plover.

5. Conduct public information and education programs about the western snowy plover.

6. Review progress towards recovery of the western snowy plover and revise recovery efforts, as appropriate.

7. Dedicate U.S. Fish and Wildlife Service staff to allow the Arcata Fish and Wildlife Office to coordinate western snowy plover recovery implementation.

8. Establish an international conservation program with the government of Mexico to protect western snowy plovers and their breeding and wintering locations in Mexico.

Appendices B and C address Actions 1 and 2, providing site-specific recommendations for breeding numbers and management actions. Appendix J addresses Action 1, providing guidelines for monitoring western snowy plovers during the breeding and wintering seasons. Appendix K addresses Action 5, providing a public information and education plan.

**ESTIMATED COST OF RECOVERY:** $149,946,000 plus additional costs that cannot be estimated at this time.

**DATE OF RECOVERY:** Delisting could occur by 2047 if the recovery criteria above have been met.

## LIST OF TABLES

## LIST OF FIGURES

# I. INTRODUCTION

On March 5, 1993, the Pacific coast population of the western snowy plover (*Charadrius alexandrinus nivosus*) (western snowy plover) was listed as threatened under provisions of the Endangered Species Act of 1973, as amended (16 U.S.C. 1531 *et seq.*). The Pacific coast population is defined as those individuals that nest within 50 miles of the Pacific Ocean on the mainland coast, peninsulas, offshore islands, bays, estuaries, or rivers of the United States and Baja California, Mexico (U.S. Fish and Wildlife Service 1993*a*) (Figure 1). General locations of the western snowy plover's breeding and wintering locations in the United States are shown in Appendix A. Surveys, status reviews, and literature searches have identified 159 current or historical western snowy plover breeding or wintering locations on the U.S. Pacific coast. These localities include 6 in Washington, 19 in Oregon, and 134 in California (Appendix B). In Baja California, breeding western snowy plovers concentrate at coastal wetland complexes as far south as Bahia Magdalena, Mexico (Palacios *et al.* 1994). The locations listed in Appendix B are important for the recovery of the United States Pacific coast population of the western snowy plover because they represent important breeding, feeding, and sheltering habitat for the species.

In Washington, the western snowy plover was listed as endangered under Washington Department of Fish and Wildlife Policy #402 in 1981. In 1990 the Washington Fish and Wildlife Commission (Washington Administrative Code 232-12-014) reaffirmed the endangered status. In 1975, the Oregon Fish and Wildlife Commission listed the western snowy plover as threatened. Its threatened status was reaffirmed in 1989 under the Oregon Endangered Species Act and again in 1993 and 1998 by the Oregon Fish and Wildlife Commission as part of its periodic review process. Since 1978, the California Department of Fish and Game has classified both the inland and coastal population of western snowy plover as a "species of special concern." (Remsen 1978, California Natural Diversity Database 2001).

In August 2002, we received a petition from the Surf Ocean Beach Commission of Lompoc, California to delist the Pacific Coast population of the western snowy

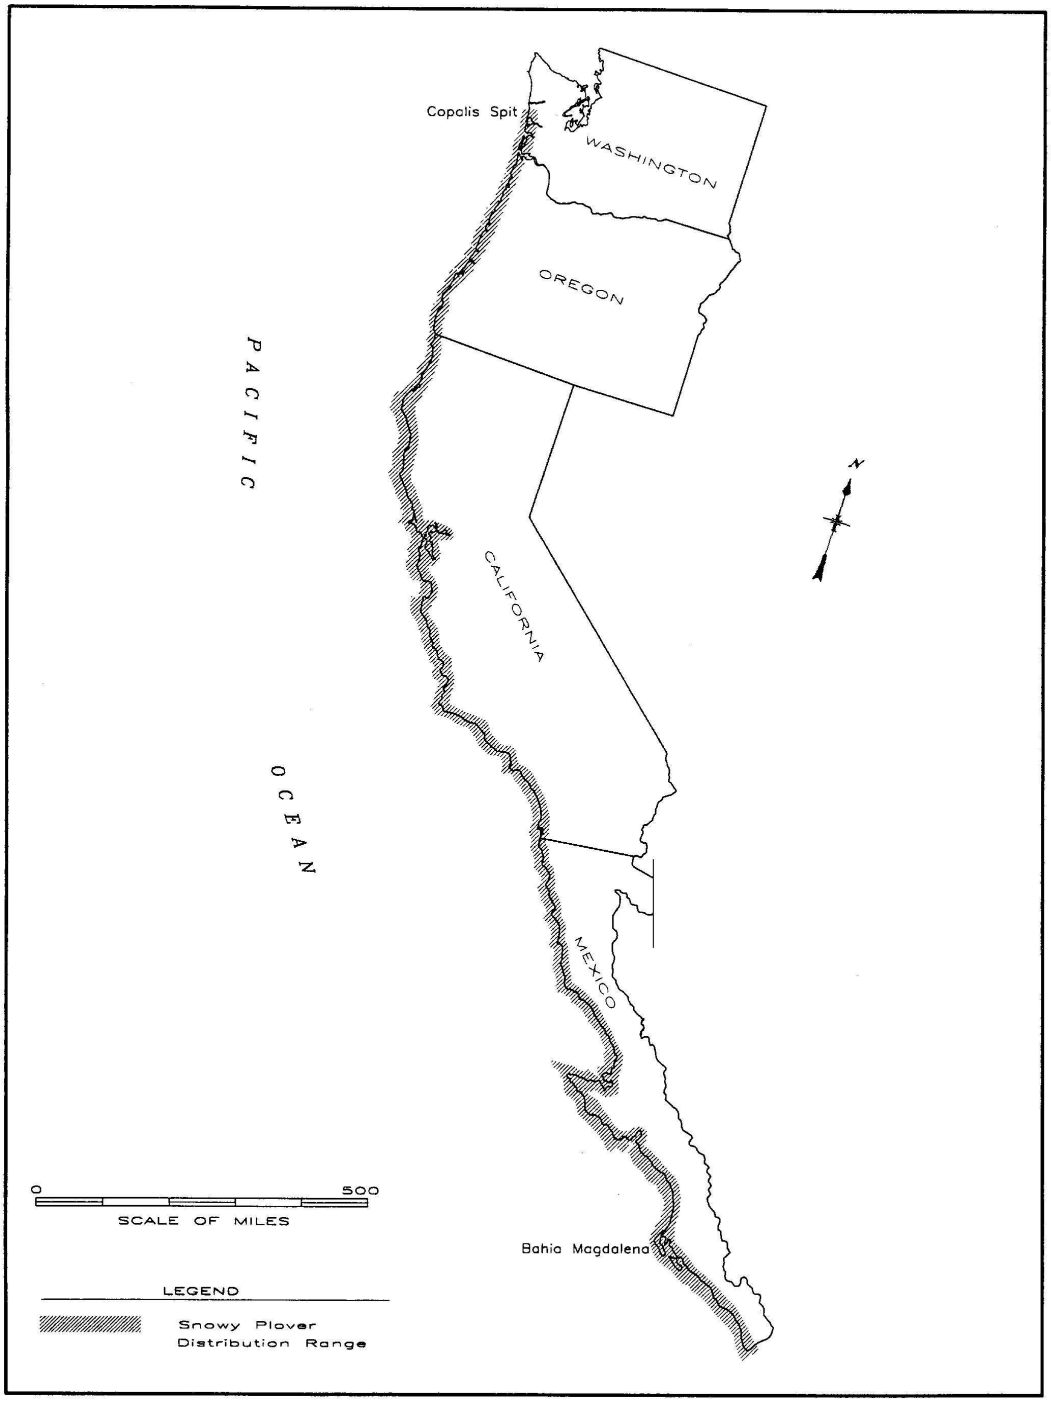

**Figure 1.** Map of known breeding and wintering distribution of the Pacific coast population of the western snowy plover.

plover. The City of Morro Bay, California submitted substantially the same petition dated May 30, 2003. On March 22, 2004, we published a notice that the petition presented substantial information to indicate that the delisting may be warranted (U.S. Fish and Wildlife Service 2004*a*). This notice also announced our initiation of a 5-year status review for the Pacific coast population of western snowy plover.

Under sections 4(b)(3)(B) and 4(c)(2) of the Endangered Species Act, we conducted a 5-year status review and evaluated whether the petitioned action was warranted. On April 21, 2006, we published a 12-month finding that concluded the petitioned action was not warranted (U.S. Fish and Wildlife Service 2006*a*). We also proposed a special rule pursuant to section 4(d) of the Endangered Species Act (U.S. Fish and Wildlife Service 2006*b*), which would exempt counties that have met western snowy plover recovery goals from most prohibitions on take as long as populations remain above recovery goals. The 5-year status review was completed on June 8, 2006.

Section 4 of the Endangered Species Act of 1973, as amended, requires us to develop a recovery plan for the conservation and survival of a species after it is federally listed as threatened or endangered, unless it is determined that such a plan will not promote the conservation of the species. Recovery is the process of reversing the decline of a listed species, eliminating threats, and ensuring the species' long-term survival. This recovery plan recommends actions necessary to satisfy the biological needs and assure recovery of the Pacific coast population of the western snowy plover. These actions include protection, enhancement, and restoration of all habitats deemed important for recovery; monitoring; research; and public outreach.

This recovery plan will serve as a guidance document for interested parties including Federal, State, and local agencies; private landowners; and the general public. It includes recommendations for western snowy plover management measures for all known breeding and wintering locations (Appendix C). These locations have been divided into six recovery units, as follows: (1) Oregon and Washington; (2) northern California (Del Norte, Humboldt, and Mendocino Counties); (3) San Francisco Bay (locations within Napa, Alameda, Santa Clara, and San Mateo Counties); (4) Monterey Bay (including coastal areas along Monterey, Santa Cruz, San Mateo, San Francisco, Marin, and Sonoma Counties); (5) San Luis Obispo, Santa Barbara, and Ventura Counties; and (6) Los Angeles, Orange, and San Diego Counties. Designation of these locations and recovery units assists in identifying priority areas for conservation planning across the western snowy plover's breeding and wintering range.

This recovery plan emphasizes management on Federal and State lands, including opportunities to improve or expand upon current efforts. Because of this emphasis on public lands, the cost associated with this emphasis, and potential restrictions of public use on these lands, public support and involvement will be crucial to the recovery of the western snowy plover. Opportunities for public participation in recovery efforts are emphasized in Appendix K (Information and Education Plan).

## A. DESCRIPTION AND TAXONOMY

The western snowy plover, a small shorebird in the family Charadriidae, weighs from 34 to 58 grams (1.2 to 2 ounces) and ranges in length from 15 to 17 centimeters (5.9 to 6.6 inches) (Page *et al.* 1995*a*). It is pale gray-brown above and white below, with a white hindneck collar and dark lateral breast patches, forehead bar, and eye patches (Figure 2). The bill and legs are blackish. In breeding plumage, males usually have black markings on the head and breast; in females, usually one or more of these markings are dark brown. Early in the breeding season a rufous crown may be evident on breeding males, but it is not typically seen on females. In non-breeding plumage, sexes cannot be distinguished because the breeding markings disappear. Fledged juveniles have buffy edges on their upper parts and can be distinguished from adults until approximately July through October, depending on when in the nesting season they hatched. After this period, molt and feather wear makes fledged juveniles indistinguishable from adults. Individual birds 1 year or older are considered to be breeding adults. The mean annual life span of western snowy plovers is estimated at about 3 years, but at least one individual was at least 15 years old when last seen (Page *et al.* 1995*a*).

**Figure 2.** Adult male western snowy plover (photo by Peter Knapp, with permission).

The species was first described in 1758 by Linnaeus (American Ornithologists' Union 1957). Two subspecies of the snowy plover have been recognized in North America (American Ornithologists' Union 1957): the western snowy plover (*Charadrius alexandrinus nivosus*) and the Cuban snowy plover (*C. a. tenuirostris*). The Pacific coast population of the western snowy plover breeds on the Pacific coast from southern Washington to southern Baja California, Mexico. Wintering birds may remain at their breeding sites or move north or south to other wintering sites along the Pacific coast. The interior population of the western snowy plover breeds in interior areas of Oregon, California, Nevada, Utah, New Mexico, Colorado, Kansas, Oklahoma, and north-central Texas, as well as coastal areas of extreme southern Texas, and possibly extreme northeastern Mexico (American Ornithologists' Union 1957). Although previously observed only as a migrant in Arizona, small numbers have bred there in recent years (Monson and Phillips 1981, Davis and Russell 1984). Interior population birds breeding east of the Rockies generally winter along the Gulf coast, while most interior population birds breeding west of the Rockies winter in coastal California and Baja

California, often intermingling with birds from the Pacific coast breeding population. The Cuban snowy plover breeds along the Gulf coast from Louisiana to western Florida and south through the Caribbean (American Ornithologists' Union 1957). More recent works recognize only subspecies *C. a. nivosus* for North America (Hayman *et al.* 1986, Binford 1989, Sibley and Monroe 1990).

A large amount of breeding data indicates that the Pacific coast population of the western snowy plover is distinct from western snowy plovers breeding in the interior (U.S. Fish and Wildlife Service 1993*a*, 2006*a*). A study conducted between 1977 and 1982 reported that western snowy plovers tend to exhibit breeding site fidelity (Warriner *et. al.* 1986). Banding and resighting data show that the Pacific Coast breeding populations and the western interior breeding populations experience limited or rare reproductive interchange (G. Page *in litt.* 2004*a*). Between 1984 and 1995, the period with the most extensive banding studies and search efforts, 907 plovers color-banded in coastal and interior populations were subsequently resighted (excluding birds banded on the coast during winter and birds resighted in their original region without evidence of nesting). Of these, 894 birds (98.6 percent) were observed during the breeding season using the same breeding range in which they were originally banded. Twelve birds (1.3 percent) were banded on the coast and later observed in the interior, only one of which was known to nest in the interior. Only one male (0.1 percent) was banded in the interior (without evidence of nesting) and later found nesting on the coast. Moreover, data from a period of less intensive surveys and banding from 1977 to 1983 corroborate this pattern (G. Page *in litt.* 2004*a*, U.S. Fish and Wildlife Service 2006*a*). During this period, of 400 birds banded in the interior, none were observed on the coast during breeding season, and of 599 birds banded on the coast only one was found nesting in the interior. Finally, 304 retrievals of numbered metal bands reported between 1969 and 2002 show no evidence of movement from interior to coast and only one bird (G. Goldsmith *in litt.* 2004, U.S. Fish and Wildlife Service 2006*a*) that moved from coast to interior (the dates being consistent with a bird from the interior population having been banded on the coast during the non-breeding season).

Thus, intensive banding and monitoring studies have documented only two clear instances of interbreeding between coastal and interior populations, and a few cases of inter-population movement without confirmed breeding, among thousands of birds observed. These results illustrate that the amount of interchange between coastal and interior populations is likely to be extremely low, though not zero. Movement of birds from coastal to interior populations has been documented more often than the reverse (see also U.S. Fish and Wildlife Service 2006a).

Genetic studies using mitochondrial DNA and microsatellite DNA markers (Gorman 2000, Funk *et al.* 2006) have found no significant genetic differentiation between the Pacific coast and interior populations of the western snowy plover. However, because a small number of dispersing individuals per generation is sufficient to prevent genetic differentiation between two semi-isolated populations (Mills and Allendorf 1996, Funk *et al.* 2006), this result is consistent with the banding data reported above. Because the small number of dispersing individuals indicated by banding data appear insufficient to substantially affect rates of population growth or decline in either population, the two populations evidently function demographically as largely independent of one another. Moreover, the infrequency of observed dispersal from coast to interior further indicates that any declines in the coastal population are not likely to be effectively offset by immigration of interior birds to the coast. Consequently there is no evidence that existing unoccupied habitat along the Pacific coast is currently being or in future would be naturally colonized by birds from the interior population (Funk et al. 2006).

## B. LIFE HISTORY AND ECOLOGY

### 1. Breeding

The Pacific coast population of the western snowy plover breeds primarily on coastal beaches from southern Washington to southern Baja California, Mexico (*e.g.*, Figure 3). Sand spits, dune-backed beaches, beaches at creek and river mouths, and salt pans at lagoons and estuaries are the main coastal habitats for nesting (Stenzel *et al.* 1981, Wilson 1980). This habitat is unstable because of

**Figure 3.** Coastal beach in Oregon Dunes National Recreational Area (photo by Ruth Pratt, with permission)

unconsolidated soils, high winds, storms, wave action, and colonization by plants. Less common nesting habitats include bluff-backed beaches, dredged material disposal sites, salt pond levees, dry salt ponds, and river bars (Wilson 1980, Page and Stenzel 1981, Powell *et al.* 1996, Tuttle *et al.* 1997).

***a. Population Size and Distribution***

Population estimates referenced below are based on window surveys as well as on more intensive studies involving repeated surveys of populations with individually identifiable color-banded birds. Window surveys are a one-time pass of a surveyor, or team of surveyors, through potential western snowy plover nesting habitat during May or June (see survey protocol in Appendix J). The surveyor counts all adult western snowy plovers in the habitat and identifies the adults as male or female, when possible. Because window surveys may not detect all birds, they are not directly comparable to more intensive studies. A correction factor can be estimated by comparing window survey data with concurrent population estimates from detailed studies of color-banded populations; currently the best rangewide estimate of the correction factor is 1.3 (U.S. Fish and Wildlife Service 2006*a*), but it is preferable to determine corrections on a more specific regional or site basis if possible due to differences in survey efficiency in different habitats (see action 4.3.1).

Western snowy plovers concentrate in suitable habitat, with the number of adults at coastal breeding locations ranging from 1 to 315, depending in part, on the size of the area (Appendix B). The largest number of breeding birds occurs from south San Francisco Bay to southern Baja California (Page and Stenzel 1981, Palacios *et al.* 1994).

The locations of the following parenthetical references to western snowy plover breeding and wintering locations in Washington, Oregon, and California are shown in Figures A-1 through A-7 of Appendix A, and mapped in greater detail in Appendix L. Information on the numbers of breeding and wintering western snowy plovers at these locations is described in Appendix B.

Four breeding areas currently exist in southern Washington: Damon Point (Washington location 2 [WA-2]) in Grays Harbor; Midway Beach (WA-4); and Leadbetter Point (WA-5) and Graveyard Spit (discovered in 2006) in Willapa Bay. Prior to the 1998 breeding season, fewer than 25 western snowy plovers and 12 nests were found in Washington during regular, standardized surveys. However, surveys from 1998 through 2006 (Sundstrom 2003, 2005; Brennan and Fernandez 2004*a*, 2006; Pearson *et al.* 2006; Washington Department of Fish and Wildlife unpub. data) indicate greater numbers of western snowy plovers are nesting at Leadbetter Point (WA-5) and Midway Beach (WA-4), with a maximum estimated population of 70 western snowy plovers statewide in 2006.

In Oregon, nesting birds have been recorded at 14 sites since 1990 (Castelein *et al.* 2002, Lauten *et al.* 2006*a*, 2006*b*). Nesting has occurred most frequently at 9 sites, including Sutton (OR-8), Siltcoos (OR-10), Dunes Overlook (OR-10), Tahkenitch (OR-10), Tenmile Spits (OR-12), Coos Bay North Spit (OR-13), Bandon (OR-15), New River (OR-15), and Floras Lake (OR-15). An estimated 177-179 adult western snowy plovers were observed at Oregon sites during the 2006 breeding season. A total of 135 individuals were known to have nested in

2006, with 147 nests located. Individual nests have also been found between 1990 and 2002 at several other Oregon sites, including Necanicum (OR-1); Bayocean Spit (OR-3); North Siuslaw (OR-8); Threemile-Umpqua River (OR-11); and Menasha Spoils, North Bend.

Western snowy plover populations in California have fluctuated between roughly one thousand and two thousand birds over the past 30 years, as detailed in section I.C.1.c below. Eight geographic areas support over three-quarters of the California coastal breeding population: San Francisco Bay (CA-27 to CA-47), Monterey Bay (CA-63 to CA-65), Morro Bay (CA-79 to CA-81), the Callendar-Mussel Rock Dunes area (CA-83), the Point Sal to Point Conception area (CA-84 to CA-88), the Oxnard lowland (CA-96 to CA-99), Santa Rosa Island (CA-93), and San Nicolas Island (CA-100) (Page *et al.* 1991, G. Page *in litt.* 2005*a*).

A survey of breeding western snowy plovers along the Pacific coast of Baja California, Mexico between 1991 to 1992 found 1,344 adults, mostly at four coastal wetland complexes: Bahia San Quintin, Lagunas Ojo de Liebre and Guerrero Negro, Laguna San Ignacio, and Bahia Magdalena (Palacios *et al.* 1994).

***b. Arrival and Courtship***

Nesting western snowy plovers at coastal locations consist of both year-round residents and migrants (Warriner *et al.* 1986). Migrants begin arriving at breeding areas in southern Washington in early March (Widrig 1980) and in central California as early as January, although the main arrival is from early March to late April (Page *et al.* 1995*a*). Since some individuals nest at multiple locations during the same year, birds may continue arriving through June (Stenzel *et al.* 1994).

Mated birds from the previous breeding season frequently reunite. Pair bonds are associated with territorial defense by males and nest scraping behavior, but early in the season birds begin to associate with one another in pairs within and apart from roosting flocks before nest scraping activity is observed, suggesting that pair bonds can be established prior to overt displays (Warriner *et al.* 1986). A scrape is a depression in the sand or substrate that a male constructs by leaning forward on his breast and scratching his feet while rotating his body axis (Page *et al.* 1995*a*). Copulations are associated with scraping behavior (Warriner *et al.* 1986). Females choose which scrape becomes the nest site by laying eggs in one of them. In California, pre-nesting bonds and courtship activities are observed as early as mid-February. Similar activities begin by March in Oregon. During courtship, males defend territories and usually make multiple scrapes.

***c. Duration of Breeding Season***

Along the west coast of the United States, the nesting season of the western snowy plover extends from early March through late September. Generally, the breeding season may be 2 to 4 weeks earlier in southern California than in Oregon and Washington. Fledging (reaching flying age) of late-season broods may extend into the third week of September throughout the breeding range.

The earliest nests on the California coast occur during the first week of March in some years and by the third week of March in most years (Page *et al.* 1995*a*). Peak initiation of nesting is from mid-April to mid-June (Warriner *et al.* 1986; Powell *et al.* 1997). Hatching lasts from early April through mid-August, with chicks reaching fledging age approximately 1 month after hatching (Powell *et al.* 1997). On the Oregon coast nesting may begin as early as mid-March, but most nests are initiated from mid-April through mid-July (Wilson-Jacobs and Meslow 1984); peak nest initiation occurs from mid-May to early July (Stern *et al.* 1990). In Oregon, hatching occurs from mid-April through mid-August, with chicks reaching fledging age as early as mid- to late May. Peak hatching occurs from May through July, and most fledging occurs from June through August. On the Washington coast, most adults arrive during late April, with maximum numbers present from mid-May to late June. Fledging occurs from late June through August (Washington Department of Fish and Wildlife 1995).

***d. Nests and Nest Sites***

Nests typically occur in flat, open areas with sandy or saline substrates; vegetation and driftwood are usually sparse or absent (Widrig 1980, Wilson 1980, Stenzel *et al.* 1981). Western snowy plovers also regularly nest on the gravel bars along the

Eel River in northern California. In southern California, western snowy plovers nest in areas with 6 to 18 percent vegetative cover and 1 to 14 percent inorganic cover; vegetation height is usually less than six centimeters (2.3 inches) (Powell *et al.* 1995, 1996). Nests consist of a shallow scrape or depression, sometimes lined with beach debris (*e.g.*, small pebbles, shell fragments, plant debris, and mud chips); nest lining increases as incubation progresses. Driftwood, kelp, and dune plants provide cover for chicks that crouch near objects to hide from predators. Invertebrates are often found near debris, so driftwood and kelp are also important for harboring western snowy plover food sources (Page *et al.* 1995*a*). Page and Stenzel (1981) found that nests were usually within 100 meters (328 feet) of water, but could be several hundred meters away when there was no vegetative barrier between the nest and water. They believed the absence of such a barrier is probably important for newly-hatched chicks to have access to the shore. Powell *et al.* (1995, 1996) also reported that nests from southern California were usually located within 100 meters (328 feet) of water, which could be either ocean, lagoon, or river mouth. Although the majority of western snowy plovers are site-faithful, returning to the same breeding area in subsequent breeding seasons, some also disperse within and between years (Warriner *et al.* 1986, Stenzel *et al.* 1994). Western snowy plovers occasionally nest in exactly the same location as the previous year (Warriner *et al.* 1986).

### *e. Egg Laying, Clutch Size, and Incubation*

Initiation (eggs and laying) occurs from mid-February/early March through the third week of July (Wilson 1980, Warriner *et al.* 1986). The approximate periods required for nesting events are: scrape construction (in conjunction with courtship and mating), 3 days to more than a month; egg laying, usually 4 to 5 days; and incubation, 26 to 31 days (mean 27 days) (Warriner *et al.* 1986). The usual clutch size (*e.g.*, number of eggs in one nest) is three (Figure 4) with a range from two to six. (Warriner *et al.* 1986, Page *et al.* 1995*a*). Both sexes incubate the eggs, with the female tending to incubate during the day and the male at night (Warriner *et al.* 1986). Adult western snowy plovers frequently will attempt to lure people and predators from hatching eggs with alarm calls and distraction displays. Occasionally, adults behave similarly during the egg-laying period or

**Figure 4.** Western snowy plover clutch (photo by Bruce Casler, with permission).

incubation of completed clutches. More typical, however, is for the incubating adult to run away from the eggs without being seen. Incomplete clutches are those in which all eggs have not been laid. Partly-incubated clutches are those clutches having some degree (in days) of incubation.

Western snowy plovers will re-nest after loss of their eggs (Wilson 1980, Warriner *et al.* 1986). Re-nesting occurs 2 to 14 days after failure of a clutch, and up to five re-nesting attempts have been observed for a pair (Warriner *et al.* 1986).

Double brooding with polyandry (meaning the female successfully hatches more than one brood [*i.e.* sibling chicks of a hatched nest] in a nesting season with different mates) is common in coastal California (Warriner *et al.* 1986) and Oregon (Wilson-Jacobs and Meslow 1984). On the California coast, the breeding season is long enough for some females to triple brood and for some males to double brood (Page *et al.* 1995*a*). Triple brooding in a male has, on rare occasion, been recorded; a male triple brooded at Moss Landing salt ponds in 2001 (D. George *in litt.* 2001). After losing a clutch or brood or successfully hatching a nest, western snowy plovers may re-nest at the same site or move up to several hundred kilometers to nest at other sites (Stenzel *et al.* 1994, Powell *et al.* 1997 ).

### *f. Clutch Hatching Success*

Widely varying clutch hatching success (percent of clutches hatching at least one egg) is reported in the literature. Clutch hatching success ranging from 0 to 90 percent has been recorded for coastal western snowy plovers (Widrig 1980, Wilson 1980, Saul 1982, Wilson-Jacobs and Dorsey 1985, Warriner *et al.* 1986, Wickham unpubl. data *in* Jacobs 1986). Low clutch hatching success has been attributed to a variety of factors, including predation, human disturbance, high tides, and inclement weather. Heavy recreational beach use coincides with the peak hatching period for western snowy plover eggs (Powell 2001), adding additional pressures to western snowy plover adults and chicks that are more exposed to human disturbance. Observed clutch hatching success ranged from 12.5 to 86.8 percent and averaged 50.6 percent in eight studies of coastal breeding western snowy plovers (Page *et al*. 1995*a*). In San Diego County, estimated nesting success ranged from 43 to 68 percent between 1994 and 1998, averaging 54 percent (Powell *et al.* 2002); nesting western snowy plovers in San Diego County likely benefitted from predator management efforts for snowy plovers and California least terns (*Sternula antillarum browni*) (A. Powell, U.S. Geological Survey, pers. comm. 1998). In Monterey Bay, hatching rate was significantly increased from 43 percent (during 1984-1990) to 68 percent (during 1991-1999) by intensive control of mammalian predators and use of nest exclosures (Neuman *et al.* 2004).

### *g. Brood-rearing*

The first chick hatched remains in or near the nest until other eggs (or at least the second egg) hatch. The adult western snowy plover, while incubating the eggs, also broods the first chick. The non-incubating adult also may brood the first-born chick a short distance from the nest. If the third egg of a clutch is 24 to 48 hours behind the others in hatching, it may be deserted. Western snowy plover chicks are precocial, leaving the nest within hours after hatching to search for food. They are not able to fly (fledge) for approximately 1 month after hatching;

fledging requires 28 to 33 days (Warriner *et al.* 1986). Broods rarely remain in the nesting area until fledging (Warriner *et al.* 1986, Stern *et al.* 1990). Western snowy plover broods may travel along the beach as far as 6.4 kilometers (4 miles) from their natal area (Casler *et al.* 1993).

Adult western snowy plovers do not feed their chicks, but lead them to suitable feeding areas. Adults use distraction displays to lure predators and people away from chicks. With vocalizations, adult western snowy plovers signal the chicks to crouch as another way to protect them (Page *et al.* 1995*a*). They also may lead chicks, especially larger ones, away from predators. Warriner *et al.* (1986) reported that most chick mortality occurs within 6 days after hatching.

Females generally desert mates and broods by the sixth day after hatching and thereafter the chicks are typically accompanied by only the male. While males rear broods, females obtain new mates and initiate new nests (Page *et al.* 1995*a*). Females typically help rear the last brood of the season.

***h. Fledging success***

The fledging success of western snowy plovers (percentage of hatched young that reach flying age) varies greatly by location and year. Even western snowy plovers nesting on neighboring beach segments may exhibit quite different success in the same year. For example, the percentage of chicks fledged on different beach segments of Monterey Bay in 1997 varied from 11 to 59 percent (average 24 percent) (Page *et al.* 1997). During the prior 13 years, fledging success on Monterey Bay beaches averaged 39 percent (Page *et al.* 1997). From the former Moss Landing salt ponds (now known as the Moss Landing Wildlife Area) in Monterey Bay (CA-64), fledging success ranged from 13.2 percent to 57.1 percent from 1988 to 1997. In San Diego County, fledging success ranged from 32.6 to 51.4 percent (Powell *et al.* 1997). In Oregon, annual fledging success for 1992 to 2006, for all coastal sites combined, ranged from 26 to 55 percent (Lauten *et al.* 2006*a*, 2006*b*). As in California, there is considerable variation among sites within years. For example, in 2005, the fledging success ranged from 24 percent at New River (OR-15) to 70 percent at Coos Bay South Beach (OR-13). There also is variation at individual sites among years. At the Coos Bay North Spit

(OR-13), one of the larger nesting areas in coastal Oregon, annual fledging success for 1992 to 2006 ranged from 38 to 74 percent.

### *i. Productivity*

The productivity information most useful for this recovery plan is reproductive success (the annual number of young fledged per adult male). For the population viability analysis (Appendix D), males were used in the model because their population parameters can be estimated with greater certainty than for females. In addition, it is reasonable to consider that the availability of males is limiting reproductive success because they are responsible for post-hatching parental care, and females can lay clutches for more than one male (Warriner *et al.* 1986).

Chicks are considered fledged at 28 to 33 days after hatching. Estimates of the number of young fledged per adult male are available for Oregon; northern California from Mendocino to Del Norte Counties; Monterey Bay, California; and San Diego County, California. Along the Oregon coast, the average number of young annually fledged per male during the period between 1992 and the initiation of predator management (2002 to 2004 depending on site) was estimated as 0.87 (Lauten *et al.* 2006*b*); this fledging success significantly increased to 1.44 since implementation of predator management. Male fledging success in Oregon has annually ranged between 0.70 and 1.64 (Lauten *et al.* 2006*a*). In northern California, fledging success ranged from 0.8 to 1.7 fledglings per male between 2001-2005, with birds nesting on river gravel bars consistently achieving greater success than those nesting on beaches (Colwell *et al.* 2005). At Monterey Bay, California, from 1984 to 1990, when little effort was made to protect chicks from predators and people, males averaged 0.86 fledglings annually. When intensive efforts were undertaken to control mammalian predators from 1993 to 1999, the number of young fledged per adult male initially increased above 1.1, then declined sharply as avian predation on chicks became increasingly significant (Neuman *et al.* 2004). After live trapping and removal of avian predators was initiated, fledging success again increased in target areas (G. Page *in litt.* 2004b). Over 16 years of study at Monterey Bay, the annual number of young fledged ranged from 0.32 to 1.23 per male (Neuman *et al.* 2004). In San Diego County from 1994 to 1998, an average of 0.15 to 0.44 young were fledged per male

(Powell et al. 2002). Fledging success in Washington cannot be accurately estimated due to lack of banded chicks and adults and variable monitoring effort prior to 2006 (S. Pearson *in litt.* 2006); however it was roughly estimated at between 0.76 and 1.45 young fledged per male in 2006, excluding Leadbetter Point which was insufficiently surveyed but may have had poorer fledging success (Pearson *et al.* 2006).

### *j. Survival*

Annual survival rates for adult and juvenile western snowy plovers have been calculated from studies of color banded birds from the coast of Oregon (M. Stern unpubl. data), the shoreline of Monterey Bay, California (Point Reyes Bird Observatory unpublished data), and the coast of San Diego County, California (A. Powell and J. Terp unpublished data) using the program SURGE (Lebreton *et al.* 1992, Cooch *et al.* 1996). Annual juvenile survival rates for fledged young average 48.5 percent (1992-2002) from the Oregon coast, 45 percent from Monterey Bay, and 45 percent from the San Diego coast. Annual survival rates for adult females and males, respectively, averaged 75 and 75 percent from the Oregon coast, 69 and 75 percent from Monterey Bay, and 72 and 71 percent from the San Diego coast. Differences between males and females were statistically significant only for the Monterey Bay area. Appendix D explains how these survival rates were incorporated into the population viability analysis.

## 2. Feeding Habitat and Habits

Western snowy plovers are primarily visual foragers, using the run-stop-peck method of feeding typical of *Charadrius* species. They forage on invertebrates in the wet sand and amongst surf-cast kelp within the intertidal zone, in dry sand areas above the high tide, on salt pans, on spoil sites, and along the edges of salt marshes, salt ponds, and lagoons. They sometimes probe for prey in the sand and pick insects from low-growing plants. At the Bolsa Chica wetlands in California, western snowy plovers have been observed pecking small, flying insects from mid-air and shaking one foot in very shallow water to agitate potential prey (Fancher *et al.* 1998). Western snowy plover food consists of immature and adult forms of aquatic and terrestrial invertebrates. Little quantitative information is available on food habits. In San Diego, California, invertebrates found in western snowy plover feces during the breeding season included rove beetles (Staphylinidae), long-legged flies (Dolichopodidae), shore flies (Ephydridae), water bugs (Saldidae), hymenopterans (Braconidae), and unidentified insect larvae (Tucker and Powell 1999). During the breeding season, Jacobs (1986) observed adult western snowy plovers feeding on sand hoppers (Orchestoidea) and small fish on the Oregon coast. Other food items reported for coastal western snowy plovers include Pacific mole crabs (*Emerita analoga*), striped shore crabs (*Pachygrapsus crassipes*), polychaetes (Neridae, *Lumbrineris zonata, Polydora socialis, Scoloplos acmaceps),* amphipods (*Corophium* ssp., *Ampithoe* spp., *Allorchestes angustus*), tanadacians (*Leptochelia dubia*), shore flies (Ephydridae), beetles (Carabidae, Buprestidae, Tenebrionidae), clams (*Transenella* sp.), and ostracods (Page *et al.* 1995*a*). In salt evaporation ponds in San Francisco Bay, California, the following prey have been recorded: brine flies (*Ephydra cinerea*), beetles (*Tanarthrus occidentalis, Bembidion* sp.), moths (*Perizoma custodiata*), and lepidopteran caterpillars (Feeney and Maffei 1991). Opportunities for foraging are directly dependent on salinity levels. Specifically, salt ponds of medium salinity seem to provide the best quality foraging habitat (M. Kolar, San Francisco Bay National Wildlife Refuge, pers. comm. 2004).

**3. Migration**

While some western snowy plovers remain in their coastal breeding areas year-round, others migrate south or north for winter (Warriner *et al.* 1986, Page *et al.* 1995*a,* Powell *et al.* 1997). In Monterey Bay, California, 41 percent of nesting males and 24 percent of the females were consistent year-round residents (Warriner *et al.* 1986). At Marine Corps Base Camp Pendleton in San Diego County, California, about 30 percent of nesting birds stayed during winter (Powell *et al.* 1995, 1996, 1997). The migrants vacate California coastal nesting areas primarily from late June to late October (Page *et al.* 1995*a*). There is evidence of a late-summer (August/September) influx of western snowy plovers into Washington; it is suspected that these wandering birds are migrants (S. Richardson, Washington Department of Fish and Wildlife, pers. comm. 1998).

Most western snowy plovers that nest inland migrate to the coast for the winter (Page *et al.* 1986, 1995*b*). Thus, the flocks of non-breeding birds that begin forming along the U.S. Pacific coast in early July are a mixture of adult and hatching-year birds from both coastal and interior nesting areas. During migration and winter, these flocks range in size from a few individuals to up to 300 birds (Appendix B).

## 4. Wintering

### *a. Distribution and Abundance*

In western North America, the western snowy plover winters (here defined as late October to mid-February) mainly in coastal areas from southern Washington to Central America (Page *et al.* 1995*a*). Both coastal and interior populations use coastal locations in winter. Small numbers of western snowy plovers occur at two locations on the Washington coast: Midway Beach (WA-4) (S. Richardson, pers. comm. 1998, J. Grettenberger, U.S. Fish and Wildlife Service, pers. comm. 2004), and Leadbetter Point (WA-5), Willapa Bay (Washington Department of Fish and Wildlife 1995), both in Pacific County. Increasing numbers of wintering western snowy plovers are being documented along the Washington coast, with 32 counted in 2005 (L. Kelly *in litt.* 2005). As many as 97 western snowy plovers were observed wintering on the Oregon coast in 2005 (L. Kelly *in litt.* 2005). During the survey period between 1990 and 2005, at least 9 Oregon locations (Appendix B) have been used by wintering plovers. Probably as many as 2,500 plovers overwinter along the mainland California coast, and hundreds more at San Francisco Bay and in the Channel Islands (Appendix B, Page *et al.* 1986). The majority of wintering western snowy plovers on the California coast are found from Bodega Bay, Sonoma County, southward (Page *et al.* 1986). Appendix B gives the range of years over which each state's data was collected as well as the minimum and maximum number of western snowy plovers inventoried.

Nesting western snowy plovers from the Oregon coast have wintered as far south as Monterey Bay, California; those from Monterey Bay in central California have wintered north to Bandon, Oregon, and south to Laguna Ojo de Liebre, Baja California, Mexico (Page *et al.* 1995*a*); and those from San Diego in southern

California have wintered north to Vandenberg Air Force Base in Santa Barbara County and south to Laguna Ojo de Liebre, Baja California, Mexico (Powell *et al.* 1995, 1996, 1997).

In winter, western snowy plovers are found on many of the beaches used for nesting, as well as some beaches where they do not nest (Appendix B). They also occur in man-made salt ponds and on estuarine sand and mud flats. In California, the majority of wintering western snowy plovers concentrate on sand spits and dune-backed beaches. Some also occur on urban and bluff-backed beaches, which are rarely used for nesting (Page *et al.* 1986). Pocket beaches at the mouths of creeks and rivers on otherwise rocky shorelines are used by wintering western snowy plovers south, but not north, of San Mateo County, California.

***b. Site Fidelity***

Western snowy plovers that breed on the coast and inland are very site faithful in winter (Point Reyes Bird Observatory unpublished data). For example, after 166 adults and 204 chicks were banded at Lake Abert, Oregon during summer, many were subsequently found along the California and Baja California, Mexico coasts. Of those for which a wintering location was identified, 67 percent of the adult males, 73 percent of the adult females, and 60 percent of the birds banded as chicks (immatures) were found at the same winter location in at least 2 consecutive years; and 33 percent of the males, 32 percent of the females, and 35 percent of the immatures for at least 3 years (Page *et al.* 1995***b***).

***c. Behavior***

Western snowy plovers are typically gregarious in winter. Although some individuals defend territories on beaches, most usually roost in loose flocks; frequently western snowy plovers also are observed foraging in loose flocks (Page *et al.* 1995***a***). Roosting western snowy plovers usually sit in small depressions in the sand, or in the lee of kelp, other debris, or small dunes (Page *et al.* 1995***a***). Sitting behind debris or in depressions provides some shelter from the wind and probably makes the birds more difficult for predators to detect. When roosting western snowy plovers are disturbed, they frequently run a few meters to a new spot where they sometimes displace other individuals. Alternatively, the whole flock may fly to a new location.

## C. POPULATION STATUS AND TRENDS

### 1. Historical Trends

Historical records indicate that nesting western snowy plovers were once more widely distributed and abundant in coastal Washington, Oregon, and California.

#### *a. Washington Coast*

In Washington, western snowy plovers formerly nested at five coastal locations (Washington Department of Fish and Wildlife 1995). Three of these sites have had active nesting in recent years, as summarized in Table 1. One new site was also recently discovered in 2006. Populations appear to have increased overall since the early 1990s, although consistent, intensive surveys have been conducted only since the mid-1990s. Quantitative comparisons prior to that are not possible because of the inconsistency in surveys. Estimated numbers of breeding adults (Table 1) substantially exceed window survey data (M. Jensen *in litt.* 2006), partially because of adverse weather during window survey periods in recent years.

#### i. Grays Harbor County

Copalis Spit (WA-1) held 6 to 12 western snowy plover pairs in the late 1950s or early 1960s (Washington Department of Fish and Wildlife 1995). No other information on breeding at Copalis Spit is available. Suitable habitat was judged capable of supporting four pairs in 1984 (Washington Department of Fish and Wildlife 1995). Periodic surveys since 1983 have revealed just a single western snowy plover (Washington Department of Fish and Wildlife unpubl. data). Two post season juvenile western snowy plovers were observed at Copalis Spit in 2001 (Sundstrom 2002*a*). There is no longer vehicle access to the site since the road washed out several years ago, which has reduced the potential for disturbance from recreational activities. Erosion caused by the northward shift of Connor

Creek has reduced the amount of habitat, but some suitable habitat remains at the end of the spit and the area has potential as a nesting site with habitat restoration and public education (U.S. Fish and Wildlife Service 2005, M. Jensen *in litt.* 2006).

Damon Point and Oyhut Wildlife Area (WA-2) lack western snowy plover records prior to 1971, but this is likely due to limited visitation rather than western snowy plover absence. Between 1971 and 1983, birders reported up to six western snowy plovers during infrequent visits-to Damon Point (Washington Department of Fish and Wildlife 1995). Western snowy plover research in 1985 and 1986 revealed up to 20 western snowy plovers and 8 nests at Damon Point (Anthony 1987). Although most of the locality is suitable habitat, increasing levels of public use have reduced the secure nesting areas to a small portion of the site that is difficult to access, and the breeding population has declined over the last two decades (M. Jensen *in litt.* 2006). From 1993 to 2006 the number of adults at Damon Point has ranged from 2 to 10 (Table 1). Only one nest was found in 2006 (Pearson *et al.* 2006).

Westport Spit (WA-3) held low numbers of western snowy plovers from before 1915 until at least 1968, and scientific collecting was concentrated there through 1934 (Washington Department of Fish and Wildlife 1995). A single nest, poorly documented, was reported in 1983 (Washington Department of Fish and Wildlife unpublished data). No other quantitative information on abundance or nesting is available for this site. Erosion of the site has rendered the beach too narrow to support successful nesting, and there is little opportunity for habitat restoration through beachgrass removal due to private ownership of upland dune habitat (M. Jensen *in litt.* 2006). Recreational use is also substantial. This location is no longer being surveyed due to lack of suitable habitat.

**ii. Pacific County**

Midway Beach (WA-4) and Cape Shoalwater once contained several hundred acres of suitable western snowy plover habitat, but the area lacks historical records of these birds except for specimens collected in 1914 and 1960 and labeled "Tokeland" (Washington Department of Fish and Wildlife 1995). In recent years, Midway Beach has been accreting sand and creating high quality habitat. Recent nesting was first documented in 1998 (Richardson *et al.* 2000). Numbers of breeding adults have increased since 1998, and during 2003-2006 the numbers of adults during the breeding season have ranged from 23-33, with a peak number of 30 nests (M. Jensen *in litt.* 2006; Pearson *et al.* 2006). Approximately one third of the habitat is on State Park land with controlled access; on the privately owned land recreational disturbance is fairly high and contributes to high rates of nest failure.

In 2006, western snowy plovers were discovered nesting on Graveyard Spit in northern Willapa Bay, which is primarily on the Shoalwater Indian Reservation and State lands (M. Jensen *in litt.* 2006; Pearson *et al.* 2006). Three pairs of plovers used the spit in 2006 and produced three fledglings.

Leadbetter Point (WA-5) was rarely visited by western snowy plover observers prior to 1964. In the 1960s and 1970s, birders reported up to 35 western snowy plovers, with nesting confirmed in 1967 by the sighting of two chicks (Washington Department of Fish and Wildlife 1995). Western snowy plover numbers were estimated at up to 24 individuals and between 7 and 11 nests during surveys done between 1978 to 1997 (Widrig 1980, 1981; Willapa National Wildlife Refuge unpublished data; Williamson 1995, 1996, 1997). Numbers increased slightly from 1998-2006, with numbers ranging from 24 to 45 adults present (Table 1). The distribution of nesting by western snowy plovers has changed, however, with recent habitat loss from erosion on the tip of Leadbetter Point and shifting of nesting southwards. Since 2002 the refuge has cleared 25 hectares (63 acres) of non-native beachgrass and the habitat restoration site has been consistently used by nesting plovers. Western snowy plovers are also nesting in Leadbetter State Park and State-owned lands south of the Park. Use of predator exclosures at the refuge since 2004 has greatly improved hatching success in the habitat restoration area and outer beach. Gunpowder Sands Island became intertidal in 2001 and no longer is suitable for nesting western snowy plovers (K. Brennan *in litt.* 2006).

**Table 1.** Status of western snowy plovers at four nesting sites in Washington (Sundstrom-Bagley *et. al.* 2000; Jaques 2001; Sundstrom 2001, 2002*a*, 2002*b*, 2003, 2004, 2005; Brennan and Jaques 2002; Brennan 2003; Brennan and Fernandez 2004*a*, 2004*b*, 2006; Pearson *et al.* 2006).

| Year | Estimated Number of Adults Present | | | | |
|---|---|---|---|---|---|
| | Leadbetter Point | Midway Beach | Damon Point | Graveyard Spit | Total |
| 1993 | 16 | - | 7 | - | 23 |
| 1994 | 13 | - | 6 | - | 19 |
| 1995 | 25 | 0 | 9 | - | 34 |
| 1996 | 19 | 0 | 4 | - | 23 |
| 1997 | 21 | 0 | 3 | - | 24 |
| 1998 | 45 | 6 | 5 | - | 56 |
| 1999 | 26 | 12 | 5 | - | 43 |
| 2000 | 25 | 21 | 4 | - | 50 |
| 2001 | 27 | 14 | 4 | - | 45 |
| 2002 | 32 | 23 | 4 | - | 59 |
| 2003 | 30 | 33 | 5 | - | 68 |
| 2004 | 24 | 19 | 10 | - | 53 |
| 2005 | 38 | 25 | 5 | - | 68 |
| 2006 | 39 | 23 | 2 | 6 | 70 |

### *b. Oregon Coast*

In Oregon, western snowy plovers historically nested at over 20 sites on the coast. At present only seven core nesting sites are consistently used, with a few additional areas occupied during some years (Lauten *et al*. 2006*a*, 2006*b*). Annual window surveys of western snowy plovers in Oregon (Table 2), including both adults and young of the year, began in 1978, with counts ranging from a high of 139 at 13 sites (1981) to a low of 30 observed at 9 sites (1992). Populations reached a low from 1991 to 1993 with a mean of 33 individuals recorded annually. From 1994 to 2006 western snowy plover numbers have generally

**Table 2.** Number of adult western snowy plovers observed on window surveys of the Oregon coast during the breeding season (1978-2006). Window surveys record the number of birds seen during 1-day censuses in May to June (Lauten *et al.* 2006*a*, 2006*b*).

| Year | Number | Year | Number |
|---|---|---|---|
| 1978 | 93 | 1993 | 45 |
| 1979 | 100 | 1994 | 51 |
| 1980 | 80 | 1995 | 64 |
| 1981 | 139 | 1996 | 85 |
| 1982 | 78 | 1997 | 73 |
| 1983 | 52 | 1998 | 57 |
| 1984 | 46 | 1999 | 49 |
| 1985 | 48 | 2000 | no surveys conducted |
| 1986 | 73 | 2001 | 71 |
| 1987 | 61 | 2002 | 71 |
| 1988 | 53 | 2003 | 63 |
| 1989 | 58 | 2004 | 82 |
| 1990 | 59 | 2005 | 100 |
| 1991 | 35 | 2006 | 91 |
| 1992 | 30 | | |

increased, with an average of 71 plovers observed. The increase in the numbers of plovers observed in recent years is believed to be related to intensive management that began at the time of Federal listing.

Since 1993, the population on the Oregon coast has been intensively monitored, with many of the adults and chicks being uniquely color-banded. The presence of marked birds has allowed for the development of two other means of estimating the population (Table 3, Lauten *et al.* 2006b). The number of western snowy plovers, as indicated by the three indices in Table 3, has increased between 1993 and 1997, declined in 1998/1999, then increased again through 2006. The trends

**Table 3.** Comparison of population estimates of adult western snowy plovers on the Oregon coast during the breeding season (1993 to 2005) based on three different measures of abundance (Lauten *et al.* 2006*a*, 2006*b*).

| **Year** | **Estimates** | | |
|---|---|---|---|
| | **A** | B | C |
| 1993 | 45 | 55 to 61 | 72 |
| 1994 | 51 | 67 | 83 |
| 1995 | 64 | 94 | 120 |
| 1996 | 85 | 110 to 113 | 134 to 137 |
| 1997 | 73 | 106 to 110 | 141 |
| 1998 | 57 | 75 | 97 |
| 1999 | 45 | 77 | 95 to 96 |
| 2000 | no survey | 89 | 109 |
| 2001 | 71 | 79 to 80 | 111 to 113 |
| 2002 | 71 | 80 | 99 to 102 |
| 2003 | 63 | 93 | 102 to 107 |
| 2004 | 82 | 120 | 136 to 142 |
| 2005 | 100 | 104 | 153 to 158 |
| 2006 | 91 | 135 | 177 to 179 |

A = Window census.

B = Estimated number of breeding adults. This number is lower than those in column C because it is an estimate of the number of individual birds thought to be breeding birds.

C = Total number of individual adults present during breeding season (includes depredated adults).

for all three indices remained relatively consistent throughout that measurement period.

Management measures (Lauten *et al.* 2006a, 2006b) have included the use of exclosures to reduce predation, predator control measures, restoration of breeding habitat by removing European beachgrass (*Ammophila arenaria*), increased presence of law enforcement personnel, additional and improved signs, additional symbolic fencing (consisting of one or two strands of light-weight string or cable tied between posts to delineate areas where pedestrians and vehicles should not enter), and increased efforts on public information and education.

### *c. California Coast*

#### i. Coastwide Perspective

In California, there also has been a significant decline in breeding locations, especially in southern California. By the late 1970s, nesting western snowy plovers were absent from 33 of 53 locations with breeding records prior to 1970 (Page and Stenzel 1981). The first quantitative data on the abundance of western snowy plovers along the California coast came from window surveys conducted during the 1977 to 1980 breeding seasons by Point Reyes Bird Observatory (Page and Stenzel 1981). An estimated 1,593 adult western snowy plovers were seen on these pioneer surveys (Table 4). The surveys suggested that the western snowy plover had disappeared from significant parts of its coastal California breeding range by 1980. It no longer bred along the beach at Mission Bay or at Buena Vista Lagoon in San Diego County. In Orange County, the only remaining breeding location was the Bolsa Chica wetlands; historically, the western snowy plover was known to breed along the beach from Upper Newport Bay to Anaheim Bay. It was absent from Los Angeles County where it formerly nested along the shores of Santa Monica Bay. In Ventura County, it had ceased breeding on Ventura Beach (San Buenaventura Beach), and in Santa Barbara County on Carpinteria, Santa Barbara (East Beach), and Goleta Beaches. Nesting no longer occurred along the northernmost portion of Monterey Bay in Santa Cruz County or on Doran Beach at Bodega Harbor in Sonoma County.

Subsequent coast-wide surveys by Point Reyes Bird Observatory in 1989 and 1991 indicated a further decline in numbers of breeding adult western snowy plovers during the decade after the 1977 to 1980 survey. Along the mainland coast, including the shores of the Channel Islands, western snowy plover populations had declined by about 5 percent, and in San Francisco Bay by about 44 percent (Table 4).

**Table 4.** Number of adult western snowy plovers observed during breeding season window surveys of the California coast.

| Location | 1977/80 | 1989 | 1991 | 1995 | 2000 | 2002 | 2003 | 2004 | 2005 | 2006 |

[1] 260 adults during the survey; 28 additional adults extrapolated for unsurveyed portions of Santa Rosa Island.

The more recent coast-wide surveys, during the summers of 1995, 2000, and 2002-2006, were accomplished through the collaboration of researchers studying western snowy plovers along the California coast. Between the 1977 to 1980 surveys and the 1995 survey, western snowy plovers apparently ceased nesting at Los Penasquitos, and Agua Hedionda Lagoons in northern San Diego County (A. Powell, pers. comm. 1998). Nesting has been absent or sporadic at San Elijo Lagoon; Año Nuevo State Beach and Pescadero State Beach in San Mateo County; Bolinas Lagoon in Marin County; the south and north spits of Humboldt Bay and Big Lagoon in Humboldt County; and the Lake Talawa region of Del Norte County (Point Reyes Bird Observatory, unpublished data).

By 2000 populations had declined further to 71 percent of the 1977-1980 levels along the California coast and 27 percent of the 1977-1980 levels in San Francisco Bay. However, since then populations have grown substantially, roughly doubling along the coast while fluctuating irregularly in San Francisco Bay (Table 4). Recent population increases along the coast have been associated with implementation of management actions for the benefit of western snowy plovers and California least terns, including predator management and protection and restoration of habitat.

**ii. Regional Perspective**

**Del Norte, Humboldt, and Mendocino Counties -** Numbers of western snowy plover breeding adults declined and then somewhat rebounded in this northern California region since the initial Point Reyes Bird Observatory survey in 1977. In this region where there were 80 adults counted in 1977, a low of 19 were found in 1995 and 52 in 2006. In 1996, breeding was documented on the gravel bars of the Eel River, Humboldt County, and this area has continued to be a successful nesting site for western snowy plover breeding (Colwell *et al.* 2002, 2005). Even with the nest success at the gravel bars there is still a reduction in western snowy plovers from 1977; Del Norte County has no breeding birds, and Mendocino County has very few.

**San Francisco Bay -** As indicated in Table 4, western snowy plover numbers in San Francisco Bay declined markedly between the initial survey in 1978 and follow-up surveys. Western snowy plover numbers steadily declined over 26 years, reaching a low of 72 in 2003, followed by a moderate but irregular increase (124 in 2005 surveys; 99 in 2006).

Recent surveys in South San Francisco Bay (Strong and Dakin 2004, Strong *et al.* 2004, Tucci *et al.* 2006) indicate that the largest breeding populations are concentrated at Eden Landing Ecological Reserve/Baumberg North (CA-33), managed by California Department of Fish and Game. Other population centers occur at Oliver Salt Ponds (CA-31), managed by Hayward Area Recreation District and East Bay Regional Parks District; and at Dumbarton (CA-36), Warm Springs (CA-39), Alviso (CA-41), and Ravenswood (CA-44), managed by Don Edwards San Francisco Bay National Wildlife Refuge. Foraging and nesting activities are concentrated in specific salt ponds within these areas. Small numbers of western snowy plovers have been observed at Ponds 7 and 7A in Napa County (CA-25 and vicinity), the only currently known nesting site in the North Bay.

**Sonoma, Marin, San Francisco, San Mateo, Santa Cruz, and Monterey Counties -** Along the segment of coastline from Sonoma County to Monterey Bay, numbers of western snowy plover adults during window surveys declined from 215 in 1977 to 162 in 1995, and subsequently increased to a maximum of 376 in 2004. The numbers of adults breeding on the beaches and salt ponds of Monterey Bay, and the beaches of northern Santa Cruz County, has increased dramatically since management actions have been undertaken to increase nesting success (Neuman *et al.* 2004; G. Page *in litt.* 2004*b*)

**San Luis Obispo, Santa Barbara, and Ventura Counties, including Channel Islands -** There is no clear evidence of an overall decline in the number of breeding western snowy plovers for this region from 1978/1980 to the present. Numbers of adults fluctuated between a high of 1089 and a low of 497 between 1978 and 2006. While numbers for the region may not have changed overall, there have been definite changes at specific locations (Table 5). Most notable are the decline and loss of the population on San Miguel Island from 1978 /1980 to 2000, the decline at Santa Rosa Island from 1991 to 2006, and the sudden increase in numbers at Vandenberg Air Force Base between 2000 and 2004 and at Coal Oil Point Reserve between 2002 and 2006 (Table 4).

**Table 5.** Breeding season window surveys of western snowy plover adults at selected sites along the coast of San Luis Obispo, Santa Barbara, and Ventura Counties.

| **Total** | 594 | 548 | 606 | 541 | 551 | 535 | 444 | 378 | 490 | 553 | 826 | 688 | 605 |

Unless footnoted, the source of all data is Point Reyes Bird Observatory.

1 The source of this data is the U.S. Air Force (Phil Persons)

2 The source of this data is the National Park Service

3 The source of this data is the U.S. Navy

**Los Angeles, Orange, and San Diego Counties -** Western snowy plover numbers detected during window surveys declined from the 276 adults tallied during the 1978 Point Reyes Bird Observatory survey to 88 during the 1991 survey. Subsequently the population has increased to 298 in 2006.

### 2. Current Breeding Distribution

The current Pacific coast breeding range of the western snowy plover extends from Damon Point, Washington, to Bahia Magdelena, Baja California, Mexico. The population is sparse in Washington, Oregon, and northern California. In 2006, estimated populations were 70 adults along the Washington coast (Pearson *et al*. 2006), 177-179 adults along coastal Oregon (Lauten *et al.* 2006*b*), and 2,231 adults in coastal California and San Francisco Bay (window survey including correction factor: G. Page *in litt.* 2006, U.S. Fish and Wildlife Service 2006*a*). Approximately 7 percent of the California population was observed in San Francisco Bay, and 4 percent in northern California north of the Golden Gate bridge. Along the coast of Baja California, Mexico, most nesting western snowy plovers are associated with the largest wetlands, especially Bahia San Quintin, Laguna Ojo de Liebre, and Bahia Magdelena (Palacios *et al.* 1994). No recent quantitative data exist on the western snowy plover population in Baja California, but it is probably roughly similar in size to the U.S. Pacific coast population.

### 3. Habitat Carrying Capacity

There is no quantitative information on carrying capacity of beaches for western snowy plovers. Determining carrying capacity of beaches is confounded by human use that affects the numbers of snowy plovers using the beaches. Beaches vary substantially in their structure, width, vegetation, and level of human use, complicating such a measurement.

The maximum reported breeding density of western snowy plovers is associated with the Moss Landing Wildlife Area, where since 1995 Point Reyes Bird Observatory staff have conducted intensive management specifically for western snowy plovers. These measures include predator control, removal of excessive vegetation, and operation of water control structures to maintain desired water levels. With extensive management of approximately 55 hectares (138 acres) of mostly dried ponds in the Moss Landing Wildlife Area, 25 active nests, 3 pairs within 5 days of initiating nests, and 10 broods have been documented simultaneously; thus a peak of 76 nesting adults was accommodated simultaneously by 55 hectares (138 acres) of playa, or 1.4 hectares (3.6 acres) per functional pair (some of the broods were only being cared for by males) (D. George, Point Reyes Bird Observatory, pers. comm.). However, the numbers of nesting western snowy plovers at the Moss Landing Wildlife Area cannot be applied to beach areas because of the physical differences between salt pond and beach habitats and because beach habitats are typically subject to much more human disturbance. Neither can these numbers necessarily be applied to other salt ponds (***e.g.***, San Francisco Bay) because habitat and management opportunities differ.

## D. REASONS FOR DECLINE AND CONTINUING THREATS

Overall, western snowy plover numbers have declined on the U.S. Pacific coast over the past century (see Population Status and Trends section). The subspecies faces multiple threats throughout its Pacific coast range. The reasons for decline and degree of threats vary by geographic location; however, the primary threat is habitat destruction and degradation. Habitat loss and degradation can be primarily attributed to human disturbance, urban development, introduced beachgrass (*Ammophila* spp.), and expanding predator populations. Natural factors, such as inclement weather, have also affected the quality and quantity of western snowy plover habitat (U.S. Fish and Wildlife Service 1993***a***). The following discussion is organized according to the five listing criteria under section 4(a)(1) of the Endangered Species Act.

### 1. The Present or Threatened Destruction, Modification, or Curtailment of Habitat or Range

#### *a. Shoreline Stabilization and Development*

The wide, flat, sparsely-vegetated beach strands preferred by western snowy plovers are an unstable habitat, subject to the dynamic processes of accretion and erosion of sand, and dependent on natural forces for replenishment and renewal. These habitats are highly susceptible to degradation by construction of seawalls, breakwaters, jetties, piers, homes, hotels, parking lots, access roads, trails, bike paths, day-use parks, marinas, ferry terminals, recreational facilities, and support services that may cause direct and indirect losses of breeding and wintering habitat for the western snowy plover.

Beach stabilization efforts may interfere with coastal dune formation and cause beach erosion and loss of western snowy plover nesting and wintering habitat. Shoreline stabilization features such as jetties and groins may cause significant habitat degradation by robbing sand from the downdrift shoreline (U.S. Fish and Wildlife Service 1996*a*). However, jetties also can redirect sand deposition, causing an increase in available habitat. Construction of homes, resorts, and parking lots on coastal sand dunes constitutes irrevocable loss of habitat for western snowy plovers. Urban development has permanently eliminated valuable nesting habitat on beaches in southern Washington (Brittell *et al.* 1976), Oregon (Oregon Department of Fish and Wildlife 1994), and California (Page and Stenzel 1981). In addition to causing direct loss of habitat, there are additional potential adverse impacts to western snowy plovers from urban development (Figure 5). Increased development increases human use of the beach, thereby increasing disturbance to nesting plovers. When urban areas interface with natural habitat areas, the value of breeding and wintering habitat to native species may be diminished by increased levels of illumination at night (***e.g.***, building and parking lot lights); increased sound and vibration levels; and pollution drift (***e.g.***, pesticides) (Kelly and Rotenberry 1996/1997). Beach raking removes habitat features for both plovers and their prey, and precludes nests from being established. Also, construction of residential development in or near western snowy plover habitat attracts predators, including domestic cats.

***b. Resource Extraction***

**i. Sand Removal and Beach Nourishment**

Sand is mined in coastal areas such as Monterey Bay. Mining sand from the coastal mid-dunes and surf zone can cause erosion and loss of western snowy plover breeding and wintering habitat. Sand removal by heavy machinery can disturb

**Figure 5.** New housing development next to beach at Monterey Bay, California (photo by Peter Baye, with permission).

incubating western snowy plovers, destroy their nests or chicks, and result in the loss of invertebrates and natural wave-cast kelp and other debris that western snowy plovers use for foraging. Mining of surface sand from the 1930s through the 1970s at Spanish Bay in Monterey County degraded a network of dunes by lowering the surface elevations, removing sand to granite bedrock in many locations, and creating impervious surfaces that supported little to no native vegetation (Guinon 1988).

Beach nourishment with sand can be beneficial for the western snowy plover if it results in an increase in habitat. However, unless beach nourishment projects are properly designed, they can result in changes to beach slope from redeposition of sediments by storm waves, and result in the loss of western snowy plover breeding and wintering habitat. For example, if an inappropriate size class of sand (*e.g.*, coarser-grained sand) and range of minerals are introduced that are different from the current composition of native sand on a beach, it can alter dune slope (making it steeper or narrower), affect mobility and color of sand, decrease the abundance of beach invertebrates, and facilitate establishment of invasive exotic plants that may have a competitive advantage over native plants. Feeney and Maffei (1991) investigated the color hues of the ground surface within San Francisco Bay salt ponds used as western snowy plover nesting habitat. Predominant soils were silty clay with varying amounts of humus, salt crystals, and shell fragments. They found a strong similarity between the color of the substrate in habitat preferred by western snowy plovers and the color of western snowy plover mantles (upper parts).

**ii. Dredging and Disposal of Dredged Materials**

Dredging is detrimental to western snowy plovers when it eliminates habitat or alters natural patterns of beach erosion and deposition that maintain habitat. Disturbances associated with dredging, such as placement of pipes, disposal of dredged materials, or noise, also may negatively affect breeding and wintering western snowy plovers. Dredging also is detrimental when it promotes water-oriented developments that increase recreational access to western snowy plover habitat (*e.g.*, marinas, boat ramps, or other facilities to support water-based recreation). In some cases, however, dredged materials may provide important nesting habitat for western snowy plovers such as those at Coos Bay, Oregon (Wilson-Jacobs and Dorsey 1985). Western snowy plovers also have been observed using dredged material during the winter; however, these areas are not used nearly as often as the adjacent ocean beach (E.Y. Zielinski and R.W. Williams *in litt.* 1999).

**iii. Driftwood Removal**

Driftwood can be an important component of western snowy plover breeding and wintering habitat. Driftwood contributes to dune-building and adds organic matter to the sand as it decays (Washington Department of Fish and Wildlife 1995). Additionally, driftwood provides western snowy plovers with year-round protection from wind and blowing sand. Often, western snowy plovers build nests beside driftwood, so its removal may reduce the number of suitable nesting sites.

Driftwood removed for firewood or decorative items can result in destruction of nests and newly-hatched chicks that frequently crouch by driftwood to hide from predators and people. Chainsaw noise may disrupt nesting, and vehicles used to haul wood may crush nests and chicks. Removal of driftwood has been documented as a source of nest destruction at Vandenberg Air Force Base where two nests were crushed beneath driftwood dragged to beach fire sites (Persons 1994). Also, driftwood beach structures built by visitors are used by avian predators of western snowy plover chicks such as loggerhead shrikes (*Lanius ludovicianus*) and American kestrels (*Falco sparverius*), and predators of adults such as merlins (*Falco columbarius*) and peregrine falcons (*Falco peregrinus*).

Although driftwood is an important component of western snowy plover habitat, too much driftwood on a beach, which may occur after frequent and prolonged storm events, can be detrimental if there is not sufficient open habitat to induce the birds to nest.

### iv. Beach Fires and Camping

Beach fires and camping may be harmful to nesting western snowy plovers when valuable driftwood is destroyed, as described above. Camping near breeding locations can cause greater impacts due to the prolonged disturbance and increased chance for possible direct mortality from associated dogs and children (S. Richardson *in litt*. 2001). Nighttime collecting of wood increases the risk of stepping on nests and chicks, which are difficult to see even during daylight hours. Fires near a western snowy plover nest could cause nest abandonment due to disturbance from human activities, light, and smoke. Fires have the potential to attract large groups of people and result in an increase of garbage, which attracts scavengers such as gulls (*Larus* spp.) and predators such as coyotes (*Canis latrans*), American crows (*Corvus brachyrhynchos*), and common ravens (*Corvus corax*). Also, after fires are abandoned, predators such as coyotes may be attracted into the area by odors lingering from the fire, particularly if it was used for cooking. Occasionally fires escape into nearby driftwood; fire suppression activities may disturb and threaten western snowy plover nests and chicks.

### v. Watercourse Diversion, Impoundment, or Stabilization

Water diversion and impoundment of creeks and rivers may negatively affect western snowy plover habitat by reducing sand delivery to beaches and degrading water quality. Water diversions are a major threat to western snowy plovers when they impair hydrologic processes (such as migration of creek and river mouths) that maintain open habitat at river and creek mouths by retarding the spread of introduced beachgrass (*Ammophila* spp.) and other vegetation. Water diversion, impoundment, or stabilization activities could include construction of dams and irrigation, flood control, and municipal water development projects (Powell *et al.* 2002).

#### vi. Operation of Salt Ponds

Salt ponds of San Francisco Bay and San Diego Bay, which are filled and drained as part of the salt production process, provide breeding and wintering habitat for western snowy plovers. Dry salt ponds and unvegetated salt pond levees are used as western snowy plover nesting habitat. Ponds with shallow water provide important foraging habitat for western snowy plovers, with ponds of low and medium salinity providing the highest invertebrate densities. Ponds of high salinity have reduced invertebrate densities and therefore provide lower quality foraging habitat. Nesting western snowy plovers can be attracted to an area when ponds are drained during the breeding season, but flooding can then destroy the nests when the ponds are refilled. Also, human disturbance resulting from maintenance activities associated with the operation of commercial salt ponds can result in the loss of western snowy plovers and disturbance of their habitat. If conducted during the western snowy plover breeding season, reconstruction of salt pond levees could destroy western snowy plover nests. Maintenance activities that are conducted by vehicles, on foot, or through the use of dredging equipment could result in direct mortality or harassment of western snowy plovers (See Dredging, Pedestrian, and Motorized Vehicle sections).

### *c. Encroachment of Introduced Beachgrass and Other Nonnative Vegetation*

One of the most significant causes of habitat loss for coastal breeding western snowy plovers has been the encroachment of introduced European beachgrass (*Ammophila arenaria*) and American beachgrass (*Ammophila breviligulata*). Foredunes dominated by introduced beachgrass have replaced the original low, rounded, open mounds formed by the native American dunegrass (*Leymus mollis*) and other beach plants. Native dune plants do not bind sand like *Ammophila* spp., and thus allow for sand movement and regenerating open expanses of sand. However, *Ammophila* spp. forms a dense cover that excludes many native taxa. On beaches dominated by this invasive grass, species richness of vegetation is halved, in comparison with foredunes dominated by native dune grass (Barbour and Major 1990). Similarly, American beachgrass greatly depresses the diversity of native dune plant species (Seabloom and Wiedemann 1994).

European beachgrass was introduced to the west coast around 1898 to stabilize dunes (Wiedemann 1987). Since then, it has spread up and down the coast and now is found from British Columbia to Ventura County in southern California. This invasive species is a rhizomatous grass that sprouts from root segments, with a natural ability to spread rapidly. Its most vigorous growth occurs in areas of wind-blown sand, primarily just above the high-tide line, and it thrives on burial under shifting sand. In 1988, European beachgrass was considered a major dune plant at about 50 percent of western snowy plover breeding areas in California and all of those in Oregon and Washington (J. Myers *in litt.* 1988).

American beachgrass is native to the East coast and Great Lakes region of North America. The densest populations of American beachgrass on the Pacific coast are currently located between the mouth of the Columbia River and Westport, Washington. Like European beachgrass, American beachgrass is dominant on the mobile sands of the foredune and rapidly spreads through rhizome fragments. American beachgrass occurs along the entire coast of Washington, ranging from Shi Shi Beach, Washington, in the north, to Sand Lake, Oregon, in the south, although its frequency decreases markedly at the northern and southern limits of this range. Currently, American beachgrass is the dominant introduced beachgrass species in much of the western snowy plover range in the State of Washington (Seabloom and Wiedemann 1994).

Stabilizing sand dunes with introduced beachgrass has reduced the amount of unvegetated area above the tideline, decreased the width of the beach, and increased its slope (Wiedemann 1987). These changes have reduced the amount of potential western snowy plover nesting habitat on many beaches and may hamper brood movements. In Oregon, the beachgrass community may provide habitat for western snowy plover predators (*e.g.*, skunks [*Mephitis* spp.], weasels [*Mustela* spp.], coyotes [*Canis latrans*], foxes [*Urocyon cinereoargenteus* and *Vulpes vulpes*.], raccoons [*Procyon lotor*], and feral cats [*Felis domesticus*]) that historically would have been largely precluded by the lack of cover in the dune community (Stern *et al.* 1991; K. Palermo, U.S. Forest Service, pers. comm. 1998).

In areas with European beachgrass, it has caused the development of a vegetated foredune that effectively blocks movement of sand inland and creates conditions favorable to the establishment of dense vegetation in the deflation plain, which occurs behind the foredunes (Wiedemann *et al.* 1969). In natural sand dunes, deflation plains consist of open sand ridges and flat plains at or near the water table. Thus, in areas with European beachgrass, the open features that characterize western snowy plover breeding habitat are destroyed. The establishment of European beachgrass has also caused sand spits at the mouths of small creeks and rivers to become more stable than those without vegetation because of the creation of an elevated beach profile. This elevated profile, in effect, reduces the scouring of spits during periods of high run-off and storms. A secondary effect of dune stabilization has been human development of beaches and surrounding areas (Oregon Department of Fish and Wildlife 1994). This development, in turn, has reduced available beach habitat and focused human activities on a smaller area that must be shared with western snowy plovers and other shorebirds.

On the Oregon coast, the establishment of European beachgrass has produced dramatic changes in the landscape (Oregon Department of Fish and Wildlife 1994). The spread of this nonnative species was greatly enhanced by aggressive stabilization programs in Oregon in the 1930s and 1940s (Wiedemann 1987). European beachgrass spread profusely along the Washington coast, and was well established by the 1950s (Washington Department of Fish and Wildlife 1995). In 1988, the spread of beachgrass was termed an "increasing threat" to traditional western snowy plover nesting areas at Leadbetter Point, Washington, having become established where absent only 4 years earlier (Willapa National Wildlife Refuge 1988).

In California, there are many beaches where European beachgrass has established a foothold. These beaches include the dunes at Lake Earl, Humboldt Bay (from

Trinidad to Centerville Beach), MacKerricher State Beach/Ten Mile Dunes Preserve, Manchester State Beach, Bodega Bay, Point Reyes National Seashore, Golden Gate National Recreation Area, Monterey Bay, Morro Bay Beach, Guadalupe-Nipomo Dunes, and Vandenberg Air Force Base (A. Pickart *in litt.* 1996). Chestnut (1997) studied the spread of European beachgrass at the Guadalupe-Nipomo Dunes in San Luis Obispo County. He documented an increase in beachgrass from approximately 8 to 109 hectares (20 to 270 acres) between 1969 and 1997, and found that its rapid spread through native vegetation posed a serious threat to nesting western snowy plovers and rare plants.

In addition to the loss of nesting habitat, introduced beachgrass also may adversely affect western snowy plover food sources. Slobodchikoff and Doyen (1977) found that beachgrass markedly depressed the diversity and abundance of sand-burrowing arthropods at coastal dune sites in central California. Because western snowy plovers often feed on insects well above the high-tide line, the presence of this invasive grass may also result in loss of food supplies for plovers (Stenzel *et al.* 1981).

In some areas of California, such as the Santa Margarita River in San Diego County, and the Santa Clara and Ventura Rivers in Ventura County, giant reed (*Arundo donax*) has become a problem along riparian zones. During winter storms, giant reed is washed downstream and deposited at the river mouths where western snowy plovers nest (Powell *et al.* 1997). Large piles of dead and sprouting giant reed eliminate nesting sites and increase the presence of predators, which use it as perches and prey on rodents in the piles of vegetation.

Other nonnative vegetation that has invaded coastal dunes, thereby reducing western snowy plover breeding habitat, includes Scotch broom (*Cytisus scoparius*), gorse (*Ulex europaeus*), South African iceplant (*Carpobrotus edulis*), pampas grass (*Cortaderia jubata* and *Cortaderia selloana*) and iceplant (*Mesembryanthemum* sp.); shore pine (*Pinus contorta*) is a native plant species that has invaded coastal dunes and resulted in similar impacts to western snowy plovers (Schwendiman 1975, California Native Plant Society 1996, Powell 1996). Many nonnative weed species also occur on and along San Francisco Bay salt pond levees, resulting in unsuitable nesting habitat for western snowy plovers (J. Albertson *in litt.* 1999).

***d. Habitat Conversion for Other Special Status Species***

It is not known whether western snowy plovers historically nested in San Francisco Bay prior to the construction of salt evaporator ponds beginning in 1860 (Ryan and Parkin 1998). However, western snowy plovers have wintered on the San Francisco Bay since at least the late 1800's, as indicated by a specimen dated November 8, 1889, in the California Museum of Vertebrate Zoology (Grinnell *et al.* 1918). It is possible that natural salt ponds in the vicinity of San Lorenzo once supported nesting birds, but insufficient data exist to assess this possibility (U.S. Fish and Wildlife Service 1992). Today, however, the San Francisco Bay recovery unit supports an important western snowy plover source population, representing approximately 5 to 10 percent of the total breeding population. Feeney and Maffei (1991) observed a sizable population of western snowy plovers at the Baumberg and Oliver salt ponds during the breeding and nonbreeding seasons, suggesting that these ponds are important to western snowy plovers throughout the year. They suspected that these ponds are used by western snowy plovers as both a pre-breeding and post-breeding staging area, based on the high numbers of plovers in mid-February and in late August/September, respectively.

As part of the Recovery Plan for Tidal Marsh Ecosystems of Northern and Central California (U.S. Fish and Wildlife Service, in preparation), extensive tidal marsh restoration is identified as a recovery action for listed and other sensitive species of tidal salt marshes including the California clapper rail (*Rallus longirostris obsoletus*) and salt marsh harvest mouse (*Reithrodontomys raviventris*). A large area of San Francisco Bay salt ponds, especially within the South Bay, are proposed for tidal marsh restoration for the benefit of federally listed tidal marsh species. Salt ponds are large, persistent hypersaline ponds that are intermittently flooded with South Bay water. Some of these ponds currently provide valuable breeding and wintering habitat for western snowy plovers. However, they occur within the historical areas of tidal salt marsh, which once dominated San Francisco Bay. Endangered tidal marsh species would benefit from conversion of these ponds back to salt marsh; however, western snowy plovers would lose suitable nesting and wintering areas.

The Recovery Plan for Tidal Marsh Ecosystems of Northern and Central California will focus primarily on management of tidal marsh species, but will also provide for some areas to be maintained as managed ponds that would provide habitat for western snowy plovers and California least terns (*Sternula antillarum browni*). The South Bay Salt Pond Restoration Project (Philip Williams & Associates *et al.* 2006) has identified sites on National Wildlife Refuge and California Department of Fish and Game lands with potential for salt marsh restoration and managed ponds under a range of alternatives; the projected area of managed ponds ranges from 647 to 3,035 hectares (1,600 to 7,500 acres). Six of the plover locations identified in Appendices B and L (CA-33, CA-34, CA-39, CA-40, CA-41, CA-44) occur within the South Bay Salt Pond Restoration Project area. These six locations comprise about 60 percent of the western snowy plover locations in San Francisco Bay by area, and currently support over 90 percent of the western snowy plover population in San Francisco Bay (Strong *et al.* 2004, Tucci *et al.* 2006). In particular, several salt ponds at Eden Landing (location CA-33 and vicinity) currently support the largest population of western snowy plovers in San Francisco Bay. Distribution of plover populations and nesting sites within San Francisco Bay can fluctuate with salt pond management and availability of appropriate habitat, such that some locations identified in Appendix L are not currently occupied and other locations not mapped in Appendix L may nonetheless support breeding birds as management practices change. Thus the boundaries of San Francisco Bay locations as mapped in Appendix L reflect current and historical conditions and should be considered as flexible in the context of planning for future tidal marsh restoration. Specific localities to be managed for plovers should be coordinated with tidal marsh restoration in an integrated fashion, and thus may not be identical with the current or historical localities identified in this recovery plan.

Thus intensive management of designated ponds within the South Bay Salt Pond Restoration Project area will be crucial to achieving success in meeting western snowy plover recovery goals in San Francisco Bay. However, establishing western snowy plover populations at a variety of sites in San Francisco Bay, both within and outside the South Bay Salt Pond Restoration Project area, is advisable to minimize their vulnerability to loss (L. Trulio *in litt.* 2007). Potential western snowy plover habitat in San Francisco Bay outside of the South Bay Salt Pond Restoration Project area includes several sites around Alameda, Napa County, Hayward Shoreline, and

Crissy Field. In addition, large salt pond tracts in the South Bay remain under the ownership of Cargill; certain areas are still managed for salt production and could incidentally provide habitat for western snowy plovers, while approximately 600 hectares (1,400 acres) of ponds near Redwood City are no longer in salt production and provide an opportunity for significantly increasing western snowy plover habitat through active management. If these locations can be managed to encourage western snowy plover nesting, they may contribute substantially to meeting the overall goal of 500 breeding birds in San Francisco Bay. Western snowy plover management targets for the South Bay Salt Pond Restoration Project should take into account the habitat quality and management potential of plover habitat elsewhere in San Francisco Bay to meet overall goals for the recovery unit.

Don Edwards San Francisco Bay National Wildlife Refuge is currently planning pilot studies to assess how best to manage salt ponds for high densities of breeding western snowy plovers. Special management for western snowy plover may include intensive control of avian predators (*e.g.*, California gull colonies, ravens); active management of water levels to control vegetation, maintain optimal salinity, and produce brine flies; timing of inundation to avoid flooding nests; and reconfiguration of shallow salt ponds with isolated islands and furrowed areas. Locations of managed salt ponds should be planned to minimize the proximity of western snowy plover populations to landfills, gull colonies, and areas with high predator densities. Intensive management of salt ponds for western snowy plovers generally appears feasible, and plovers have been observed to opportunistically disperse among sites and use habitat that becomes suitable (V. Bloom *in litt.* 2005), so we expect relocation of plover nesting concentrations away from tidal marsh restoration areas to be possible, but management success should be carefully evaluated. Those alternatives with greater acreages of tidal marsh restoration (e.g., Alternative C at 90 percent tidal habitat) would require correspondingly more intensive management and reconfiguration of the remaining salt ponds (Philip Williams & Associates *et al.* 2006), and should be implemented gradually in conjunction with evaluation of management effectiveness for western snowy plovers.

Thus, we believe tidal marsh restoration can be compatible with the recovery of western snowy plovers and should not preclude meeting a goal of 500 breeding birds in San Francisco Bay. As described below under Recovery Action 2.6, occupied salt ponds should initially be conserved. Salt marsh restoration in occupied plover habitat, particularly at densely populated sites, should be phased in after intensive adaptive management of other compensating salt pond habitat has demonstrated success in increasing plover populations. Thus habitat quality should be continually assessed so that overall western snowy plover populations in San Francisco Bay are not adversely affected by the restoration project and can increase to meet the management goal for this recovery unit.

In southern California, unless carefully planned, conversion of western snowy plover habitat to tidal salt marsh may result in loss of western snowy plover habitat. The light-footed clapper rail (*Rallus longirostris levipes*) inhabits coastal tidal marshes from Santa Barbara County south to Baja California, Mexico. Several locations in Ventura, Orange, and San Diego Counties provide nesting and/or wintering habitat for western snowy plovers, but also provide high quality light-footed clapper rail habitat or represent high priority tidal marsh restoration sites in the recovery plan for the light-footed clapper rail (U.S. Fish and Wildlife Service 1985). These sites include Bolsa Chica, Agua Hedionda Lagoon, San Elijo Lagoon, San Dieguito Lagoon, and Los Penasquitos Lagoon. The Bolsa Chica wetlands were opened to tidal action in 2006, in a project combining tidal restoration work with construction of islands and sand flats for nesting of shorebirds and California least terns.

**2. Overutilization for Commercial, Recreational, Scientific, or Education Purposes**

Biologists and agency personnel monitor western snowy plovers to assess population status and evaluate management techniques. Additionally, nest searches at some sites allow for placement of predator exclosures that aid in hatching success. Measures to minimize disturbance from these activities include: time limits for surveys, exclosure construction and sign/rope maintenance; conducting walking surveys where feasible; and limited entries.

Egg collecting has been observed at several California nesting colonies (Stenzel *et al.* 1981, Warriner *et al.* 1986). Occasionally recreational birdwatchers also may harass western snowy plovers. The significance of these factors to nesting success is uncertain but probably relatively minor.

Qualified individuals may obtain permits to conduct scientific research and population census activities on western snowy plovers under section 10(a)(1)(A) of the Endangered Species Act. Specific activities that may be authorized include: population censuses and presence/absence surveys; monitoring of nesting activity; capturing, handling, weighing, measuring, banding, and color-marking of young and adults on breeding and wintering grounds; radio-telemetry studies; translocation studies; genetic studies; contaminant studies; behavioral, ecological, and life history studies; and placing predator exclosures around active nests. Short-term impacts of these activities may include harassment and possible accidental injury or death of a limited number of individual western snowy plovers. The long-term impacts will be to contribute to recovery of the species by facilitating development of more precise scientific information on status, life history, and ecology (U.S. Fish and Wildlife Service 1993*b*).

Banding birds with metal and plastic bands to identify individuals and to monitor bird populations is a common practice. However, a number of leg injuries to western snowy plovers, possibly resulting from banding, have been reported (G. Page *in litt.* 2005*b*). These injuries include swelling and abrasion of legs possibly from sand or other particles becoming lodged between the bands and the leg. Some banding injuries appear to have resulted in foot loss and in a few instances, death of the bird. Similar injuries have been observed in piping plovers (*Charadrius melodus*) banded on the Atlantic coast and interior U.S., and resulted in a moratorium on banding of that species (Lingle *et. al.* 1999, U.S. Fish and Wildlife Service 1996*a*, U.S. Fish and Wildlife Service 2002). Despite leg injuries, several piping plovers were observed to successfully breed and fledge young (Lingle *et. al.* 1999). However, these injuries may contribute directly or indirectly to mortalities or reduce breeding performance. It should be noted that incidents of foot loss in Pacific coast western snowy plovers usually appear to result from fine fibers wrapping around the bird's ankle, and have occurred in unbanded as well as banded individuals (J. Watkins, pers. comm. 2006). Despite risk of injuries, banding remains the best technique to study population traits such as survival, recruitment, and dispersal, and may be the most effective way to monitor populations of the western snowy plover to determine effectiveness of management strategies. Currently the percentage of banded birds range-wide that become injured from banding and the impacts of banding injuries on populations of the western snowy plover are unknown; a study was initiated in 2005 by Point Reyes Bird Observatory to assess the effectiveness of alternative banding techniques in reducing injuries and band loss (G. Page *in litt.* 2005*b*).

Concerns that color bands increase the vulnerability of western snowy plovers to predation by reducing effectiveness of camouflage do not appear to be supported by existing evidence. Because western snowy plovers crouch and flatten to the sand at the approach of avian predators, color bands are typically hidden from sight; terrestrial predators are evaded by running or taking flight at their approach (J. Watkins, pers. comm. 2006).

**3. Disease or Predation**

West Nile virus, a mosquito-borne disease which can infect birds, reptiles, and mammals, has spread rapidly across the United States from the initial introduction in New England (National Audubon Society 2006). The disease has killed birds of various species in all coastal California counties since its arrival in the state in 2003 (U.S. Geological Survey 2006). In 2004 to 2006 the disease was reported from two coastal counties (Lane and Lincoln) in Oregon but has not been reported from any coastal counties in Washington (U.S. Geological Survey 2006). The deadliness of the disease varies by species; however, the virus has been identified in dead piping plovers (*Charadrius melodus*) and killdeer (*C. vociferus*), both closely related to the western snowy plover (Center for Disease Control 2004).

Since 2004 numerous western snowy plovers in southern California have been found dead or exhibited neurological signs consistent with avian botulism (M. Long *in litt.* 2006). Confirmation of disease diagnosis is currently pending availability of specimens for autopsy. We are currently coordinating with the USGS National Wildlife Health Center to better understand the causes of these mortalities and to develop a program for treatment of ill birds diagnosed with botulism. Additionally, 32 western snowy plovers died in 2006 from unknown causes in San Diego County (U.S. Navy *in litt.* 2007).

Predator density is a significant factor affecting the quality of western snowy plover nesting habitat (Stenzel *et al.* 1994). Predation can result in the loss of adults, chicks, or eggs; separation of chicks from adults is also caused by the presence of predators. Powell *et al.* (2002) found that predation accounted for most nest failures in 1994, 1996, and 1997, in San Diego County, California. Western snowy plovers generally cannot defend themselves or their nests against predation but must rely on antipredator adaptation, including (1) pale coloration of adults, eggs, and young, which acts as camouflage against detection by predators; (2) a skulking retreat from the nest at a predator's approach; (3) extreme mobility and elusiveness of precocial young and; (4) maintenance of low nesting density (Page *et al.* 1983). In natural ecosystems, there is a co-evolution of the predator-prey relationship, where prey species slowly evolve with evading behavior as predator species slowly evolve effective prey-capturing behavior. However, when exotic predators are introduced into the ecosystem and thrive there, they frequently occur in much higher densities and possess more effective strategies than native predators and, hence, usually have a more severe effect.

Predation, by both native and nonnative species, has been identified as a major factor limiting western snowy plover reproductive success at many Pacific coast sites. Known mammalian and avian predators of western snowy plover eggs, chicks, or adults include the following native species: gray foxes (*Urocyon cinereoargenteus*), Santa Rosa Island foxes (*Urocyon littoralis santarosae*), coyotes, striped skunks (*Mephitis mephitis*), spotted skunks (*Spilogale putorius*), raccoons, California ground squirrels (*Citellus beecheyi*), long-tailed weasels (*Mustela frenata*), American crows, common ravens (*Corvus corax*), ring-billed gulls (*Larus delawarensis*), California gulls (*Larus californicus*), western gulls (*Larus occidentalis*), glaucous-winged gulls (*Larus glaucescens*), gull-billed tern (*Gelochelidon nilotica*), American kestrels (*Falco sparverius*), peregrine falcons (*Falco peregrinus*), northern harriers (*Circus cyaneus*), loggerhead shrikes, merlins (*Falco columbarius*), great horned owls (*Bubo virginianus*), burrowing owls (*Speotyto cunicularia*), great blue herons (*Ardea herodias*); and the following nonnative species: eastern red foxes (*Vulpes vulpes regalis*), Norway rats (*Rattus norvegicus*), Virginia opossums (*Didelphis marsupialis*), domestic and feral dogs (*Canis familiaris*), and cats (*Felis domesticus*). Loss or abandonment of eggs due to predation by fire ants and Argentine ants (*Iridomyrmex humilis*) has also been observed (Fancher *et al.* 2002, Powell *et al.* 2002).

In Oregon, nest predation by corvids (common ravens and American crows) is the major cause of nest failures. Of 63 unexclosed nests in 2005, corvid predation accounted for 22 nest failures, by comparison with 14 failures due to mammalian or unknown predators and 10 due to abandonment (Lauten *et al.* 2006*a*). Exclosures were effective in protecting nests against this threat (0 of 83 exclosed nests failed due to nest predation).

American crows have been consistently documented as a major predator on western snowy plover nests along the California and Oregon coasts (Page 1990; Persons and Applegate 1997; T. Applegate, Bioresources, pers. comm. 1999; M. Stern, The Nature Conservancy, pers. comm. 1999). At Coal Oil Point, American crows were the most frequent predator on western snowy plover nests and experimentally placed quail eggs (Lafferty *et al.* 2006). Populations of American crows have increased in the San Francisco Bay and central California coast over the past several decades, and are positively associated with human population density (Leibezet and George 2002).

Common ravens are known predators of western snowy plover eggs (Wilson-Jacobs and Dorsey 1985, Point Reyes Bird Observatory unpublished data, George 1997, Stein 1993, Point Reyes Bird Observatory unpublished data, J. Albertson *in litt.* 1999, Point Reyes Bird Observatory unpubl. data, Stern *et al.* 1991). Ravens have consistently been the most significant nest predator at Point Reyes, accounting for 69 percent of all predation events over 5 years and destroying approximately 50 percent of nests (Hickey *et al.* 1995). Hatching success at Point Reyes National Seashore increased after exclosures were used to protect western snowy plover nests from ravens in 1996. Approximately 12 percent of nests in San Diego County were destroyed by ravens (Powell *et al.* 1996, Powell *et al.* 1997). Raven populations in coastal California have significantly increased in recent decades (Leibezet and George 2002), and as their range expands they are becoming increasingly significant as a nest predator on western snowy plovers; ravens were observed to destroy nests in Monterey Bay for the first time in 2002 and 2003 (G. Page *in litt.* 2004*b*). In northern California ravens are the single most limiting factor on western snowy plover reproduction (Colwell *et al.* 2006). Ravens also prey on western snowy plover chicks, but not nearly to the extent that they do on eggs. However, at Point Reyes raven predation primarily affected chicks after exclosures were erected to protect snowy plover eggs (S. Allen *in litt.* 2004).

Gulls pose a special threat to breeding western snowy plovers because they not only depredate nests and chicks, but also usurp and trample western snowy plover nesting habitat and crush eggs (Persons and Applegate 1997, Point Reyes Bird Observatory unpublished data, Widrig 1980, J. Albertson *in litt.* 1999, Page *et al.* 1983).

The first time a gull-billed tern was found in San Diego County, California, was in 1985. Two years later they were nesting in south San Diego Bay (Unitt 2004). Since then, the nest colony has steadily increased with an estimated 52 pairs in 2006 (Patton 2006a). Gull-billed terns have become a concern to managers of beach-nesting birds in the region. Gull-billed terns were first documented taking California least terns (presumably chicks) in south San Diego Bay in 1992 (Caffrey 1993). Patton (2006a) summarizes recent incidents of gull-billed tern predation on both terns and western snowy plovers. He notes roughly 20 to 60 California least terns and 1 to 4 western snowy plover depredations by gull-billed terns and a greater number was suspected. Although the documented number of gull-billed tern depredations on western snow plovers is considerably lower than on California least terns, it is difficult to know the full extent of gull-billed tern impacts (Patton 2006b), especially for the plovers whose nests are more dispersed and less easily monitored.

Unlike management of other avian predators, management of gull-billed terns is problematic. The local subspecies of gull-billed tern, *G. n. vanrossemi*, is limited to western North America (Molina and Erwin 2006, but see Unitt 2004). The subspecies nests in scattered, localized colonies and "[i]n 2003 and 2005, the entire North American population of *vanrossemi* gull-billed terns ranged from about 533 to 810 pairs" (Molina and Erwin 2006). This means that this predator is considerably rarer than the listed bird species upon which it preys (California least terns and western snowy plovers), which poses a conundrum for managers of western snowy plovers and California least terns (Unitt 2004). Because of the gull-billed tern's status, lethal predator control has not been used on this species since 1999 (Unitt 2004). Gull-billed terns will likely become a greater source of management concern as the local population of this species grows. Gull-billed terns have been observed at other locations of beach-nesting birds farther north from San Diego Bay, including Camp Pendleton, San Diego County (Foster 2005); Bolsa Chica, Orange County (Hamilton and Willick 1996), and Venice Beach, Los Angeles County (McCaskie and Garrett 2005).

Loggerhead shrikes are not known to take western snowy plover eggs, but do prey upon chicks and locally can have substantial effects on fledging success (Warriner *et al.* 1986, D. George *in litt.* 2001, Page *et al.* 1997, George 1997, Page 1988, Feeney and Maffei 1991).

Although not known to be predators of western snowy plover eggs, American kestrels are predators of chicks and possibly adults (D. George, pers. comm. 1998). Fledging success increased from 9 to 64 percent after a kestrel unexpectedly disappeared from a western snowy plover nest site in Moss Landing Wildlife Area (Page *et al.* 1998). In 1997, a merlin was suspected of taking 13 banded adults within the period of a few days at Salinas River National Wildlife Refuge. Also, western snowy plover chicks and adults are among the avian prey of the peregrine falcon (B. Walton, University of California Santa Cruz, pers. comm. 1998; D. George, pers. comm. 1998; Feeney and Maffei 1991). Northern harriers are effective predators of western snowy plover chicks and adults. In 1987, a harrier was observed hunting on the islands in the Salinas River where only approximately one third of the hatched chicks reached fledging age (Point Reyes Bird Observatory unpubl. data). At the Moss Landing Wildlife Area, fledging success dropped from 61 to 23 percent after a harrier began foraging there (Page *et al.* 1997). A northern harrier was seen capturing 2 to 4 western snowy plover chicks at Moss Landing salt ponds in 2000 (D. George *in litt.* 2001).

In recent decades, alien eastern red foxes have become a serious new predator of endangered and threatened animals in coastal habitats (Jurek 1992, Golightly *et al.* 1994, Lewis *et al.* 1993). Nonnative red foxes were imported into the southern Sacramento Valley, primarily for hunting and fur farming purposes, as early as the 1870s and experienced explosive spread in the 1970s and 1980s (Jurek 1992, Lewis *et al.* 1993, 1995). The red fox now occurs throughout a significant portion of coastal California, including Marin, San Mateo, Santa Cruz, Monterey, San Luis Obispo, Santa Barbara, Ventura, Orange, and Los Angeles Counties (California Department of Fish and Game 1994). It also occurs at Monterey Bay (G. Page *in litt.* 1988) and San Francisco Bay (Harding *et al.* 1998), including the additional San Francisco Bay area counties of Napa, Solano, Contra Costa, Alameda, and Santa Clara (California Department of Fish and Game 1994). Red foxes also are present in some areas of coastal Oregon where western snowy plovers breed (D. George *in litt.* 2001, Lauten *et al.* 2006*b*).

Red foxes have been identified as a significant predator of western snowy plover eggs in the Monterey Bay area, where they are suspected of also preying on adults and chicks. On Monterey Bay beaches, red fox depredation of western snowy plover eggs resulted in a decline in clutch hatching rate of 30 percent from 1984 to 1990. After exclosures and mammalian predator control came into use to protect nests around Monterey Bay, annual clutch hatching rates have climbed from 43 to 68 percent (Neuman *et al.* 2004).

Predation of western snowy plover nests and chicks by red fox have been documented at Bandon Beach, New River and other portions of OR-15 on the Oregon coast. Biologists have documented red fox tracks around western snowy plover nest exclosures and have followed fox tracks back to dens located within western snowy plover nest areas. As part of the emergency response to the New Carissa oil spill in February 1999, a predator program was implemented. Animal and Plant Health Inspection Service (APHIS) Wildlife Services Division personnel removed 17 red fox from the New River area over a 3 month period (S. Richardson *in litt.* 2001). Ongoing predator management since 2002 has removed an average of 15 foxes per year from Bandon Beach/New River (Lauten *et al.* 2006*b*).

The U.S. Department of Agriculture, Wildlife Services Branch, has been involved in predator damage management for protection of threatened and endangered species for over 10 years in California. The management of nonnative red foxes has become a controversial issue in many areas of California, particularly in coastal habitats near urban areas (California Department of Fish and Game 1994). In November 1998, California voters approved Proposition 4, which banned the use of leghold traps in California. In February 1999, the U.S. District Court issued a Preliminary Declaratory Relief Order, which allows the use of padded leghold traps on Federal and non-Federal lands for the purpose of protecting threatened or endangered species. Trapping of nonnative and native predators of western snowy plovers will therefore not be affected by Proposition 4 (J. Albertson *in litt.* 1999).

Coyotes are known predators of western snowy plover eggs in the Pismo Beach/Santa Maria River area of San Luis Obispo County (T. Applegate, pers. comm. 1996). They are the main nest predator of eggs on Vandenberg Air Force Base where they were the cause of 43 percent of all clutch losses attributed to predators from 1994 to 1997 (Persons and Applegate 1997). At Vandenberg Air Force Base, coyotes may be attracted to marine mammal carcasses on the beach early in the western snowy plover nesting season (Page and Persons 1995). Coyotes also have been identified as predators of western snowy plover nests at Mono Lake, California (Page *et al.* 1983).

Striped skunks have been recorded as predators of western snowy plover eggs (Hickey *et al.* 1995, George 1997, Page *et al.* 1997, Hutchinson *et al.* 1987, Stein 1993, Stern *et al.* 1991). Skunks were believed to be the main cause of nest loss on Morro Bay Spit in 1987, the only year that the reproductive success of western snowy plovers has been monitored at that location (Hutchinson *et al.* 1987). Persons and Ellison (2001) reported that the striped skunk was the predominant predator of nests at Morro spit, destroying 87 percent of depredated nests in 2000.

Domestic and feral cats are widespread predators. The threat of predation of western snowy plovers by cats increases when housing is constructed near western snowy plover breeding habitat. As natural-appearing beaches continue to be surrounded by urban areas, western snowy plovers will increasingly be subjected to this predator in the future. Predation by cats is difficult to measure because of the difficulty in finding evidence of bird remains, but they are known to take western snowy plover adults and eggs (B. Farner, pers. comm. *in* Powell and Collier 1994; Page 1988; D. George *in litt.* 2001).

Predation, while predominantly a natural phenomenon, is exacerbated through the introduction of nonnative predators and unintentional human encouragement of larger populations of native predators. Elevated predation pressures result from landscape-level alterations in coastal dune habitats which, in turn, now support increased predator populations within the immediate vicinity of nesting habitat for western snowy plovers. Urbanization benefits red fox population growth by eliminating coyotes, which are the red fox's most common native predator and competitor; by providing ready sources of food, water and denning sites; and by aiding dispersion of foxes into new areas. Red foxes disperse readily in urban areas because there are no predators besides the domestic dog. Red foxes traverse most urban habitats, and readily cross busy highways and travel long distances underground through culverts (Lewis *et al.* 1993). Other predators, such as corvids, attracted by the presence of human activities (*e.g.*, improper disposal of trash), may frequent beaches in increasing numbers. Gulls have greatly expanded their range and numbers, especially along the United States portion of the Pacific coast, as a result of human-supplied food sources (trash, fish offal, and dumps). Thousands of California gulls now breed in the southern part of San Francisco Bay, where only a few were present in the early 1980s (J. Albertson *in litt.* 1999). This population growth is attributed largely to the increase in landfills along the Bay within the last 20 years. Also, crows and ravens forage at landfills. Buick and Paton (1989) found that losses of hooded plover (*Charadrius rubricollis*) nests with human footprints around them were higher than at those without footprints, suggesting "that scavenging predators may use human footprints as a visual cue in locating food." Beach litter and garbage also attract predators such as skunks and coyotes (*e.g.*, N. Read *in litt.* 1998). Unnatural habitat features such as landscaped vegetation (*e.g.*, palm trees), telephone poles, transmission towers, fences, buildings, and landfills near western snowy plover nesting areas attract predators and provide them with breeding areas (*e.g.*, J. Buffa *in litt.* 2004). These alterations all combine to make the coastal environment more conducive to various native and nonnative predators that adversely affect western snowy plovers.

Substantial evidence exists that human activities are affecting numbers and activity patterns of predators on western snowy plovers. For example, increased depredation of western snowy plover nests by ravens at the Oliver Brothers salt pond, California, may be an indirect adverse impact of nearby installation of light structures by the California Department of Transportation and high-tension power lines by the Pacific Gas and Electric Company, thereby creating corvid nesting sites

(G. Page, Point Reyes Bird Observatory, pers. comm. 1997). Raven nests have also been discovered by National Wildlife Refuge biologists in transmission towers near other snowy plover nesting areas managed by the Don Edwards San Francisco Bay National Wildlife Refuge in Warm Springs, Alviso, and Mountain View (J. Buffa *in litt.* 2004). On the Oregon coast, predation risk by mammals has increased as a result of the spread of European beachgrass, Scotch broom, and shore pine, which has transformed vast areas of open sand into dense grass-shrub habitat, providing excellent habitat for native and nonnative mammalian predators, such as skunks, raccoons, foxes, and feral cats (Stern *et al.* 1991). At Vandenberg Air Force Base, coyote predation can be exacerbated by human presence when trash or debris is left behind (N. Read *in litt.* 1998).

Signing and fencing of restricted areas on the beach may provide perches for avian predators of western snowy plover adults or chicks (Hallett *et al.* 1995). Although signs and fences are important conservation tools in many areas, land managers need to be aware that modifications to them may be necessary to deter predators in some circumstances.

**4. The Inadequacy of Existing Regulatory Mechanisms**

The western snowy plover is protected by the Federal Migratory Bird Treaty Act (16 U.S.C. 703 *et seq.*) and, in each state, by State law as a nongame species. The western snowy plover's breeding habitat, however, receives only limited protection from these laws (*e.g.*, the Migratory Bird Treaty Act prohibition against taking "nests"). Listing of the western snowy plover under State endangered species laws generally provides some protection against direct take of birds, and may require State agencies to consult on their actions, but may not adequately protect habitat. State regulations, policies, and goals include mandates both for protection of beach and dune habitat and for public recreational uses of coastal areas; consequently they may conflict with protection of western snowy plovers in some cases. Section 404 of the Clean Water Act (33 U.S.C. 1251 et seq.) and section 10 of the Rivers and Harbors Act (33 U.S.C. 403) are the primary Federal laws that could provide some protection of nesting and wintering habitat of the western snowy plover that is determined by the U.S. Army Corps of Engineers (Corps) to be wetlands or historic navigable waters of the United States. These laws, however, would apply to only a small fraction of the nesting and wintering areas of the western snowy plover on the Pacific coast. Aside from the Migratory Bird Treaty Act, western snowy plovers have no protection status in Mexico.

To effectively recover the western snowy plover, it is necessary to develop participation plans among cooperating agencies, landowners, and conservation organizations to assure protection and appropriate management of breeding, wintering, and migration areas. Since listing of the western snowy plover in 1993, several local working groups have been developed and local governments and State and Federal agencies have cooperated extensively to implement a wide variety of western snowy plover conservation actions. These partners continue to work to implement appropriate management of coastal areas for recovery of the western snowy plover. These conservation efforts and the environmental policies of State and Federal agencies are described in greater detail in the Conservation Efforts section, below.

For additional discussion of regulatory mechanisms and management actions taken by California State Parks and other entities, see U.S. Fish and Wildlife Service (2006a).

### 5. Other Natural or Manmade Factors Affecting Their Continued Existence

#### *a. Natural Events*

Western snowy plover breeding and wintering habitat is subject to constant change from weather conditions. Stenzel *et al.* (1994) reported that the quality and extent of western snowy plover nesting habitat is variable in both the short- and long-term. Coastal beaches increase in width and elevation during the summer through sand deposition, making marginal beaches more suitable for nesting later in the season. Over the longer term, an increase or decrease in habitat quality may occur after several years of winter storms. Based on the amount of flooding, the availability of dry flats at the edges of coastal ponds, lagoons, and man-made salt evaporators also varies within and between seasons. Therefore, the number of western snowy plovers breeding in some areas may change annually or even over one breeding season in response to natural alterations in habitat availability (Stenzel *et al.* 1981).

Because most western snowy plover nesting areas occur on unstable sandy substrates, nest losses caused by weather-related natural phenomena commonly occur. High tides and strong winds cause many nest losses. Events such as extreme high tides (Wilson 1980, Stenzel *et al.* 1981), river flooding (Stenzel *et al.* 1981), and heavy rain (Wilson 1980, Warriner *et al.* 1986, Page 1988) have been reported to destroy or wash away nests. The annual percentage of total nest losses attributed to weather-related phenomenon has reached 15 to 38 percent at some locations (Wilson 1980, Warriner *et al.* 1986, Page 1988).

Stormy winters can adversely affect the western snowy plover. It is suspected that the severe storms occurring during the El Niño atmospheric and oceanic phenomenon of the winter of 1997/1998 caused a 10 to 30 percent decline in the 1998 western snowy plover breeding population, depending on the coastal region. In all monitored recovery units, the number of breeding birds in 1998 was lower than in the 1997 nesting season. Additionally, a very wet spring resulted in a later than normal breeding initiation and fewer nesting attempts.

The western snowy plover population naturally varies, both spatially and temporally, because of natural changes in weather and habitat conditions from year to year. However, as described above, human influences over the past century (*e.g.*, habitat destruction, invasion of introduced beachgrass, and elevated predation levels) have reduced the western snowy plover's ability to respond to these natural perturbations.

***b. Disturbance of Breeding Plovers by Humans and Domestic Animals***

The coastal zone of the United States, including both open coastal areas and inland portions of coastal watersheds, is home to over one-third of the U.S. human population, and that proportion is increasing (U.S. Fish and Wildlife Service 1995*a*). The southern California coastal area, which constitutes the central portion of the western snowy plover's coastal breeding range, attracts large crowds on a regular basis (Figure 6). The increasing level of human recreation was cited as a major threat to the breeding success of the Pacific coast population of the western snowy plover at the time of listing (U.S. Fish and Wildlife Service 1993*a*).

**Figure 6.** Recreationists at Salt Creek Beach, California (photo by Ruth Pratt, with permission).

**i. Pedestrians**

Pedestrians (*e.g.*, beach walkers and joggers) can cause both direct mortality and harassment of western snowy plovers. Pedestrians on beaches may crush eggs or chicks and chase western snowy plovers off their nests. Separation of western snowy plover adults from their nests and broods can cause mortality through exposure of vulnerable eggs or chicks to heat, cold, blowing sand, and/or predators. Pedestrians have been known to inadvertently step on eggs and chicks, deliberately take eggs from nests, and remove chicks from beaches, erroneously thinking they have been abandoned. People also may cause broods of western snowy plovers to run away from favored feeding areas. These effects are described in more detail below. Trash left on the beach by pedestrians also attracts predators. In addition to public pedestrians, military personnel using the beach for maneuvers, boat launches, and landings have the potential to similarly cause adverse impacts to western snowy plovers.

Beach-related recreational activities that are concentrated in one location (*e.g.*, sunbathing, picnicking, sandcastle building, birding, and photography) can negatively affect incubating adult western snowy plovers when these activities occur too close to their nests. Recreational activities that occur in the wet sand area (*e.g.*, sand sailing) can adversely affect western snowy plovers when they disturb plover adults or broods, which feed at the edge of the surf along the wrack line. Recreational activities that occur in or over deep water (such as the beach- and water-oriented activities of surfing, kayaking, wind surfing, jet skiing, and boating, and the coastal-related recreational activity of hang gliding) may not directly affect western snowy plovers; however, they can potentially be detrimental to western snowy plovers when recreationists use the beach to take a break from these activities, or as access, exit, or landing points.

Concentrations of people may deter western snowy plovers and other shorebirds from using otherwise suitable habitats. Anthony (1985) found that intensive human activity at Damon Point had a "bracketing effect" on the distribution of nesting western snowy plovers, confining their breeding activity to a section of the spit and precluding their regular use of otherwise suitable habitat. Fox (1990) also found that western snowy plovers avoided humans at Damon Point, and the presence of fishermen and beachcombers kept them hundreds of yards away from potential habitat. Because early-nesting western snowy plovers have narrower beaches from which to select nest locations, recreational use may be more concentrated in the limited habitat available. Also, repeated intrusions by people into western snowy plover nesting areas also may cause birds to move into marginal habitats where their chances of reproductive success are reduced. Studies of the Atlantic coast population of the piping plover (*Charadrius melodus*), an eastern species with habitat requirements very similar to the snowy plover, indicate that some piping plovers that nest early in the season are forced to move elsewhere when human use becomes too intense (Cairns and McLaren 1980). These authors concluded that piping plovers that nest early, before beaches become heavily used for recreation, "cannot predict and avoid reproductive failure in habitats that otherwise appear suitable to them." Burger (1993) observed that piping plovers, in response to human disturbance, spent more energy on vigilance and avoidance behavior at the expense of foraging activity, and sometimes abandoned preferred foraging habitat.

Page *et al.* (1977) observed western snowy plovers' response to human disturbance at two coastal beaches where normal beach use ranged from light to heavy. The study included 156 hours of observation at 15 western snowy plover nests. At Point Reyes, they found that pedestrians disrupt incubation of nests. When humans approached western snowy plovers, adults left their nests 78 percent of the time when people were within 50 meters (164 feet) and 34 percent of the time when people were over 100 meters (328 feet). They also found that western snowy plovers' reaction to disturbance by humans varied, ranging from one bird remaining off the nest for less than 1 minute when a person walked within 1 meter (3 feet) of the nest on a heavily-used beach to another western snowy plover leaving the nest when three people were 200 meters (656 feet) away on a less-used beach. They noted that "birds exposed to prolonged human activity near the nest seemed to become accustomed to it." It has been speculated that predators of western snowy plovers may benefit from a decline in wariness by western snowy plovers nesting on beaches that are subject to ongoing high levels of human disturbance (Persons and Applegate 1997).

Lafferty (2001) observed western snowy plovers' response to people, pet dogs, equestrians, crows and other birds. Observations were made at Devereux Slough in Santa Barbara County, Santa Rosa Island, San Nicolas Island, and Naval Base Ventura County (Point Mugu). This study found that western snowy plover are most frequently disturbed when approached closely (within 30 meters) by people and animals. The most intense disturbance (causing the western snowy plover to fly away) were in response to crows, followed by horses, dogs, humans, and other birds. Lafferty (2001) created a management model based on his findings and estimated flight response disturbances under different scenarios. The model predicted a reduced disturbance response for buffer zones of 20 to 30 meters.

Fahy and Woodhouse (1995) quantified the levels of recreational disturbance, their effect on western snowy plovers, and the effectiveness of the Linear Restriction Program at Ocean Beach, Vandenberg Air Force Base in 1995. Under this program signs directed visitors not to cross from the outer beach into the Linear Restriction area (inland of mean high tide mark, in dune habitat used by western snowy plovers). Seventy percent of all disturbances were in compliance with restriction warning signs. The disturbance types that were most and least frequently in compliance with the boundary were joggers or walkers and stationary visitors, respectively. The closer the disturbance occurred to the plover, the more severe the plover response. All-terrain vehicles caused the most significant alert and flight behaviors by western snowy plovers, even though they were in compliance with the Linear Restriction. The disturbance types that caused incubating western snowy plovers to flush from their nests most frequently were joggers and walkers, followed by joggers or walkers with dogs off leash, and stationary visitors. The disturbance types that kept incubating western snowy plovers off their nests for the longest period of time were stationary visitors and surf fishermen, probably because of the duration of these stationary disturbances that occurred close to nests. Weekends accounted for 60 percent of all disturbances. The enforcement personnel appeared to have a limited presence; their presence was documented during only 14 percent of all identified disturbances.

Hoopes *et al.* (1992) quantified human use and disturbance to piping plovers in Massachusetts during the 1988 and 1989 nesting seasons. They found pedestrians caused piping plovers to flush or move at an average distance of 23 meters (75 feet). Pedestrians within 50 meters (164 feet) of the birds caused piping plovers to stop feeding 31 percent of the time.

Point Reyes Bird Observatory found that management actions that included exclusion zones around nesting areas, seasonal closure to dogs, and active weekend docent programs reduced mortality of chicks and eggs during the weekend such that the weekend and weekday mortality was the same (Peterlein and Roth 2003).

At the Pajaro River mouth in California, at least 14 percent of western snowy plover clutches were destroyed by being driven over, stepped on, or deliberately taken by people (Warriner *et al.* 1986). Since exclosures have been used to protect nests at the Pajaro River mouth and other locations at Monterey Bay, a few nests have still been deliberately destroyed by vandals in most years (Point Reyes Bird Observatory unpublished data). At South Beach, Oregon, the number of western snowy plovers declined from 25 in 1969 to 0 in 1981 when a new park was constructed next to the beach and the adjacent habitat became more accessible to vehicles and people (Hoffman 1972 *in* Oregon Department of Fish and Wildlife 1994).

At Vandenberg Air Force Base, western snowy plover monitoring during 1993 at South Beach (where recreational use was high) and North Beach (where recreational use was low) found the rate of nest loss caused by humans differed markedly: 24.3 percent of South Beach nests were lost compared to only 3.0 percent of North Beach nests (Persons 1994). Persons and Applegate (1997) reported that "rates of reproductive success, combined for 1994 through 1997, were substantially higher on North Beach than on South Beach." This difference occurred despite the fact that nesting habitat was posted as off-limits during the nesting season in 1994. However, at that time restrictions were new and not strictly enforced (R. Dyste *in litt.* 2004). Since 2000, public access has been restricted and fully enforced by Vandenberg Air Force Base personnel. Additionally, Santa Barbara County-supported volunteer docents were present at Surf Station (within Vandenberg Air Force Base) during the 2001-2003 plover breeding seasons when the beach was open for public access. In 2003, plover monitors did not document the loss of any nests within Surf Station Beach as a result of trampling by humans (R. Dyste *in litt.* 2004).

Loss of western snowy plover chicks also may occur because of human activities. The number of young produced per nesting attempt increased from 0.75 in disturbed habitat to 2.0 for nests free of disturbance at Willapa National Wildlife Refuge, Washington (Saul 1982). At Vandenberg Air Force Base, the 1997 fledging success of western snowy plovers was 33 to 34 percent on North Beach where recreational activity is restricted and only 12 percent on South Beach where recreational use is high (Persons and Applegate 1997). In 1999 and 2000, Ruhlen *et al.* (2003) found that increased human activities on Point Reyes beaches had a negative effect on western snowy plover chick survival. In both 1999 and 2000, western snowy plover chick loss was about three times greater on weekends and holidays than on weekdays. In most coastal areas, beach visitation in summer months is much higher on weekends and holidays than on weekdays.

Flemming *et al.* (1988) measured the effects of human disturbance on reproductive success and behavior of piping plovers in Nova Scotia. To assess human disturbance, they recorded positions of people, pedestrian tracks, and vehicle tracks, then defined classes based on visits per week. They found significantly fewer young survived in areas of high versus low disturbance; humans elicited a significantly higher response level from adult piping plovers than did predators or nonpredatory species; chicks fed less and were brooded less when humans were within 160 meters (525 feet); and chick peck rate during feeding was lower when humans were present. They speculated that because chicks shifted from feeding and energy conservation activities to vigilance and cryptic predator avoidance behaviors, their energy reserves would be depleted, making them more susceptible to predators and inclement weather. They postulated that a decline in piping plover abundance in Nova Scotia could be caused by human disturbance altering chick behavior. Fewer chicks survived to 17 days in areas heavily disturbed by humans.

Schultz and Stock (1993) studied the effects of tourism on colonization, distribution, and hatching success of Kentish plovers (*Charadrius alexandrinus alexandrinus*), a Eurasian subspecies of the snowy plover, at the Wadden Sea in Germany. They measured disturbance intensity by counting and mapping tourists on 50 days from April to July, during times of peak human activity (1500 to 1600 hours) and in intervals of 30 minutes throughout other days. An index of person-hours per area per day was calculated. They found that Kentish plovers did not colonize heavily-disturbed areas and that resting and sunbathing people were apparently more disruptive than walking people because the latter generally followed the high-tide line. Clutch losses were lowest in areas with little disturbance and highest in areas with heavy disturbance. They indicated that hatching success in highly disturbed areas, even with optimal habitat, is as low as in poor habitat with a low level of disturbance.

**ii. Dogs**

Dogs on beaches can pose a serious threat to western snowy plovers during both the breeding and nonbreeding seasons. Unleashed pets, primarily dogs, sometimes chase western snowy plovers and destroy nests. Repeated disturbances by dogs can interrupt brooding, incubating, and foraging behavior of adult western snowy plovers and cause chicks to become separated from their parents. Pet owners frequently allow their dogs to run off-leash even on beaches where it is clearly signed that dogs are not permitted or are only permitted if on a leash. Enforcement of pet regulations on beaches by the managing agencies is often lax or nonexistent.

A number of examples of disruptive ways that dogs affect western snowy plovers have been noted at beaches in Monterey County (Marina State Beach), Santa Cruz County (Laguna, Scott Creek, and Seabright Beaches) and San Mateo County (Half Moon Bay and Pacifica Beaches) (D. George, pers. comm. 1997). Incubating birds have been flushed from nests by dogs, including nests located inside areas protected by symbolic fencing. Dogs also have displaced adults from nests with newly-hatched chicks. Roosting and feeding flocks, as well as individual birds, have been deliberately and persistently pursued by dogs. At Laguna Creek Beach, Zmudowski State Beach, and Salinas River State Beach, dogs partially or entirely destroyed western snowy plover nests which were in several cases, protected with symbolic fencing (D. George, pers. comm. 1997; Point Reyes Bird Observatory unpublished data; G. Page, pers. comm. 1998). Feral dogs are suspected to have disturbed western snowy plover nests and chicks on San Francisco Bay salt ponds (J. Albertson *in litt.* 1999).

Even when not deliberately chasing birds, dogs on a beach may disturb western snowy plovers and other shorebirds that are roosting or feeding. Page *et al.* (1977) found that western snowy plovers flushed more frequently and remained off their nests longer when a person was accompanied by a dog than when alone. They collected data during 156 hours of observation at 15 nests at Point Reyes, California, and found the following distances at which western snowy plovers flushed from their nests as a result of disturbance by people with dogs. Within 50 meters (164 feet), people with dogs caused flushing 100 percent of the time. At a distance of over 100 meters (328 feet), people with dogs caused flushing 52 percent of the time (Page *et al*. 1977). Fahy and Woodhouse (1995) found that joggers or walkers with off-leash dogs caused a significantly greater number of avoidance responses from western snowy plovers than other types of disturbances at Ocean Beach, Vandenberg Air Force Base, California. Lafferty's (2001) management model predicted that intense disturbances could be dramatically reduced by removing dogs.

At wintering sites such as Ocean Beach in San Francisco, California, off-leash dogs have caused frequent disturbance and flushing of western snowy plovers and other shorebirds. Off-leash dogs chase wintering western snowy plovers at this beach and have been observed to regularly disturb and harass birds (P. Baye, U.S. Fish and

Wildlife Service, pers. comm. 1997). Observations by National Park Service volunteers suggest that unleashed pets represent the most significant recreational threat to wintering western snowy plovers and migratory shorebirds at Ocean Beach, because of the prolonged and repeated disturbance created when they chase birds (Hatch 1997). In 1995 and 1996, during 45 hour-long observations of wintering flocks of western snowy plovers at Ocean Beach, western snowy plovers responded by moving in 73 percent of 74 instances when dogs with or without people approached to within 15 meters (50 feet) (Golden Gate National Recreation Area unpublished data). When shorebirds are flushed, they must spend more energy on vigilance and avoidance behaviors at the expense of foraging and resting activity (Burger 1993, Hatch 1997). Disruption of foraging and roosting may result in decreased accumulation of energy reserves necessary for shorebirds to complete the migration cycle and successfully breed (Burger 1986, Pfister *et al.* 1992). Dog disturbance at wintering and staging sites, therefore, may adversely affect individual survivorship and fecundity, thereby affecting the species at the population level.

**iii. Motorized Vehicles**

Unrestricted use of motorized vehicles on beaches is a threat to western snowy plovers and their habitat. Motorized vehicles may affect remote stretches of beach where human disturbance would be slight if access were limited to pedestrians. The magnitude of this threat is variable, depending on level of use and type of terrain covered. Use of motor vehicles on coastal dunes may also be destructive to dune vegetation, especially sensitive native dune plants.

Driving vehicles in breeding habitat may cause destruction of eggs, chicks, and adults, abandonment of nests, and considerable stress and harassment to western snowy plover family groups (G. Page, pers. comm. 1997; J. Myers *in litt.* 1988; J. Price *in litt.* 1992; Stern *et al.* 1990; Casler *et al.* 1993; S. Richardson, pers. comm. 1998; Widrig 1980). In addition to recreational vehicles, vehicles used for military activities have also caused western snowy plover mortality (Powell *et al.* 1995, 1997; Persons 1994).

Driving motor vehicles at night seems to be particularly hazardous to western snowy plovers. Drivers of all-terrain vehicles at night have run over and killed western snowy plover adults at Vandenberg Air Force Base, and State park ranger patrol vehicles have crushed western snowy plover chicks at Oceano Dunes State Vehicular Recreation Area during night patrols (R. Mesta *in litt.* 1998).

On the Eel River gravel bars, vehicle use (including motorcycles, ATVs, and full-size 4x4s) has resulted in the crushing of nests and disturbance to nesting plovers (Colwell *et al.* 2006).

Western snowy plover adults and chicks have been observed using tire tracks and human footprints for loafing at Camp Pendleton and Naval Amphibious Base Coronado (Powell and Collier 1994). This behavior increases their chances of being run over. Western snowy plover chicks also may have difficulty getting out of tire ruts, thereby increasing their likelihood of being run over. Their cryptic coloring and habit of crouching in depressions like tire tracks makes western snowy plover chicks especially vulnerable to vehicular traffic. In Massachusetts, between 1989 and 1997, a total of 25 piping plover chicks and 2 adults were found dead in off-road vehicle tire ruts on the upper beach between the mean high tide line and the foredune (U.S. District Court of Massachusetts 1998).

Hoopes *et al.* (1992) found off-road vehicles caused piping plovers to flush or move at an average distance of 40 meters (131 feet). Off-road vehicles within 50 meters (164 feet) of the birds caused piping plovers to stop feeding 77 percent of the time. While most responses by piping plovers to off-road vehicles resulted in movement by the birds, they observed three instances where the plovers “froze” in response to the off-road vehicles. Both types of responses have a negative impact on plovers through either disturbance, interruption of feeding behavior, or increasing the risk that piping plovers will be hit or crushed by vehicles.

At wintering sites, disturbance from motorized vehicles may harass western snowy plovers and disrupt their foraging and roosting activities, thereby decreasing energy reserves needed for migration and reproduction. When motorcycles, most of which were in the wet sand zone, were driven at high speed along Ocean Beach in San Francisco, Hatch (1997) observed that western snowy plovers and other shorebirds were continually disturbed and often took flight.

### iv. Beach Cleaning

Removal of human-created trash on the beach is desirable to reduce predation threats by eliminating food for predators of western snowy plovers; however, the indiscriminate nature of mechanized beach-cleaning adversely affects western snowy plovers and their habitat. Mechanized beach cleaning can be dangerous to western snowy plovers by crushing their clutches and chicks or causing prolonged disturbance from the machine's noise. Also, this method of beach cleaning removes the birds' natural wrackline (area of beach containing seaweed and other natural wave-cast organic debris) feeding habitat, reducing the availability of food. Kelp and driftwood, with their associated invertebrates, are regularly removed and the upper layer of sand is disturbed. Beach grooming also alters beach topography, removes objects associated with western snowy plover nesting, and prevents the establishment of native beach vegetation (J. Watkins *in litt.* 1999). In all of Los Angeles County and parts of Ventura, Santa Barbara, and Orange Counties, California, entire beaches are raked on a daily to weekly basis. Large rakes, with tines 5 to 15 centimeters (2 to 6 inches) apart, are dragged behind motorized vehicles from the waterline to pavement or to the low retaining wall bordering the beaches (Stenzel *et al.* 1981). Even if human activity was low on these beaches, grooming activities completely preclude the possibility of successful western snowy plover nesting (Powell 1996).

### v. Equestrian Traffic

Most equestrian use on beaches is directed to wet-sand areas. However, during high tide periods, horseback riders on the beach sometimes enter coastal dunes or upper beach areas (Figure 7), where they may crush clutches or disturb western snowy plovers (Point Reyes Bird Observatory unpublished data, Page 1988, Persons 1995, Craig *et al.* 1992, Woolington 1985).

**Figure 7.** Equestrians on beach (photo by U.S. Forest Service, with permission).

### vi. Fishing

Impacts on western snowy plover nesting may be associated with surf fishing and shellfish harvesting in and near western snowy plover habitat. The improper disposal of offal (waste parts of fish), bait, and other litter attracts crows, ravens, and gulls, which are predators of western snowy plover eggs and chicks. Also, western snowy plovers may become entangled in discarded fishing lines (G. Page, pers. comm. 1998).

Surf fishing is a commercial enterprise in many coastal locations, including the ocean smelt fishery in northern California (C. Moulton *in litt.* 1997). Recreational surf fishing occurs throughout the California coast. In Humboldt County, California, Redwood National and State Parks have proposed allowing beach vehicle use, by annual permit, for commercial fishing and tribal fishing/gathering on Gold Bluffs Beach, Freshwater Spit, and Crescent Beach (J. Watkins *in litt.* 1999). In the State of Washington, the most popular season for surf fishing is April through July (Washington Department of Fish and Wildlife 1995). At present, demand for surf perch fishing is relatively low in Oregon. However, the Oregon Department of Fish and Wildlife is promoting a surf perch fishery to lessen the demand for anadromous fishing. This fishery would increase vehicle driving to remote and relatively undisturbed sites used by western snowy plovers (K. Palermo *in litt.* 1998*a*).

Because the earliest western snowy plover clutches in Washington are laid between mid-April and mid-May, harvesting of razor clams during the mid-March to mid-May clamming season may have adverse impacts on prospecting or nesting western snowy plovers. Clammers near nesting areas may disturb adults and chicks; human activity in feeding areas may restrict western snowy plover foraging activity, and increased motorized traffic may increase the risk of nest and chick loss (Washington Department of Fish and Wildlife 1995). However, observations of western snowy plover and human activities during the spring 1995 razor clam season showed clamming had no visible impact on western snowy plovers where clamming intensity was low (Kloempken and Richardson 1995). Instances of trespassing into the western snowy plover protection area were noted; however, movement of the western snowy plover protection area boundary about 327 meters (1,073 feet) west of its previous location seemed to benefit the birds by providing more space between them and pedestrian and vehicular disturbances.

**vii. Fireworks**

Fireworks are highly disturbing to western snowy plovers. All western snowy plovers flushed from Coal Oil Point Reserve during a nearby July 4, 2005, fireworks display (C. Sandoval, University of California Santa Barbara, pers. comm. 2005). At Del Monte Beach, California, a western snowy plover chick hatched on July 4, 1996, within an area demarcated by symbolic fencing, and was abandoned by its parents after a fireworks display. Disturbance from the noise of the pyrotechnics is exacerbated by disturbance caused by large crowds attracted to fireworks events. California Department of Parks and Recreation staff estimated that 6,000 people visited Del Monte Beach on that day. Because of the extensive disturbance, the adult western snowy plovers left the nest site with two chicks, abandoned the third chick, and were not seen again (K. Neuman, California Department of Parks and Recreation, pers. comm. 1997). During July 4, 1992, observations of piping plovers that nest on the Breezy Point Cooperative and adjacent beaches of Gateway National Recreation Area in Queens, New York, the birds were disturbed by fireworks displays (Howard *et al.* 1993). Management recommendations for this area included prohibition of fireworks in or near the fenced and posted nesting and brood-rearing areas.

### viii. Kite Flying and Model Airplanes

Biologists believe plovers perceive kites as potential avian predators (Hoopes *et al.* 1992, Hatch 1997). The reaction of western snowy plovers to kites at Ocean Beach in San Francisco, California, "ranged from increased vigilance while roosting in close proximity to the kite flying, to walking or running approximately 10 to 25 meters (33 to 82 feet) away and resting again while remaining alert" (Hatch 1997). It is expected that stunt-kites would cause a greater response from western snowy plovers than traditional, more stationary kites. Stunt kites include soaring-type, two-string kites with noisy, fluttering tails, which often exhibit rapid, erratic movements.

Hoopes *et al.* (1992) found that piping plovers are intolerant of kites. Compared to other human disturbances (i.e., pedestrian, off-road vehicle, and dog/pet), kites caused piping plovers to flush or move at a greater distance from the disturbance, to move the longest distance away from the disturbance, and to move for the longest duration. Piping plovers responded to kites at an average distance of 85 meters (279 feet); moved an average distance of over 100 meters (328 feet); and the average duration of the response was 70 seconds.

It is expected that model airplanes may also have a detrimental impact to western snowy plovers because western snowy plovers may perceive them as potential predators (Hatch 1997).

### ix. Aircraft Overflights

Low-flying aircraft (*e.g.*, within 152 meters (500 feet) of the ground) can cause disturbances to breeding and wintering western snowy plovers. Hatch (1997) found that all types of low-flying aircraft potentially may be perceived by western snowy plovers as predators. She also found that the general response of roosting western snowy plovers to low-flying aircraft at Ocean Beach, San Francisco, California, was to increase vigilance and crouch in depressions on the beach, whereas foraging western snowy plovers frequently took flight. Plovers may, however, become acclimated to aircraft overflights in some instances, since at Naval Air Station North Island they chose to nest repeatedly within military airfield boundaries on runway ovals next to busy military runways (S. Vissman, U.S. Fish and Wildlife Service, pers. comm. 1997). Federal Aviation Regulations, Part 91, General Operating and Flight Rules, require that over open water, aircraft may not be operated closer than 152 meters (500 feet) to any person, vessel, vehicle, or structure. Emergency operations, including those by Coast Guard helicopters, are exempted from these rules. However, helicopters may be operated at less than 152 meters (500 feet) if the operation is conducted without hazard to people or property on the surface (U.S. Federal Aviation Administration 1997). Helicopters can cause excessive noise, which can also disturb western snowy plovers, even at an altitude of 152 meters (500 feet) (Howard *et al.* 1993; J. Watkins *in litt.* 1999; D. Stadtlander, pers. comm. 1999). At Marine Corps Base Camp Pendleton, California, where military training can require aircraft (especially helicopters) to fly at very low elevations, the Marine Corps minimizes impacts to western snowy plovers and California least terns by requiring aircraft to stay at least 91 meters (300 feet) above the ground over tern and plover nesting areas during the nesting season (U.S. Marine Corps 2006).

**x. Special Events**

Special events which attract large crowds, such as media events, sporting events, and beach clean-ups, have a potential for significant adverse impacts when held in or near western snowy plover habitat. An example is the National Marine Debris Monitoring Program, implemented by the U.S. Environmental Protection Agency in conjunction with the National Oceanic and Atmospheric Administration, National Park Service, and the U.S. Coast Guard. This year-round program uses volunteers (including high school students) to document and collect trash and marine debris on coastal transects within western snowy plover nesting and wintering habitat. Potential threats from crowds of people attracted to special events are similar to those previously identified for pedestrians, including direct mortality and harassment of western snowy plovers.

### xi. Coastal Access

Expanding public access to the coast (*e.g.*, State Coastal Trails) for recreation (*e.g.*, walking, hiking, biking) may adversely affect western snowy plovers and their breeding or wintering habitat. Expanded coastal access brings significantly greater numbers of people to the beach and other coastal habitats, exacerbating potential conflicts between human recreational activities and western snowy plover habitat needs (see Pedestrian section). Expanded coastal access may exceed the threshold of beach visitors that public resource agencies (*e.g.*, State Parks and National Park Service) can effectively manage while also meeting their responsibilities to protect natural resources.

Bicycles are known to adversely affect western snowy plovers nesting on levees and roads near San Francisco Bay salt ponds within the Don Edwards San Francisco Bay National Wildlife Refuge. Many of these levees are closed to human access, but some bicyclists trespass onto closed levees. In 1998, one western snowy plover nest, located on the main access road to the Refuge, was run over by a bicycle as biologists were putting up a barrier to protect it (J. Albertson *in litt.* 1999).

### xii. Livestock Grazing

Western snowy plover nests have been trampled by cattle, causing both direct mortality of eggs and flushing of adults from the nests (U.S. Fish and Wildlife Service *in litt.* 1995). Additionally, feral pigs (*Sus scrofa*) may trample western snowy plover habitat and disturb nesting western snowy plovers (R. Klinger, The Nature Conservancy, pers comm. 1998, D. George *in litt.* 2001). Cow and horse manure can introduce seeds of non-native plants into the dunes.

### *c. Oil Spills*

The Pacific Coast population of the western snowy plover is vulnerable to oil spills. Western snowy plovers forage along the shoreline and in sea wrack (seaweed and other natural wave-cast organic debris) at the high-tide line and are thus at risk of direct exposure to oil during spills. The loss of thermal insulation is considered to be the primary cause of mortality in oiled birds (National Research Council 1985, Leighton 1991). Oiled feathers lose their ability to keep body heat in and cold water out, causing reduced insulation, increased metabolic rate, and hypothermia. Ingestion of oil may lead to physiological changes in birds, including pathological effects on the alimentary tract, blood, adrenal glands, kidneys, liver, and other organs (Fry and Lowenstine 1985, Khan and Ryan 1991, Burger and Fry 1993). Exposure of adult birds to oil also may impair reproduction, including reductions in egg laying and hatchability (Ainley *et al.* 1981, Fry *et al.* 1986) and reductions in survival and growth of chicks (Trivelpiece *et al.* 1984). Oil transferred to eggs from plumage or feet of incubating birds can kill embryos (Albers 1977, Albers and Szaro 1978, King and Lefever 1979). Oiled shorebirds may spend more time preening and less time feeding than unoiled birds, such that their body condition and ability to migrate to breeding grounds and reproduce may be impaired (Evans and Keijl 1993, Burger 1997).

Oil spills may result in contamination or depletion of western snowy plover food sources. Elevated concentrations of total petroleum hydrocarbons have been found in the sand crab (*Emerita analoga*), a potential western snowy plover food item, following a southern California oil spill (J.E. Dugan, unpublished data). Oil or other chemicals washed onto mudflats or sand beaches may result in reduction in the availability of invertebrate prey (Kindinger 1981). Elimination of shorebird food resources on intertidal flats of the Saudi Arabian Gulf coast as a result of the large oil spills associated with the 1991 Gulf War led to drastic reductions in the number of shorebirds supported by this habitat (Evans *et al.* 1993). Disturbance and other adverse impacts to western snowy plovers also may occur during oil clean-up activities if response teams are not careful when driving heavy equipment and vehicles or traversing on foot through western snowy plover habitat.

During the 1990s, at least six oil spill incidents in California and one in Oregon resulted in adverse impacts to western snowy plovers. The U.S. Coast Guard and various other State and Federal agencies and the responsible parties responded to these spills. One of these incidents occurred between 1984 and 1998 at Unocal's Guadalupe Oil Field in San Luis Obispo, California contaminated western snowy plover habitat with toxic hydrocarbons. In 1993, oil spilled from a ruptured oil transfer line into McGrath Lake, Ventura County, California and then flowed into the Pacific Ocean. Western snowy plover habitat and prey were contaminated with oil and wintering western snowy plovers were displaced during the cleanup activities (S. Henry *in litt.* 1998, McGrath Oil Spill Restoration Scoping Document 1995). In 1996, the SS Cape Mohican discharged fuel oil into the San Francisco Drydock Shipyard, California, where it spread throughout the central bay and into the Pacific Ocean, oiling western snowy plovers and their beach habitat (Cape Mohican Trustee Council 2002, Point Reyes Bird Observatory unpublished data). In 1997, a pipeline extending between an offshore oil platform (Platform Irene) and the mainland ruptured near Pedernales Point, Santa Barbara County, California, oiling western snowy plovers and wrack where western snowy plovers were seen feeding (Applegate 1998, Ford 1998, Lockyer *et al.* 2002). In 1997 and 1998, large numbers of tarballs became stranded on beaches at Point Reyes National Seashore and resulted in oiling of snowy plovers and their habitat. Subsequent tarball incidents in 2001 and 2002 resulted in identification of the source of the tarballs as the SS Jacob Luckenbach, an oil tanker that sank in 1953 (Carter and Golightly 2003, Point Reyes Bird Observatory unpublished data, Hughes 2003). In 1999, the dredge M/V Stuyvesant spilled fuel oil into the Pacific Ocean off Humboldt Bay, California (U.S. Coast Guard 2001), resulting in oiling of western snowy plovers and their habitat (LeValley *et al.* 2001).

In February 1999, the freighter New Carissa went aground near the North Jetty of Coos Bay, Oregon, breaking apart and spilling 25,000 to 70,000 or more gallons of oil into coastal water. (U.S. Bureau of Land Management 2001). The incident oiled approximately 52 snowy plovers, representing at least 60 percent of the Oregon wintering population of western snowy plover (Stern *et al.* 2000). In Washington, the 1988 Nestucca oil spill and the 1991 Tenyo Maru oil spill may also have affected western snowy plovers or their habitats, although impacts are not as well documented as in the above cases (Larsen and Richardson 1990).

In addition to catastrophic spills like those described above, chronic oil pollution may affect western snowy plovers. Surveys of beached birds have shown that small-volume, chronic oil pollution is an ongoing source of avian mortality in coastal regions (Burger and Fry 1993). Dead oiled birds and tarballs are found regularly on Pacific coast beaches in the absence of reported oil spills (Roletto *et al.* 2000). Potential sources of chronic oiling include natural seeps, bilge water pumping, sunken vessels, urban runoff, and small or unreported spills from vessels, tankers, pipelines, and offshore oil platforms. Elevated concentrations of total petroleum hydrocarbons have been found in the sand crab *(Emerita analoga*), a potential western snowy plover food item, in the vicinity of natural oil seeps (Dugan *et al.* 1997).

Intensive oil spill cleanup operations, including use of vehicles to deploy beach booms, move personnel, and remove debris, cause disturbance to nesting and foraging activities of western snowy plovers. These temporary impacts are offset by restoration of habitat and cleaning affected birds.

***d. Contaminants***

The most likely route of exposure of western snowy plovers to contaminants other than spilled oil is through the diet. Western snowy plovers feed on aquatic and terrestrial insects, and the bioaccumulation of environmental contaminants on western snowy plover nesting and wintering grounds may adversely affect their health and reproduction. Organochlorines are known to have caused reduced avian egg production, aberrant incubation behavior, delayed ovulation, embryotoxicosis, and mortality of chicks and adults (Blus 1982). Selenium has caused decreased hatchability of avian eggs, developmental abnormalities, altered nesting behavior, and embryotoxicosis in birds in field and laboratory studies (Ohlendorf *et al.* 1986, Heintz *et al.* 1987). Mercury can cause decreased hatchability of avian eggs (Connors *et al.* 1975), boron has been shown to reduce hatchability of waterfowl eggs in laboratory experiments (Smith and Anders 1989), and arsenic may also adversely affect avian reproduction (Stanley *et al.* 1994).

Hothem and Powell (2000) analyzed 23 western snowy plover eggs collected from 5 sites (Camp Pendleton Marine Corps Base, Batiquitos Lagoon, Naval Amphibious Base Coronado, Sweetwater Marsh National Wildlife Refuge, and Tijuana Estuary) in southern California from 1994 to 1996 for metals and trace elements, and 20 eggs for organochlorine pesticides and metabolites. All eggs were either abandoned or failed to hatch. Organochlorines, including dieldrin, o,p’-DDD, o,p’-DDE, o,p’-DDT, p,p’-DDD, p,p’-DDE, p,p’-DDT, oxychlordane, and trans-nonachlor were found above the detection limits in western snowy plover eggs. Median DDE and PCB concentrations were less than those normally associated with eggshell thinning. deformities, or other detrimental effects on birds. Twelve metals and trace elements (arsenic, boron, chromium, copper, iron, magnesium, manganese, mercury, nickel, selenium, strontium and zinc) were detected in at least 90 percent of the samples, but generally at background levels. Mean concentrations of all contaminants were below those that would adversely affect reproduction.

Concentrations of mercury in western snowy plover eggs that failed to hatch at Point Reyes National Seashore were five to ten times higher than the mercury concentrations in the five Southern California locations studied by Hothem and Powell (Schwarzbach *et al.* 2003). The mean mercury concentration of 1.07 micrograms/gram (1.07 parts per million), wet weight, in western snowy plover eggs from Point Reyes National Seashore is probably high enough to account for egg failure through direct toxic effects to western snowy plover embryos (Schwarzbach *et al.* 2003). Because only failed and abandoned eggs were taken rather than randomly collected eggs, the extent of mercury contamination of the entire breeding western snowy plover population at Point Reyes can not be reliably assessed from these data; however, the data from the 2000 field season would suggest that about one fifth of the nests appeared to be at risk from adverse effects of mercury (Schwarzbach *et al.* 2003).

***e. Litter, Garbage, and Debris***

Placement of litter, garbage, and debris in the coastal ecosystem can result in direct harm to western snowy plovers and degradation of their habitats. Litter and garbage feed predators and encourage their habitation at higher levels than would otherwise occur along the coast, making predators a greater threat to western snowy plovers. For example, as noted previously, the California gull (*Larus californicus*) has become far more prevalent in the South San Francisco Bay area. Currently, the estimated 25,000 California gulls in this area feed in landfills and forage in salt marshes using habitat that once supported the western snowy plover (J. Albertson, pers. comm. 2005).

Marine debris and contaminated materials on the beach also adversely affect western snowy plovers. Marine debris is attributed to both ocean and shoreline sources. Ocean sources of marine debris and contamination include fishing boats, ships, and cruise lines. Cruise line debris may include small plastic shampoo, conditioner, hand lotion, and shoe polish containers, plastic cups, and balloons (Center for Marine Conservation 1995). Shoreline debris is usually from land sources. Western snowy plovers may become entangled in discarded fishing line, fishing nets, plastic rings that hold together six-packs of canned drinks, and other materials on the beach. Containers of contaminated materials (***e.g.***, motor oil, cleaning fluid, and syringes) can introduce toxic chemicals to the beach. The National Marine Debris Monitoring Program, headed by the U.S. Environmental Protection Agency, was established to clean and track sources of marine debris in coastal areas. This monitoring program, while beneficial to western snowy plovers in the long-term, could potentially adversely affect nesting western snowy plovers since the program is conducted year-round. Similarly, the annual spring SOLV beach cleanup held on the Oregon Coast in late March and the annual Coastal Cleanup Day held on the California coast in September are two organized beach events that are poorly timed with respect to prospecting and nesting western snowy plovers. These programs could greatly improve western snowy plover habitat if timed appropriately.

***f. Water Quality and Urban Run-off***

Many coastal beaches used as habitat by western snowy plovers contain channelized streams or outfalls receiving run-off from urban, industrial, and agricultural areas. Nonpoint sources of water pollution (including hydrocarbons, heavy metals, and household chemicals) could end up at coastal beaches used as western snowy plover foraging areas. In 1995, three dead male western snowy plovers (all banded and local breeders) were found in an area containing local outfalls, including an outfall connected to a sewage treatment plant at Monterey Bay. By the beginning of the next breeding season, it was discovered that another male western snowy plover from this area disappeared and possibly died. Factors unrelated to the outfall have not been ruled out in the disappearance of this bird. One of the birds was analyzed through necropsy and found to have an enlarged liver, but it could not be determined whether there was a relationship between the mortality and the outfall (Point Reyes Bird Observatory unpublished data).

### *g. Management for Other Special Status Species*

In several instances fencing used to enclose California least tern colonies has caused mortality of western snowy plover chicks that have become entangled within the fence mesh (Powell and Collier 1995, Powell *et al.* 1995), or prevented western snowy plover chicks from following their parents to feeding areas by blocking their movement (Powell *et al.* 1996). These issues have largely been resolved by utilizing fencing with a mesh size of less than 0.64 centimeter (0.25 inch), tightening gaps in fencing seams, and installing "gates" in tern fencing (Foster 2005). Monitoring and minimization measures to avoid these impacts continue to be implemented in coordination with the appropriate Fish and Wildlife Offices. Increasing density and abundance of California least terns within colonies may also result in western snowy plovers being displaced a short distance, but the benefits of tern management for western snowy plovers appear to outweigh such conflicts.

At the Channel Islands and other lands managed by the National Park Service and the Department of the Navy, a decline of western snowy plovers may be caused by disturbance and habitat loss resulting from the large increase in numbers of marine mammals on beaches (U.S. Fish and Wildlife Service *in litt.* 1995, U.S. Department of the Navy *in litt.* 2001). Breeding pinnipeds, including northern elephant seals (*Mirounga angustirostris*), northern fur seals (*Callorhinus ursinus*) and California sea lions (*Zalophus californianus*) at San Miguel Island and San Nicolas Island, have occupied western snowy plover nesting habitat. Beach-cast dead whales have, on occasion, posed threats to nesting western snowy plovers. At Point Reyes beaches, large, whole carcasses have washed ashore and other agencies such as the National Marine Fisheries Service have sought to collect them for scientific purposes. They also attract people who are curious about whales. These activities could potentially cause direct mortality and disturbance to western snowy plovers. In addition, mammal carcasses attract scavengers such as gulls, ravens, crows, and coyotes that are potential predators to western snowy plovers.

## E. IMPLICATIONS FOR THE COASTAL BEACH-DUNE ECOSYSTEM

The western snowy plover lives in an ecosystem that has been significantly degraded. Environmental stressors (*i.e.*, development, human recreation, degraded water quality, etc.) have adversely affected the biological diversity of the coastal dune ecosystem. Many of the characteristics that attract people to coastal areas make these areas prime habitat for fish and wildlife resources. Although they comprise less than 10 percent of the Nation, coastal ecosystems are home to over one-third of the United States human population, nearly two-thirds of the Nation's fisheries, half of the migratory songbirds, and one-third of our wetlands and wintering waterfowl (U.S. Fish and Wildlife Service 1995*a*). The coasts also provide habitat for 45 percent of all threatened and endangered species, including three-fourths of the federally-listed birds and mammals (U.S. Fish and Wildlife Service 1995*a*). Proper stewardship of this unique ecosystem is needed to maintain its ecological integrity while meeting its human demands.

**1. Description of Coastal Beach-Dune Ecosystem**

The coastal beach-dune ecosystem may include several features such as beaches, foredunes, deflation plains, blow-outs, and reardunes. The beach includes the expanse of sandy substrate between the tide line and the foredune or, in the absence of a foredune, to the furthest inland reach of storm waves. Beach steepness, height, and width are affected by wave height, tidal range, sand grain size, and sand supply. The beach has high exposure to salt spray and sand blast and contains a shifting, sandy substrate with low water-holding capacity and low organic matter content. Dunes include sandy, open habitat, extending from the foredune to typically inland vegetation on stabilized substrate. Major differences occur between beach and dune in salt spray, soil salinity, and air and soil temperatures (Barbour and Major 1990).

Coastal dunes generally consist of three primary zones (Powell 1981). The foredunes are the line of dunes paralleling the beach behind the high tide line. Foredunes are characterized by unstabilized sand and a simple community of low-growing native dune plant species, such as American dunegrass (*Leymus mollis*). Foredunes also support a rich community of sand-burrowing insects (Powell 1981). Behind the foredunes is the deflation plain, which is at or near the water table and is characterized by a mixture of water tolerant plants and dune species. Deflation plains are also called dune hollows and can be invaded by hydrophilic (having a strong affinity for water) trees, shrubs, or herbs (*e.g.*, species of *Carex, Juncus, Salix, Scirpus*) (Barbour and Major 1990). The inner zone of coastal dunes consists of stabilized dunes, which are dominated by woody perennial plants (Powell 1981). Beach flora can also colonize inland dune areas, where the sand is actively moving (Barbour and Major 1990).

Barren dunes, receiving sand from the beach and losing it to wind erosion, are mobile. Older, more inland dunes are stabilized by a nearly continuous plant cover; these dunes are referred to as stable dunes or fixed dunes. Localized openings in the plant cover, which permit wind erosion, are called blowouts, but they are not deep enough to allow invasion by mesophytes (plants growing in moderately moist environments). The innermost ridge of sand is generally high and is called a precipitation ridge; sand is blown over the ridge and down the slipface, continuing the process of dune advance (Barbour and Major 1990). The conditions necessary for dune growth at the coast are partly climatic, but more important is the occurrence of strong onshore winds, abundant sand supply, and vegetation that traps sand. Low, near-shore slopes with a large tidal range providing wide expanses of sand that dries at low tide are ideal for dune growth (Pethick 1984).

Very few coastal dunes are “natural,” because they have been extensively altered over time by humans for agriculture, mineral extraction, military training, and recreation (Carter 1988). Before the introduction of European beachgrass, foredunes were low and rose gradually, and a large number of native species shared this habitat. They were composed of a series of dunes alternating with swales oriented perpendicular to the coast and aligned with prevailing onshore winds. Since the introduction of European beachgrass, most systems have been replaced by a steep foredune that gives way inland to a series of dunes and swales oriented parallel to the coast (Barbour and Major 1990).

Western snowy plovers use the beach and mobile dunes as nesting habitat. Other habitat features that occur within or adjacent to the coastal beach-dune ecosystem, and serve as important foraging habitat for the western snowy plover, include river, stream, and creek mouths, river bars, lagoons, and tidal and brackish-water wetlands.

## 2. Sensitive Species of the Coastal Beach-Dune Ecosystem

Along with the western snowy plover, many other sensitive species inhabit the coastal beach-dune ecosystem and adjacent habitats. Appendix E contains a list of, and brief species accounts for, sensitive species associated with this ecosystem and adjacent habitats. We recognize these fish and wildlife species as endangered, threatened, candidate species, or species of concern. This list includes a number of sensitive species recognized by the states of California, Oregon, and Washington. This appendix also describes several marine mammals associated with the coastal beach-dune ecosystem and protected under the Marine Mammal Protection Act of 1972 (16 U.S.C. 1361 *et. seq.*), as amended.

Some of these sensitive species have many threats in common with the western snowy plover. Habitat loss and degradation from shoreline development and beach stabilization, invasion of exotic species, and crushing by off-road vehicles are cited as major factors contributing to the status and listing of these species. European beachgrass is a current or potential threat to six federally-listed endangered plants that occur in coastal dunes of California: beach layia (*Layia carnosa*), Howell's spineflower (*Chorizanthe howellii*), Monterey spineflower (*Chorizanthe pungens* var. *pungens*), Menzies' wallflower (*Erysimum menziesii*), Monterey gilia *(Gilia tenuiflora* ssp. *arenaria*), and Tidestrom's lupine (*Lupinus tidestromii*) (Pickart 1997). European beachgrass is also a current and potential threat to native and sensitive plants in Washington and Oregon, including the pink sand-verbena (*Abronia umbellata* ssp. *breviflora*), which is classified as endangered in the State of Oregon. Equestrian use has also been identified as a threat to several endangered plant species, including the endangered Howell's spineflower, Menzies' wallflower, Monterey gilia, and the coastal dunes milk vetch (*Astragalus tener* var. *titi*). Off-road vehicles are cited as threats to several sensitive plant and animal species, including the endangered beach layia, Menzies' wallflower, Monterey gilia, Tidestrom's lupine, Hoffman's slender-flowered gilia (*Gilia tenuiflora* var. *hoffmanii*), and Smith's blue butterfly (*Euphilotes enoptes smithi*); the federally endangered La Graciosa thistle (*Cirsium longholepis*), and the following species considered to be of Federal concern: beach spectacle pod (*Dithyrea maritima*) and Morro blue butterfly (*Icaricia icarioides morroensis*).

The precarious status of these species is a symptom of a highly stressed ecosystem. Remedial efforts aimed at restoration of the natural processes that maintain this ecosystem, rather than single-species “fixes,” are likely to have the greatest and most successful long-term benefits. Important components of ecologically-sound coastal beach-dune ecosystem management include (1) removal of exotic, invasive vegetation; (2) management of human recreation to prevent or minimize adverse impacts on dune formation, vegetation, invertebrate and vertebrate fauna; and (3) efforts to counter the effects of human-induced changes in the types, distribution, numbers, and activity patterns of predators. Implementation of more ecosystem-oriented approaches to western snowy plover protection would provide important benefits to other sensitive species within the coastal dune ecosystem and merits serious consideration.

Some western snowy plover recovery efforts implemented to date (*e.g.*, removal of European beachgrass) support the natural functions of the coastal dune ecosystem. Furthermore, many protection efforts for western snowy plovers should benefit other sensitive beach species, such as California least terns, and vice versa. Many of the same predators that take western snowy plover eggs also prey on California least tern eggs. The relatively low rate of predation of western snowy plover nests in San Diego County has been attributed to predator control programs to benefit California least terns and other species, funded primarily by the Department of Defense and National Wildlife Refuge System (Powell *et al.* 1995). These programs are implemented under contract with the U.S. Department of Agriculture, Wildlife Services branch. Control of ants at California least tern colonies probably also benefits western snowy plovers nesting nearby. Opportunities also may exist for reestablishment of special status plant species that occur in coastal dunes, including Menzies’ wallflower, beach spectacle pod, Tidestrom’s lupine, beach layia, and pink sand verbena.

Some conflicts have occurred in management of western snowy plovers and California least terns in southern California, including harm to western snowy plover chicks due to entanglement in the mesh of California least tern fencing as described above. These problems have now largely been minimized with the use of new methods and materials, however such management measures should continue to be coordinated to meet the habitat needs of both western snowy plovers and California least terns.

Potential conflicts also exist between native dune restoration and western snowy plover habitat. Revegetation efforts could result in too much cover, thereby reducing the amount of suitable breeding habitat available for western snowy plovers.

Conflicting habitat requirements for western snowy plovers and pinnipeds have also occurred on lands where marine mammals haul out or breed on beaches that would otherwise be suitable for nesting western snowy plovers (U.S. Fish and Wildlife Service *in litt.* 1995, U.S. Department of the Navy *in litt.* 2001). Where this conflict continues to occur, coordination with land management agencies and NOAA's National Marine Fisheries (NMFS) may be helpful to identify methods for modifying or discouraging use by breeding pinnipeds during the western snowy plover nesting season.

Although some management measures may benefit a broad array of sensitive species within the coastal dune ecosystem (*i.e.*, control of *Ammophila,* access restrictions, and integrated predator management programs), some single-species protection measures for the western snowy plover, such as exclosures, are needed. Although exclosures can be risky to nesting western snowy plovers in some situations (see Lauten *et al.* 2006), they can be an effective way to protect nests against heavy recreational use and predation, especially where reductions in predator numbers would otherwise be temporary and difficult to achieve or would have adverse ecological effects.

## F. CONSERVATION EFFORTS

Western snowy plover recovery efforts have accelerated since this population was federally listed as a threatened species in 1993. Current breeding and wintering site protection efforts are documented in Appendix C (Summary of Current and Additional Needed Management Activities). The most common management strategies include protection of nests with predator exclosures; signing and symbolic fencing of nesting areas; restrictions on motorized vehicles in the vicinity of western snowy plover nests and broods; restrictions on dogs (even though enforcement of dogs on-leash has been problematic); and public information and outreach. These strategies are effective means of improving western snowy plover reproductive success.

**1. Conservation Planning on Federal and State Lands**

The direction of land management on Federal lands is often outlined in management plans or agency regulations that provide objectives and guidelines for western snowy plovers. These plans include the Naval Base Coronado Integrated Natural Resources Management Plan (U.S. Navy 2001), Camp Pendleton Integrated Natural Resources Management Plan (U.S. Marine Corps 2006), San Diego Bay National Wildlife Refuge Comprehensive Conservation Plan (U.S. Fish and Wildlife Service 2006*c*), Oregon Dunes National Recreation Area Management Plan (U.S. Forest Service 1994), the Coos Bay Shorelands Final Management Plan (U.S. Bureau of Land Management 1995*a*), the New River Area of Critical Concern Management Plan (U.S. Bureau of Land Management 1995*b*), the Draft Snowy Plover Management Plan for Ocean Beach, Golden Gate National Recreation Area (Hatch 1997), and the Western Snowy Plover Management Plan for the Point Reyes National Seashore (White and Allen 1999).

Wildlife protection, especially the preservation, restoration, and enhancement of threatened and endangered species and migratory birds, is the primary goal of national wildlife refuges, as stated in the National Wildlife Refuge System Administration Act of 1997 (16 U.S.C. 668dd *et. seq.*). Western snowy plover habitat on national wildlife refuges has been accorded intensive protection, including (1) integrated predator management and (2) closures during the nesting season where appropriate, to minimize adverse effects of disturbance. Consistent with requirements of the National Wildlife Refuge System Administration Act and the Refuge Recreation Act of 1962, as amended (16 U.S.C. 460k *et. seq.*) regarding compatibility of refuge activities, western snowy plover nesting areas within some national wildlife refuges are closed to public use during the breeding season. Western snowy plover use areas within some national wildlife refuges (such as Salinas River National Wildlife Refuge) are closed to public use year-round.

Additionally, the Department of Defense manages for western snowy plovers on military installations through actions associated with section 7 of the Endangered Species Act and through conservation planning efforts (*e.g.*, Programmatic Activities and Conservation Plans in Riparian and Estuarine/Beach Ecosystems on Marine Corps Base Camp Pendleton, 1995; see also Federal Regulatory Program, below). This includes avoidance and minimization measures, which have resulted in individual military installations placing limits on or otherwise restricting military activities and implementing management actions to specifically benefit western snowy plovers, such as monitoring, predator control, habitat improvement, and research. This management, in conjunction with other factors such as habitat availability and restricted public access, has allowed certain Department of Defense lands to significantly contribute to regional western snowy plover populations.

The *Washington State Recovery Plan for the Western Snowy Plover* recommends strategies to recover this species, including protection of the population, evaluation, and management of habitat, and initiation of research and education programs (Washington Department of Fish and Wildlife 1995).

The State of Oregon's *Conservation Program for the Coastal Population of the Western Snowy Plover*, required by the Oregon Endangered Species Act and adopted by the Oregon Fish and Wildlife Commission (Oregon Revised Statutes 496.171 through 496.192), requires a variety of actions to protect this subspecies. These actions include: (a) protecting all existing western snowy plover sites from negative impacts; (b) monitoring impacts and responding to damaging activities (*e.g.*, urban development and recreation disturbance) to minimize or eliminate their effects to western snowy plovers; (c) maintaining a long-term monitoring program to track numbers, distribution, and nesting success; (d) habitat management, such as local control of European beachgrass and maintaining predator protection measures to maximize breeding success for as long as deemed necessary; (e) conducting additional research to maintain and recover western snowy plovers; and (f) enhancing information availability, education, and awareness of western snowy plovers and their requirements for survival and recovery (Oregon Department of Fish and Wildlife 1994).

The California Public Resources Code (Section 5019.71) allows designation of natural preserves, the most protective designation given to a part of any California State Park system unit. The purpose of natural preserves is to preserve such features as rare or endangered plant and animal species and their supporting ecosystems, and representative examples of plant or animal communities existing in California prior to the impact of civilization. The Pajaro Rivermouth Natural Preserve, Wilder Creek Natural Preserve, and Salinas Rivermouth Natural Preserve were designated by the California State Park and Recreation Commission in recognition of the need to protect western snowy plovers. In addition, Section 5019.62 of the California Resources Code allows the designation of State seashores to preserve the outstanding values of the California coastline and provide for public enjoyment of those values. Within the state of California, the following California State seashores containing western snowy plover habitats have been established: Del Norte State Seashore; Clem Miller State Seashore; Sonoma Coast State Seashore; Año Nuevo State Seashore; Monterey Bay State Seashore; San Luis Obispo State Seashore; Point Mugu State Seashore; Capistrano Coast State Seashore; and San Diego Coast State Seashore. Under the California Public Resources Code, the California Department of Parks and Recreation has the authority to identify additional lands appropriate for inclusion in California State seashores and recommend land acquisition for these purposes.

Special management actions for western snowy plovers are conducted within the portions of California State Seashores that are owned by the California Department of Parks and Recreation. An example is the Monterey State Seashore, where the California Department of Parks and Recreation has conducted intensive management activities for western snowy plovers since 1991. Strategies include resource management, interpretation, law enforcement, and park operations. Resource management actions include monitoring, predator trapping, and use of exclosures, symbolic fences, and signage, and consideration of snowy plovers during planning recreational access and trails in San Francisco Bay. Interpretative efforts include informational signage at nesting areas, information brochures, small handout cards with photographs and information on western snowy plovers, several annual public outreach programs (***e.g.***, slide programs and field trips), and actions to engage community support for the western snowy plover guardian program (***i.e.***, recruitment, training, and scheduling for volunteer presence in sensitive habitat).

Enforcement actions include verbal warnings, written warnings, citations, and arrests as necessary. Key enforcement concerns include dogs off-leash and off-road vehicles, which are prohibited on all beaches. Operational management includes a permit process that screens special events to avoid the nesting season in sensitive areas, and regulation of recreational use of beaches to avoid sensitive areas (*i.e.*, kite flying, hang gliding, fishing, etc.). Other management actions on California Department of Parks and Recreation property within some other State seashores are shown in Appendix C.

**2. Conservation Efforts on Federal and State Lands**

***a. Exclosures, Symbolic Fencing, and Signs***

Since 1991, one of the primary techniques to protect nesting western snowy plovers has been the use of exclosures (Appendix F). Exclosures are small, circular, square, or triangular metal fences that can be quickly assembled and are designed to keep predators out of nests and/or prevent people from trampling nests (Figure 8). Exclosure designs are described in Appendix F; modifications to exclosure design in response to site specific predator conditions may be appropriate on a case by case basis but should be coordinated in advance with the Fish and Wildlife Service.

Nests protected from predators by exclosures have consistently had increased nest success (White and Hickey 1997, Stern *et al.* 1991, Craig *et al.* 1992, Mabee and Estelle 2000, U.S. Fish and Wildlife Service 2002, Lauten *et al.* 2006). At some locations in Oregon and California, exclosures are designed with tops consisting of parallel lengths of nylon seine lines spaced approximately 15 centimeters (6 inches) apart -or- mesh netting with a minimum spacing of approximately 10 centimeters (4 inches), designed to discourage entry by avian predators. At Eden Landing State Ecological Reserve in San Francisco Bay, nest predation decreased from 32 percent in 2000 to 3 percent in 2001, largely due to a switch from string tops to net tops on exclosures (Marriott 2001).

**Figure 8.** Erecting western snowy plover exclosure (photo by Sue Powell, with permission).

Although exclosures are contributing to improved productivity and population increases in some portions of the western snowy plover's Pacific coast range, problems have been noted in some localities. Potential risks associated with exclosures include vandalism, disturbance of the birds by curiosity seekers, and use of exclosures as predator perches. Over time, exclosures may provide a visual cue to predators, making it easier for them to target adults, chicks, and eggs, and requiring predator management. On several occasions depredations of adult western snowy plovers have been documented in or near exclosures, and efforts have been made to establish exclosures later in the season after the peak migration of raptors (Brennan and Fernandez 2004, Lauten *et al.* 2006). Also, predator exclosures may be impractical where western snowy plovers nest within California least tern colonies or other instances where such exclosures may conflict with the needs of other threatened or endangered species.

Symbolic fencing also is used to passively protect western snowy plover nests, eggs, and chicks during nesting season. This fencing consists of one or two strands of light-weight cord or cable strung between posts to delineate areas where humans (*e.g.*, pedestrians and vehicles) should not enter (Figure 9). It is placed around areas where there are nests or unfledged chicks, and is intended to prevent accidental crushing of eggs, flushing of incubating adults, and, if large enough, to provide an area where chicks can rest and seek shelter when large numbers of people are on the beach. Directional signs (regarding closed areas, nesting sites, etc.) also are used within western snowy plover habitats and near protective fencing to alert the public and other beach users of the sensitivity of western snowy plover nesting and wintering areas. Installation of symbolic fencing at Coal Oil Point Reserve (CA-88) in conjunction with a docent program has allowed management of

**Figure 9.** Symbolic fencing on beach at Monterey Bay, California (photo by Ruth Pratt, with permission).

recreational use and resulted in successful re-establishment of a breeding population of western snowy plovers at the site (Lafferty *et al.* 2006).

Additionally, land managers may prevent or restrict access to areas used by nesting western snowy plovers. For example, military installations often curtail or redirect training activities near western snowy plover nesting areas and some State parklands and recreation areas restrict public access in certain areas during the breeding season.

### *b. Law Enforcement*

Management agencies recognize that law enforcement is needed for protection measures to be effective. Though a majority of beach visitors respect restrictions to protect western snowy plovers, there will always be a certain percentage who do not. Enforcement of western snowy plover area restrictions shows that managers are serious about compliance. In Oregon, biologists have established a working relationship with a variety of law enforcement agencies who have jurisdiction in western snowy plover habitat. Their goal is to increase awareness, gain advice, increase communication and coordination to alleviate jurisdictional conflicts, and train officers on how to minimize disturbance while patrolling western snowy plover habitat. Conflicting priorities and personnel turnover require perseverance to maintain effective working relationships across law enforcement jurisdictions.

### *c. Predator Control*

Lethal and nonlethal means of predator control have been used with mixed success to protect western snowy plovers on Pacific beaches. Nonlethal methods include litter control at campgrounds (to reduce available food sources), exclosures and fencing, and trapping and relocation. Lethal methods include reducing local populations of avian predators by addling (*i.e.* killing the developing chick within the egg) of raptor and corvid eggs, trapping and euthanizing nonnative mammalian predators, and killing individual predators upon which nonlethal methods have proven ineffective.

On the Oregon Coast, snowy plover predator control has historically been in the form of nest exclosures and site specific lethal control. The use of nest exclosures, adaptively modified in response to predator behavior, has been very successful in increasing hatching success. However, because in some cases predation on adults has been linked to the presence of exclosures, their use is presently targeted to specific instances where it appears most beneficial, and the program is working toward elimination of exclosure use (Lauten *et al.* 2006a, 2006b).

In 2002, Federal and State agencies approved an integrated predator management program to improve western snowy plover nesting and fledging success in Oregon. The decision followed public review and comment on an analysis of the effects of the proposed predator control methods and alternatives to protect the western snowy plover in Oregon (U.S. Department of Agriculture 2002). To date lethal predator control has been implemented at selected plover breeding sites along the Oregon Coast at Coos Bay North Spit, Bandon Beach, New River, Siltcoos, Overlook, Tahkenitch, and Tenmile, resulting in an overall positive effect on western snowy plover productivity (Lauten *et al.* 2006*a*, 2006*b*).

Another form of predator control is fencing, which is used on the south spoils area of Coos Bay, North Spit, where the U.S. Bureau of Land Management, U.S. Army Corps of Engineers, and Oregon Department of Fish and Wildlife have fenced 8 hectares (20 acres) of western snowy plover nesting habitat. This wire mesh fence was installed to exclude mammalian predators, especially skunks, and to discourage human disturbance from off-highway vehicle use. The original fence, constructed in 1991, suffered from the effects of weathering and although it continued to deter vehicles, it was no longer an effective barrier to predators. In 1998, the U.S. Army Corps of Engineers and U.S. Bureau of Land Management jointly constructed a new fence and removed the old fence. The new fence matched the design of the 1991 fence (5-centimeter by 5-centimeter (2-inch by 2-inch) mesh fence material with an effective fence height of about 1.2 meters (4 feet) after burial of the bottom). However, the new fence has increased the protected area from 8 hectares (20 acres) to 28 hectares (71 acres), and includes both the south spoils area and the 1994 Habitat Restoration Area (E.Y. Zielinski and R.W. Williams *in litt.* 1999).

At the Don Edwards San Francisco Bay National Wildlife Refuge, fences are sometimes constructed across salt pond levees to block access by terrestrial predators (J. Albertson *in litt.* 1999). However, fences are not feasible in many areas, and do not restrict aerial predators.

Exclosures are much more effective when used in conjunction with an integrated predator management program that includes selective removal of non-native predators and other individual problem predators. Otherwise, exclosures may promote better hatching success, but not fledging success if predators such as red fox

(*Vulpes vulpes*) focus on adults protecting the nest or newly-hatched chicks that leave the exclosure to feed. These measures are also much more effective where combined with other access restrictions to increase survival of clutches and broods. Trapping the nonnative red fox has been credited with substantially increased western snowy plover abundance and productivity at Salinas River National Wildlife Refuge (E. Fernandez, U.S. Fish and Wildlife Service, pers. comm. 1998). At the Don Edwards San Francisco Bay National Wildlife Refuge, predation on western snowy plovers and California clapper rails by red foxes prompted the initiation of a predator management program targeting red foxes, feral cats, skunks, and raccoons, in conjunction with use of western snowy plover nest exclosures (J. Albertson *in litt.* 1999, Strong *et al.* 2004). This ongoing program has resulted in improved nest success. Use of exclosures has subsequently been discontinued due to the success of the trapping program and incidents of nest abandonment at exclosures. At Eden Landing Ecological Reserve selective removal of problem corvids and their nests has also been practiced by USDA Wildlife Services since 2004 (Tucci *et al.* 2006).

The U.S. Air Force has used electric fencing around the California least tern colony at Purisima Point, Vandenberg Air Force Base, California, where western snowy plovers also nest and winter. The electrified portion of this fence is approximately 273 meters (300 yards) long and 1.2 meters (4 feet) high. The electric fence contains six strands of electrified wire placed approximately 10.2 centimeters (4 inches) apart. This fence is generally effective at keeping out mammalian predators of California least terns. It has also incidentally protected a small population of western snowy plovers by deterring western snowy plover predators.

Proposals have been developed to test a conditioned taste aversion technique on predators of piping plovers (*i.e.*, red fox) by using quail eggs treated with the chemical emetine (McIvor 1991). The purpose of this technique is to condition foxes to avoid eating plover eggs, expecting that if foxes eat treated quail eggs prior to the nesting season and become sick, they might develop a conditioned aversion to eating plover eggs. This technique requires that the predator consumes the needed dose that will produce short-term illness but no mortality. Due to uncertainty in effectiveness, at this point in time we do not advocate this taste aversion technique. Proposals to test conditioned taste aversion techniques on predators of piping plovers on the east coast have not been implemented due to difficulties obtaining permission to field test emetine (A. Hecht, U.S. Fish and Wildlife Service, pers. comm. 1996). Avery *et al.* (1995) found that deployment of quail eggs treated with the chemical methiocarb might be a useful means of reducing predation of California least terns by ravens and crows. However, subsequent tests of aversion methods have proven to be unsuccessful (E. Copper and B. Foster *in litt.* 2001).

With proper research, techniques that have been used to deter predators of other wildlife species may prove beneficial to western snowy plovers. Strategic placement of crow and gull carcasses around the perimeter of a California least tern colony has been used at Vandenberg Air Force Base (Persons and Applegate 1996), however, this method may not be effective for more loosely colonial species such as snowy plover (J. Buffa *in litt.* 2004). Moreover, the presence of gull carcasses could prove counterproductive by attracting mammalian predators (N. Read, U.S. Air Force, pers. comm. 1998).

In 1999 Vandenberg Air Force Base initiated studies of coyote ecology and movements, with the goal of developing non-lethal alternatives for reducing coyote predation on western snowy plover. Although results are preliminary, in 2001 beach access restrictions and regular pick-up of trash, in combination with availability of alternative prey such as rabbits, may have contributed to the lowest incidence of coyote predation ever recorded at Vandenberg Air Force Base, even though evidence of coyote presence continued to be observed on a daily basis.

For top-level predators such as coyotes, western snowy plover nests are not a primary food source. Vandenberg Air Force Base has avoided large-scale coyote removal to prevent exacerbated predation on listed species from mesopredators such as racoons, and to prevent expansion of non-native predators such as feral cats and red foxes into western snowy plover nesting areas (N. Read Francine *in litt.* 2001).

***d. European Beachgrass Control***

Experiments to find cost-effective methods to control or eradicate European beachgrass are ongoing. Control methods employed in various situations have included foredune grading and foredune breaching with front-end loaders and bulldozers, subsoiling with a winged subsoiler (essentially a heavy duty three-point plow), discing with a standard farm tractor and disk, burning, saltwater irrigation, spraying of herbicide, and hand-pulling. Herbicide treatment is not always possible, however, when rare or federally-listed plants are present. In these cases hand-pulling or other mechanical removal may need to be employed. At Point Reyes National Seashore mechanical and hand-removal were used to remove non-native beach grass on 12 hectares (30 acres) with immediate beneficial response by nesting snowy plovers (Peterlein and Roth 2003). Some control methods are only suitable for the inland sites. Areas containing heavy growth of European beachgrass and woody vegetation are prescribed-burned prior to using heavy equipment. Areas are leveled to allow discing for maintenance. In some areas, oyster shell hash provided by a local oyster grower has been distributed after vegetation has been removed. Effectiveness of the various control methods varies, though some form of maintenance may always be required. Maintenance is critical and achieved through multiple treatments over a succession of years. Discing requires maintenance twice per year to keep beachgrass from reestablishing. Comparatively, yearly maintenance in portions of some restoration sites may not be needed after employing several years of bull-dozing, herbicides, or hand-pulling following initial mechanical removal.

Since 1994, multiple projects have been conducted in Oregon to control beachgrass on existing nest sites and to clear and maintain additional areas. These Habitat Restoration Areas (HRAs) are essential for the recovery of the western snowy plover. Three significant HRAs established on the Oregon Coast between 1994 and 2002 include the Dunes Overlook (Oregon Dunes National Recreation Area), Coos Bay North Spit, and New River. Other habitat restoration areas have recently been established or are planned at Baker Beach (140 acres), Tenmile Creek (200 acres) and Bandon Beach State Natural Area (30 acres). HRAs accounted for 34 percent of nests (Table 6) and 43 percent of fledglings (Table 7) found on the Oregon Coast between 1999 and 2004.

The Oregon Dunes National Recreation Area contains about 2,428 hectares (6,000 acres) of European beach grass and now has few remaining examples of intact native plant communities (Pickart 1997). Habitat restoration was initiated in the summer of 1998 and by 2002, the U.S. Forest Service had treated 24 hectares (60 acres) of the 208 hectares (516 acres) of habitat planned for restoration. Prior to 1999, no western snowy plovers were found at the Overlook site, but after habitat was restored, western snowy plovers began nesting there successfully (Table 6, Table 7).

The U.S. Forest Service employs a combination of mechanical, manual, and herbicide treatments to control European beachgrass. Mechanical treatment consists of scalping off the top 1 meter (3 feet) of beachgrass and then burying it in an adjacent trench with a minimum covering of l meter (3 feet) of sand. Moderate to heavy resprouting occurs with this method, requiring manual or chemical follow-up treatment. Other mechanical treatments have consisted of placement of dredged material on the beachgrass and scalping the top half of foredunes to remove beachgrass and allow for inland sand movement and tidal action to maintain open dunes (K. Palermo *in litt.* 1998*b*).

Herbicide treatments have been conducted as a primary control method and as follow-up to mechanical control. In recent years, from 2 to 26 hectares (5 to 65 acres) of beachgrass were sprayed with an herbicide treatment of 8 percent Rodeo and nonionic surfactant (spray-to-wet) at three locations. Employees found that a follow-up application within 2 weeks of the first application was critical to obtain optimum coverage and initial die-off rates (90 percent). Additionally, herbicide treatments were most effective when conducted consecutively over 2 to 3 years depending on density. Beachgrass control at the Oregon Dunes is still considered experimental. Preliminary results suggest that maintenance will always be necessary (K. Palermo *in litt.* 1998*b*).

**Table 6.** Total number of nests at habitat restoration areas on the Oregon Coast 1994-2004 (J. Heaney, pers. comm. 2003; C. Burns, pers. comm.; M. VanderHeyden, pers. comm.; Castelein *et. al.* 2002; Lauten *et al.* 2006).

On Coos Bay North Spit, the Bureau of Land Management has cleared and maintained approximately 67 hectares (166 acres) of vegetation dominated by European beachgrass, shore pine, Sitka spruce, and Scotch broom. The objective is to remove predator cover, remove encroaching beachgrass, and expand the existing habitat. The goal is to create an area for western snowy plovers to nest that is large enough to lessen possible detection of nests and chicks by predators. Nest sites used by western snowy plovers on the North Spit include both beach habitat and inland areas of previous dredged material deposition. Many of the cleared areas were used almost immediately by nesting western snowy plovers or for brood rearing activities. Prior to 1994, western snowy plovers were not nesting in these areas, but after 1994, the Coos Bay North Spit became the most productive western snowy plover nesting sites on the Oregon Coast (Table 6, Table 7) (M. VanderHeyden, Bureau of Land Management, pers. comm.).

At the Coos Bay North Spit, an inmate crew from the Shutter Correctional Facility, hired by the U.S. Bureau of Land Management, hand pulled European beachgrass on approximately 6 hectares (15 acres) of the south spoil area. The 4-month project cost $11,500; most of these costs covered the crew supervisor’s salary and transport vehicle charges. Another European beachgrass removal project around the south spoil areas of the Coos Bay North Spit, included burning European beachgrass, followed by scarification using a bulldozer in March 1994. By August, most of the area had resprouted (Oregon Department of Fish and Wildlife 1996). New beachgrass sprouts are relatively easy to remove. However, initial and maintenance work can be costly and labor intensive. At the Coos Bay North Spit, eradication of European beachgrass using 91.4 centimeters (36 inches) of sprayed seawater was attempted in 1996. The saltwater application was not effective because desiccated sand layers did not allow seawater penetration to the grass’s root zone. Future experimentation using wetting agents to achieve water penetration on small-scale applications could demonstrate potential applicability of this technique (G. Dorsey, U.S. Army Corps of Engineers, pers. comm. 1997).

The New River Spit is another key nesting area for the western snowy plover that is managed by the Coos Bay U.S. Bureau of Land Management. Each year since 1998, the U.S. Bureau of Land Management has used heavy equipment (i.e., front-end loader, bulldozer) to remove European beachgrass from in and around a target restoration site. Typically, the bulldozer is used to push the beachgrass into depressions and bury it under several feet of sand, or to push sand and beachgrass out into the surf zone. Just over two miles of foredune have been lowered and select areas along the foredune have been removed to allow ocean surf to overwash into interior portions of the spit. The overwashing aids in scouring vegetation and appears to self-maintain portions of the overwashes throughout the restoration area. By 2002, approximately 48 hectares (120 acres) of foredune and overwash were cleared of beachgrass (Jim Heaney, Bureau of Land Management, pers. comm. 2003).

Work at Lanphere-Christensen Dune Preserve in Humboldt County, California, showed that hand pulling can eliminate European beachgrass, but 3 years of multiple maintenance treatments were required (Pickart and Sawyer 1998). Use of heavy equipment (*e.g.*, "V" ripper) and herbicides may be more cost-effective; however, resprouting of the grass occurs, necessitating follow-up, manual pulling for long-term beachgrass removal (A. Pickart, The Nature Conservancy, pers. comm. 1997).

The effective strategy used by the California Department of Parks and Recreation to remove beachgrass at Marina Dunes and Salinas River State Beaches, Monterey Bay, included multiple herbicide applications of 10 percent Round-Up. Approximately 25 patches of beachgrass covering a total of approximately 0.5 hectare (1.3 acres) have been treated along a 6.4-kilometer (4-mile) section of beach. Each patch of beachgrass was sprayed every 3 months over a 3-year period. All treated sites were marked so that they could be easily located and monitored for regrowth and spread. Current plans include beachgrass removal on approximately 30 hectares (75 acres) at Zmudowski State Beach at the Pajaro River mouth (D. Dixon *in litt.* 1998).

Western snowy plover habitat restoration efforts at the Leadbetter Point Unit of the Willapa National Wildlife Refuge began in 2002 and continue. American beachgrass and some European beachgrass have been mechanically removed, clearing approximately 25 hectares (63 acres) as of 2006. In addition, cuts have been made through the foredune and oystershell placed to cover 11 hectares (28 acres) within the restored area (K. Brennan *in litt.* 2006).

Pickart (1997) suggested that chemical treatment of European beachgrass is likely to be the most cost-effective method used to date. Herbicides that have been used for this purpose are glyphosates (trade names Rodeo and Round-Up). The most effective period for herbicide treatment of beachgrass is during its flowering stage (Wiedemann 1987); plants should be treated during periods of active growth (Pickart 1997). However, potential adverse biological impacts to other native plants and animals must be considered when using herbicides, and selective spraying may be difficult in some areas. Chemical treatment in active western snowy plover nesting areas may need to be limited to the period outside the breeding season in certain areas to avoid disturbing nesting western snowy plovers.

Additional management options for beach and dune erosion control are needed. Beachgrass continues to be used because it has been tried successfully in the past, nursery stock is available, and field planting technology is well known. However, negative aspects of its monoculture are recognized. Proper planting and management of a mixture of native vegetation, together with the provision of walkways for pedestrian traffic and the elimination of horse traffic, cattle grazing, and off-road vehicles, may result in stabilization as effective as beachgrass, yet there has been minimal experimentation with this technique (Barbour and Major 1990).

***e. Off-Road Vehicle Restrictions and Management***

Management strategies to reduce off-road and other vehicle impacts have been implemented at some western snowy plover breeding areas. At Pismo/Oceano Dunes State Vehicular Recreation Area, California, management strategies include fenced-off nesting areas; placement of exclosures around nests; restrictions on vehicle speed and access areas; and requirements that car campers remove all trash. At Pismo/Oceano Dunes State Vehicle Recreation Area, the California Department of Parks and Recreation, Off-Road Vehicle Division, has developed an interim management plan, which is adapted annually in coordination with us to address what effects current management measures have on hatching rates and fledging success, as well as recruitment into the western snowy plover population (California Department of Parks and Recreation 2005). The Off-Road Vehicle Division of the California Department of Parks and Recreation is now funding the development of a habitat conservation plan (in anticipation of applying for a section 10(a)(1)(B) permit under the Endangered Species Act) for the Pismo/Oceano Dunes State Vehicular Recreation

Area and other State parks within the San Luis Obispo Coast District of the California Department of Parks and Recreation.

The conservation issues for western snowy plovers and California least terns at the Pismo/Oceano Dunes State Vehicular Recreation Area are directing the development of the habitat conservation plan, but other species also will be covered. This plan will evaluate the effects that recreation and park management activities are having on the covered species.

On Camp Pendleton, the Marine Corps conducts its vehicle operations in and near nesting areas in ways that minimize impacts to western snowy plovers. Under the Marine Corps' Base Regulations all training activities, including vehicle training, are prohibited within 300 meters of fenced nesting areas during the breeding season (1 March to 15 September). Further, amphibious vehicles are directed to transit adjacent to nesting areas with tracks in the ocean whenever possible (U.S. Marine Corps 2006).

On the Don Edwards San Francisco Bay National Wildlife Refuge, part of the main access road (Marshlands Road) is closed to motorized vehicles from April 1 to August 31, to protect western snowy plovers nesting near the roadway. Highway traffic cones and ribbons are installed to discourage vehicle access to nesting areas on roads and levees (J. Albertson *in litt.* 1999).

In 1995, after the Oregon Dunes National Recreation Area completed its management plan, the U.S. Forest Service petitioned the Oregon Parks and Recreation Department to close several kilometers of beach that had been open to vehicles. Resulting closures reduced conflicts between off-highway vehicles and nonmotorized recreationists, western snowy plovers, and other wildlife (E.Y. Zielinski and R.W. Williams *in litt.* 1999).

Leadbetter State Park (immediately to the south of Willapa National Wildlife Refuge) is closed to beach driving from April 15 to the day after Labor Day. The entire beach along Willapa National Wildlife Refuge is closed to driving year round, except during razor clam openers (K. Brennan *in litt.* 2006). Diligent surveillance and enforcement by applicable agencies is extremely important due to the potential for violations.

### *f. Population Monitoring*

Western snowy plover researchers in Washington, Oregon and California conduct intensive population monitoring programs. Tasks include some or all of the following: (1) conducting winter and breeding season window surveys; (2) banding adults and chicks; (3) determining nest success; (4) determining fledging success, (5) monitoring and documenting brood movements; and (6) collecting general observational data on predators.

The Point Reyes Bird Observatory has been monitoring the distribution and breeding success of western snowy plovers since 1977. Monitoring at Vandenberg Air Force Base has been conducted by Point Reyes Bird Observatory and SRS Technologies. Additionally, Santa Barbara County-supported volunteer docents stationed at Surf Station, within Vandenberg Air Force Base, keep tallies of numbers of visitors, violations prevented, and predators seen (R. Dyste *in litt.* 2004). The U.S. Geological Survey Biological Resources Division monitored western snowy plovers in San Diego County from 1994 to 1998. Teams led by Elizabeth Copper, Robert Patton, Shauna Wolf, and Brian Foster have monitored western snowy plovers in San Diego County since 1999 for military installations. The Oregon Natural Heritage Program and The Nature Conservancy have conducted western snowy plover monitoring since 1990 in Oregon. The Point Reyes Bird Observatory, Oregon Natural Heritage Program, and U.S. Geological Survey, Biological Resources Division, also band western snowy plovers at some locations (Figure 10). The California Department of Parks and Recreation conducts annual monitoring throughout the state and at the Pismo/Oceano Dunes State Vehicular Recreation Area (J. Didion *in litt.* 1999). Mad River Biologists and Humboldt State University are currently conducting intensive population monitoring in northern California. Department of Defense installations continue to maintain long-term programs for monitoring and management of western snowy plover populations and predators in San Diego and Ventura Counties, including programs at Camp Pendleton, Naval Amphibious Base Coronado, Naval Radio Receiving Facility Imperial Beach, North Island, and San Clemente Island.

***g. Salt Pond Management***

Intensive management at the Moss Landing Wildlife Area has made a major contribution to western snowy plover breeding success in the Monterey Bay area. Management by Point Reyes Bird Observatory staff, in coordination with the California Department of Fish and Game, has been ongoing since 1995. Management activities include draw-down of water levels in part of the salt ponds at the beginning of the nesting season to provide dry sites for nests, and flooding of remnant wet areas twice per month through the nesting season to maintain foraging habitat for adults and their young. Predator control is conducted by the U.S. Department of Agriculture, Wildlife Services Branch.

The Don Edwards San Francisco Bay National Wildlife Refuge manages a former salt pond called the “Crescent Pond” (within location CA-36, mapped in Appendix L) for western snowy plovers by reducing the water levels prior to the breeding season. In the early 1990s, this pond was mostly unvegetated salt flat, but since then native pickleweed (*Salicornia virginica*) has slowly increased on the site, making the areas less valuable for western snowy plover nesting habitat. The Refuge has begun to conduct winter flooding in the Crescent Pond to reduce vegetative cover and improve western snowy plover nesting habitat.

The 2003 acquisition of Cargill's West Bay, Alviso, and Baumberg Salt Ponds in the South Bay by California Department of Fish and Game and Don Edwards San Francisco Bay National Wildlife Refuge will greatly further the goal of achieving 810 hectares (2,000 acres) of ponds managed for western snowy plover habitat (see Recovery Action 2.6). The Refuge's long-term management plans for these areas will include management that is compatible with western snowy plover and will coordinate with the recovery goals of this Recovery Plan (J. Albertson, pers. comm. 2005). Many of the salt ponds are currently used for breeding and wintering by western snowy plovers. San Francisco Bay Bird Observatory is assisting the Refuge with salt marsh management and western snowy plover monitoring.

### *h. Habitat Acquisition*

Acquisition and management of key sites is an important conservation effort. In October 1998, The Nature Conservancy transferred the approximately 193-hectare (483-acre) Lanphere-Christensen Dunes Preserve (part of Mad River Mouth and Beach, California, CA-7) to us for conservation purposes. The area will be managed by the Humboldt Bay National Wildlife Refuge for natural resources, including the western snowy plover. In October 1998, the Port of San Diego announced an agreement enabling approximately 560 hectares (1,400 acres) of Western Salt Company land (CA-131) to be managed by the San Diego National Wildlife Refuge. The salt ponds are a western snowy plover nesting and wintering area. As noted above, Cargill's transfer of the West Bay, Alviso, and Baumberg salt ponds, including 6,110 hectares (15,100 acres), to California Department of Fish and Game and Don Edwards San Francisco Bay National Wildlife Refuge was completed in 2003; portions of this area will be managed as western snowy plover habitat.

### *i. Use of Volunteers*

Volunteers contribute to the conservation of western snowy plovers and their habitat at many beach locations, including Morro Bay and Oceano Dunes State Vehicular

Recreation Area, Point Reyes National Seashore, and Golden Gate National Recreation Area. Volunteers and docents assist public land managers in many ways (Appendix K), including informing park visitors about threats to the western snowy plover, reducing human and pet disturbances, and assisting with direct habitat enhancement (*e.g.*, manual removal of European beachgrass; Figure 11). In 1998, the Western Snowy Plover Guardian Program was developed to assist the conservation and recovery of western snowy plovers in Monterey Bay. This program is mainly a volunteer effort by local citizens who assist in protecting western snowy plovers through monitoring, reporting, and educational activities (D. Dixon *in litt.* 1998).

**Figure 11.** High school students removing European beachgrass (photo by Kerrie Palermo, with permission).

### *j. Public Outreach and Education*

Public land managers and private conservation organizations have produced public educational materials, including brochures, posters, flyers, and informational/interpretative signs regarding western snowy plovers (Appendix K). Environmental education/interpretation is recognized by land management agencies as an important tool that supports their mission of resource stewardship. Increased understanding and appreciation of natural resources (specifically threatened and endangered species) often results in increased public support. This support is not easily measured and when the audience is children, results may not be seen until they reach adulthood. However, those agencies conducting western snowy plover education to date have found a positive response by individuals. In Oregon, on-site monitors of the U.S. Forest Service (Oregon Dunes National Recreation Area) and U.S. Bureau of Land Management report a willingness of the majority of contacted individuals to comply with restrictions after better understanding the reasons for them.

The La Purisima Audubon Society, Santa Barbara County, produced an educational video about the western snowy plover and the California least tern in 1999. It was distributed to public schools and museums within Santa Barbara County in 2000.

***k. Section 6 Cooperative Agreements***

Section 6 of the Endangered Species Act allows us to enter into cooperative agreements with states that establish and maintain active programs for the conservation of listed species. Through funding under section 6, those states assist the recovery of endangered and threatened species and monitor their status. Between 2000 and 2006, traditional section 6 funds have been used for creation of a docent program at Silver Strand State Beach in California ($8,300); development of a water management plan at Moss Landing Wildlife Area, California ($4,886); surveillance and protection of snowy plover nests on California beaches ($92,000); and surveys, nest monitoring, protecting nests with exclosures, collecting data on human uses of beaches, and encouraging beach uses compatible with snowy plovers in Oregon ($64,386) and Washington ($48,677). HCP Planning grants were used for development of a habitat conservation plan to address management of beach use by the Oregon Parks and Recreation Department ($103,950) and development of an Environmental Impact Statement for this Habitat Conservation Plan ($200,000). A Recovery Land Acquisition grant ($307,000) supported purchase of a conservation easement on 89 hectares (220 acres) of western snowy plover habitat along 3.7 kilometers (2.3 miles) of the Elk River Spit.

### 3. Conservation Efforts on Private Lands

Private landowners interested in conservation efforts for western snowy plovers and coastal dune habitats have made important contributions to recovery efforts for coastal dune species. At Ormond Beach, California, Southern California Edison has enhanced approximately 60 hectares (150 acres) of degraded wetlands and coastal dune habitat for several special status species, including the western snowy plover and California least tern (D. Pearson, Southern California Edison, pers. comm. 1996).

### 4. Federal Regulatory Program

#### *a. Critical Habitat*

On March 2, 1995, we published a proposed rule to designate critical habitat for western snowy plover at 28 areas along the coast of California, Oregon, and Washington (U.S. Fish and Wildlife Service 1995*b*). At that time, critical habitat was proposed to fulfill an outstanding requirement under section 4 of the Endangered Species Act to highlight important habitat areas on which activities that require Federal actions need to be evaluated under section 7 of the Endangered Species Act. A funding moratorium by the U.S. Department of the Interior for listing actions was in place during the period April 1995 to April 1996. We subsequently acknowledged a serious backlog of listing actions and the need to prioritize them (U.S. Fish and Wildlife Service 1996*b*). Hence, we developed guidance for assigning relative priorities to listing actions conducted under section 4 of the Endangered Species Act during fiscal years 1998 and 1999 (U.S. Fish and Wildlife Service 1998). Designation of critical habitat was placed in the lowest priority (Tier 3). Under this guidance, we placed higher priority on listing imperiled species that currently have limited or no protection under the Endangered Species Act than on devoting limited resources to the process of designating critical habitat for currently-listed species. In addition, we found that because the protection afforded by critical habitat designation applies only to Federal actions, such designation provides little or no additional protection beyond the "jeopardy" prohibition of section 7 of the Endangered Species Act, which also applies only to Federal actions (U.S. Fish and Wildlife Service 1998).

In December 1995, legal challenges by the Environmental Defense Center, Santa Barbara, California, against the U.S. Department of the Interior to finalize designation of critical habitat for the western snowy plover were overruled by the California District Court (U.S. District Court, Central District of California 1995). At that time, the Court's order was based on its decision that lack of funding prevented the Secretary of the Interior from taking final action on proposals for designating critical habitat. However, on November 10, 1998, the U.S. District Court for the Central District of California ruled that the Secretary of the Interior must publish a final designation of critical habitat for the western snowy plover before December 1, 1999 (U.S. District Court, Central District of California 1998).

A final rule designating critical habitat was published on December 7, 1999 (U.S. Fish and Wildlife Service 1999). In May of 2002 the Coos County Board of County Commissioners, Friends of Oceano Dunes, and Concerned Citizens for western Lane County filed a complaint asking for invalidation of the rule. The United States moved for voluntary remand to reconsider the economic analysis and for partial vacatur of the existing designation. On July 19, 2003, the District Court for the District of Oregon granted the United States' motion, ordering the Service on remand to consider the economic impact analysis and ensure that the new rule is based on the best scientific evidence available. This Order was converted to Judgment on July 2, 2003. Based on the potential for harm to the population, at the Service's request the court left most of the established units in place during the redesignation process, but vacated two units in southern California and two units in Washington.

On December 17, 2004, we published a new proposal to designate critical habitat for the Pacific coast distinct population segment of the western snowy plover (U.S. Fish and Wildlife Service 2004*b*). The final rule to designate critical habitat was published on September 29, 2005 (U.S. Fish and Wildlife Service 2005). This rule designated critical habitat in 32 units, compared to 28 units in the 1999 critical habitat final rule, but covers only 4,921 hectares (12,145 acres) compared to 7,881 hectares (19,474 acres) in the 1999 rule. Of the 32 units, 23 are in California, 5 are in Oregon, and 3 are in Washington. Of the total acreage, 1,002 hectares (2,478.5 acres), or 20 percent, are on Federal lands; 2620.5 hectares (6,474 acres), or 53 percent, are on land owned by States or local agencies; and 1294.5 hectares (3,191 acres), or 26 percent, are privately-owned.

It is important to understand what critical habitat means and how it differs from this recovery plan. Section 3 of the Endangered Species Act defines critical habitat to mean: (i) the specific areas within the geographical area occupied by the species at the time it is listed on which are found those physical or biological features (I) essential to the conservation of the species and (II) which may require special management considerations or protection; and (ii) specific areas outside the geographical area occupied by the species at the time it is listed, upon determination that such areas are essential for the conservation of the species. The term "conservation" is defined in section 3 as "the use of all methods and procedures which are necessary to bring any endangered species or threatened species to the point at which the measures provided pursuant to this Act are no longer necessary." Therefore, critical habitat is to include biologically suitable areas necessary to recovery of the species.

Section 7 of the Endangered Species Act requires Federal agencies to consult with us to evaluate the effects that any activities they fund, authorize, or carry out may have on designated critical habitat. Agencies are required to ensure that such activities are not likely to adversely modify (*e.g.*, damage or destroy) critical habitat. Because the issuance of permits under section 10(a)(1)(B) of the Endangered Species Act constitutes a Federal action or connection and is subject to an internal section 7 consultation, habitat conservation plans developed for actions on private lands must also analyze the potential for adverse modification of critical habitat. Accordingly, where Federal activities may affect western snowy plover critical habitat, we will consult with Federal agencies under section 7 to ensure that these actions do not adversely modify critical habitat.

Critical habitat designation does not create a wilderness area, preserve, or wildlife refuge, nor does it close an area to human access or use. It applies only to activities sponsored at least in part by Federal agencies. Such federally-permitted land uses as grazing and recreation may take place if they do not adversely modify critical habitat. Designation of critical habitat does not constitute a land management plan, nor does it signal any intent of the government to acquire or control the land. Therefore, if there is no Federal involvement (*e.g.*, Federal permit, funding, or license), activities of a private landowner, such as farming, grazing, or constructing a home, generally are not affected by a critical habitat designation, even if the landowner's property is within the geographical boundaries of critical habitat (U.S. Fish and Wildlife Service 1993*c*). Without a Federal connection to a proposed action, designation of critical habitat does not require that landowners of State or other non-Federal lands do anything more than they would otherwise do to avoid take of listed species under provisions of section 9 of the Endangered Species Act.

By comparison, a recovery plan delineates site-specific management actions that we believe are required to recover and/or protect listed species, establishes objective, measurable criteria for downlisting or delisting the species, and estimates time and cost required to carry out these actions. A recovery plan is not a regulatory document and does not obligate cooperating or other parties to undertake specific tasks or expend funds.

Critical habitat designation is not necessarily intended to encompass a species' entire current range. Recovery plans, however, address all areas determined to be important for recovery of listed species and identify needed management measures to achieve recovery. Because critical habitat designations may exclude areas based on factors such as economic cost, approved or pending management plans, or encouragement of cooperative conservation partnerships with landowners, the areas identified in recovery plans as important for recovery of the species may not be identical to designated critical habitat. The recovery units described in this recovery plan include but are not restricted to the 32 areas designated as critical habitat: Damon Point, Midway Beach, Leadbetter Point, Bayocean Spit, Baker/Sutton Beaches, Siltcoos to Tenmile, Coos Bay North Spit, and Bandon to Floras Creek in Recovery Unit 1; Lake Earl, Big Lagoon, McKinleyville area, Eel River area, MacKerricher Beach, and Manchester Beach in Recovery Unit 2; Point Reyes Beach, Limantour Spit, Half Moon Bay, Santa Cruz Coast, Monterey Bay Beaches, and Point Sur Beach in Recovery Unit 4; San Simeon Beach, Estero Bay, Devereaux Beach, Oxnard Lowlands in Recovery Unit 5; and Zuma Beach, Santa Monica Bay, Bolsa Chica area, Santa Ana River Mouth, San Onofre Beach, Batiquitos Lagoon, Los Penasquitos, and South San Diego in Recovery Unit 6. Implementation of the recovery actions in this recovery plan (*e.g.*, monitoring, habitat improvement, nest protection, recreation management) may not be limited to designated critical habitat areas.

### *b. Section 9 Take Prohibitions*

Section 9 of the Endangered Species Act of 1973, as amended, prohibits any person subject to the jurisdiction of the United States from taking (i.e., harassing, harming, pursuing, hunting, shooting, wounding, killing, trapping, capturing, or collecting) listed wildlife species. It is also unlawful to attempt such acts, solicit another to commit such acts, or cause such acts to be committed. Regulations implementing the Endangered Species Act (50 CFR 17.3) further define "harm" to include significant habitat modification or degradation that results in the killing or injury of wildlife by significantly impairing essential behavioral patterns including breeding, feeding, or sheltering. "Harass" means an intentional or negligent act or omission that creates the likelihood of injury to wildlife by annoying it to such an extent as to significantly disrupt normal behavioral patterns, which include, but are not limited to, breeding, feeding, or sheltering.

As an example under the authority of section 9 of the Endangered Species Act, on May 15, 1998, we received preliminary injunctive relief against the Town of Plymouth, Massachusetts, because their beach management failed to prevent take (killing) of a piping plover chick by an off-road vehicle (U.S. District Court for Massachusetts 1998). The judge's order prohibited off-road vehicle traffic through the piping plover's nesting season unless the town implemented specific management measures to preclude take, including twice-daily monitoring of nests and a 400-meter (1,148-foot) buffer of protected habitat for newly-hatched chicks.

The proposed special rule under section 4(d) of the Endangered Species Act (U.S. Fish and Wildlife Service 2006b) would exempt most recreational and commercial activities within a county from section 9 prohibitions on take of western snowy plovers, if documentation of conservation actions was provided and populations within the county met targets based on the Management Goal Breeding Numbers in Appendix B of the recovery plan. Research and monitoring actions would continue to require recovery permits under section 10(a)(1)(A) of the Endangered Species Act.

### *c. Section 10 Permits*

Section 10 of the Endangered Species Act and related regulations provide for permits that may be granted to authorize activities otherwise prohibited under section 9, for scientific purposes or to enhance the propagation or survival of a listed species (i.e., section 10(a)(1)(A) permits). These permits have been granted to certain biologists of conservation organizations (***e.g.***, Point Reyes Bird Observatory and Oregon Natural Heritage Program) and Federal and State agencies to conduct western snowy plover population monitoring and banding studies and construct predator exclosures. It is also legal for employees or designated agents of certain Federal or State agencies to take listed species without a permit if the action is necessary to aid sick, injured, or orphaned animals or to salvage or dispose of a dead specimen.

Section 10(a)(1)(B) of the Endangered Species Act also allows permits to be issued for take of endangered and threatened species that is "incidental to, and not the purpose of, carrying out an otherwise lawful activity" if we determine that certain conditions have been met. An applicant for an incidental take permit must prepare a habitat conservation plan that specifies the impacts of the take, the steps the applicant will take to minimize and mitigate the impacts, funding that will be available to implement these steps, alternative actions to the take that the applicant considered, and the reasons why such alternatives are not being utilized. Conditions that we must meet include a determination: (1) whether the taking will be incidental, (2) whether the applicant will minimize and mitigate the impacts of such taking to the maximum extent possible, (3) that adequate funding for the recovery will be provided, (4) that the taking will not appreciably reduce the likelihood of the survival and recovery of the species in the wild, and (5) of any other measures that we may require as being necessary or appropriate for the recovery plan. Section 10(a)(1)(B) of the Endangered Species Act provides for permits that have the potential to contribute to conservation of listed species. Such permits are intended to reduce conflicts between the conservation of listed species and economic activities, and to develop partnerships between the public and private sectors.

### *d. Section 7 Requirements and Consultations*

Section 7(a)(1) of the Endangered Species Act requires all Federal agencies to "utilize their authorities in furtherance of the purposes of [the] Act by carrying out programs for the conservation of endangered species and threatened species". Hence, Federal agencies have a greater obligation than do other parties, and are required to be pro-active in the conservation of listed species regardless of their requirements under section 7(a)(2) of the Act. Section 7(a)(2) of the Endangered Species Act requires Federal agencies to consult with us prior to authorizing, funding, or carrying out activities that may affect listed species. Section 7 obligations have caused Federal land management agencies to implement western snowy plover protection measures that go beyond those required to avoid take; for example, eradicating European beachgrass and conducting research on threats to western snowy plovers. Other examples of Federal activities that may affect western snowy plovers along the Pacific coast, thereby triggering a section 7 consultation, include permits for sand management activities or major restoration projects that affect coastal processes or that are targeted to protect other species on Federal lands such as dune plants (National Park Service, U.S. Department of the Interior); disposal of dredged materials (U.S. Army Corps of Engineers); military training (U.S. Department of Defense); and funding to public agencies for projects to repair beach facilities, such as public access paths (Federal Emergency Management Agency).

### *e. Other Federal Regulations, Executive Orders, and Agreements*

Section 404 of the Clean Water Act, as amended, and section 10 of the Rivers and Harbors Act of 1899 are the primary Federal laws that could provide some protection of nesting and wintering habitat of the western snowy plover that is determined by the U.S. Army Corps of Engineers (Corps) to be wetlands or historic navigable waters of the United States. Excavation or placement of any fill material (including sand) below the high tide line, as defined under 33 CFR, Section 328.3(d), Definition of Waters of the United States, also requires a permit from the U.S. Army Corps of Engineers.

Executive Order 11644, Use of Off-Road Vehicles on Public Lands, and Executive Order 11989, Off-Road Vehicles on Public Lands, pertain to lands under custody of the Secretaries of Agriculture, Defense, and Interior (except for Native American Tribal lands). Executive Order 11644 requires administrative designation of areas and trails where off-road vehicles may be permitted. Executive Order 11989 states that "... the respective agency head shall, whenever he determines that the use of off-road vehicles will cause or is causing considerable adverse effects on the soil, vegetation, wildlife, wildlife habitat ... immediately close such areas or trails to the type of off-road vehicles causing such effects, until such time as he determines that such effects have been eliminated and that measures have been implemented to prevent future recurrence". Compliance with this executive order would promote prohibitions or restrictions on off-road vehicles so that they are not allowed to adversely affect sensitive habitats used by western snowy plovers.

Executive Order 11988, Floodplain Management, and Executive Order 11990, Protection of Wetlands, provide protective policies that apply to western snowy plover habitats. Executive Order 11988 mandates that all Federal agencies avoid direct or indirect support of floodplain development wherever there is a practicable alternative. Executive Order 11990 mandates that all Federal agencies shall "provide leadership and shall take action to minimize the destruction, loss or degradation of wetlands, and to preserve and enhance the natural and beneficial values of wetlands..." Compliance with Executive Order 11988 would promote protection of beach and dune habitats through restrictions on development within floodplains. Application of Executive Order 11990 would promote protection of wetland habitats used by western snowy plovers.

Executive Order 13112, Invasive Species, directs Federal agencies to prevent the introduction of invasive species; control their populations in a cost-effective and environmentally sound manner; monitor invasive species; restore native species and habitat conditions in ecosystems that have been invaded; conduct research and develop technologies to prevent their introduction; and promote public education on invasive species and the means to address them. This executive order also requires that a Federal agency "not authorize, fund, or carry out actions that it believes are likely to cause or promote the introduction or spread of invasive species..." Compliance with this executive order would enhance western snowy plover habitats through (1) avoidance of use, approval, or funding the planting of invasive species like European beachgrass; and (2) active programs to remove this invasive species and restore coastal dune habitats with native plant species.

The Fish and Wildlife Coordination Act (16 U.S.C. 661-667e), as amended, requires that whenever a proposed public or private water development project is subject to Federal permit, funding, or license, the conservation of fish and wildlife resources shall be given equal consideration. This Act also requires that project proponents shall consult with us and the State agency responsible for fish and wildlife resources. Compliance with the Fish and Wildlife Coordination Act highlights the importance of considering and providing for the habitat needs of fish and wildlife resources when reviewing projects that would adversely affect these resources.

The National Environmental Policy Act of 1969, (42 U.S.C. 4321-4347), as amended, requires that each Federal agency prepare an environmental impact statement on the potential environmental consequences of major actions under their jurisdiction. Environmental impact statements must include the impacts on ecological systems, any direct or indirect consequences that may result from the action, less environmentally damaging alternatives, cumulative long-term effects of the proposed action, and any irreversible or irretrievable commitment of resources that might result from the action. Compliance with the National Environmental Policy Act highlights the need to disclose, minimize, and mitigate impacts to biological resources, including western snowy plovers.

The Coastal Zone Management Act of 1972 (16 U.S.C. 1451-1464), as amended, established a program for states to voluntarily develop comprehensive programs to protect and manage coastal resources. To receive Federal approval and funding under this Act, states must demonstrate that they have programs and enforceable policies that are sufficiently comprehensive and specific to regulate land uses, water uses, and coastal development, and must have authorities to implement enforceable policies. Local coastal plans, local comprehensive plans, and implementing measures by coastal planning jurisdictions pursuant to the Coastal Zone Management Act should be developed, updated, and implemented with protective measures for western snowy plovers.

Western snowy plovers are protected under the Migratory Bird Treaty Act of 1918 (16 U.S.C. 703-712), as amended. Under the Migratory Bird Treaty Act, prohibited acts include pursuing, hunting, shooting, wounding, killing, trapping, capturing, or collecting any migratory bird, nest, or eggs without a permit from the U.S. Fish and Wildlife Service.

**5. State Regulatory Protection, Policies, and Agreements**

In Washington, Oregon, and California, each state holds title to, and has regulatory jurisdiction over, the coastal intertidal zone. In Washington, the area between mean high tide to extreme low tide is the seashore conservation area under the authority of the Washington State Parks and Recreation Commission. In California, the California State Lands Commission has regulatory authority to the mean high tide line along the California coast.

In Oregon, the Oregon Parks and Recreation Department administers the State beach for the ocean shore recreation area, which is defined as the area between the line of extreme low water and the statutory vegetation line, which is a line surveyed to the approximate line of vegetation that existed in 1969 (Oregon Revised Statutes 390.770). The Oregon Division of State Lands also has jurisdiction over waters of the state along the Pacific coast to the line of highest tide or the line of established vegetation, whichever is higher. Therefore, the Oregon Parks and Recreation Department has direct jurisdiction, authority, and responsibility for management of western snowy plover habitats in the State of Oregon, which owns not only to the mean high tide line, which is western snowy plover foraging habitat, but also into the vegetation line, which is essentially the dry sand area used by western snowy plovers for nesting.

State coastal planning and regulatory agencies, such as the California Coastal Commission, require preparation of local coastal zone management plans by local coastal municipalities. These local coastal zone management plans must comply with the Coastal Zone Management Act of 1972 regarding protection of coastal resources, including natural resources. Under the California Coastal Management Program, coastal resources are managed and cumulative impacts addressed through: (1) coastal permits and appeals; (2) planning and implementation of local coastal programs; and

(3) Federal consistency review. However, effective management of cumulative impacts is difficult under the existing management framework because multiple jurisdictions have varying policies and standards in different geographic areas (California Coastal Commission 1995). Through the Coastal Commission's regional cumulative assessment program, cumulative impacts to coastal resources can be addressed through the periodic review of local coastal programs. In California, most local coastal programs and general plans were completed prior to 1993 (when we listed the western snowy plover as a threatened species); therefore, many do not reflect protective measures specifically for the western snowy plover.

The Oregon Department of Land Conservation and Development is the designated coastal zone management agency for the State of Oregon. The State of Oregon's land use planning system has several elements that are related to conservation of western snowy plovers and their habitats. In Oregon, local jurisdictions (cities and counties), service districts, and State agencies are required to develop Local Comprehensive Plans and Implementing Measures, such as zoning and land division ordinances, to effect these plans. Each plan must satisfy a set of 19 goals established through Oregon land use law and policy. Plans must be reviewed by the Land Conservation and Development Commission for consistency with these goals before they can be put into effect. Several of the planning goals have application to, or should be considered during, planning for western snowy plover conservation and recovery. These goals include: Goal 5 - Open Spaces, Scenic and Historic Areas, and Natural Resources; Goal 7 - Areas Subject to Natural Disasters and Hazards; Goal 8 - Recreational Needs; Goal 16 - Estuarine Resources; Goal 17 - Coastal Shorelands; and Goal 18 - Beaches and Dunes.

Taken in aggregate, the elements of these goals that can contribute to western snowy plover recovery include:

- several requirements for protection of wildlife habitat;
- requiring protection of estuarine ecosystems including habitats, diversity, and other natural values;
- establishing that uses of beaches and dunes shall be based on factors including the need to protect areas of critical environmental concern and significant wildlife habitat;

- requiring that coastal plans provide for uses of beaches and dunes that are consistent with their ecological values and natural limitations;
- requiring an evaluation of the beneficial effects to natural resources from allowing continuation of natural events that are hazardous to human developments (such as erosion and ocean flooding);
- establishing a preference for nonstructural solutions to erosion and flooding of coastal shorelands over structural approaches (such as seawalls and rip-rap);
- requiring that development of destination resorts be compatible with adjacent land uses and maintain important natural features such as threatened and endangered species habitats;
- encouraging coordination among State, Federal, and local governmental agencies while developing recreation plans, and discouraging development of recreation plans that exceed the carrying capacity of the landscape;
- encouraging planning for Open Space, Scenic and Historic Areas, and Natural Resources (Goal 5), Recreational Needs (Goal 8), and Coastal Shorelands (Goal 17) in close coordination; and
- allowing dune stabilization programs only when in conformance with the overall comprehensive plan and after assessment of the potential impacts.

Some aspects of these planning goals could be interpreted to be contrary to western snowy plover conservation and recovery when viewed in isolation. However, when viewed in the context of the entire goal or all the planning goals, these elements should be compatible with western snowy plover conservation and carefully-planned habitat restoration activities. Two such elements are the directive to increase recreational access to coastal shorelands and the restrictions placed on dune grading and removal of vegetation. Goal 17 - Coastal Shorelands directs local governments and the Oregon Parks and Recreation Department to develop a program to increase public access. In many areas, recreational use of western snowy plover habitat during the nesting season is detrimental to or incompatible with western snowy plover conservation. However, this goal also recognizes that many shorelands have unique or exceptional natural area values, includes the objective of reducing adverse impacts to fish and wildlife habitat associated with use of coastal shorelands, clearly establishes that significant wildlife habitat shall be protected, establishes that uses of such habitat areas shall be consistent with protection of natural values, and directs recreation plans to provide for "appropriate" public access and recreational use. Goal

18 - Beaches and Dunes directs local governments and State and Federal agencies to regulate actions in beach and dune areas to minimize any resulting erosion and only allows foredune breaching to replenish interdune areas or in the case of an emergency. Western snowy plover habitat restoration efforts in areas that have been overtaken by European beachgrass (*Ammophila arenaria*) may involve foredune breaching, vegetation removal, dune grading, and other actions that will remove the European beachgrass and restore the natural beach and dune processes of sand movement, including erosion and deposition. However, this goal also recognizes the need to protect areas of critical environmental concern, areas of biological importance, and areas with significant habitat value, specifically identifies removal of "desirable" vegetation as an action requiring minimization of erosion, and requires that any foredune breaching be consistent with sound principles of conservation.

The Washington State Parks and Recreation Commission administers the Seashore Conservation Act of 1988 in accordance with the Revised Code of Washington and the Washington Administrative Code. The Seashore Conservation Area (Revised Code of Washington 43.51) emphasizes the importance of beaches to the public for recreational activities. In designating beach areas to be reserved for pedestrian use, it considers natural resources, including protection of shorebird and marine mammal habitats, preservation of native beach vegetation, and protection of sand dune topography. Chapter 352-37 (Ocean Beaches) of the Washington Administrative Code requires local governments within the Seashore Conservation Area to prepare recreation management plans that designate at least 40 percent of the ocean beach for use by pedestrians and nonmotorized vehicles from April 15 to the day after Labor Day. These regulations also identify restrictions on certain uses within ocean beaches, including motor vehicles, equestrian traffic, speed limits, aircraft, wind/sand sailers, parasails, hovercraft, group recreation events, and beach parking and camping. In 1989, an interagency agreement was signed by the Washington Department of Natural Resources, Washington State Parks and Recreation Commission, Washington Department of Wildlife, and City of Ocean Shores regarding management of mixed uses at Damon Point. The intent of the agreement was to protect western snowy plovers while allowing recreation.

State regulations, policies, and goals for the States of California, Oregon, and Washington provide many protective measures for western snowy plovers. However, because they frequently emphasize public uses of beach habitat, there is potential for conflicts between human uses of the coastal zone and needed management measures for recovery of the western snowy plover.

The California Department of Parks and Recreation has written management guidelines for the western snowy plover which are meant to be used in conjunction with the recovery plan. Management actions will be implemented from the guidelines and may result in changes in how coastal units are operated. Increased emphasis will be required for monitoring, nest area protection, prohibition of certain activities in important nesting areas, and public education.

**6. Consultations, Habitat Conservation Plans, and Other Regulatory Actions**

Through consultations with Federal agencies under section 7 of the Endangered Species Act and through the development of habitat conservation plans with non-Federal agencies developed under section 10 of the Endangered Species Act, we provide nondiscretionary terms and conditions that minimize (sections 7 and 10) and mitigate (section 10) the impacts of covered activities on listed species and their habitat. Several major consultations and habitat conservation planning efforts to benefit the western snowy plover have been completed or are currently under way.

In 1995 our Sacramento Fish and Wildlife Office completed formal consultation with the National Park Service, Golden Gate National Recreation Area, on the effects of their management of Ocean Beach, San Francisco on the western snowy plover. Ocean Beach experiences tremendous visitor use year-round because of its proximity to San Francisco, yet it supports high numbers of nonbreeding western snowy plovers, which may be present from May through July. The consultation covered actions and policies the National Park Service had taken that resulted in unnecessary harassment of nonbreeding western snowy plovers. Most significant of these measures was their policy not to enforce regulations requiring pets to be leashed and under control by their owners on all National Park Service lands. Data collected by the National Park Service clearly identified that unleashed dogs were the most significant disturbance factor of the many sources of disturbance to western snowy plovers on Ocean Beach. As a result of the consultation, the National Park Service began to enforce their "leash law" along 3.2 kilometers (2 miles) of beach utilized by western snowy plovers. The

National Park Service implemented this policy despite vocal and persistent opposition by the San Francisco Society for the Prevention of Cruelty to Animals and other local advocacy groups, including the "Rovers for Plovers", which organized themselves to challenge the National Park Service's leash law. These groups were successful in advocating their position in numerous television news stories and articles in local newspapers. At the height of this discourse, the local public radio station held a round-table discussion between the National Park Service, U.S. Fish and Wildlife Service, and Society for the Prevention of Cruelty to Animals, and solicited audience members to call in and identify their viewpoint. The overwhelming majority of callers supported leash law restrictions that would minimize harassment of western snowy plovers.

Our Arcata Fish and Wildlife Office has formally consulted with the U.S. Army Corps of Engineers regarding gravel extraction on the Eel River, California. Gravel mining operations are subject to permits from the U.S. Army Corps of Engineers under Section 404 of the Clean Water Act. The western snowy plover breeds on the Eel River gravel bars. Impacts to the western snowy plover and its designated critical habitat associated with gravel mining operations have been assessed based on nesting surveys and changes to habitat resulting from gravel extraction. The Arcata Fish and Wildlife Office has also worked with Humboldt County, the California Department of Fish and Game, and the California Department of Parks and Recreation to implement additional protections for nesting western snowy plovers at MacKerricher, Manchester, Little River, Humboldt Lagoons, and Prairie Creek State Parks; Clam Beach County Park, and the Eel River Wildlife Area. These measures include installation of nest exclosures, signing, and development of educational material for kiosks. Technical assistance has also been provided to Prairie Creek State Park and MacKerricher State Park on exotic vegetation management programs (J. Watkins *in litt.* 1999, pers. comm. 2001). A section 7 consultation with the Bureau of Land Management on finalization of a management plan for Humboldt Bay South Spit is expected to be initiated soon (J. Watkins, pers. comm. 2006).

Our Ventura Fish and Wildlife Office is attempting to initiate a regional approach to habitat conservation planning for western snowy plovers and other listed species along Monterey Bay in Monterey County, California. Currently, there are several proposed development projects within the city of Sand City and a "city wide" habitat conservation plan has been prepared for these projects. The City of Sand City has yet to present a complete draft of their habitat conservation plan to the Ventura Fish and Wildlife Office for review. Formerly, the City of Marina was also proposing several coastal developments that were expected to have adverse effects on western snowy plovers, but these projects are no longer planned due to changes in land ownership and other factors. The City of Marina has halted the drafting of a habitat conservation plan for lands within their jurisdiction. We have expressed concerns about projects being presented in a piecemeal fashion, which does not allow an adequate assessment of their cumulative effects, and have recommended a regional approach through preparation of a regional habitat conservation plan. This plan would provide greater conservation benefits to the western snowy plover. In addition to the adverse effects of development on western snowy plovers and their habitat, recreation on the extensive public lands along Monterey Bay is also adversely affecting western snowy plovers. Therefore, public land managers, including our Refuges Division, the California Department of Parks and Recreation, the California Department of Fish and Game, and the Monterey Peninsula Regional Park District, need to be involved in planning efforts along Monterey Bay.

Through the consultation process, our Ventura Fish and Wildlife Office determined that a draft biological opinion on Vandenberg Air Force Base’s initial proposed beach management plan for the western snowy plover, concluding that the plan would "likely jeopardize the continued existence of the western snowy plover and adversely modify its critical habitat." Our draft biological opinion of January 2001 pointed out that the Air Force's beach plan would have allowed twice as much nesting habitat to be open to public recreation as was allowed during the 2000 breeding season, and it would have reduced the time the Air Force spends patrolling the beaches by about 80 percent. Based on this feedback, the Air Force subsequently reinitiated consultation on a modified version of the beach management plan, including commitments to signage, information kiosk, and enforcement patrols. The Ventura Fish and Wildlife Office issued a non-jeopardy biological opinion on the modified action in March 2001. Beach opening and full implementation of conservation measures was implemented on May 25, 2001, with hours and days of open beach limited due to limited availability of enforcement personnel. For the next three breeding seasons (2002, 2003, 2004), the Service issued biological opinions on annual beach management plans proposed by the Air Force. In 2004, we had a series of meetings with the Air Force to discuss their beach management strategy and its effects on the western snowy plover. Through a cooperative effort, the Service and the Air Force came to agreement on a 5-year beach management plan that includes many of the same protective measures that had been in place the last several years, yet allows the Air Force to provide recreational access seven days a week. On March 1, 2005, the Ventura Fish and Wildlife Office issued a new non-jeopardy biological opinion on the Air Force's proposed 5-year beach management plan (2005-2009).

Our Ventura Fish and Wildlife Office is also involved with the development of a habitat conservation plan being funded by the Off-Road Vehicle Division of the California Department of Parks and Recreation for the Pismo/Oceano Dunes State Vehicular Recreation Area and other State parks within the San Luis Obispo District of the California Department of Parks and Recreation. The Ventura Fish and Wildlife Office is also involved in the development of a HCP for the Rancho Guadalupe County Park, Santa Barbara, California. These habitat conservation plans will evaluate and mitigate for effects that recreation and park management activities are having on the covered species, including the western snowy plover.

Recent consultations handled by our Newport Field Office include those in response to the New Carissa Oil Spill, a consultation on BLM management actions at the New River Area of Critical Environmental Concern (ACEC), and a consultation on the Integrated Predator Damage Management Program 2002 to 2007. The Oregon Parks and Recreation Department is currently developing a Habitat Conservation Plan that proposes restrictions on some Oregon beaches to help the plover population recover.

The New Carissa oil spill was a long and complicated incident involving a variety of Federal, State, local and private participants. On February 4, 1999, the *New Carissa*, carrying 359,000 gallons of bunker oil and 37,400 gallons of diesel, grounded on the north spit of Coos Bay and began leaking oil shortly thereafter. Subsequently, oil and oiled wildlife were observed on the beach. Attempts were made to burn off the oil. The vessel broke into two pieces during the second attempt. There were three formal consultations associated with the *New Carissa* between 1999 and 2000. The first consultation addressed the effects of issuing permits for salvage of the *New Carissa* stern section, the second the effects of restoring recreational access to the Coos Bay north spit, and the third the response efforts led by the Coast Guard. In all three consultations, it was concluded that the proposed actions would not jeopardize the western snowy plover if protective measures required to limit take were implemented.

A consultation on the New River ACEC was completed in 2005. The purpose of the biological opinion was to address a variety of issues: recreation management at Floras Lake where measures were not adequately protecting nesting plovers; the periodic construction of a breach on the New River spit to improve fish and wildlife habitat and alleviate flooding; increased habitat restoration; and the development of a primitive beach camping area.

A consultation on Oregon’s Integrated Predator Damage Management Program was completed in 2001. The objective of this program is to assist in recovery of the western snowy plover in Oregon by improving western snowy plover nesting and fledging success, through 1) expanding assessment efforts to all western snowy plover breeding and nesting locations to determine predator species responsible for nest, chick and adult predation; and 2) reducing the local predator populations where feasible and where the predator species or individual is known. The consultation calls for a variety of lethal and non-lethal methods to be used by APHIS-WS personnel to control the predator population.

The Oregon Parks and Recreation Department has been working with various cooperating agencies to develop a Habitat Conservation Plan for Oregon beaches. The Oregon Parks and Recreation Department is responsible for various management activities for most of Oregon's coast, including recreation management, general beach management, and the management of natural resources. In addition, the Oregon Parks and Recreation Department is responsible for issuing various permits along the Oregon coast. Some of these activities may result in "take" of or harm to the snowy plover. A draft version of the Habitat Conservation Plan was distributed to the public in January 2004. The Oregon Parks and Recreation Department conducted public meetings in seven coastal communities to solicit public comment. The area covered under the HCP includes the portions of the ocean shore along the Oregon coast that extend between the mouth of the Columbia River South Jetty on the north and the California/Oregon border on the south (approximately 230 miles of beach). In addition, specific portions of six key state parks, state natural areas, and state recreation areas are included in the covered lands to be managed for snowy plover recovery. Implementation of the plan will begin after approval and completion of the Habitat Conservation Plan and its associated documents.

In southern California, we, through our Carlsbad Fish and Wildlife Office, have worked with local jurisdictions to develop regional habitat conservation plans under section 10 of the Endangered Species Act. The Multiple Species Conservation Program addresses southwestern San Diego County, including, for example, western snowy plover breeding habitat in south San Diego Bay through the City of San Diego. The Multiple Habitat Conservation Program addresses northwestern San Diego County. This plan provides for the conservation of western snowy plover breeding habitat and will potentially result in more management in association with a proposed preserve.

Also in San Diego County, we have been working with the Navy and the Marine Corps to avoid and minimize impacts to western snowy plovers. For example, with the assistance of our programmatic biological opinion in 1995, the Marine Corps has addressed training-related impacts on western snowy plovers and other species on approximately 17 miles of coastline on Camp Pendleton. We have likewise worked with the Navy at Naval Base Coronado to develop a program to conserve western snowy plover nesting and breeding habitat and allow necessary military training. As a result of successful management on these San Diego County military installations, they support a majority of the western snowy plover population in Recovery Unit 6 (*e.g.*, roughly 65 percent in 2006 from window survey data) while the military installations accomplish their respective training missions.

In the past, several instances were documented of western snowy plover nests being trampled by cattle belonging to the Vail and Vickers Company on Santa Rosa Island within the Channel Islands National Park, owned and managed by the National Park Service. In 1996, a lawsuit to remove cattle from Santa Rosa Island was initiated by the Environmental Defense Center, Santa Barbara, on behalf of the National Park Conservation Association. It was initiated under the authority of the Clean Water Act and the Endangered Species Act, based on concerns about management of livestock by the National Park Service and associated impacts to water quality and sensitive plant and animal species. As a result of a lawsuit settlement, all cattle were removed from Santa Rosa Island in early 1998.

**7. Regulatory Protection and Policies of Local Governments**

Local governments regulate municipal land uses through development of local land use plans, general plans, comprehensive plans, and zoning policies. On April 21, 1998, we requested that county and coastal city planners within the states of Washington, Oregon, and California complete land-use management surveys regarding the western snowy plover. We sent surveys to 91 State, county, or coastal city planners and received responses from 37 percent of the recipients. Approximately 50 percent of the respondents were aware that western snowy plover habitats occur within their jurisdictions. However, only about one-third knew whether sandy beach and other habitats within their jurisdictions provided breeding and/or wintering habitat for western snowy plovers. Many general plans, coastal zone programs, and comprehensive plans prepared by local governments contain land use designations that are protective of western snowy plover habitats (*e.g.*, parkland, open space, and conservation designations for sandy beach). However, allowable uses in or adjacent to these zones, such as development (*e.g.*, seawalls, recreational facilities, single-family homes), recreation and public access, could cause direct or indirect threats to breeding or wintering western snowy plovers.

Whereas 43 percent of the respondents include regulatory policies that protect western snowy plover habitat (*e.g.*, sandy beach) in their general plans, local coastal programs or comprehensive plans, only 8 percent have developed regulatory policies specifically to protect the western snowy plover. These respondents included the City of Half Moon Bay, California, and Coos and Curry Counties, Oregon. Only 23 percent of the respondents specifically explain the threatened status of the western snowy plover, identify western snowy plover breeding/wintering locations, or specify shorebird nesting/roosting habitats as environmentally sensitive habitat areas in their jurisdictions. About 50 percent of the respondents indicated they either (1) have approved development within or adjacent to sandy beach or other habitats used by the western snowy plover, or (2) did not know whether such development had been approved by their agency. About half of these same respondents could provide some information on the number of permits authorized, area or linear distance affected, percentage of development types (*e.g.*, housing, recreational) permitted, and permit conditions.

Based on these responses, it seems that specific locations of, and protective measures for, western snowy plover breeding and/or wintering locations are not included in most of the existing general plans, comprehensive plans, local coastal programs, or their implementing ordinances. Also, to better assess cumulative impacts, these responses indicate a need for a better tracking method regarding development projects approved within and adjacent to western snowy plover habitat.

**8. Interagency Coordination**

Each of the six recovery units for the western snowy plover is represented by a working group which meets at least once a year to coordinate western snowy plover recovery efforts. The working groups have provided a forum for the participation of affected Federal and State agencies and others in discussion, implementation, and adjustment of recovery efforts. Items addressed include research and monitoring needs, predator control, recreation management, habitat restoration, public outreach and law enforcement. In addition, a joint meeting of all six working groups is held annually. This group, consisting of beach managers, researchers, and outreach staff, meet to discuss range-wide issues (within the United States), to coordinate recovery actions, to learn from the experience of others, and to share information and research. Attendees have included local, State, and Federal agency staff, non-governmental organizations, consulting firms, private citizens, and volunteers.

The recovery unit working groups vary somewhat in organizational structure depending on major local issues, patterns of land ownership within the area, and specific agencies responsible for management. For example, the Oregon/Washington working group is composed of several subcommittees, including Outreach, Media, Predator Control, Research, Law Enforcement, and Recovery Plan Implementation. They facilitate funding partnerships for monitoring and management programs, thus promoting the best use and leveraging of limited funds. They also act as the main forum for discussing and tracking the status and trends of the snowy plover population. The subcommittees have worked on or supported a variety of cooperative projects, such as monitoring of yearly reproductive success, predator control, and outreach materials. Products developed by the Outreach subcommittee include an outreach plan for Oregon/Washington and “Share the Beach” bookmarks, table tents, dog leashes, brochures, interpretive signs, and coloring books. The Media subcommittee is producing a media outreach CD for distribution to various media outlets and inter-agency press releases. The Predator Control subcommittee approved a predator management plan for Oregon, which first went into effect in 2002. The purpose of the Research subcommittee is to identify research and monitoring priorities, establish criteria for setting priorities, review proposed projects, and address funding mechanisms. The Law Enforcement subcommittee focuses on improving compliance with rules and regulations in plover nesting areas and the Recovery Plan Implementation subcommittee is working on guidance that would assist in “stepping down” the recovery plan for Oregon and eventually Washington.

In 1998, an interagency effort in Oregon produced a slide show and portable display to educate beach visitors about western snowy plover conservation. Outdoor education specialists and/or western snowy plover biologists from the U.S. Bureau of Land Management, U.S. Forest Service, Oregon Department of Fish and Wildlife, Oregon Parks and Recreation Department, and U.S. Fish and Wildlife Service participated in this effort. The show provides basic information about the western snowy plover, the reasons for its decline, and actions needed for its recovery, emphasizing the contribution that beach visitors can make.

# II. RECOVERY

## A. RECOVERY STRATEGY

The recovery strategy for the Pacific coast population of the western snowy plover (western snowy plover) includes three major components: 1) increase population numbers distributed across the range of the Pacific coast population of the western snowy plover; 2) ameliorate or eliminate threats by conducting intensive ongoing management for the species and its habitat, and developing mechanisms to ensure management in perpetuity; and 3) monitor western snowy plover populations and threats to determine success of recovery actions and to refine management actions. Developing and implementing intensive adaptive management actions, ensuring that management will continue in perpetuity, and monitoring to refine management actions, are all necessary to achieve the targeted population increases across the range. These three major components of the recovery strategy each include many actions and multiple partners that are described in further detail below.

### 1. Recovery Strategy Components

The following recovery strategy components will guide future recovery efforts for the U.S. Pacific coast population of the western snowy plover.

a. Population increases should be distributed across the western snowy plover's Pacific coast range.

A key component of recovering western snowy plovers is to ensure that population increases are distributed throughout the species' Pacific coast range. In order to achieve this, management goals (Appendix B) and needed management actions (Appendix C) have been determined for 155 sites distributed along the coasts of southern Washington, Oregon, and California. Additionally, the population's range has been divided into six recovery units (see discussion below) with population goals established for each recovery unit. The six recovery units correspond to regions of the U.S. Pacific coast and to the six subpopulations used in the Population Viability Analysis for the Pacific coast Snowy Plovers (Appendix D). In the population viability analysis, the Pacific coast population of the western snowy plover is treated as a metapopulation, defined as a set of subpopulations among which there is limited dispersal.

The population viability analysis assumes dispersal among subpopulations is limited; however, even limited dispersal among subpopulations is important to species survival and recovery. Dispersal of the population across its breeding range helps to counterbalance catastrophes, such as extreme climatic events, oil spills, or disease that might depress regional survival and/or productivity. Maintaining robust, well-distributed subpopulations should reduce variance in survival and productivity of the Pacific coast population of the western snowy plover as a whole, facilitate interchange of genetic material between subpopulations, and promote recolonization of any sites that experience declines or local extirpations due to low productivity and/or temporary habitat loss.

This recovery plan and the population viability analysis (Appendix D) consider the U.S. Pacific coast population of the western snowy plover to be a single management entity, and population goals and objectives are based on that premise. No portion of the Pacific coast population of the western snowy plover appears to function as a distinct population segment. The Recovery Team therefore recommends that no State, geographic region, or subpopulation of the Pacific coast population of the western snowy plover be considered for delisting separately from the others.

b. Remove or reduce threats by conducting intensive ongoing management for the species and its habitat, and develop mechanisms to ensure management in perpetuity to prevent a reversal of population increases following delisting under the Endangered Species Act.

Management consists of multiple components, including identifying actions to ameliorate or eliminate threats, developing mechanisms to ensure management in perpetuity, continuing outreach and education to provide information to the public, partners, and stakeholders on recovery needs and opportunities, and developing of partnerships among Federal, State, and local agencies and groups to develop and implement effective management. Management actions for the western snowy plover are described in the recovery action outline and in Appendix C. These management actions are necessary to eliminate or ameliorate threats to the western snowy plover, including loss, degradation, and alteration of habitat; disease, predation; and other manmade factors including disturbance of breeding and wintering birds, contaminants, and oil spills.

In addition to specific management recommendations to ameliorate or eliminate threats, the recovery action outline and recovery strategy for the western snowy plover include several recovery actions to develop mechanisms to ensure that management actions continue in perpetuity to ensure that threats remain neutralized. These include establishing working groups and developing participation plans for each recovery unit; ensuring sufficient U.S. Fish and Wildlife Service staff to coordinate recovery of the Pacific coast population of the western snowy plover; developing and implementing management plans for publicly owned lands; assisting local governments and private land owners in developing habitat conservation plans, developing land use protection measures, and developing landowner agreements; and acquiring habitat where necessary. A key component of these efforts includes education and outreach to inform partners and the public about recovery needs and opportunities for the western snowy plover. Actions for outreach are included in the recovery action outline, and the Information and Education Plan (Appendix K) provides greater detail on implementing these outreach and education actions.

Participation of many different groups will be essential to achieve both short-term and long-term management for the western snowy plover and its habitat. The roles of various groups, potential conservation tools and funding available, and the Recovery Team's vision for participation and coordination of partners are further described below.

c. Annual monitoring of western snowy plover subpopulations and reproductive success, and monitoring of threats and effects of management actions in reducing threats, is essential for adaptive management and to determine the success of recovery efforts.

The recovery action outline describes monitoring for breeding, wintering, and migration areas both to determine whether population numbers and survival of western snowy plovers is increasing and whether threats continue to limit population increases. Additional research actions are also recommended to study certain threats and develop management techniques and monitoring methods. Results from research and monitoring efforts will be used to develop, refine, and improve management of western snowy plovers and their habitat. Monitoring of demographic characteristics will be necessary to demonstrate that population goals in the recovery criteria are being achieved. Monitoring of threats and effects of management actions in reducing those threats also is essential in demonstrating progress toward recovery and ultimately will assist in threats analyses necessary to make a delisting determination.

## 2. Roles of Federal, State, Local, and Private Sectors

### *a. Role of Federal Lands*

Federal lands administered by the U.S. Fish and Wildlife Service, National Park Service, U.S. Forest Service, U.S. Bureau of Land Management, the National Marine Sanctuary Program, U.S. Marine Corps, and the U.S. Departments of the Army (including Corps of Engineers), Navy, and Air Force are extremely important to the conservation of the western snowy plover. In California, breeding occurs on National Wildlife Refuge lands, Department of Defense lands, Bureau of Land Management lands, and National Park Service lands. In Oregon, the major Federal landowners are the U.S. Forest Service and Bureau of Land Management, although the State also has jurisdiction over much of the Federally owned area (from mean high tide to the vegetation line) through a recreational easement (E.Y. Zielinski and R.W. Williams *in litt.* 1999). In Washington, the breeding area at Leadbetter Point is within a National Wildlife Refuge.

Under section 7(a)(1) of the Endangered Species Act, Federal agencies are required to actively promote the conservation of listed species. The western snowy plover cannot be recovered simply through general habitat protection or complying with required section 7(a)(2) consultations. The western snowy plover must be actively monitored and managed for the purpose of recovery or its population size will decline. Federal agencies alone cannot assure recovery of the western snowy plover, but should have a leading role in monitoring and management efforts to assure survival and recovery of this species. Some Federal lands contain large areas of contiguous habitat, including adjacent inland areas that are easier to manage for conservation of natural resources than fragmented, linear strips of land that may be owned by states, counties, cities, and private landowners. Protection of western snowy plovers and their habitat on Federal lands is important not only because of the direct benefits to plovers that use these areas, but also because plover protection programs on Federal lands frequently utilize state-of-the art management measures and therefore serve as examples to non-Federal landowners. The Federal Government also should take the lead in addressing the sensitive issue of predator control.

***b. Role of State Lands***

State lands administered by the California Department of Parks and Recreation, California Department of Fish and Game, Oregon Department of Fish and Wildlife, Oregon Parks and Recreation Department, Washington Department of Fish and Wildlife, Washington State Parks and Recreation Commission, and Washington Department of Natural Resources play an important role in conservation of western snowy plovers and their habitats. Intensive management for western snowy plovers occurs at a number of State-owned plover habitat areas. The western snowy plover cannot be preserved simply through general habitat protection. Western snowy plovers must be actively monitored and managed to achieve recovery goals on State lands or their population size will decline.

***c. Roles of State and Local Governments***

State and local government agencies, including state planning agencies and city and county planning and community resources departments, have the primary responsibility for overseeing land uses within their jurisdictions. Therefore, their involvement in future recovery planning and implementing processes is critical. All Appendix B locations should be identified as environmentally sensitive habitat areas requiring protective measures for the western snowy plover in state and local planning documents and zoning designations. Local coastal programs should be amended to include these areas. To facilitate this effort, Federal and State agencies managing western snowy plover habitat should provide technical assistance and information to local governments (see Actions 3.1.6, 3.1.7 and 5.2). We can provide detailed maps of current western snowy plover breeding and/or wintering locations; these maps will be updated periodically as needed.

### *d. Role of Municipal Lands*

Regional, county, and city lands, including regional and municipal park districts, also serve a role in conserving breeding and wintering habitats for western snowy plovers. Because these areas frequently receive heavy pedestrian and recreational use, local jurisdictions with active public outreach programs can reach a large segment of the coastal community regarding the plover's status and habitat needs.

### *e. Role of Private Lands*

Conservation efforts on private lands are needed for the survival and recovery of many listed and other sensitive species. Private landowners can also make important contributions to western snowy plover conservation through facilitating or allowing the monitoring of western snowy plover populations on their land and implementing protective measures.

## 3. Conservation Tools and Strategies

There are numerous conservation tools and strategies available to Federal, State, municipal, and private landowners interested in western snowy plover protection and recovery. Appendix H includes a summary of conservation tools and strategies that may be adopted by landowners, nonprofit organizations, and regulatory agencies to protect western snowy plover habitat.

## 4. Funding Sources

Appendix I includes a summary of some potential sources of funds for implementation of recovery actions for the western snowy plover. This list is not intended to be exhaustive, however, and other funding opportunities may also be available.

An essential mechanism for recovery of the western snowy plover is the development and implementation of participation plans for each of the six recovery units (see Action 3.1.2). A key element of these participation plans is the long-term commitment by participating agencies to seek annual, ongoing funding for western snowy plover management and monitoring activities so that funding within agency budgets can be secured.

In many areas a significant portion of western snowy plover conservation resources are expended in efforts to minimize the adverse impacts of recreation. Often, the primary objective of signs, ropes, on-site interpretation, and enforcement is to manage the behavior of beach-goers such that impacts to western snowy plovers are reduced as much as possible. In areas that have suffered extensive habitat loss or degradation, such recreation management activities are an extremely high priority in order to protect the western snowy plovers using the limited habitat that remains. For some beach managers, much of the funding and staff time expended on recreation management in and near western snowy plover habitat comes from resources targeted for threatened and endangered species recovery. In absence of the need to coordinate and pay for recreation management activities, more of these limited conservation dollars and staff resources could be directed toward western snowy plover management actions such as biological monitoring, habitat restoration, and predation control.

This situation is unique in the experience of many resource biologists. More typically, avoidance, minimization, and mitigation measures are integral components of projects or programs that entail adverse impacts to sensitive resources, and the costs of these activities are regarded as part of the overall cost of the project or program. Applying this traditional construct to recreation projects and programs could significantly promote western snowy plover recovery in several ways. First, it would require impacts to western snowy plovers to be considered up front when planning beach access or other recreation projects. Second, it would encourage impact avoidance and minimization since such measures are often less expensive than mitigation. Third, it would promote involvement of recreation professionals in designing and implementing recreation management measures. And fourth, it would eliminate or reduce the diversion of biological resource management funds toward recreation management activities, thus enabling more of those dollars to be spent on western snowy plover recovery actions.

## 5. Coordination, Participation, and Working Groups

We strongly believe that a collaborative stewardship approach to the proactive management of listed species involving government agencies (Federal, State, and local) and the private sector is critical to achieving the ultimate goal of recovery of listed species under the Endangered Species Act. An essential mechanism to achieve recovery of the western snowy plover is the formation and maintenance of working groups for each of the six recovery units (Appendix A), (see Action 3.1.1). Representation from the full range of Federal, State, local, and private landowners and other parties who have a stake in western snowy plover conservation within each of these six recovery units is needed to advance the recovery actions recommended in this recovery plan. Working group membership should include land managers, environmental groups, user groups, and groups involved in conservation projects (including local chapters such as the National Audubon Society, Sierra Club, Native Plant Society, Americorps, California Conservation Corps, Boy Scouts, Surfrider Foundation, and other recreational use groups). These groups can provide large networks of volunteers who can be mobilized to assist public resource agencies in the implementation of management measures for protection and recovery of the western snowy plover.

Working groups for each of the six recovery units currently exist and convene annually for regional and rangewide meetings. Through evaluation, communication, and coordination, members of each of the six working groups should manage the western snowy plover population and monitor progress towards recovery. They should produce annual reports on population monitoring and the effectiveness of management activities for the working group and our Arcata Fish and Wildlife Office. Each of the six working groups should prepare a participation plan, thereby formalizing recovery implementation efforts and the intentions of responsible agencies to seek ongoing, annual funding for recovery implementation. The Recovery Coordinator should coordinate and communicate with each recovery unit to support recovery efforts and assure implementation of the recovery plan (see Actions 3.1 through 3.4, 6, and 7). The Recovery Coordinator also should coordinate with other western snowy plover survey efforts and assessments throughout the west and throughout North America. Coordination with these other efforts may provide valuable information on the status and distribution of the western snowy plover, as well as valuable information on management actions that may benefit the Pacific coast population of the western snowy plover. A coordinated international conservation program with Mexico also should be established to protect western snowy plover populations and their habitat in that country (see Action 8).

## B. RECOVERY UNITS

The Pacific coast population of the western snowy plover has been divided into six recovery units (Appendix A, Figures A-1 through A-7). Establishing recovery units with specific recovery goals for each recovery unit will assist in meeting the objective of ensuring that population increases are distributed throughout the western snowy plover's Pacific coast range. A recovery unit is a special unit of a listed species that is geographically or otherwise identifiable and is necessary to the survival and recovery of the entire listed entity. Recovery units are individually necessary to conserve genetic robustness, demographic robustness, important life history stages, or other features for long-term sustainability of the entire listed species. However, recovery units are not listed as separate entities and cannot be delisted individually. Each recovery unit must be recovered before the species can be delisted.

The resilience to extinction of a widespread species can be negated if the species is subjected to a new stress over a large area (Raup 1991:122, 182). For the western snowy plover the primary stresses that led to the listing of the species were the loss of habitat due to encroachment of European beachgrass and urban development. As a consequence of such widespread habitat loss and the subsequent reduction in the range and vigor of the species, the western snowy plover is now more vulnerable to environmental fluctuations and catastrophes that the species would otherwise be able to tolerate. Chance events such as oil and contaminant spills, windstorms, and continued habitat loss from European beachgrass expansion, described earlier in this plan, could now cause or facilitate the extirpation of the entire listed species or one or more of the breeding populations.

The recovery unit approach in this recovery plan addresses this risk to the long-term survival and recovery of the western snowy plover by employing two widely recognized and scientifically accepted goals for promoting viable populations of listed species: (1) creation or maintenance of multiple populations so that a single or series of catastrophic events cannot destroy the whole listed species; and (2) increasing the size of each population in the respective recovery unit to a level where the threats of genetic, demographic, and normal environmental uncertainties are diminished (Mangel and Tier 1994; National Research Council 1995:91; Tear *et al.* 1993; Meffe and Carroll 1994:192).

In general, the larger the number of populations and the larger the size of each population, the lower the probability of extinction (Raup 1991:182; Meffe and Carroll 1994:190). This basic principle of redundancy applies to the western snowy plover. By maintaining viable populations at the breeding locations within multiple recovery units, the threats represented by a fluctuating environment are alleviated and the species has a greater likelihood of achieving long-term survival and recovery. Conversely, loss of one or more important breeding locations within a recovery unit could result in an appreciable increase in the risk that the entire listed species may not survive and recover. Because western snowy plovers tend to exhibit site fidelity, migration to new nesting sites could increase stress to breeding birds and reduce nesting success.

Therefore, when evaluating the potential impact of land management actions that may affect the western snowy plover, we will consider whether a significant loss of western snowy plover breeding or wintering habitat in one recovery unit --without adequate compensation alleviating the impacts of that loss-- would adversely affect the viability of the population in that recovery unit as well as the long-term viability of populations in other recovery units.

Several aspects of the biology and life history of the western snowy plover indicate that designation of recovery units is necessary to ensure the long term health and sustainability of the western snowy plover. A portion of the Pacific coast population of western snowy plovers do not migrate up or down the coast and are year round residents. Additionally, the majority of western snowy plovers that do migrate are site-faithful, returning to the same breeding areas in subsequent breeding seasons (Warriner *et al.* 1986, Stenzel *et al.* 1994). Western snowy plovers occasionally nest in exactly the same location as the previous year (Warriner *et al.* 1986). These two features indicate that the Pacific coast population of western snowy plover likely exhibits subpopulation and metapopulation structure (see also Appendix D).

Designation of separate recovery units across the range will ensure that metapopulation dynamics can be maintained for the species.

The area covered by the six recovery units encompasses all the known breeding and wintering sites for the Pacific coast population of the western snowy plover. In addition to exhibiting site fidelity to breeding locations, western snowy plovers also exhibit fidelity to wintering locations. In contrast to many migratory birds, winter migration of the Pacific coast population of western snowy plovers is not uni-directional. Western snowy plovers may move both north and south along the coast from breeding locations. Nesting birds from Oregon have wintered as far south as Monterey Bay, California, while birds from Monterey Bay in central California have wintered north to Bandon, Oregon and south to Laguna Ojo de Liebre in Baja California, Mexico (Page *et al*. 1995*a*). Nesting birds from San Diego County in southern California have wintered north to Vandenberg Air Force Base in Santa Barbara County and south to Baja California (Powell *et al*. 1995, 1996, 1997). Designation of separate recovery units, each essential to the recovery of the western snowy plover, will ensure that wintering and migratory habitat is distributed across the western snowy plover's Pacific coast range and is protected and managed to maximize western snowy plover population survival.

The six recovery units for the Pacific coast population of the western snowy plover are: (1)Washington and Oregon; (2) Del Norte to Mendocino Counties, California; (3) San Francisco Bay, California; (4) Sonoma to Monterey Counties, California; (5) San Luis Obispo to Ventura Counties, California; and (6) Los Angeles to San Diego Counties, California. These recovery units were designated partly based on gaps in distribution of western snowy plover breeding and wintering locations, and on gaps in available habitat along the coast. For example, a significant portion of the coast of Sonoma County and southern Mendocino County is rocky and composed of steep bluffs lacking beach, dune, or estuary habitat suitable for the western snowy plover. This area constitutes a gap in the distribution of breeding and wintering locations between recovery units 2 and 4. This situation is repeated along the coast of Monterey County, where a gap in western snowy plover locations and suitable habitat occurs between recovery units 4 and 5. Smaller gaps also occur between recovery units 1 and 2, and between recovery units 5 and 6. Recovery unit 3 is unique and has been designated as a separate recovery unit because much of the habitat in the San Francisco Bay area consists of salt ponds and salt pond levees.

The six recovery units designated for the western snowy plover also vary significantly in numbers of breeding western snowy plovers. Recovery unit 5 supports the greatest number of western snowy plovers, approximately half of the U.S. population, and has the greatest amount of available suitable habitat. Recovery units 4 and 6 support, or have the potential to support, a lesser number of western snowy plovers, collectively about a third of the population. The population in Recovery Unit 3 is relatively lower but has potential to increase with intensive management of salt pond habitat. Recovery units 1 and 2 also support relatively low numbers of western snowy plovers, probably due to suitable habitat being lesser in extent and more widely separated, but represent about half of the geographic range of the Pacific coast population of western snowy plovers within the United States and provide essential wintering, migratory, and breeding habitats.

Collectively, recovery of western snowy plovers within each of the six recovery units is necessary to maintain metapopulation dynamics, ensure protection and appropriate management of wintering and migratory habitat, and ensure the long term health and sustainability of the Pacific Coast population of western snowy plovers across its current range.

## C. RECOVERY GOALS AND OBJECTIVES

The goal of this recovery plan is to ensure the long-term viability of the Pacific coast western snowy plover population so that this population can be removed from the Federal list of endangered and threatened species. The specific objectives to achieve this goal are the major components of the recovery strategy described above:

1) Increase population numbers distributed across the range of the Pacific coast population of the western snowy plover;

2) Conduct intensive ongoing management for the species and its habitat and develop mechanisms to ensure management in perpetuity; and

3) Monitor western snowy plover populations and threats to determine success of recovery actions and refine management actions.

## D. RECOVERY CRITERIA

Recovery criteria for the Pacific coast population of the western snowy plover include numeric subpopulation targets, reproductive productivity targets, and establishment of management actions. Under each of these three major recovery criteria are additional subcriteria that must be achieved in order to progress toward the major criteria or that must be achieved in order to determine whether the major criteria are being met. Subcriteria include completing development and implementation of population, demographic and threat monitoring programs, incorporating specific management actions into participation and management plans, and completing research actions necessary to refine management actions.

Recovery criteria in this recovery plan are necessarily preliminary and will need periodic reassessment because additional data upon which to base decisions about western snowy plover recovery are needed (***i.e.***, effective predator management techniques, effective restoration techniques, improved monitoring techniques, additional demographic information for some subpopulations). Research actions, monitoring programs, and periodic recovery implementation review are included as recovery actions in order to obtain this information. The completion of many of these actions have been incorporated into recovery criteria in order to ensure that new information is incorporated into recovery implementation decisions.

The recovery criteria recommend that the Pacific Coast population of the western snowy plover be maintained at 3,000 breeding birds. This population increase to 3,000 breeding individuals could occur within 25 years with intensive management of breeding and wintering sites (see Appendix D. Population Viability Analysis for Pacific Coast Snowy Plovers). This population level must be maintained for at least ten years. In addition, average annual productivity of at least one (1.0) fledged chick per male in each recovery unit must be maintained in the last 5 years prior to delisting. Forty years may be required to achieve these demographic components of the recovery criteria, assuming that mechanisms to assure long-term protection and management of breeding, wintering, and migration areas necessary to maintain the subpopulation sizes and average productivity have been developed and are in place.

The Pacific coast population of the western snowy plover will be considered for delisting when the following criteria have been met:

**Criterion 1. Monitoring shows that an average of 3,000 breeding adults distributed among 6 recovery units as specified below have been maintained for a minimum of 10 years:**

| *Recovery Unit* | *Subpopulation Size* |
|---|---|
| 1. Washington and Oregon | 250 breeding adults |
| 2. Del Norte to Mendocino Counties, California | 150 breeding adults |
| 3. San Francisco Bay, California | 500 breeding adults |
| 4. Sonoma to Monterey Counties, California | 400 breeding adults |
| 5. San Luis Obispo to Ventura Counties, California | 1,200 breeding adults |
| 6. Los Angeles to San Diego Counties, California | 500 breeding adults |

Subpopulation sizes represent the best professional judgment of the Western Snowy Plover Recovery Team's technical subteam. Numbers are based on a site-by-site evaluation of historical records, recent surveys, and future potential (assuming dedicated, proactive management at breeding and wintering locations). Collectively, these numbers represent an approximately 70 percent increase in the Pacific coast population size from the time of listing. On a cumulative range-wide basis the recovery criteria are approximately 83 percent of the total of the "Management Goal Breeding Numbers" identified in Appendices B and C, which represent site-specific target populations under an intensive management scheme. The recovery criteria for population size and distribution for the Pacific coast population of the western snowy plover represent only a portion of its historical abundance and distribution.

To reach these subpopulation sizes will require proactive management to attain a level of productivity that will allow the population to grow. The population viability analysis (Appendix D) suggests that reproductive success between 1.2 to 1.3 fledglings per male per year, with adult survival of 76 percent and juvenile survival of 50 percent, provides a 57 to 82 percent probability of reaching a population of 3,000 western snowy plovers within 25 years. Enhancing productivity is critical to population growth. Once the population size criterion is met, a lower rate of productivity can sustain the population.

**1a. A program is developed and implemented to monitor the western snowy plover breeding population and wintering locations (see Actions 1.1 and 1.2) to determine whether recovery unit subpopulation criteria are being achieved.**

The monitoring program must include monitoring of population size and distribution, survival, and productivity. Monitoring population size and distribution are necessary as a means of measuring whether the recovery criterion is being met. Monitoring demographic characteristics such as survival and productivity also will be necessary to determine population trends and progress toward achieving the recovery criterion. The monitoring program should also assess whether management goals for breeding and wintering sites listed in Appendix B are being achieved. Collectively, the breeding management goal numbers are about 20 percent higher than the recovery criteria subpopulation sizes. Monitoring of individual sites will assist in determining the effectiveness of management actions and whether any refinements are necessary. Monitoring of wintering sites will assist in indicating whether survival of western snowy plovers is sufficient to make progress toward meeting breeding population size criteria.

When the species has recovered sufficiently to be delisted, the ongoing program of monitoring actions should be integrated into a post-delisting monitoring plan to cover a minimum of 5 years after delisting and ensure ongoing recovery and effectiveness of management actions. This monitoring plan should be developed and ready for implementation before delisting.

**1b. A program is developed and implemented to monitor the site-specific threats identified in Appendix C (Action 1.3) and monitoring results are used to refine site-specific management actions identified in Appendix C.**

In conjunction with monitoring of breeding subpopulation sizes and distribution and demographic characteristics, threats at each breeding and wintering site must be monitored in order to determine whether management actions are effective in increasing western snowy plover survival and reproduction. If threats continue limiting population increases, or additional threats are identified, management actions recommended in Appendix C may require modification.

**1c. Management activities identified in Appendix C that are necessary to ameliorate threats and achieve increases in reproductive success, survival, and overall population size are incorporated into participation and management plans developed and implemented under Criterion 3.**

Appendix C provides location-specific summaries of current management activities at western snowy plover breeding and wintering sites based on: 1) responses by public land managers and private conservation organizations to a survey prepared by the Recovery Team on western snowy plover management and beach use; and 2) supplemental information from the Recovery Team and from our field office staff. Appendix C also identifies additional management activities needed at each site to ameliorate threats and achieve management goals. These management recommendations are intended to provide preliminary guidance but additional management needs likely will be identified through monitoring, research, and site-specific experience.

**1d. Research actions (Action 4) are completed and incorporated into management and participation plans and into monitoring plans.**

Several research needs identified under Action 4 are necessary to refine and improve management activities for the western snowy plover and also to improve monitoring of western snowy plover population sizes, demographics, and threats. Improving and refining management actions will increase the effectiveness of management actions in increasing population numbers, survivorship, and productivity. Improved monitoring techniques are needed to ensure that monitoring efforts are adequate to determine whether recovery actions are successful and recovery criteria are being met.

**Criterion 2. A yearly average productivity of at least one fledged chick per male has been maintained in each recovery unit in the last 5 years prior to delisting.**

From currently available data, it is estimated that males must average one fledged young annually for population equilibrium (see Appendix D). Higher rates of productivity will be necessary to reach the target population size of 3,000 breeding adults. After this population size is achieved and maintained for a minimum of 10 years, a lower rate of productivity of one fledged chick per male will be necessary to maintain the population size at an average of 3,000 breeding adults. Monitoring programs developed and implemented under criteria 1a and 1b should continue throughout this period. We also assume that management designed to ameliorate threats (criteria 1c and 3) will continue through this period and after delisting.

**Criterion 3. Mechanisms have been developed and are in place to assure long-term protection and management of breeding, wintering, and migration areas listed in Appendix B to maintain the subpopulation sizes and average productivity specified in Criteria 1 and 2.**

Development of mechanisms to ensure long-term management and protection of western snowy plovers and their habitat are listed under Action 3, which outlines the recovery actions recommended to meet these recovery criteria. The recovery action outline section describes each action in detail. The recovery action outline lists all subactions necessary to fulfill the main recovery action. It also represents a prioritization of measures to be implemented. Completion of these actions will ensure that threats to western snowy plovers and their habitat are ameliorated and that management will continue after delisting to prevent a reversal of population increases.

**3a. Working groups for each of the six recovery units are established.**

Action 3.1 recommends the establishment of working groups for each recovery unit. Working groups should be diverse and include representatives from Federal, State, local, and private sectors. At present working groups are in existence for all recovery units, and should continue to be maintained and meet regularly. The roles of the working groups are to coordinate and facilitate recovery efforts within each recovery unit, assess population trends, and carry out outreach activities.

**3b. A participation plan for each recovery unit working group has been developed and implemented.**

Each working group is tasked with developing a participation plan that delineates and prioritizes recovery activities within each recovery unit and for each location identified in Appendix B. These plans should identify the roles and responsibilities of each member of the working group and their commitments to carry out identified recovery actions.

**3c. Management plans for all Federal and State lands identified in Appendix C have been developed and implemented.**

Appendix C identifies the landowners of western snowy plover wintering and breeding sites. Many of the sites are owned or managed by Federal or State agencies. Development and implementation of management plans that incorporate the management goals and recommendations in Appendix C for all these sites are necessary to ensure that population goals are reached, threats ameliorated, and long-term protection and management of western snowy plovers and their habitat are in place.

**3d. Mechanisms to protect and manage western snowy plover breeding and wintering sites identified in Appendices B and C are in place for all areas owned or managed by local governments or private landowners.**

Appendix C also identifies many western snowy plover breeding and wintering locations that are owned or managed by local governments, private conservation organizations, or private landowners. These lands also require protection and management to ensure that population goals are reached, threats ameliorated, and long-term protection and management of western snowy plovers and their habitat are in place. Because of the diverse ownership and management of these lands, many different mechanisms may be used to ensure protection and management of these locations. These mechanisms are further described in the recovery action outline and Appendices H and I.

**3e. Public information and education programs are developed and implemented.**

Outreach is a major component of developing and putting in place mechanisms to assure long-term protection and management of breeding, wintering, and migration areas listed in Appendix B. Outreach efforts will be needed to solicit participation of the many Federal, State, local, and private groups in recovery efforts and notify groups and individuals of recovery opportunities and incentives for the western snowy plover. Outreach efforts also must be used as a component of management of western snowy plovers and their habitats. These efforts will include informing the public and gaining their support for measures intended to protect western snowy plovers.

## E. RELATIONSHIP OF RECOVERY ACTIONS AND CRITERIA TO THREATS

The goal of this recovery plan is to ensure the long-term viability of the Pacific coast population of western snowy plovers so that they can be removed from the Federal list of endangered and threatened species. The delisting process requires demonstrating that threats to the western snowy plover have been reduced or eliminated such that the species survival in the wild is assured. Table 8 lists the threats to the western snowy plover that have been identified during and since the listing process and indicates the actions and recovery criteria in the recovery plan that address each threat.

The western snowy plover faces multiple threats throughout its Pacific coast range. Major threats to the western snowy plover include habitat destruction and modification and lack of habitat protection mechanisms (listing factors A and D), disease or predation (listing factor C), and manmade factors that primarily result in disturbance or mortality of breeding birds (listing factor E). Effects of research on western snowy plovers (listing factor B) is also a threat but is comparatively minor and easily addressed through permitting processes. Many of the threats to western snowy plovers are interrelated or have complex interactions with each other. For example, coastal development that destroys or modifies habitat (listing factor A) also results in increased disturbance from recreational activities (listing factor E) and in increased predator populations (listing factor C). Recovery actions and criteria therefore may address multiple threats.

The majority of threats to the western snowy plover, other than habitat destruction or modification, affect the western snowy plover's productivity (breeding success) and survival within otherwise suitable habitat. Criteria 1 and 2 are directed at determining whether the effects of threats on productivity and survival have been removed and expected population and productivity increases are being achieved. Threats addressed by these recovery criteria primarily fall under listing factors B, C, and E. Reduction and elimination of these threats, and the expected increases in productivity and survival, rely primarily on developing intensive management and monitoring programs for the western snowy plover. Criterion 3 is directed at achieving the management and habitat protections necessary to reduce and eliminate threats that fall primarily under listing factors A and D, but also address threats under listing factors B, C, and E that can be eliminated or ameliorated by ensuring long-term management.

**Table 8.** Threats to the Pacific coast population of the western snowy plover and steps within the recovery plan to reduce or eliminate threats.

| Factor* | Threat | Action | Criterion |
|---|---|---|---|
| **A** | **The present of threatened destruction, modification, or curtailment of its habitat or range.** | | |
| A* | Encroachment of introduced beachgrass and nonnative vegetation. | 1.1-1.3, 2.2.1, 3.1-3.10, 4.1.1, 5.1-5.7 | 1b-d,<br>2,<br>3a-e |
| A* | Shoreline stabilization | 1.1-1.3, 2.1, 3.1-3.10, 5.1-5.7 | 1b, 1c,<br>3a-e |
| A* | Urban development and construction | 1.1-1.3, 2.1, 3.1-3.10, 5.1-5.7 | 1b, 1c,<br>3a-e |
| A | Dredging disturbance and tailings deposit | 1.1-1.3, 2.1, 3.1-3.10, 5.1-5.7 | 1b, 1c,<br>3a-e |
| A* | Sand mining | 1.1-1.3, 2.1, 2.2.2, 3.1-3.10, 5.1-5.7 | 3a-e |
| A | Beach nourishment with inappropriate design and/or sand type | 1.1-1.3, 2.2.3, 3.1-3.10, 5.1-5.7 | 3a-e |
| A | Driftwood removal | 1.1-1.3, 2.3.4, 3.1-3.10, 5.1-5.7 | 1b, 1c,<br>2<br>3a-e |
| A | Beach fires and camping | 1.1-1.3, 2.3.3, 3.1-3.10, 5.1-5.7 | 1b, 1c,<br>2<br>3a-e |

| Factor* | Threat | Action | Criterion |
|---|---|---|---|
| A | Water course diversion, impoundment, or stabilization | 1.1-1.3, 3.1-3.10, 5.1-5.7 | 1b, 1c,<br>3a-e |
| A | Habitat conversion for other species | 1.1-1.3, 3.1-3.10, 5.1-5.7 | 1d,<br>3a-e |
| A | Operation of salt ponds | 1.1-1.3, 3.1-3.10, 5.1-5.7 | 1b, 1c,<br>3a-e |
| **B** | **Overutilization for commercial, recreational, scientific or educational purposes.** | | |
| B* | Egg collecting | 1.1-1.3, 2.3.8 | none, 1c |
| B | Studying and monitoring plovers | 1.4, 1.5, 3.1-3.2, 4.3 | 1a-d<br>2 |
| B | Banding | 4.6 | 1a-d |
| **C** | **Disease or predation.** | | |
| C* | Introduced nonnative predators | 1.1-1.3, 2.4, 4.2, 3.1-3.10, 5.1-5.7 | 1b, 1c,<br>2<br>3a-e |
| C | Increased populations of native predators due to human influences | 1.1-1.3, 2.4, 4.2,3.1-3.10, 5.1-5.7 | 1b, 1c, 1d,<br>2,<br>3a-e |
| C* | Predator attractants | 1.1-1.3, 2.4, 4.2, 3.1-3.10, 5.1-5.7 | 1b, 1c, 1d,<br>2,<br>3a-e |
| C | Predation by domestic and feral cats | 1.1-1.3, 2.4, 4.2, 3.1-3.10, 5.1-5.7 | 1a-d,<br>2,<br>3a-e |
| **D** | **The inadequacy of existing regulatory mechanisms.** | | |

| Factor* | Threat | Action | Criterion |
|---|---|---|---|
| D* | Limited habitat protection under the Migratory Bird Treaty Act and State laws | 2.3.8, 3.1-3.10, 5.1-5.7 | 3a-e |
| D | Conflicting beach management methods and mandates | 1.1-1.3, 2.3.8, 3.1-3.10, 5.1-5.7 | 1b, 1c, 3a-e |
| D* | Sections 404 of Clean Water Act and 10 of Rivers and Harbors Act apply to limited amount of habitat | 2.3.8, 3.1-3.10, 5.1-5.7 | 1b-d 3a-e |
| D* | Lack of protection in Baja California, Mexico | 8 | |
| **E** | **Other natural or manmade factors affecting its continued existence.** | | |
| E* | Loss of nests and habitat due to natural events | 1.1-1.3, 1.6, 2.1, 2.2, 2.3.8, 3.1-3.10, 4.4, 4.5, 4.10 | 1b, 1c, 3a-e |
| E* | Disturbance by pedestrians | 1.1-1.3, 2.3.1, 2.3.8, 3.1-3.10, 4.9, 5.1-5.7 | 1b, 1c, 2, 3a-e |
| E* | Disturbance by dogs | 1.1-1.3, 2.3.1, 2.3.2, 2.3.8, 3.1-3.10, 4.9, 5.1-5.7 | 1b, 1c, 2, 3a-e |
| E* | Disturbance by motorized vehicles | 1.1-1.3, 2.3.5, 2.3.8, 3.1-3.10, 4.9, 5.1-5.7 | 1b, 1c, 2, 3a-e |

| Factor* | Threat | Action | Criterion |
|---|---|---|---|
| E* | Disturbance by beach cleaning | 1.1-1.3, 2.3.5, 2.4.1, 3.1-3.10, 4.9, 5.1-5.7 | 1b, 1c,<br>2,<br>3a-e |
| E* | Disturbance from equestrian traffic | 1.1-1.3, 2.3.6, 2.3.8, 3.1-3.10, 4.9, 5.1-5.7 | 1b, 1c,<br>2,<br>3a-e |
| E | Disturbance from fishing activities | 1.1-1.3, 2.3.3, 2.3.8, 3.1-3.10, 4.9, 5.1-5.7 | 1b, 1c,<br>2<br>3a-e |
| E | Disturbance by fireworks | 1.1-1.3, 2.3.3, 2.3.8, 3.1-3.10, 4.9, 5.1-5.7 | 1b, 1c,<br>2,<br>3a-e |
| E | Disturbance by kites and model airplanes | 1.1-1.3, 2.3.3, 2.3.8, 3.1-3.10, 4.9, 5.1-5.7 | 1b, 1c,<br>2,<br>3a-e |
| E* | Military exercises and aircraft overflights | 1.1-1.3, 2.3.8, 2.3.9, 3.1-3.10, 5.1-5.7 | 1b, 1c,<br>2<br>3a-e |
| E | Large crowds associated with special events | 1.1-1.3, 2.3.3, 2.3.8, 3.1-3.10, 4.9, 5.1-5.7 | 1b, 1c,<br>2<br>3a-e |
| E | Increased coastal access to beaches | 1.1-1.3, 2.3.1.2, 2.3.8, 3.1-3.10, 4.9, 5.1-5.7 | 1b, 1c,<br>2<br>3a-e |
| E | Livestock grazing | 1.1-1.3, 2.3.7, 2.3.8, 3.1-3.10, 5.1-5.7 | 1b, 1c,<br>3a-e |

| Factor* | Threat | Action | Criterion |
|---|---|---|---|
| E | Oil spills and disturbance from oil spill clean-ups | 1.1-1.3, 2.5, 4.7, 5.6 | 1b-d<br>3a-e<br>1b, 1c,<br>2<br>3a-e |
| E | Environmental contaminants | 1.1-1.3, 4.8, 5.6 | 1b-d,<br>3a-e |
| E | Litter, garbage, & debris | 1.1-1.3, 2.3.8, 2.4.1, 3.1-3.10, 4.9, 5.1-5.7 | 1b, 1c,<br>2<br>3a-e |
| E | Urban runoff and impaired water quality | 1.1-1.3, 2.1, 2.3.8, 3.1-3.10, 5.1-5.7 | 3a-e |
| E | Management for other special status species | 1.1-1.3, 1.7, 2.6, 2.7, 2.3.3, 3.1-3.10, 4.2.2, 5.1-5.7 | 3a-e |

* Indicates threats originally identified during the listing process.

## III. NARRATIVE OUTLINE OF RECOVERY ACTIONS

1 **Monitor breeding and wintering population and habitats of the Pacific coast population of the western snowy plover to determine effects of recovery actions to maximize survival and productivity.** To assure the long-term viability of western snowy plover populations, their populations and breeding and wintering habitat should be monitored and managed in a systematic, ongoing fashion. Systematic, ongoing monitoring of breeding birds and wintering birds should be undertaken at the recovery-unit level to measure progress towards recovery and identify management and protection efforts that are needed. In addition to the known breeding sites, all known wintering locations (Appendix B) are considered currently important to western snowy plover conservation. These sites include both wintering locations that currently support breeding birds and locations that may potentially support nesting birds in the future. These locations also may support migrating western snowy plovers. There is a need for better information about wintering and migration sites, including spatial and temporal use patterns, feeding areas, habitat trends, and threats. Appendix C, Table C-1 identifies 147 locations where monitoring western snowy plover populations is occurring or recommended to achieve management goals.

1.1. **Annually monitor western snowy plover abundance, population size, and distribution at breeding and wintering locations in each recovery unit using window surveys.** Comprehensive range-wide window surveys of breeding locations and wintering locations (Appendix B) should be conducted annually to determine population trends and fluctuations, and to determine whether management goal breeding numbers (Appendix B) are being achieved. The window survey described in Appendix J (Monitoring Guidelines) should be employed as the primary index of population size to minimize the probability of double-counting birds nesting at multiple locations during the same season. Window surveys are conducted over a relatively short time period to minimize double-counting of birds that change location during the season, but may not fully account for all breeding or wintering birds. Window survey methodology should be improved and correction factors estimated (Action 4.3.1) to improve the accuracy and utility of population indices. This correction may require some banding at sites where there are currently no marked birds on which to base correction factors.

1.2 **Develop and implement a program to monitor western snowy plover productivity and annual survival in each recovery unit.** Development and implementation of a program to monitor western snowy plover productivity and survival, in addition to comprehensive population size and distribution monitoring, is necessary to measure progress toward achieving recovery criteria and to assess the effectiveness of management in removing threats that affect nesting success and survival. Results from this monitoring program also may be used to update the population viability analysis and assess progress toward recovery goals (Actions 4.11 and 6). Monitoring productivity and survival likely will be much more intensive than monitoring population sizes and distribution (Action 1.1), and cannot be implemented at all breeding sites because of insufficient color band combinations to monitor the entire Pacific coast population. Plans for monitoring these demographic characteristics instead should utilize methods to sample demographic characteristics across the breeding range and in each recovery unit. Actions 4.3.2 and 4.3.3 recommend developing methodologies to estimate productivity and survival. The monitoring program should incorporate these methods and should specify the number of sites sampled in each recovery unit, how sites will be selected, and indicate control sites from intensively monitored breeding locations (*i.e.*, the coast of Oregon, extreme northern California, and the shoreline of Monterey Bay).

1.3 **Develop and implement a program to monitor at all breeding and wintering sites the habitat conditions, disturbances, predation, and other threats limiting abundance of breeding and wintering birds, clutch hatching success, chick fledging success, and survival.** Monitoring of threats to the western snowy plover is necessary to determine effectiveness of recovery actions in ameliorating or eliminating threats, assess progress toward recovery, and refine site-specific managements as necessary. A standardized threats monitoring program should be developed and applied to all breeding and wintering sites in conjunction with monitoring developed and implemented under actions 1.1 and 1.2. At a minimum, monitoring should include determining substrate characteristics and vegetation composition (level of nonnative species), frequency and levels of disturbance (*e.g.*, recreational activities, pets, vehicles, horses), and presence and abundance of predators. Appendix J (Monitoring Guidelines) provides general guidance on monitoring but may require revision as research actions under action 4 are completed. Opportunities to incorporate monitoring into Federal activities subject to section 7 of the Endangered Species Act, such as dredging and discharges regulated by the U.S. Army Corps of Engineers, should be utilized when possible.

**1.4 Develop and implement training and certification programs for western snowy plover survey coordinators and observers, consistent with recommendations in Appendix J (Monitoring Guidelines).** Classroom and field training are required for observers who survey for western snowy plovers, and before we can issue a section 10(a)(1)(A) permit. Instruction programs and materials should be developed for comparable training to occur throughout the western snowy plover range to improve consistency of data collection. Classroom topics should include, but not be limited to: (1) biology, ecology, and behavior of breeding western snowy plovers; (2) identification of adult plovers, their young, and their eggs; (3) threats to plovers and their habitats; (4) survey objectives, protocols, and techniques; (5) regulations governing the salvage of carcasses or eggs; (6) special conditions of existing recovery permits; (7) field identification of potential western snowy plover predators; (8) biology and behavior of predator and scavenger species; and (9) other activities (*e.g.*, banding). Field training should include, as appropriate: (1) locating, identifying, and monitoring nests; (2) handling eggs and capturing and handling adults or chicks; (3) specifics on the target activity for which a recovery permit is to be issued, or under which an observer will work; (4) practical field exercises; and (5) field review of appropriate classroom topics.

1.5 **Develop a submittal system for monitoring data to ensure consistent reporting among recovery units and sites, and annually review and revise the system as necessary.** Initially, range-wide survey data will be limited to results from 2 annual window surveys. As population and demographic monitoring methods are developed and implemented (Actions 1.1, 1.2, 4.3.1, 4.3.2, and 4.3.3), a more sophisticated reporting and compiling system will be necessary. Our lead office should coordinate with researchers involved with monitoring to ensure that data collection, submittal, and entry systems remain current, include correction factors that account for lack of detections during surveys, and are consistent among recovery units and sites. An annual range-wide report should be developed and distributed to all interested parties. Additionally, consistent reporting of sightings of banded western snowy plovers is needed. Sightings of banded birds provide information on the wintering sites of breeding birds, use of multiple sites by breeding and wintering plovers, and survival and dispersal of adults and juveniles. In accordance with procedures of the U.S. Geological Survey, Bird Banding Laboratory, the Point Reyes Bird Observatory should continue to act as the color band coordinator for the Pacific coast population to avoid use of duplicate color banding schemes among researchers.

1.6 **Assess and evaluate new breeding, wintering, and migration areas as they are discovered to determine threats and management needs and update lists of areas identified in Appendices B and C as data become available.** As new western snowy plover breeding and wintering areas are discovered, data should be collected to assess site boundaries, habitat characteristics, population levels, and any significant threats. The current list of important breeding and wintering locations (Appendix B) should be expanded or refined as appropriate, and any new areas incorporated into management and monitoring plans. Areas determined to be important for migration through action 4.4.4 also should be evaluated and added to the list of areas requiring protection, management, and monitoring. Management goals and needed management to ameliorate or eliminate threats should be developed for all new breeding, wintering, and migration areas and should be included in periodic revisions of Appendices B and C of this recovery plan.

**1.7 Annually coordinate monitoring of western snowy plovers and California least terns to minimize effects of disturbance to both species.** Coordination with least tern monitors and managers is needed in all areas where western snowy plovers share breeding sites with California least terns. Coordination should take place at biannual pre-and post-season California least tern monitoring meetings. Protocols for monitoring California least terns should be revised as necessary so that western snowy plovers are not detrimentally affected. Human activities within some least tern colonies in southern California include monitoring by one to four people several days per week; maintenance of tern fences; predator management; site preparation; and banding/observation efforts. Human activities associated with tern monitoring must be recognized as additional disturbance to western snowy plovers. Section 10(a)(1)(A) permits, issued under the authority of the Endangered Species Act for western snowy plovers and least terns, should include both species where applicable. Monitoring efforts for both species should be kept separate because of differences in monitoring techniques and species' behaviors. Monitors of least terns and western snowy plovers should be aware of species' differences in nest spacing, brood-rearing, foraging behavior, time of breeding, vulnerability to disturbance, and monitoring and banding techniques.

Western snowy plovers generally begin nesting at least 1 month before the arrival of breeding least terns; thus, tern management often begins well after western snowy plovers have initiated nests. Site preparation (vegetation removal and fence construction) should be coordinated to minimize disturbance to nesting western snowy plovers, and if possible to enhance breeding success for both species (as well as considering other sensitive species, including plants, that may be present). Predator management also should be coordinated to benefit both species.

1.8 **Develop post-delisting monitoring plan.** Prior to delisting a five-year monitoring plan should be developed. Methodology and scope of post-delisting monitoring should be appropriately integrated with existing monitoring efforts for continuity and comparability. Monitoring and research results should be used to guide the long-term conservation of the species.

2 **Manage breeding and wintering habitat of the Pacific coast population of the western snowy plover to ameliorate or eliminate threats and maximize survival and productivity.** The Pacific coast population of the western snowy plover is sensitive to changes in productivity and in adult and juvenile survival rates (see Appendix D). Furthermore, recovery of this species is contingent on intensive management of breeding habitat and availability of wintering habitat for more than the current number of western snowy plovers (see recovery criteria). Appendix C provides a summary of site-specific management needs at 155 breeding and wintering locations (actions 2 and 3). Management efforts may be time-consuming, costly, and sometimes require intensive management. Western snowy plover breeding habitat is extremely dynamic and factors affecting breeding success, such as types and numbers of predators, can change quickly; therefore, managers should be prepared to modify protection as needed. Action 6 recommends annual review of progress toward recovery and revision of site-specific management actions based on monitoring and research results and site-specific experience. Management and protection of western snowy plovers on Federal and State lands are especially important. In addition, protection on Federal and State lands furnishes leadership by example to local land managers. Land managers should recognize that components of breeding habitat include: areas where plovers prospect for nesting sites, make scrapes, lay eggs, feed, rest, and rear broods. Breeding habitat also includes travel corridors between nesting, resting, brood-rearing, and foraging areas. Wintering and migration habitats should also be monitored and managed to maximize survival and recruitment of western snowy plovers into the breeding population.

**2.1 Maintain natural coastal processes that perpetuate high quality breeding and wintering habitat by incorporating the following recommendations into development of participation plans, management planning, and habitat protection (action 3) for the sites identified in Appendix C and any additional sites identified through surveys and monitoring.** The dynamic nature of beach strand habitats as storm-maintained ecosystems should be recognized and allowed to function. Natural process that contribute to maintaining wide, flat, sparsely-vegetated beach strands preferred by western snowy plovers include: inlet formation, migration, and closure; erosion and deposition of sand dunes; and overwash and blowouts of beach and dune habitat. Coastal development, beach stabilization, construction of rock jetties and seawalls, sand removal and dredging, water diversion and impoundment, and planting of nonnative vegetation interfere with these processes and result in loss and degradation of habitat.

Maintenance of natural coastal processes can be accomplished through establishment of management plans, conservation easements, fee title acquisition, zoning, and other means. Coastal development, beach stabilization, resource extraction, and water diversion and/or impoundment projects should be carefully assessed for impacts to wintering western snowy plovers. Recommendations from U.S. Fish and Wildlife Service offices (under the Endangered Species Act and Clean Water Act) and/or State agencies should focus on avoiding or minimizing adverse impacts to wintering habitat. Where adverse effects cannot be avoided, agencies should document impacts so that cumulative effects on this species' habitat can be assessed and compensated. When beach development cannot be avoided, the following protections should be implemented: (1) construction should take place outside the nesting season, (2) developers and others should be advised during planning stages that stabilization of shorelines will result in additional habitat degradation and that these impacts may affect evaluation and issuance of permits under the jurisdiction of the U.S. Army Corps of Engineers or State coastal management agencies, and of measures to minimize the impacts, (3) property owners (*e.g.*, hotel or resort owners) should tailor recreational activity on the beach and dunes to prevent disturbance or destruction of nesting western snowy plovers, their eggs, and chicks, (4) lights for parking areas and other facilities should not shine on western snowy plover habitat, (5) sources of noise that would disturb western snowy plovers should be avoided, and (6) the establishment of predator perches and nesting sites should be avoided when designing facilities. Appendix C, Table C-1 identifies 86 locations which currently have development restrictions in place and 16 locations where development should be restricted or avoided to achieve management goals.

**2.1.1 Develop a prioritized list of western snowy plover wintering and breeding sites where natural coastal processes need protection, or where impaired natural coastal processes should be enhanced or restored.** Recovery Unit working groups should evaluate the sites within their recovery unit and determine where natural processes are likely to be disrupted or are in need of being enhanced or restored, or are of particular importance to maintaining high quality western snowy plover habitat. Sites should be prioritized based on their importance to western snowy plover breeding and the degree of threat to the western snowy plover and its habitat should natural processes be disrupted.

**2.1.2 Identify mechanisms necessary to protect, enhance, or restore natural coastal processes for the sites identified in action 2.1.1 and implement through incorporating into actions 3.1 -3.10.** Mechanisms to protect, enhance, or restore natural processes may include development of management plans that prohibit or restrict activities that disrupt natural process (*i.e.* dredging or sand removal, recreational activities that contribute to excessive erosion or compaction), acquisition of habitat, landowner agreements, local land use protection measures, or enhancement activities. Identification of these sites and mechanisms should be used to guide implementation of long-term management and protection under action 3.

2.2 **Create and enhance existing and potential breeding and wintering habitat.** Past and ongoing impacts to western snowy plover breeding habitat from development, artificial beach stabilization, and other projects have resulted in loss and degradation of western snowy plover habitat. Habitat enhancement and creation are needed at multiple sites to offset these losses. Where impacts cannot be avoided, projects should remediate and compensate habitat loss and degradation by maintaining natural long-shore sand budgets and minimizing interference with natural patterns of sand accretion and depletion. When these types of projects are planned, complex natural sand movement patterns should be taken into account. Beach management policies should recognize that many current erosion and sedimentation problems are the result of past property and/or inlet "protection" efforts. Habitat restoration projects in historic or potential breeding sites, where feasible, is encouraged. Creation of habitat should be emphasized in areas not subject to recreational impacts.

2.2.1 **Remove nonnative and other invasive vegetation from existing and potential habitat and replace with native dune vegetation.** Land managers should implement remedial efforts to remove or reduce vegetation that is encroaching on western snowy plover breeding habitat or obstructing movement of chicks from nesting to feeding areas. Particular attention should be given to the eradication of introduced beachgrass (*Ammophila* spp.) within coastal dunes.

2.2.1.1 **Develop and implement prioritized removal and control strategies for introduced beachgrass and other nonnative vegetation for each recovery unit.** These strategies should include early intervention to prevent expansion into breeding areas where introduced beachgrass and other nonnative vegetation have not yet spread or are in early stages of spreading. Attention also should be given to the removal of giant reed, Scotch broom, gorse, iceplant, and shore pine. Remove/manage vegetation on salt ponds, including levees.

Schedule/coordinate removal efforts to avoid disturbing nesting western snowy plovers. Appendix C, Table C-1 identifies 86 locations where removal of nonnative and other vegetation is either currently occurring or needs to be initiated to achieve management goals.

**2.2.1.2 Replace exotic dune plants with native dune vegetation where it is likely to improve habitat for western snowy plovers.** Land managers should make special efforts to reestablish native dune plants in western snowy plover nesting habitat, while concentrating on removal of nonnative vegetation. Native dune vegetation includes American dunegrass (*Leymus mollis*), beach morning glory (*Calystegia soldanella*), pink sand-verbena (*Abronia umbellata*), yellow sand verbena (*Abronia latifolia*), beach bursage (*Ambrosia chamissonis*), grey beach pea (*Lathyrus littoralis*), whiteleaf saltbush (*Atriplex leucophylla*), and California saltbush (*Atriplex californica*). These efforts should be targeted for coastal dune sites that currently support nonnative vegetation species such as introduced beachgrass (*Ammophila* spp), and should be combined with removal of this invasive plant. Seeds of local native dune plants collected within approximately 32 kilometers (20 miles) of the site to be planted should be used as replacement plant stock. Revegetation efforts should be monitored to ensure that the amount of vegetative cover is compatible with suitable breeding habitat for plovers.

**2.2.2 Deposit dredged material to enhance or create nesting habitat.** Near-shore (littoral drift) and on-shore disposal of dredged material seems to be beneficial for perpetuating high quality western snowy plover nesting habitat in some instances and should be encouraged where appropriate. However, monitoring of habitat characteristics before, during, and after projects is needed, particularly in cases of large operations occurring on sites where western snowy plovers nest or are deemed likely to nest following the disposal operation. On-shore disposal of dredged material should be scheduled outside the nesting season and, where possible, during seasons when birds are not present. In addition, dredged material must be clean sand or gravel of appropriate grain size and must be graded to a natural slope.

**2.2.2.1 Evaluate western snowy plover breeding and wintering sites listed in Appendix C and potential breeding sites to determine whether dredged materials may be used to enhance or create nesting habitat.** Recovery Unit working groups should identify sites where dredged material may be used to enhance or create nesting habitat. Evaluation of sites should include impacts (short- and long-term) to existing western snowy plover habitat, likelihood of use by western snowy plovers, whether appropriate sources of clean dredged material exist, and opportunities to utilize material from dredging projects.

**2.2.2.2 Develop and implement plans, including pre- and post-project monitoring, to use dredged material to enhance or create nesting habitat at the sites identified in action 2.2.2.1.** Plans to implement use of dredged material to enhance or create nesting habitat should be developed for sites identified in action 2.2.2.1. Plans should include measures to minimize impacts to western snowy plovers and existing habitat and should include pre- and post-project monitoring to determine effectiveness of the project in enhancing or creating nesting habitat.

**2.2.3. Implement beach nourishment activities if action 4.1.2 indicates beach nourishment activities are effective in enhancing western snowy plover habitat.** Beach nourishment activities have the potential to enhance western snowy plover habitat, but should be carefully evaluated to weigh the probable adverse and beneficial effects on plovers and on other sensitive coastal dune species.

**2.2.3.1 Evaluate and identify sites where beach nourishment activities may be effective in creating and enhancing western snowy plover habitat.** Potential sites include those sites where natural coastal processes have been disrupted (*i.e.* by coastal development, beach stabilization, construction of rock jetties and seawalls, etc.). Evaluation of sites should consider potential for adverse effects to existing western snowy plover habitat, whether appropriate sand sources are available, and whether long-term benefits are likely to occur.

**2.2.3.2 Develop and implement beach nourishment plans, including pre- and post-project monitoring for the sites identified in action 2.2.3.1.** Plans to implement beach nourishment activities to enhance or create nesting habitat should be developed for sites identified in action 2.2.3.1. Plans should include measures to minimize impacts to western snowy plovers and existing habitat and should include pre- and post-project monitoring to determine effectiveness of the project in enhancing or creating nesting habitat.

**2.2.4 Create, manage, and enhance coastal ponds and playas for breeding habitat.** Coastal ponds and playas, including salt ponds, should be enhanced and created to improve breeding habitat. Significant opportunities for management of nesting plovers currently exist within San Francisco Bay salt ponds, Moss Landing

Wildlife Area, Bolsa Chica wetlands, and south San Diego Bay salt ponds. However, salt ponds should only be created or enhanced at existing salt pond habitat; they should not be used for mitigation or compensation of coastal beach-dune or other western snowy plover habitats. Creation of habitat should be emphasized in areas that would preclude or reduce recreational impacts. Appendix C, Table C-1 identifies 15 locations where habitat enhancement is either currently in place or needs to be initiated to achieve management goals. Additional sites also may provide opportunities to enhance western snowy plover breeding habitat.

**2.3 Prevent disturbance of breeding and wintering western snowy plovers by people and domestic animals.** Disturbance by humans and domestic animals causes significant adverse impacts to breeding and wintering western snowy plovers. Because human disturbance is a primary factor affecting western snowy plover reproductive success, land managers should give the highest priority to implementation of management techniques to prevent disturbance of breeding birds. Western snowy plover breeding and wintering sites are highly variable in their amount of recreational activity. Land managers should conduct site-specific evaluations to determine whether recreational activities, domestic animals, and off-road vehicles pose a threat to plovers and implement appropriate measures. As information is gathered, it should be incorporated into conservation efforts. Management plans (Actions 3.3.1, 3.3.2, and 3.4) should include appropriate human/domestic animal access restrictions to prevent disturbance of western snowy plovers. Management techniques described below can reduce impacts of beach recreation on western snowy plovers, but they must be implemented annually as long as the demand for beach recreation continues.

**2.3.1 Prevent pedestrian disturbance.** Management measures to protect western snowy plovers should be determined on a site-by-site basis; factors to consider include the configuration of habitat as well as types and amounts of on-going pedestrian activity. On national wildlife refuges and State natural preserves within the

California State Parks system, where protection of wildlife is the paramount purpose of Federal and State ownership, western snowy plover habitat should be closed during the breeding season. Other areas also should be closed when necessary to adequately protect breeding western snowy plovers.

**2.3.1.1 Restrict access to areas used by breeding western snowy plovers, as appropriate.** Unless a beach is closed to public entry, or use is minimal, posting and/or fencing of nesting areas is recommended to discourage pedestrian use of the area and allow for plover courtship and prenest site selection, to prevent obliteration of scrapes, crushing of eggs or chicks, and repeated flushing of incubating adults. Any access restrictions should be accompanied by outreach programs to inform the public of any restrictions and provide educational material on the western snowy plover (see action 5).

**2.3.1.1.1 Seasonally close areas used by breeding western snowy plovers.** Dates of seasonal closures/restrictions should be based on the best data available, and be coordinated by geographic region for consistency in communicating with the public. Closures may be determined on a year-to-year basis and other options such as fencing may be considered first. To provide broods with access to foraging areas, closures should cover the area down to and including the water line, where practical. Areas where territorial plovers are observed also should be closed to prevent disruption of territorial displays and courtship. Because nests can be difficult to locate, especially during egg-laying, closure of these areas will also prevent accidental crushing of undetected nests. Appendix C, Table C-1 identifies 81 locations where public access is either currently restricted or it is recommended it be restricted to achieve management goals.

2.3.1.1.2 **Fence areas used by breeding western snowy plovers.** Fencing to keep people and beach activities out of nesting/brood rearing areas should not hinder chick movements, unless fencing is specifically meant to keep chicks from being harmed. Areas with a pattern of nesting activity in previous year(s) or where territorial plovers are observed should be fenced before plovers begin nest-site selection. Because nests can be difficult to locate, especially during egg-laying, closure of these areas will also prevent accidental crushing of undetected nests. Symbolic fences (one or two strands of 1/4 inch plastic-coated steel cable strung between posts) with signs identifying restricted areas substantially improve compliance of beach-goers and decrease people's confusion about where entry is prohibited. On portions of beaches that receive heavy human use during the breeding season, fencing of prime brood-rearing areas to exclude or reduce numbers of pedestrians also should be implemented to contribute to the survival and well-being of unfledged chicks. Appendix C, Table C-1 identifies 64 locations where nesting areas are fenced or where fencing is recommended to achieve management goals.

**2.3.1.1.3 Post signs in areas used by breeding western snowy plovers.** Areas with a pattern of nesting activity in previous year(s) should be posted before plovers begin nest-site selection. On portions of beaches that receive heavy human use during the breeding season, posting of prime brood-rearing areas to exclude or reduce numbers of pedestrians also should be implemented to contribute to the survival and well-being of unfledged chicks. Appendix C, Table C-1 identifies 65 locations where exclusionary signs are in place or recommended to achieve management goals.

**2.3.1.2 Locate new access points and trails well away from western snowy plover nesting and wintering habitat, and modify existing access and trials as necessary.** Recreational users such as campers, clammers, anglers, equestrians, collectors, *etc.*, should be encouraged to consistently use designated access points and avoid restricted areas. Roads, trails, designated routes, and facilities should be located as far away from western snowy plover habitat as possible. Recreationists using boats should be restricted or prohibited from areas being used by the western snowy plover. Appendix C, Table C-1 identifies 67 locations where boat use is currently and/or is recommended to be prohibited or restricted, and 81 locations where access is currently and/or is recommended to be prohibited or restricted to achieve management goals.

2.3.1.2.1 **Evaluate existing and planned access at all breeding and wintering locations and determine whether access may adversely affect western snowy plovers and their habitat.** Review of access points should include evaluating level of and timing of use by recreational users and level of effects on the western snowy plover.

2.3.1.2.2 **For sites where access is determined in action 2.3.1.2.1 to adversely affect western snowy plovers, develop and implement plans to minimize effects.** Actions that could minimize effects of access include seasonal restrictions, signs, fencing, or relocation or modification of access points or trails.

**2.3.2 Implement and enforce pet restrictions.** It is preferable that land managers prohibit pets on beaches and other habitats where western snowy plovers are present or traditionally nest or winter because any noncompliance with leash laws can cause serious adverse impacts to western snowy plovers. If pets are not prohibited, they should be leashed and under manual control of their owners at all times. Pets should be prohibited on beaches and other western snowy plover habitats if, based on observations and experience, pet owners fail to keep pets leashed and under full control.

Land managers should document the type and frequency of infractions of rules and regulations requiring pets on leash. This information, including the number of verbal warnings, written warnings, and notices to appear (citations), should be documented so that comparisons can be made between locations. This documentation could help ensure that adequate effort is being made to enforce pet regulations. Appendix C, Table C-1 identifies 120 locations where pets are currently prohibited or restricted and where they are recommended to be prohibited or restricted to achieve management goals.

**2.3.3 Annually review existing recreational activities at breeding and wintering sites listed in Appendix C and develop and implement plans to prevent disturbance from disruptive recreational activities where western snowy plovers are present.** Some recreational activities may disrupt western snowy plover breeding and foraging, attract predators, destroy nests, or degrade habitat. Management of a variety of recreational activities is needed to minimize these effects. Special events, including sporting events, media events, fireworks displays, and beach clean-ups, attract large crowds and require special attention. Special events planned in western snowy plover nesting areas should not be held during the plover nesting season. Early planning and coordination with local resource agencies should be emphasized. Fireworks should be prohibited on beaches where plovers nest. When fireworks displays are situated to avoid disturbance to western snowy plovers, careful planning also should be conducted to assure that spectators will not walk through and throw objects into plover nesting and brood-rearing areas. Sufficient personnel also must be on-site during these events to enforce plover protection measures and prevent use of illegal fireworks in the vicinity of the birds.

Flying of kites and model airplanes should be managed to avoid adverse impacts in areas where nesting plovers are present. Sports such as ball- and frisbee-throwing should be managed within hitting and throwing distance of western snowy plover nesting areas because of tendencies for stray balls and frisbees to land in closed areas where they can smash nests and where efforts to remove them can disturb territorial or incubating birds. Camping and beach fires should be prohibited in western snowy plover nesting areas during the nesting season. Appendix C, Table C-1 identifies 11 locations where kites are and/or should be prohibited and/or restricted to achieve management goals, but additional recreational activities also should be reviewed for potential adverse effects to western snowy plovers.

2.3.4 **Inform beach users of restrictions on driftwood removal through posting of signs.** Driftwood removal should not be allowed unless needed to create sufficient open habitat to induce nesting activities. In such cases, driftwood removal should occur outside of the breeding season. Appendix C, Table C-1 identifies 26 locations where driftwood collection restrictions currently occur and/or are recommended for restriction to achieve management goals. Driftwood removal should also be minimized through enforcement as identified in Action 2.3.8.

2.3.5 **Prevent disturbance, mortality, and habitat degradation by prohibiting or restricting off-road vehicles, including beach-raking machines.** Recreational off-road vehicles should be prohibited or restricted at western snowy plover breeding areas, as appropriate. Violations associated with unauthorized entry of recreational off-road vehicles into closed or fenced nesting areas should be strictly enforced. During the nonbreeding season, enforcement of violations regarding recreational off-road vehicle use should continue where western snowy plover use of beaches occurs year-round. Because of potential habitat degradation caused by mechanized beach cleaning, alternatives to this type of beach cleaning are recommended, including manual beach cleaning by agency staff and volunteers knowledgeable about the need to maintain coastal dune habitat characteristics and to protect western snowy plovers. Appendix C, Table C-1 identifies 101 locations where off-highway vehicles are currently and/or recommended for prohibition or restriction to achieve management goals.

Essential vehicles within western snowy plover nesting areas should: (1) travel on sections of beaches where unfledged chicks are present only if absolutely necessary; (2) when possible, travel through chick habitats only during daylight hours; (3) travel at less than 8 kilometers (5 miles) per hour; (4) use a guide familiar with western snowy plovers; (5) use open four-wheel motorized off-highway vehicles or nonmotorized all-terrain bicycles to improve visibility; (6) avoid driving on the wrack (marine vegetation) line and during high-tide periods; (7) travel below the high tide mark and as close to the water line as is feasible and safe; and (8) avoid previous tracks on the return trip.

2.3.6 **Implement restrictions on horseback riding in nesting areas through annual coordination with commercial and private equestrian operations and groups.** Strategies to reduce adverse impacts to nests from commercial and private equestrian use of western snowy plover habitat should include: (1) use of designated trail systems or, when absent, use of the wet sand area in areas not closed to the water line; (2) advance coordination with local resource agencies regarding locations of nests and broods; (3) compliance with closed or restricted areas; and (4) informing riders of the need for restrictions to protect habitats used by western snowy plovers and other sensitive coastal dune species. Avoid high-tide periods. Violations regarding unauthorized entry into closed or restricted breeding areas by equestrians should be strictly enforced. Appendix C, Table C-1 identifies 72 locations where restriction or prohibition of horses currently exists or is recommended to achieve management goals.

2.3.7 **Implement and enforce restrictions on livestock in nesting areas through annual coordination with land managers, landowners, and grazing lessees.** Strategies to reduce adverse impacts to nests from livestock grazing in western snowy plover habitat should include: (1) advance coordination with local resource agencies regarding locations of nests and broods; (2)

compliance with closed or restricted areas; and (3) informing landowners of the need for restrictions to protect habitats used by western snowy plovers and other sensitive coastal dune species. Violations regarding unauthorized entry into closed or restricted breeding areas by livestock should be strictly enforced. Appendix C, Table C-1 identifies 18 locations where restriction or prohibition of livestock currently exists or is recommended to achieve management goals.

**2.3.8 Enforce regulations in areas used by breeding western snowy plovers.** Land managers should monitor violations and enforce regulations within all closed and restricted areas, with particular attention to areas where nests or broods are present.

**2.3.8.1 Determine enforcement needs for western snowy plover breeding and wintering sites and provide sufficient wardens, agents, or officers to enforce protective measures in breeding and wintering habitat.** Wardens are especially needed on heavily-used beaches during the peak recreational season, which coincides with the western snowy plover breeding season in many locations. Federal, State, and local authorities should provide a coordinated law enforcement effort to eliminate activities that may adversely impact western snowy plovers, such as illegally-parked vehicles, trespassing off-road vehicles, pedestrians, pets in restricted areas, illegal or unauthorized activities (*e.g.*, fireworks, beach fires, driftwood removal), pets off leash, and littering. Patrols and enforcement are needed to ensure compliance and to make sure restrictive measures are successful. Specific actions to be implemented include patrols in protected areas (see action 2.3.8.2) and car patrols to prevent illegal driving and parking. Appendix C, Table C-1 identifies 105 locations where enforcement of regulations currently occurs or is recommended to occur to achieve management goals.

**2.3.8.2 Develop and implement annual training programs for enforcement personnel and others who work in western snowy plover breeding habitat to improve enforcement of regulations and minimize effects of enforcement actions on western snowy plovers and their habitat.** Federal, State, and local enforcement personnel and others who work in western snowy plover habitat should be trained to be familiar with the Endangered Species Act and other wildlife conservation statutes, and with the measures recommended in this recovery plan. Training, especially specific training for professional law enforcement agents regarding investigation of potential wildlife and Endangered Species Act violations, should be coordinated with local U.S. Fish and Wildlife Service Law Enforcement offices. It is essential that wardens, whether professional or volunteers, (1) be thoroughly trained in procedures for conducting patrols in a manner that minimizes risk to plovers; (2) have at least basic knowledge of western snowy plovers for public education purposes; and (3) be trained to handle potentially confrontational situations. *In cases involving take of listed species, it is essential that investigations be conducted only by trained, certified, and professional law enforcement agents*. Our local Law Enforcement office should be informed *immediately* whenever evidence of suspected take of western snowy plovers is encountered.

Enforcement personnel should be instructed in measures that can minimize effects of enforcement actions on western snowy plovers. Where the extent of habitat to be protected is large, making foot patrols infeasible, horses, four-wheel all-terrain vehicles/off-road vehicles, or nonmotorized all-terrain bicycles, are preferred over trucks, automobiles, *etc.*, because they afford improved visibility for operators. Except during emergencies, vehicle speed should not exceed 8 kilometers (5 miles) per hour and horses should be ridden at a walk only. In addition to providing maximum visibility for operators, horse and foot patrols by uniformed personnel have the added advantage of providing informational/educational interactions with beach visitors to promote compliance with plover protection measures.

Enforcement and emergency response personnel (such as search and rescue, and fire) should be well aware of potential western snowy plover locations. These locations should be named as avoidance areas as a part of their plans and training exercises. Enforcement patrols should use the same access trails as beach visitors; if additional access points are needed, they should be the minimum necessary and as far away from nesting plovers as possible.

**2.3.9 Develop and implement a program to annually coordinate with local airports, aircraft operations, and agency aircraft facilities to facilitate compliance with aviation regulations regarding minimum altitude requirements.** Each recovery unit working group should develop a list of local airports, aircraft operations, and agency aircraft facilities within each recovery unit. Working groups, land managers, and the U.S. Fish and Wildlife Service should annually inform them of western snowy plover breeding areas that should be avoided by aircraft operations or where minimum altitude requirements should be enforced to minimize disturbance of western snowy plovers. Aircraft operations within western snowy plover habitat should require a minimum altitude of 152 meters (500 feet) for aircraft and a possibly higher altitude for helicopters. Aircraft operations that have already established guidelines allowing aircraft to fly under the 152-meter (500-foot) threshold should raise the limits to this minimum threshold or higher as needed. Exceptions such as use for low-altitude military training should be addressed in coordination with the appropriate Fish and Wildlife Office through section 7 consultation.

Ultralight aircraft are a new potential source for negative effects to the snowy plover. Ultralight aircraft landed on nesting plover beaches at Point Reyes National Seashore in 2003. These aircraft are sometimes associated with an airport but often are kept on ranches or other private lands (S. Allen ***in litt.*** 2004).

In addition, land managers should report suspected violations of aviation regulations in western snowy plover nesting areas during the breeding season. Suspected violations and the aircraft's registration number should be reported to law enforcement officers and, if appropriate, the Federal Aviation Administration. If not in violation of aviation regulations (***e.g.***, helicopters), a description of the helicopter should be reported to law enforcement officers so they can notify the operator of the presence of, and potential for take of, western snowy plovers in nesting areas.

**2.4 Prevent excessive predation for western snowy plovers.** Land managers should employ an integrated approach to predator management that considers a full range of management techniques. Managers may need to reevaluate and clarify their policies on the management of predator populations and/or habitat where predation might be limiting local western snowy plover populations. In particular, policies that prohibit management of native predator populations, even when human-abetted factors have caused substantial increases in their abundance, may be counter-productive to the overall goal of protecting "natural" ecosystems.

In addition to predator management activities by on-site biologists, assistance from the U.S. Department of Agriculture (Wildlife Services

Branch) biologists, State wildlife agency furbearer biologists, biologists specializing in avian predators, and professional trappers should be sought and used as needed and appropriate. Federal, State, and local agencies and the general public should be aware of the adverse consequences to listed species if needed predator control measures are prohibited or restricted. Appendix C, Table C-1 identifies 61 locations where predator control currently occurs or is recommended to achieve management goals. Below are specific means of predator control.

**2.4.1 Manage litter and garbage and its removal to minimize attracting predators on western snowy plover habitat.** Litter and garbage in western snowy plover habitat may increase predation of western snowy plovers by providing food that attracts predators and encourages increased predator populations. Appropriate management of litter and garbage, particularly in areas that receive heavy recreational use, is needed to prevent or minimize excessive predation.

**2.4.1.1 Implement and enforce anti-littering regulations.** Litter should not be allowed in western snowy plover breeding areas to avoid attracting predators. Littering ordinances should be enforced year-round.

**2.4.1.2 Evaluate the effects of current litter and garbage management on predation of western snowy plover at breeding and wintering sites.** All sites in Appendix C should be evaluated to determine whether garbage and litter affect predation on western snowy plovers by attracting predators.

**2.4.1.3 Develop and implement garbage and litter management plans for all sites identified in action 2.4.1.2 where litter and garbage contribute to predation on western snowy plovers.** Plans for managing litter and garbage should be incorporated into long-term protection and management efforts developed and implemented under action 3. Beachgoers should be discouraged from leaving or burying trash or food scraps on the beach. Trash cans should not be located on the beach unless there is no other recourse to prevent littering. Emptying cans in the evening instead of leaving them overnight is preferable. Fish-cleaning stations should be located well away from plover breeding areas. Land managers should supply covered or scavenger-proof trash receptacles at access points and away from western snowy plover habitat, and receptacles should be routinely emptied. Until predator-proof trash containers can be installed, existing trash cans should be emptied frequently to reduce attractiveness and availability of their contents to scavenging predators. Land managers should also provide toilets at access points and away from western snowy plover habitat to discourage people from using the dunes.

Although removal of trash from the beach reduces predation threats, beach-raking should be avoided year-round to protect breeding and wintering western snowy plovers (see action 2.3.5). Beach-raking of western snowy plover habitat also should be avoided because it removes plover food sources. Trash should be selectively removed from the beach manually, but natural materials, including shells, kelp, and driftwood, should be left intact (see action 2.3.4).

2.4.2 **Annually identify predator perches and unnatural habitats attractive to predators and remove where feasible.** Planners should not allow unnatural habitats or other predator attractants to be placed near western snowy plover nesting locations. Where feasible, land managers should remove from western snowy plover breeding locations any exotic vegetation, perches, and other features that attract avian and mammalian predators. Where signs and fences are necessary as part of management to protect plover breeding areas, attempts should be made to design them in a way that will deter their use by predators (*e.g.*, install spikes on fence posts).

**2.4.3 Erect predator exclosures to reduce western snowy plover egg predation and improve productivity (number of fledglings per male) where appropriate.** Guidelines for the use of predator exclosures to protect nesting western snowy plovers are contained in Appendix F. Exclosures are a valuable tool for countering human-abetted predation threats to western snowy plover eggs, but they are not appropriate for use in all situations, nor do they provide any protection for mobile plover chicks, which generally leave the exclosure within one day of hatching and move extensively along the beach to feed. Exclosures should be used in conjunction with an integrated predator management program. Also, exclosures must be carefully constructed, monitored, and evaluated by qualified persons. In some areas, avian predators have learned over time to associate exclosures with a source of prey (J. Buffa *in litt.* 2004). String (twine) or a more substantial plastic stealth material may be needed on top of exclosures to deter avian predators. Appendix C, Table C-1 identifies 53 locations where exclosures are currently used or recommended for use to achieve management goals.

The use of exclosures (small circular, square, or triangular metal fences that can be quickly assembled) to deter predator and human intrusion is recommended as one of the most effective management tools to protect nests (see Appendix F for exclosure protocols). However, it should be recognized that while exclosures provide nest protection, they do not ensure survival of chicks to fledging age and may contribute to predation on adults, so their use should be evaluated carefully and may not substitute for other measures that reduce human disturbance (2.3) or control predation (2.4.1, 2.4.2, 2.4.3, 2.4.5).

**2.4.4 Evaluate the need for and feasibility of predator removal and implement removal where warranted.** Where predators have been identified through monitoring to adversely affect western snowy plover breeding success and/or survival and cannot be adequately controlled through use of exclosures, land managers should evaluate the need for and feasibility of predator removal. Removal of predators should be pursued where it is feasible, warranted, humanely conducted, and useful. Situations that may especially warrant predator removal include those where nonnative predators such as red fox (*Vulpes vulpes regalis*), feral cats, and Norway rats (*Rattus norvegicus*) are present, where predators have been introduced to islands, where predator range extensions have been human-abetted, or where high rates of western snowy plover adult, chick, or egg predation (which cannot be countered with predator exclosures or other aversion methods) are occurring. Nonnative predators should be lethally controlled in plover nesting habitat. Native predators should be removed or controlled by nonlethal means whenever possible. Gulls also should be discouraged from establishing and expanding nesting colonies at western snowy plover nesting areas, and land managers should determine whether existing gull colonies warrant removal. If removal is not warranted, exclosures around plover nests should be used to prevent large flocks of roosting gulls from trampling plover nests.

Federal and State permits must be obtained to legally capture, kill, or hold and release birds protected under the Migratory Bird Treaty Act and State laws. Also, individuals responsible for capturing such birds and the holding facility must have the proper Federal and State permits, and Federal land managers must document that such activities are in compliance with the National Environmental Policy Act. Biological considerations for determining whether removal of avian predators is appropriate include the time of year (to assess whether the predator is caring for young or is a fledgling itself), whether the predatory bird is a resident or migrating through western snowy plover nesting habitat, and whether the predatory bird is a sensitive species or listed under the Endangered Species Act. Because of the potential for swift and significant losses of plovers by avian predators, land managers should plan in advance to complete the necessary procedures and secure needed permits to effectively deal with cases of high negative impact on western snowy plovers. If feasible, removal of native predators should focus on problem individuals rather than populations. Possible control methods include egg addling, nest removal, translocation of problem individuals, and holding in captivity with later release after plover breeding season. State permits must also be obtained as appropriate for the capture and removal of problem mammals (*e.g.*, raccoons, skunks, and opossums). In 2001, the California Coastal Commission determined that predator management in western snowy plover habitat on Vandenberg Air Force Base was also subject to Coastal Consistency review under the Coastal Zone Management Act.

**2.4.5 Remove bird and mammal carcasses in western snowy plover nesting areas.** Where practical and not disturbing to western snowy plovers, dead birds and mammals that wash up on the beach in close proximity to plover nests should be removed to reduce the attraction of predators to plover nests. Removal of carcasses of marine mammals and species listed under the Endangered Species Act should be coordinated with the National Marine Fisheries Service and the U.S. Fish and Wildlife Service.

**2.5 Protect western snowy plovers and their breeding and wintering habitat from oil or chemical spills.** Land managers should develop oil/chemical spill emergency response plans that provide for protection of known western snowy plover breeding areas. The U.S. Coast Guard should update their emergency response measures to include protective measures for the western snowy plover. In the event of a spill in the vicinity of a western snowy plover nesting or feeding area, efforts should be made to prevent oil/chemicals from reaching these beaches. Clean-up operations should be prompt, but agencies should exercise special care during remediation efforts and coordinate closely with us to prevent accidental destruction of nests and/or excessive disturbance of breeding adults, nests, or chicks. Response plans should include applicable recommendations contained in this recovery plan (*e.g.*, Action 2.3.5 regarding essential vehicles).

Efforts must be made to minimize the likelihood of oil or chemical spills in plover wintering areas. Land managers should develop oil/chemical spill emergency response plans that provide for protection of known plover wintering areas. The U.S. Coast Guard should update their emergency response measures to include protective measures for the western snowy plover. Shorebird or coastal ecosystem protection plans developed by State or local agencies to address oil/chemical spills should also include protection measures for western snowy plovers. In the event of a spill in a known western snowy plover wintering area, efforts should be made to prevent oil/chemicals from impacting plovers and unavoidable impacts should be documented. Restoration efforts should begin expeditiously, but agencies should exercise special care and coordinate closely with us to prevent excessive disturbance to wintering western snowy plovers. Further, habitat restoration efforts must be conducted in compliance with the National Environmental Policy Act and the Coastal Zone Management Act.

If western snowy plovers or their habitat sustain injury due to oil/chemical spills, the responsible parties should restore the areas to their original condition or the Federal Government (U.S. Coast Guard) should lead the clean-up effort; appropriate claims should also be filed under the Natural Resource Damage Assessment regulations to recover damages and undertake relevant restoration work. Assessment of natural resource damages is facilitated by availability of baseline data on pre-spill conditions. Therefore, whenever possible, agencies that own or manage western snowy plover habitat should collect baseline data on behavior, reproduction, distribution, abundance, and habitat use. The baseline information on plover distribution and habitat use should also be supplied to the Area Committees that develop and update regional spill contingency plans so that this information can be incorporated into pre-spill planning efforts for protection of sensitive environments and species. Oil spill emergency response personnel should be well aware of potential plover locations. These locations should be named as avoidance areas as a part of their training exercises. Appendix C, Table C-1 identifies 4 locations where contaminant removal is occurring or is recommended to achieve management goals.

2.5.1 **U.S. Fish and Wildlife Service biologists should participate in Area Committees responsible for maintaining the Area Contingency Plans for the Pacific Coast to facilitate the updating of spill response plans to include protection of western snowy plovers.** Active participation in the Area Committees would require funding for staff participation from the six U.S. Fish and Wildlife Service offices responsible for the coastlines of California, Oregon and Washington.

2.5.2 **Assign monitors to beaches that are inhabited by western snowy plovers to protect western snowy plovers from injury during spill responses.** Monitors would be responsible for identifying areas of beach that are in use by plovers and directing response personnel and vehicles around these sensitive areas. Potential monitors should be identified in advance, and, where necessary, retained under contract so they can begin work immediately in the event of a spill. Spill response may require approximately two weeks of cleanup work that should be monitored, with potentially five incidents of this magnitude per year.

**2.6 Reduce adverse impacts of recovery efforts for other sensitive species, including those within the San Francisco Bay Recovery Unit, by compensating for the loss of western snowy plover breeding and wintering habitat.** Management and recovery actions for other sensitive species carried out in western snowy plover habitat should be evaluated for adverse effects to western snowy plover habitat. All efforts should be made to conserve western snowy plover habitat and minimize adverse effects. Where this is not possible, any loss of western snowy plover habitat values should be compensated. Within coastal beach-dune habitats in Washington, Oregon, and California, compensation efforts should emphasize the removal of beachgrass (*Ammophila* spp.) for lost western snowy plover breeding habitat resulting from management for other sensitive species.

To compensate for the loss of existing western snowy plover breeding habitat values in San Francisco Bay from planned conversion to tidal marsh, appropriate salt ponds should be designated for protection and enhancement as western snowy plover breeding habitat. Currently, most western snowy plover breeding habitat occurs on levee roads, margins of active salt ponds, and pond bottoms of inactive salt ponds. Roads and levees provide lower quality habitat because of disturbance and ease of predator access. Any losses of western snowy plover breeding habitat should be replaced with habitat that provides similar or higher values (*i.e.*, salt ponds or salt pans) in concert with recovery actions implemented from the Recovery Plan for Tidal Marsh Ecosystems of Northern and Central California (U.S. Fish and Wildlife Service in prep.). Habitat enhancement for western snowy plovers should be phased in with scheduled tidal marsh restoration for other listed species. During this interim period, land managers should make all efforts to achieve the recovery criteria of 500 breeding adults within the San Francisco Bay Recovery Unit by intensively managing existing western snowy plover breeding habitat.

Any replacement of western snowy plover breeding habitat in San Francisco Bay should concentrate on areas where the necessary components of western snowy plover breeding habitat can be created.

These areas include locations where unvegetated salt pans, salt ponds, islets and levees, and tidal mudflats/sandflats can be created or enhanced. Also, attempts should be made to avoid areas that are adjacent to landfills or other high concentrations of potential predators. Unless it is shown to be infeasible, creation and enhancement of western snowy plover breeding habitat should be emphasized in areas that currently support high numbers of breeding plovers and/or are not conducive to salt marsh restoration. The area to be managed for western snowy plovers should be sufficient to support a population of 500 breeding birds, estimated at 809 hectares (2,000 acres) of managed salt ponds. Most of these managed salt ponds should be located in South San Francisco Bay, which supports most of the existing western snowy plover population; however, some should also be located in the North Bay. Created or enhanced salt ponds should be intensively managed, similar to the Moss Landing Wildlife Area salt ponds. Management measures practiced at these salt ponds include maintenance of water control structures to maintain desired water levels, removal of excessive vegetation, and predator control.

2.7 **Discourage pinnipeds from usurping western snowy plover nesting areas.** Land managers should monitor pinniped colonies adjacent to western snowy plover breeding habitat and seek to keep breeding pinnipeds from occupying western snowy plover nesting areas during the breeding season where possible. Where conflicts occur, breeding pinnipeds should be discouraged from hauling out at western snowy plover breeding areas or be relocated, if feasible. Implementation of this action should be coordinated with the National Marine Fisheries Service to ensure compliance with the Endangered Species Act of 1973 and the Marine Mammal Protection Act of 1972 (16 U.S.C. 1361 *et seq.*).

2.7.1 **In coordination with National Marine Fisheries Service, investigate feasibility and methods for discouraging pinniped use of western snowy plover nesting areas.** Marine mammal populations have increased in many western snowy plover nesting areas. However, methods, effectiveness, and impacts of discouraging pinniped use of beaches are unknown and should be investigated. Methods considered should be evaluated for their effects on western snowy plovers and their habitat as well as effectiveness in discouraging pinniped use. Workshops, such as those conducted by NMFS, for developing methods to reduce conflicts between pinnipeds and other species and human users should be held.

**2.7.2 Identify areas where pinniped use is negatively affecting western snowy plover nesting and implement any appropriate methods identified in action 2.7.1.** If effective methods are determined through action 2.7.1, sites where pinniped use negatively affects western snowy plover nesting should be identified and methods to discourage pinniped use implemented. Implementation of any methods to discourage pinniped use should be closely coordinated with the National Marine Fisheries Service to ensure compliance with the Endangered Species Act of 1973 and the Marine Mammal Protection Act of 1972 (16 U.S.C. 1361 *et seq.*).

**3 Develop mechanisms for long-term management and protection of western snowy plovers and their breeding and wintering habitat.** Long-term management and protection will be needed on Federal and non-Federal lands to meet recovery criteria for each recovery unit and to meet management goals for individual breeding and wintering locations. Development of long-term protection mechanisms should include opportunities for participation of various stakeholders in development of management options.

**3.1 Establish and maintain western snowy plover working groups for each of the six recovery units to facilitate regional cooperative networks and programs.** Development of regional cooperative networks and programs, coordinating local public and private land use planning with State and Federal land use planning, recovery planning, and biodiversity conservation is needed (Figure 12). To facilitate and develop regional cooperative programs, working groups have been established for each of the six recovery units and should be maintained. U.S. Fish and Wildlife

Service field offices should facilitate exchange of information among working groups. The working groups should be composed of representatives from the Federal, State, local, and private sectors; and meet regularly to assess western snowy plover population trends and coordinate plover recovery efforts. Each of the six working groups should use this recovery plan as a guide, but members will prioritize in cooperation with our Arcata Fish and Wildlife Office what management measures need to be implemented in their recovery unit because they have on-the-ground, day-to-day, experience about what is currently being done in these areas. Working groups should assist with updating information contained in Appendices B and C, tracking whether management goals are being met, and recommending changes in management goals and site-specific management actions, if necessary. Public outreach also should be a major focus of the working groups. An interchange of ideas between all six working groups should also occur on an on-going basis.

**3.2 Develop and implement regional participation plans for each of the six recovery units that outline strategies to implement recovery actions.** The 1994 Interagency Cooperative Policy on Recovery Plan Participation and Implementation Under the Endangered Species Act (U.S. Fish and Wildlife Service and National Oceanic and Atmospheric Administration 1994) provides for a participation plan process, which involves all appropriate agencies and affected interests in a mutually-developed strategy to implement recovery actions. Participation plans for implementing recovery actions for the western snowy plover that include all partners should be developed by each of the six recovery unit working groups. In addition to outlining a strategy to implement recovery actions, the participation plan should include strategies for evaluation of progress and needs for plan revision. Participation plans may also achieve the policy's goal of providing for timely recovery of species while minimizing social and economic impacts. Plans should identify and prioritize specific recovery activities for each location identified in Appendices B and C,while considering the needs of the entire Pacific coast population. They

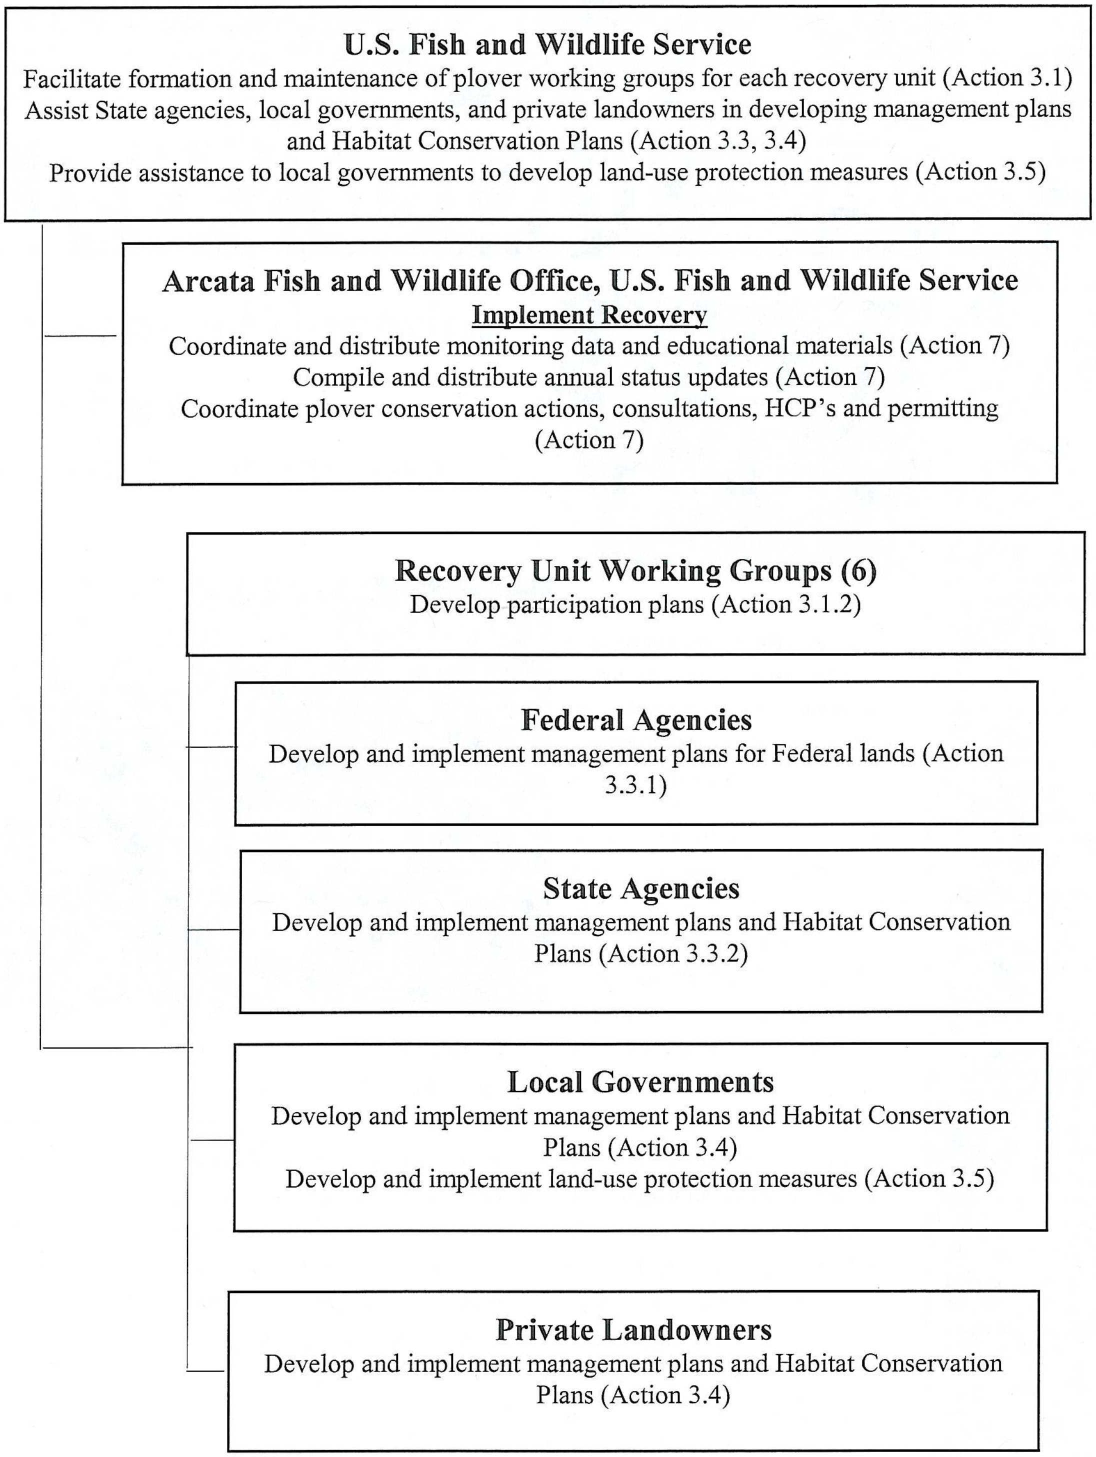

Figure 12. Chart of recovery planning and implementation efforts.

should include, but not be limited to: (1) endorsements by responsible agencies of their intent to seek economic resources for ongoing recovery actions; (2) outreach efforts to enhance the public's understanding of the western snowy plover's habitat needs (including an information and education strategy specific to area demographics and recreational activities); (3) economic incentives for conservation of western snowy plovers on private lands; and (4) all actions necessary to maintain western snowy plover productivity after delisting. Participation plans may also identify ways in which recovery actions for western snowy plovers will be covered as part of coastal ecosystem plans or other conservation measures.

3.3 **Develop and implement management plans for all Federal and State lands to provide intensive management and protection of western snowy plovers and their habitat.** Federal and State land managers should develop and implement management plans for all breeding and wintering locations (listed in Appendix B) that occur on Federal or State lands. Intensive management programs for western snowy plovers at national wildlife refuges should be implemented and annually evaluated to ensure they provide sufficient plover protection. Intensive management programs also should be implemented and periodically evaluated on lands administered by the National Park Service, U.S. Forest Service, U.S. Bureau of Land Management, U.S. Army Corps of Engineers, and Federal military bases, State wildlife areas, State ecological reserves, and State park lands (including State natural preserves and State seashores).

3.3.1 **Develop and implement management plans for Federal lands.** Federal agencies should develop or update, as appropriate, site-specific management plans that address threats to western snowy plovers, and adopt management measures for habitat protection and enhancement on Federal lands. Management plans should be implemented on an ongoing basis. Federal agencies also should review their proposed actions under the requirements of sections 7 and 10 of the Endangered Species Act prior to implementing the management plans because they may require authorization under section 7(a)(2) or 10(a)(1)(A).

**3.3.2 Develop and implement management plans and habitat conservation plans on State wildlife areas, State ecological reserves, and State beaches.** State agencies that manage State beaches, wildlife areas, or ecological reserves should develop and implement site-specific management plans and habitat conservation plans to minimize and mitigate impacts to western snowy plovers, and management measures for habitat protection and enhancement on State lands. State agencies should coordinate the development of habitat conservation plans with us and apply for section 10(a)(1)(B) permits under the Endangered Species Act if their management actions and allowed uses are resulting in incidental take of western snowy plovers.

**3.4 Develop and implement habitat conservation plans or other management plans for western snowy plover breeding and wintering sites owned or managed by local governments and private landowners.** We should provide assistance in the development of habitat conservation plans or other management plans to: (1) county and city governments that manage western snowy plover habitats; (2) private resource managers; and (3) owners of large amounts of private natural land. Habitat conservation plans are only required if an incidental take permit under section 10(a)(1)(B) of the Endangered Species Act is desired or required.

**3.5 Provide technical assistance to local governments in developing and implementing local land use protection measures through periodic workshops.** Federal and State agencies should assist local governments with jurisdiction over western snowy plover habitats in developing western snowy plover protection policies as part of new or revised local general plans, zoning policies, implementing measures, land use plans, comprehensive plans, and local coastal programs. For areas where beach closures are necessary, appropriate ordinances, administrative rules, and regulations should be developed by State and local governments to enable law enforcement officers to conduct necessary enforcement actions.

Technical assistance such as maps of western snowy plover habitats, identification of local threats, and recommended site-specific protective measures should be provided to coastal planners. At least two workshops within each recovery unit that provide local governments with basic information on the western snowy plover, its habitats, threats, and recommended protective measures should be conducted during the first 10 years of recovery plan implementation. Additional technical assistance likely will be required but should be provided on an as needed basis as new or revised general plans, policies, ordinances, and other land use protection measures are developed.

3.6 **Develop and implement cooperative programs and partnerships with the California State Coastal Commission, the Oregon Department of Land Conservation and Development, the Washington State Parks and Recreation Commission, the Oregon Parks and Recreation Department, the California Department of Parks and Recreation, and the Oregon Department of Fish and Wildlife to ensure that they use their authorities to the fullest extent possible to promote the recovery of the western snowy plover.** Federal and State agencies should assist the California State Coastal Commission, Oregon Department of Land Conservation and Development, Washington State Parks and Recreation Commission, Oregon Parks and Recreation Department, California Department of Parks and Recreation, and Oregon Department of Fish and Wildlife in reviewing, updating, and amending local coastal programs and policies for consistency with the western snowy plover recovery plan. This review should include protection of western snowy plover habitats, cumulative impacts to western snowy plovers, and policies or restrictive measures recommended in this recovery plan.

3.7 **Obtain long-term agreements with private landowners.** Agreements between Federal and State agencies and private landowners interested in western snowy plover conservation should be developed and implemented. Landowners should be informed of the significance of plover populations on their lands and be provided with information about available conservation mechanisms, such as agreements and incentive programs. For private lands with potential occurrences of western snowy plovers, permission should be sought from landowners to conduct on-site surveys. If surveys identify plover populations, landowners should be informed of their significance and offered incentives to continue current land uses that support species habitat. Appendix C, Table C-1 identifies 69 locations where landowner cooperation/cooperative agreements are occurring or are recommended to achieve management goals.

3.8 **Identify and protect western snowy plover habitat available for acquisition.** Federal, State, and private conservation organizations should protect western snowy plover habitat as it becomes available, through fee title or conservation easement, *etc.* We and other organizations should identify sites that may become available for acquisition, and we should continue to evaluate excess Federal lands for western snowy plover habitat and apply to acquire them as they become available. Each recovery unit working group should develop a list of priority properties for acquisition, and Federal, State, and nongovernmental organizations should work with land conservancy groups to implement land trades and acquisitions. Management plans for the western snowy plover should be developed during the land acquisition process.

3.9 **Ensure that section 10(a)(1)(B) permits contribute to Pacific coast western snowy plover conservation.** Recommendations contained in this recovery plan should guide the preparation of habitat conservation plans under section 10(a)(1)(B) of the Endangered Species Act for western snowy plovers on the Pacific coast by providing information to: (1) guide potential applicants in developing plans that minimize and mitigate the impacts of take and (2) assist us in evaluating the impacts of any proposed conservation plans on the recovery of the Pacific coast western snowy plover population. The section 10(a)(1)(B) permit process may be a valuable mechanism for developing the long-term protection agreements called for in Actions 3.3.2 and 3.4, especially where significant population growth has already occurred and productivity exceeds l.0 fledged chick per male.

**3.10 Ensure that consultations conducted pursuant to section 7 of the Endangered Species Act contribute to Pacific coast western snowy plover conservation.** The recovery plan should also guide the evaluation of impacts to western snowy plovers pursuant to section 7(a)(2) of the Endangered Species Act. In evaluating these impacts, we and other Federal agencies should consider each of the breeding and wintering locations listed in Appendix B as important for recovery, and should also refer to the management goal breeding numbers for applicable locations and determine how the proposed project will affect those goals. Coordination with military bases which have western snowy plover populations is important to ensure that military activities do not affect the western snowy plovers or their habitat. Appendix C, Table C-1 identifies 54 locations where military uses are either restricted or recommended for restriction to achieve management goals.

**4 Undertake scientific investigations that facilitate recovery efforts.** Major gaps remain in our understanding of useful protection measures and conservation efforts for the western snowy plover. These include effective methods for habitat restoration, predator control, and monitoring population numbers and demographic characteristics.

**4.1 Investigate effective methods for habitat restoration**.

**4.1.1 Evaluate the effectiveness of past and ongoing methods for habitat restoration by removal of introduced beachgrass and identify and carry out additional investigations necessary.** Land managers, in coordination with recovery unit working groups, should summarize methods used to date for removal of introduced beachgrass and review their effectiveness. They also should pursue any additional field studies necessary to determine the most effective and cost-efficient methods for habitat restoration through removal of introduced beachgrass. Controlled studies with improved monitoring would provide needed direction for management decisions.

**4.1.2 Evaluate the impacts and potential benefits of past and ongoing beach nourishment activities and identify and carry out any additional studies necessary to determine effects of beach nourishment activities on western snowy plover habitat.** Beach nourishment activities should be carefully evaluated to weigh the probable adverse and beneficial effects on plovers and on other sensitive coastal dune species. Pre- and post-deposition beach profiles and faunal studies (including invertebrates) should be conducted to determine effects on habitat suitability for western snowy plovers. Consideration should be given to whether the projected long-term benefits are likely to occur.

**4.2 Develop and test new predator management techniques to protect western snowy plover nests and chicks.** Because many of the techniques currently used to reduce predation have disadvantages or limitations in effectiveness, new predator management techniques should be investigated. Assistance from the U.S. Department of Agriculture, Wildlife Services Branch, from State wildlife agency furbearer biologists, and other predatory bird and mammal specialists should be sought on these matters.

**4.2.1 Develop higher-efficiency nest exclosures.** Because exclosures must be deployed quickly, and currently-designed exclosures are heavy and labor- and time-intensive to erect, new exclosure designs should be tested. Prototypes should include lightweight materials that are easier to transport and a design that is easy to assemble and install.

**4.2.2 Develop California least tern exclosures that prevent harm to western snowy plovers.** Resource managers should continue to investigate modified designs for California least tern enclosures to further minimize western snowy plover mortality.

**4.2.3 Identify, prioritize, and carry out needed investigations on control of native and nonnative predators.** Aspects of the ecology of problematic avian predators (*e.g.*, ravens and shrikes) and native mammals (*e.g.*, coyotes and gray foxes) that could be used to gain an understanding of how to control their impact on western snowy plover nesting areas during the plover breeding season should be investigated. Information also is needed on the applicability and usefulness of other control methods, including aversive techniques for conditioning predators to avoid foraging in western snowy plover nesting areas or preying on western snowy plover eggs, chicks, or adults. Investigation is also needed to develop methods to discourage gull colonies. Aversive techniques may include taste aversions, displaying predator carcasses, or installing electric fences. Effective modifications of signs and fencing to prevent their use as predator perches also requires investigation. While in many cases there appear to be practical obstacles to development of effective aversion techniques that can be efficiently applied in the field, the goal of reducing predation with minimum disruption to native predator populations that are important to overall ecosystem balance is desirable and any methods that appear potentially practical and useful should be evaluated for success and cost-effectiveness. Initial study trials might be done at sites or seasons where western snowy plovers are not present in order to minimize unplanned adverse impacts. Recovery unit working groups should identify and prioritize studies needed and inform us of their recommendations.

**4.2.4 Identify, prioritize, and carry out needed investigations on predator management at the landscape level.** Resource managers should investigate landscape-level management of predators that inhabit western snowy plover nesting areas. This management could include removal of predator nest sites and other predator attractants or habitat on lands surrounding western snowy plover breeding areas. Recovery unit working groups should identify and prioritize studies needed and inform us of their recommendations.

**4.2.5 Investigate techniques for identifying predators responsible for individual nest predation events.** Techniques should be developed to identify predators responsible for nest predation events so that appropriate management measures can be applied. Such techniques could include installation of a remote video camera to monitor western snowy plover nests and exclosures and identify problematical predators.

**4.3 Improve methods of monitoring population size and reproductive success of western snowy plovers.** Methods used to monitor western snowy plover populations have differed over time and from site to site. To measure progress toward recovery reliably, standard monitoring guidelines have been developed (Appendix J). Logistical and financial constraints likely will preclude complete coverage of all areas, so sampling methods should be developed.

**4.3.1 Improve methods of monitoring western snowy plover population size.** Not all western snowy plovers at a given location are detected during a single survey, such as the annual breeding-season window survey. Consequently, correction factors are necessary to extrapolate population size from window surveys. Correction factors are determined on a site-specific basis. Intensive monitoring and/or color banding make it possible to know the number of western snowy plovers present at a site. When a window survey is completed, the ratio of the total number of western snowy plovers to the number of western snowy plovers counted provides a correction factor that may be used for future window surveys of the site and for other sites with window surveys but without intensive monitoring. Site-specific correction factors should be obtained for all major nesting locations. When correction factors have been determined for many sites, patterns may emerge that allow correction factors to be applied more broadly.

**4.3.2 Develop sampling methods for annually estimating reproductive success within each recovery unit.** While it is extremely valuable to monitor clutch hatching success and chick fledging success at each site as a measure of habitat quality, it is critical to determine the number of young fledged per male for each recovery unit to measure the potential for population stability and growth. Measuring the number of young fledged per male requires intensive monitoring, and at sites with large numbers of birds, some method of identifying individual males. Extensive color banding of adults and their young, enabling determination of young fledged per male, has been undertaken in large portions of coastal Oregon, the shoreline of Monterey Bay, and coastal San Diego County for the past several years. These efforts should continue. Since there are insufficient color band combinations to monitor all individuals in every recovery unit, sampling procedures should be developed to color band adequate samples of males, and if necessary their chicks, in the other recovery units to obtain estimates of the number of young fledged per male. Color banding for measuring reproductive success should be integrated with banding for estimating population size.

**4.3.3 Develop methods to monitor western snowy plover survival rates within each recovery unit.** Extensive color banding of adult plovers and their young in coastal Oregon, the shoreline of Monterey Bay, and coastal San Diego County has enabled survival rates of adults and young to be calculated for several years (see Population Status and Trends and Survival sections). These efforts should continue. Information on survival rates of birds from other recovery units can be derived from birds banded for monitoring reproductive success or estimating population size.

**4.4 Conduct studies on western snowy plover habitat use and availability.**

**4.4.1 Identify western snowy plover brood habitat and map brood home ranges.** Brood movements should be mapped and distances quantified to identify how large an area must be protected for broods. Determine home ranges of western snowy plovers through radio telemetry studies. Traditionally used brood habitat should be identified and protected through actions 2 and 3.

4.4.2 **Identify components of high-quality western snowy plover brood rearing habitat.** The elements of high-quality brood habitat should be determined to facilitate creation and enhancement of suitable characteristics at other breeding locations.

4.4.3 **Quantify wintering habitat needs of western snowy plovers along the Pacific coast.** The amount of habitat needed to support wintering western snowy plovers along the Pacific coast should be determined. This effort should include estimating the numbers of western snowy plovers that can be supported at wintering locations listed in Appendix B and identifying important site characteristics. This action will require consideration of wintering habitat quality along the Pacific coast of the United States and Mexico, and quantifying the combined interior and coastal populations.

4.4.4 **Identify any important migration stop-over areas used by migrating but not by breeding or wintering western snowy plovers.** Additional information on western snowy plover migration patterns is needed because migration involves expenditure of energy that may affect survival or productivity. Although monitoring and protection of breeding and wintering locations are currently higher priorities than protection of migration sites, further investigations of, and protective measures for, migration sites should be undertaken when feasible. Threats and management needs of identified migration stop-over habitat should be evaluated and included in management monitoring, and protection tasks (see action 1.6).

4.5 **Develop and implement a research program to determine causes of adult western snowy plover mortality, including investigation of possible causes, magnitude, and frequency of catastrophic mortality.** Determine causes of mortality and the stage in the annual cycle (*e.g.*, post-breeding, migration, winter, pre-breeding, breeding) at which mortality occurs for each sex and age class. This assessment can be done through intensive, bi-weekly monitoring to determine relative health and potential for disease. Monitoring could include fat content and weight related to the season.

4.6 **Improve techniques for banding western snowy plovers.** Improve the technique for banding birds to reduce injuries. Because western snowy plover injuries are usually associated with Federal metal bands but not with plastic bands, removal of U.S. Fish and Wildlife Service lettering from the inside of the metal band should be investigated. Eliminating use of the U.S. Fish and Wildlife Service metal band also should be considered. Experimentation with new techniques must be conducted cautiously and may need to include pre-testing on nonlisted surrogate species.

4.6.1 **Compile information regarding number and types of banding injuries to western snowy plovers to determine extent and causes of banding injuries.** Several banding injuries to western snowy plovers have been reported. However, there is currently no consistent reporting of injuries to determine the extent or types of injuries. Working groups should compile information on banding injuries to use in determining the type and extent of the problem and in developing a course of action. Information collected should include number of injuries, type of injury (abrasion, foot loss, broken leg, *etc.*), probable cause of injuries (foreign object lodged between band and leg, wearing of band, *etc.*), effect of injuries on behavior (breeding, foraging, predator avoidance), type of bands (plastic or metal) associated with injuries, whether metal bands had writing on the inside or other rough areas likely to cause abrasion or lodging of foreign object.

**4.6.2 Review compiled information and determine and implement a appropriate course of action to minimize banding injuries.** The information complied in step 4.6.1 should be reviewed to determine the appropriate course of action to minimize banding injuries. Review may reveal that banding injuries are rare or have little impact on breeding success or survival, in which case no changes to banding procedures may be necessary. However, extensive numbers of injuries or impacts on breeding success and survival may require actions such as changing the location of metal bands from the tarsus to tibiotarsus, discontinuing use of metal bands, or using different band types. All decisions regarding changes to banding procedures should consider effects of such changes to the type, quantity, and quality of data that may be gathered from banding efforts, and whether such changes will affect the ability to determine population trends, monitor success of management actions, or otherwise affect recovery efforts. For example, discontinuing use of metal bands may affect the ability to gather information on survival, longevity, and dispersal useful in analyzing population viability.

**4.7 Identify effects of oil spills on western snowy plovers.** Research should be conducted on the direct and indirect effects of oil spills on western snowy plovers, including, but not limited to: (1) how oil spills affect the plover's prey base; (2) chronic effects of oiling; (3) transmission of oil on partially-oiled birds from the breast to the egg; (4) at what stage oiled plovers need to be captured or re-captured; (5) preferable methods to remove oil from soiled birds; and (6) impacts to plovers during oil clean-up and remediation activities.

**4.8 Monitor levels of environmental contaminants in western snowy plovers.** When abandoned eggs and/or dead chicks that are not needed for law enforcement investigations become available, they should be collected for potential contaminants assessment. Egg removal and salvage of dead chicks should only be done by individuals possessing proper Federal and State authorizations. Chemical analysis of salvaged specimens should be coordinated through our Division of Environmental Contaminants. All salvaged eggs should be analyzed for organochlorine pesticides, total polychlorinated biphenyls (PCB's), selenium, mercury, and boron.

All sampling should be opportunistic, based on availability of eggs that are known to be abandoned. Eggs should never be removed from the beach as long as there is any realistic chance that they might hatch. In the case of unhatched eggs from a partially hatched clutch, eggs should not be collected until at least 36 hours after the known hatch date of the other eggs. Full clutches should not be collected unless it is known that 35 or more days have elapsed since the last egg was laid. When this opportunistic sampling of failed eggs indicates potential problems with contaminants, follow up studies should be carried out (see action 4.9).

**4.9 Design and conduct contaminants studies if monitoring of contaminants in action 4.8 indicates potential contaminants effects.** When opportunistic sampling of failed eggs (action 4.8) indicates potential problems with contaminants, additional studies should be carried out to evaluate the extent of contamination in western snowy plover diets, its effects on nest success and egg hatchability, and its effects on various life stages of snowy plovers (eggs vs. adults). Thresholds when management action is required should be identified. When the target threshold is exceeded research should be conducted to identify the source.

**4.10 Identify, prioritize, and carry out needed investigations of the effects of human recreation on western snowy plovers.** Many studies on the effects of recreational activities on western snowy plovers have already been conducted. To avoid duplicating previous or ongoing efforts, recovery unit working groups should evaluate and prioritize additional study needs to determine the effects of human recreation on western snowy plover. Western snowy plover should be monitored for effects from recreational activities such as off-road vehicle riding, horseback riding, walking, jogging, fishing, aircraft, ultralight aircraft, and kite-flying.

**4.11 Revise the population viability analysis (Appendix D), if needed, when sufficient additional information on demographic characteristics (survival rates, reproductive success) is available from each recovery unit and information is obtained on the probability and magnitude of catastrophic mortality events.** As new information on population numbers, survival rates, and reproductive success are acquired from monitoring (actions 1.1 and 1.2), monitoring techniques are improved (action 4.3), and mortality sources and rates of mortality are determined (action 4.5), the population viability analysis should be reviewed and revised if additional information differs significantly from that used to construct the original analysis.

**5 Undertake public information and education programs.** Expanded efforts are needed to increase public awareness of the needs of western snowy plovers, other rare beach species, and the beach and dune ecosystem. Public outreach efforts should be a major focus of each of the working groups for the six recovery units. Appendix C, Table C-1 identifies 84 locations where public information and education is either currently occurring or is recommended to achieve management goals.

**5.1 Develop and implement public information and education programs.** Millions of beach recreationists come in contact with western snowy plover nesting and wintering areas each year. Disregard to signs, symbolic fencing, and leash laws by beach users can directly affect the productivity and health of western snowy plovers on those beaches. Public information and education efforts play a key role in obtaining compliance of beach recreationists with plover protection measures that, in turn, affect the birds' recovery. Central messages to the beach-going public include: (1) respect areas fenced or posted for protection of plovers and other rare beach species; (2) do not approach or linger near western snowy plovers or their nests; (3) if pets are permitted on beaches used by plovers, keep the pets leashed; (4) don't leave or bury trash or food scraps on beaches, as garbage attracts predators that may prey upon plover eggs or chicks; and (5) do not build wood structures that can be used as predator perches.

Because of the importance of information and education for the western snowy plover recovery effort, as part of this recovery plan, we developed an Information and Education Plan for the Western Snowy Plover, Pacific coast population (Appendix K).

5.2 **Inform Federal, State, and local resource/regulatory agencies and local planning departments of threats to breeding and wintering western snowy plovers and their habitats.** Periodic meetings and/or workshops should be held to inform Federal, State, and local resource management and regulatory agencies, and city and county planning departments about threats, research, and management needs for plovers. A network of public agency staff from each of the six recovery unit working groups should develop a coordinated approach to present this information to these agencies periodically, or as needed.

5.3 **Develop and maintain updated information and education materials on western snowy plovers.** Members of the six recovery unit working groups should develop new western snowy plover information and education materials for target audiences to stimulate public interest and awareness. In addition, all materials should be kept reasonably current regarding the status of the species and protection efforts. These materials should also explain the need for conservation of the beach and dune ecosystem and the plight of other rare beach-dwelling species. Videos detailing needed western snowy plover recovery actions by location and recovery unit should be developed, and might be efficiently produced in conjunction with updated public service advertisements.

5.4 **Alert landowners and beach-goers about access restrictions within western snowy plover habitats.** Land managers should begin providing informational and educational outreach at least 2 weeks prior to the onset of the nesting season to provide beach-goers and interested landowners with advance notice of impending restrictions on publicly-owned western snowy plover breeding habitats. This outreach is particularly important for the first year of restrictions. If necessary, follow-up publicity that includes information on citations issued to violators should be implemented to help reinforce the message.

5.5 **Provide trained personnel to facilitate protective measures, provide public education, and respond to emergency situations.** Biologists, docents, volunteers, and other personnel should be trained to patrol western snowy plover nesting areas to monitor birds, distribute educational materials, respond to emergency situations, and ensure that beach-goers stay out of fenced areas and adhere to other plover protection measures. Biologists engaged in monitoring, management, or research activities should also advance the public's understanding of plover management needs.

5.6 **Develop protocols for handling sick, displaced, injured, oiled, and dead birds or salvaged eggs.** Land managers within each recovery unit should develop protocols for all trained personnel identifying who should be contacted when injured, dead, oiled, or displaced birds are found, and who is permitted to handle these birds. Federal and State salvage permits are necessary for the disposal of dead birds and the transportation of injured birds. Federal and State endangered species permits are necessary for wildlife rehabilitators to accept and care for injured and sick birds. Coordination with biologists that are monitoring and banding western snowy plovers is essential for capture and release of injured/rehabilitated birds. Live chicks that are found should not be moved or taken for rehabilitation as these chicks are often not abandoned, even though plover adults may not be obvious at the time the chicks are seen. Protocols should also be developed on how to collect and preserve salvaged eggs used for contaminants analysis.

5.7 **Establish a distribution system and repository for information and education materials.** Land managers must distribute information and education materials to target audiences. To reach the large population of potential beach-goers within a few hours' drive of many major metropolitan areas, broad-scale information and education mechanisms should be implemented, including distribution by mass media such as newspapers, radio and television announcements, and internet web sites. Land managers should also focus their information and education efforts on user groups at beach parking lot entry stations and kiosks, visitor centers, marinas, beach-front housing developments, equestrian and angler access points, and locations providing off-road vehicle permits. Public outreach efforts should be directed to groups within the geographical location of the managed beaches (***e.g.***, to private and commercial equestrian users) and to groups outside of the area who use the beaches on a regular or seasonal basis (***e.g.***, to off-road vehicle associations from out-of-state or inland locations). Land managers, with the help of docents and volunteers, should coordinate with local school teachers to develop and present environmental education lesson plans and participatory activities for elementary and middle school groups.

We will act as a central repository for current and new information and education materials received; upon request, we will make these materials available to recovery unit working groups and the general public. We will also maintain information on western snowy plovers at our website (http://www.fws.gov/arcata). Major distributional efforts should also continue by Federal, State, and local agencies, and private conservation organizations.

**5.8 Establish a reporting and distribution system for annual monitoring data and management techniques.** Our Arcata Fish and Wildlife Office should coordinate and produce an annual report of submitted breeding and wintering monitoring data and distribute it to recovery unit working groups. This report should describe results of monitoring throughout the western snowy plover population's range. A distribution system should also be established for sharing information on predator management techniques, nest protection, etc. among working groups.

**6 Review progress towards recovery and revise recovery efforts as appropriate.** Communication, evaluation, and coordination play a major role in western snowy plover recovery efforts. Land managers within each of the six recovery unit working groups should review the effectiveness of their management activities in coordination with other members of their working group, and revise management measures as appropriate. They should also provide results of annual population monitoring and the effectiveness of management activities to their working group and to our Arcata Fish and Wildlife Office.

**6.1 Develop and implement a tracking process for the completion of recovery actions and the achievement of delisting criteria.** A tracking process should be developed to track the completion of recovery actions and progress toward delisting. Utilizing information from specific actions, the recovery criteria such as the implementation of management activities can be tracked. Information from the tracking process can be used in outreach and in helping identify when the western snowy plover can be delisted.

**6.2 Review progress toward recovery annually within each recovery unit working group and revise site-specific recovery efforts as appropriate to meet recovery goals.** Communication, evaluation, and coordination play a major role in western snowy plover recovery efforts. Land managers within each of the six recovery unit working groups should review the effectiveness of their management activities in coordination with other members of their working group, and revise management measures as appropriate. They should also provide results of annual population monitoring and the effectiveness of management activities to their working group and to our Arcata Fish and Wildlife Office.

Additionally, the working groups in conjunction with land managers should review success in meeting management goal breeding numbers recommended in Appendix B, and develop recommendations for any necessary revisions to those numbers based on site-specific conditions. Ongoing and needed management activities recommended in Appendix C also should be evaluated and revised according to site specific conditions. Revisions to management goals and management activities should be provided to our Arcata Fish and Wildlife Office.

**6.3 Assess the applicability, value, and success of this recovery plan to the recovery of the western snowy plover every 5 years until the recovery criteria are achieved.** Rather than revising the entire recovery plan, it is proposed that minor revisions, clarifications, and prioritization changes be made through an addendum, to be produced and distributed every 5 years. This addendum would address data gaps identified in this version of the recovery plan including recommended management prescriptions, specific habitat management recommendations, management goal breeding numbers, directed surveys; and necessary changes discussed in previous recovery actions. It would provide a summary of the recovery actions implemented to date, and it would be a forum to solicit comments from the Recovery Team, stakeholders, and others interested parties on any proposed major changes. Major changes, elimination, or addition of recovery actions may initiate a revision.

**6.4 Prepare a delisting package for the Pacific coast population of the western snowy plover.** If actions 6.1 through 6.3 indicate recovery criteria have been met, actions to ameliorate or eliminate threats have been implemented and determined to be effective, and analyses of threats demonstrate that threats identified during and since the listing process have been ameliorated or eliminated, prepare a delisting package.

**6.5 Prepare and implement a post-delisting monitoring plan.** If delisting is warranted, prepare a post-delisting monitoring plan. Section 4 of the Endangered Species Act requires, in cooperation with the States, monitoring for a minimum of five years all species that have been recovered (*i.e.*, delisted).

**7 Dedicate sufficient U.S. Fish and Wildlife Service staff for coordination of western snowy plover recovery implementation.** Our Arcata Fish and Wildlife Office holds lead responsibility for coordinating implementation of western snowy plover recovery. We should assure that the Arcata Fish and Wildlife Office has sufficient staff to handle the primary responsibility of implementing the western snowy plover recovery plan. Duties should include coordination and distribution of monitoring information and educational materials; transmission of copies of annual population monitoring results to our field offices that are responsible for western snowy plover issues; compilation and distribution of annual population status updates to all working groups; coordination with our other field offices in CNO and Region 1 regarding western snowy plover conservation actions, consultations, habitat conservation plans, and permits; facilitating coordination among the working groups created for the six recovery units; and fund raising to support recovery implementation actions.

**8** Establish an international conservation program with the government of Mexico to protect western snowy plovers and their breeding and wintering locations in Mexico. Meeting the recovery goals outlined in this recovery plan is dependent only on actions recommended for implementation along the Pacific coast of the United States. However, other actions are identified for Mexico to complement conservation efforts in the United States. Efforts should be made to establish an international conservation program between the U.S. Fish and Wildlife Service and Mexico's National Institute of Ecology, Ministry of Environment, Natural Resources and Fisheries. Programs to facilitate implementation of this conservation program should include Partners in Flight, North American Waterfowl Management Plan, and the Borderlands Initiative.

**8.1** **Develop a joint effort between the United States and Mexico to protect western snowy plover populations and their habitat.** Joint efforts should be implemented to determine important habitat in Mexico and protect these breeding and wintering locations from human disturbance.

**8.2** **Encourage research and monitoring of breeding and wintering western snowy plovers in Baja California, Mexico, by universities and authorities of Mexico.** Joint efforts should be made to develop and implement a long-term monitoring program for western snowy plover populations of Mexico. They should include developing methods for consistent monitoring, coordination of banding and color-marking with banders from the United States, assessment of the population status of breeding and wintering birds, and assessment of environmental impacts that may adversely affect plover populations.

8.3 **Encourage development and implementation of public information and conservation education in Mexico for western snowy plovers.** Public information and educational efforts should be coordinated and implemented by the United States and Mexico. They should include development of bilingual pamphlets for distribution to anglers, tourists, and local communities, and construction and placement of bilingual signs alerting them of the presence of nesting western snowy plovers.

9 **Coordinate with other survey, assessment, and recovery efforts for the western snowy plover throughout North America.** Western snowy plovers range through much of North America, and many individuals of the Pacific Coast population of western snowy plovers may overwinter in areas that overlap with other populations. Participation and coordination with other groups working on survey, assessment, and recovery efforts may yield valuable information on the distribution, status, and management needs for the Pacific Coast population of the western snowy plover. This coordination effort should be included in establishment of an international conservation program with Mexico.

# IV. IMPLEMENTATION SCHEDULE

The following Implementation Schedule outlines actions needed, responsible parties, and estimated costs to recover the United States portion of the Pacific coast population of the western snowy plover. Considering the recovery criteria, results of the population viability analysis (Appendix D), and fulfillment of the recommendations contained in the recovery plan, recovery of the western snowy plover could occur in approximately 40 years. This time estimate assumes dedicated, proactive efforts toward improvements in western snowy plover management in the near-term, and subsequent management at a maintenance level commensurate with fulfillment of the recovery criteria.

The total cost of implementing actions outlined in this recovery plan over 40 years is $149,946,000. However, this figure represents only a portion of the overall costs because the cost of many actions cannot be estimated at this time. For example, costs associated with intensive protection and management on Federal and State lands (Action 3.3) should be determined by members of each of the six recovery unit working groups because they are most familiar with their site-specific needs and constraints. Costs of many actions were estimated based on current management recommendations provided in Appendix C. However, coastal ecosystems are dynamic and necessary management actions may vary with time, as site conditions change. Improvements over time in methods for predator control, control of nonnative vegetation, and monitoring are also expected and may affect actual costs.

It should be recognized that expenditure of funds for recovery of the western snowy plover will provide far-reaching benefits beyond those gained for a single species. Allocation of these funds will also benefit many other sensitive fish and wildlife species, the coastal beach-dune ecosystem, public appreciation for natural habitats, and aesthetics. These estimated costs do not reflect a cost/benefit analysis that incorporates other values or economic effects with implementation of the recommendations contained in this recovery plan.

We believe that protection and management costs could be substantially reduced by selecting protection strategies that are more restrictive of other beach uses.

While we believe that it is neither feasible nor desirable to completely eliminate beach recreation in most western snowy plover habitat, we also recognize that management strategies that protect western snowy plovers on beaches where public use is also maintained require a continuing commitment of person-power, and are inherently expensive.

The Implementation Schedule lists and ranks actions that should be undertaken within the next 5 years.  This schedule will be reviewed routinely until the recovery objective is met, and priorities and actions will be subject to revision.

## Key to Acronyms used in the Implementation Schedule

Definition of action priorities:

**Priority 1** - An action that must be taken to prevent extinction or prevent the species from declining irreversibly in the foreseeable future.

**Priority 2** - An action that must be taken to prevent a significant decline in species population or habitat quality, or some other significant negative impact short of extinction.

**Priority 3** - All other actions necessary to provide for full recovery of the species.

Definition of action durations and costs:

**Annual** - An action that will be implemented each year.

**Continual** - An action that will be implemented on a routine basis once begun.

**Ongoing** - An action that is currently being implemented and will continue until action is no longer necessary.

**As needed** - An action that will be implemented on an "as needed" basis.

**Unknown** - Either action duration or associated costs are not known at this time.

**To Be Determined (TBD)** - Costs to be determined at a later date.

**Responsible parties*:**

* All responsible parties listed for actions in Implementation Schedule are considered lead agencies for those actions.

## IMPLEMENTATION SCHEDULE

Western Snowy Plover Pacific Coast Population Recovery Plan

| | | | | | | Cost Estimate (in $1,000 units) | | | | | |
|---|---|---|---|---|---|---|---|---|---|---|---|
| Priority No. | Action Description | Action Number | Action Duration | Responsible Parties | Total Costs | FY1 | FY2 | FY3 | FY4 | FY5 | Comments/Notes |
| 1 | Annually monitor abundance, population size and distribution at breeding and wintering locations. | 1.1 | annual | LMAO, CO, CI, RSCH | 2,194 | 54.9 | 54.9 | 54.9 | 54.9 | 54.9 | Assumes 157 window survey days, with 2 biologists per location at. Action needed to determine fulfillment of recovery criteria. |
| 1 | Develop and implement a program to monitor productivity and annual survival. | 1.2 | annual | LMAO, CO, CI. RSCH | TBD | | | | | | Action needed to determine fulfillment of recovery criteria. Depends partly on completion of 4.3.2 and 4.3.3. |
| 1 | Develop and implement a program to monitor habitat condition and threats at all breeding and wintering sites. | 1.3 | annual | LMAO, RSCH | 1,125 | 60 | 27 | 27 | 27 | 27 | Assumes initial cost for development of standardized monitoring program and subsequent monitoring for 155 sites. |
| 3 | Develop and implement training and certification programs for western snowy plover survey coordinators and observers. | 1.4 | continual | ES, LMAO, RSCH | 363.5 | 32 | 8.5 | 8.5 | 8.5 | 8.5 | Assumes initial cost to develop program and subsequent implementation. |

| | | | | | | Cost Estimate (in $1,000 units) | | | | | |
|---|---|---|---|---|---|---|---|---|---|---|---|
| Priority No. | Action Description | Action Number | Action Duration | Responsible Parties | Total Costs | FY1 | FY2 | FY3 | FY4 | FY5 | Comments/Notes |
| 3 | Improve submittal system for monitoring data to ensure consistent reporting. | 1.5 | continual | ES, LMAO, BBL, PRBO | 346 | 32 | 8 | 8 | 8 | 8 | Assumes initial cost to develop submittal and reporting system and subsequent annual review. |
| 3 | Assess and evaluate new breeding wintering and migration areas for threats and management needs and update lists as data become available. | 1.6 | continual | ES, LMAO, PRBO | TBD | | | | | | Depends on results of annual surveys and monitoring. |
| 3 | Coordinate monitoring of snowy plovers and California least terns to minimize disturbances. | 1.7 | annual | ES, RW, NAVY, USMC, USAF, CDFG, CDPR, WS, BRD | 1,020 | 25.5 | 25.5 | 25.5 | 25.5 | 25.5 | Coordinate at biannual pre- and post-season Califomia least tern monitoring meeting. Assumes 2 meetings at 2 days per meeting with 9 agency staff attending. |
| 3 | Develop a post-delisting monitoring plan. | 1.8 | TBD | ES, LMAO, CO, CI, RSCH | TBD | | | | | | |

| | | | | | | Cost Estimate (in $1,000 units) | | | | | |
|---|---|---|---|---|---|---|---|---|---|---|---|
| Priority No. | Action Description | Action Number | Action Duration | Responsible Parties | Total Costs | FY1 | FY2 | FY3 | FY4 | FY5 | Comments/Notes |
| 1 | Develop a prioritized list of wintering and breeding sites where natural coastal processes need protection and/or enhancement. | 2.1.1 | 2 yrs | ES, LMAO, CO, CI, RSCH | 59.65 | 59.65 | | | | | Assumes time to evaluate sites and development of the prioritized list. |
| 1 | Identify and implement mechanisms to protect, enhance or restore natural coastal processes. | 2.1.2 | continual | ES, LMAO, CO, CI, RSCH | TBD | | | | | | Incorporate into ongoing management in action 3. Costs will depend on mechanisms identified and carried out. |
| 1 | Develop and implement prioritized removal and control for introduced beachgrass and other non-native vegetation. | 2.2.1.1 | continual | CE, LMAO, CO, CI | TBD | | | | | | App C identifies 86 sites. Costs range for mechanical, manual and/or chemical control: $1,000 to $87,000/hectare ($400 to $35,000 per acre). |
| 2 | Replace exotic dune plants with native dune vegetation where it is likely to improve habitat. | 2.2.1.2 | continual | CE, LMAO, CO, CI | TBD | | | | | | Estimated cost of planting native vegetation: $30,000 per hectare ($12,000 per acre). Number of sites to be determined. |

| | | | | | | Cost Estimate (in $1,000 units) | | | | | |
|---|---|---|---|---|---|---|---|---|---|---|---|
| Priority No. | Action Description | Action Number | Action Duration | Responsible Parties | Total Costs | FY1 | FY2 | FY3 | FY4 | FY5 | Comments/Notes |
| 3 | Evaluate breeding and wintering sites to determine whether dredged materials may be used to enhance or create nesting habitat. | 2.2.2.1 | 2 yrs | CE, ES, LMAO, CO, CI | 110 | 55 | 55 | | | | Assumes cost to evaluate each site. |
| 3 | Develop and implement plans to use dredged materials may be used to enhance or create nesting habitat. | 2.2.2.2 | ongoing | CE, ES, LMAO, CO, CI | TBD | | | | | | Costs will depend on completion of acts on 2.2.2.1. |
| 3 | Identify sites where beach nourishment may be effective in creating and enhancing habitat. | 2.2.3.1 | 2yrs | CE, ES, LMAO, CO, CI | 110 | 55 | 55 | | | | Assumes cost to evaluate each site. |
| 3 | Develop and implement beach nourishment plans for site identified in action 2.2.3.1. | 2.2.3.2 | ongoing | CE, ES, LMAO, CO, CI | TBD | | | | | | Cost dependent on number of sites identified in 2.2.3.1 and outcome of 4.1.1. |

| | | | | | | Cost Estimate (in $1,000 units) | | | | | |
|---|---|---|---|---|---|---|---|---|---|---|---|
| Priority No. | Action Description | Action Number | Action Duration | Responsible Parties | Total Costs | FY1 | FY2 | FY3 | FY4 | FY5 | Comments/Notes |
| 1 | Create, manage, and enhance coastal ponds and playas for breeding habitat. | 2.2.4 | ongoing | ES, RW, CE, CDFG, NASA, HARD, LMAO | TBD | | | | | | App C identifies 15 sites. Costs dependent on type and area of restoration. |
| 1 | Seasonally close areas used by breeding snowy plovers. | 2.3.1.1.1 | annual | LMAO, CO, CON, CI | 559.2 | 13.98 | 13.98 | 13.98 | 13.98 | 13.98 | App C identifies 81 sites. Assumes cost to close these sites. |
| 1 | Fence areas used by breeding snowy plovers | 2.3.1.1.2 | annual | LMAO, CO, CON, CI | 14,840 | 371 | 371 | 371 | 371 | 371 | App C identifies 64 sites. Cost assumes 1 kilometer fencing required per site at a cost of $5,900 per kilometer. |
| 1 | Post signs in areas used by breeding snowy plovers | 2.3.1.1.3 | annual | LMAO, CO, CON, CI | 202 | 5 | 5 | 5 | 5 | 5 | App C identifies 65 sites. Cost dependent on number of signs needed at each site, but assumes cost for installation and a minimum of 4 signs at $20 per sign. |
| 1 | Evaluate effects of existing and planned access at all breeding and wintering locations and any new locations identified. | 2.3.1.2.1 | 1 year | LMAO, CO, CI | 455 | 455 | | | | | Appendix C identifies 81 sites. Assumes cost to conduct use survey for the identified sites. |
| 1 | Develop and implement plans to minimize adverse access effects. | 2.3.1.2.2 | continual | LMAO, CO, CI | TBD | | | | | | Costs depend on outcome of 2.3.1.2.1. |

| Priority No. | Action Description | Action Number | Action Duration | Responsible Parties | Total Costs | Cost Estimate (in $1,000 units) FY1 | FY2 | FY3 | FY4 | FY5 | Comments/Notes |
|---|---|---|---|---|---|---|---|---|---|---|---|
| 3 | Implement and enforce pet restrictions. | 2.3.2 | continual | LMAO, CO, CI | 39,406 | 985 | 985 | 985 | 985 | 985 | Appendix C identifies 120 sites Assumes staff time to implement and enforce restrictions at the identified sites. |
| 1 | Annually review recreational activities and develop and implement plans to prevent disturbance from disruptive recreational activities at breeding and wintering sites | 2.3.3 | annual | LMAO, CO, CI | 21,948 | 549 | 549 | 549 | 549 | 549 | Assumes staff cost to develop and implement plans at each site annually. |
| 3 | Prevent driftwood removal through posting of signs | 2.3.4 | continual | LMAO, CO, CI | 1,805 | 50 | 45 | 45 | 45 | 45 | Appendix C identifies 26 sites. Cost dependent on number of signs needed at each site, but assumes cost for installation and a minimum of 4 signs at $20 per sign. |
| 1 | Prevent disturbance, mortality, and habitat degradation by prohibiting or restricting off-road vehicles and beach-raking machines. | 2.3.5 | continual | LMAO, CO, CI | 18,760 | 469 | 469 | 469 | 469 | 469 | Appendix C identifies 101 sites. Assumes staff time for monitoring on weekends. |
| 3 | Implement restrictions on horseback riding through annual coordination. | 2.3.6 | annual | LMAO, CO, CI | 1,033.7 | 25.8 | 25.8 | 25.8 | 25.8 | 25.8 | Appendix C identifies 72 sites. Assumes staff time to implement restrictions. |

| | | | | | | Cost Estimate (in $1,000 units) | | | | | |

| Priority No. | Action Description | Action Number | Action Duration | Responsible Parties | Total Costs | FY1 | FY2 | FY3 | FY4 | FY5 | Comments/Notes |
| 3 | Identify areas where pinniped use is negatively affecting nesting and implement any appropriate methods. | 2.7.2 | TBD | ES, NMFS, NAVY, LMAO | TBD | | | | | | Costs dependent on number of sites identified and methods determined in 2.7.1. |
| 1 | Establish and maintain snowy plover working groups for each of the six recovery units. | 3.1 | continual | ES, LMAO, CO, C I, P | 3,650 | 96 | 96 | 91 | 91 | 91 | Essential mechanism to advance plover recovery. Includes biannual meeting costs and staff costs to establish new working groups. |
| 2 | Develop and implement regional participation plans for each of the six recovery units. | 3.2 | 1 yr for develop-ment, continual thereafter | ES, LMAO | 193 | | 193 | | | | Assumes staff cost to develop and implement participation plans. |
| 3 | Develop and implement management plans for Federal lands. | 3.3.1 | ongoing | RW, ARMY, BLM, CE, NASA, NAVY, NPS, USAF, USMC, USFS | TBD | | | | | | Implementation cost dependent on content of plans developed. |

| | | | | | | Cost Estimate (in $1,000 units) | | | | | |
|---|---|---|---|---|---|---|---|---|---|---|---|
| Priority No. | Action Description | Action Number | Action Duration | Responsible Parties | Total Costs | FY1 | FY2 | FY3 | FY4 | FY5 | Comments/Notes |
| 3 | Develop and implement management plans and Habitat Conservation Plans on State wildlife areas, State ecological reserves, and State beaches. | 3.3.2 | 5 years | CDFG, CDPR, ODFW, OPRD, WDFW, WDNR, WSPRC | 966 | 193 | 193 | 193 | 193 | 193 | Assumes cost for each recovery unit to assist in development. Implementation cost to be determined. |
| 3 | Develop and implement Habitat Conservation Plans or other management plans for sites owned by local governments or private landowners. | 3.4 | 5 years | ES, LMAO, CO, CI, P, EBRPD, HARD, MPOSD, MPRPD, PGH, PO, SL, TNC, SDRPJPA | 966 | 193 | 193 | 193 | 193 | 193 | Assumes cost for each recovery unit to assist in development. Implementation cost to be determined. |
| 2 | Provide technical assistance to local governments in developing and implementing local land use protection measures through periodic workshops. | 3.5 | 10 years | ES, CCC, CDFG, CDPR, CON, ODFW, ODLCD, OPRD, WDNR, WDFW, WSPRC, CO, CI | TBD | | | | | | Estimated at 2 workshops per recovery unit at a cost of $ <br><br>(Patty Carol in RO) |

| | | | | | | Cost Estimate (in $1,000 units) | | | | | |
|---|---|---|---|---|---|---|---|---|---|---|---|
| Priority No. | Action Description | Action Number | Action Duration | Responsible Parties | Total Costs | FY1 | FY2 | FY3 | FY4 | FY5 | Comments/Notes |
| 3 | Develop and implement cooperative programs and partnerships with the California State Coastal Commission, the Oregon Department of Land Conservation and Development, the Washington State Parks and Recreation Commission, the Oregon Parks and Recreation Department, the California Department of Parks and Recreation, and the Oregon Department of Fish and Wildlife. | 3.6 | continual | ES, CCC, ODLCD, ODFW, OPRD, CDPR, WSPRC | TBD | | | | | | Costs may vary from year to year based on identified program needs. |
| 3 | Obtain long-term agreements with private landowners. | 3.7 | 12 years | ES, CDFG, P CDPR, ODFW, WDFW, WSPRC, LMAO | 2,319 | 193 | 193 | 193 | 193 | 193 | Assumes staff time to facilitate 6 agreements per year per recovery unit. Appendix C identifies 72 sites. |
| 3 | Identify and protect habitat available for acquisition. | 3.8 | ongoing | CON, ES, RW, LMAO | TBD | | | | | | |

| | | | | | | Cost Estimate (in $1,000 units) | | | | | |
|---|---|---|---|---|---|---|---|---|---|---|---|
| Priority No. | Action Description | Action Number | Action Duration | Responsible Parties | Total Costs | FY1 | FY2 | FY3 | FY4 | FY5 | Comments/Notes |
| 3 | Ensure that any section 10(a)(1)(B) and section 7(a)(2) permits contribute to Pacific coast western snowy plover conservation. | 3.9 | ongoing | ES, Federal agencies | 1,288 | 32`32 | 32 | 32 | 32 | 32 | Assumes staff time for annual evaluation. |
| 3 | Ensure that section 7 consultations contribute to Pacific coast western snowy plover conservation. | 3.10 | ongoing | ES, Federal agencies | 1,288 | 32`32 | 32 | 32 | 32 | 32 | Assumes staff time for annual evaluation. |
| 2 | Evaluate effectiveness of habitat restoration by removal of introduced beachgrass and identify additional studies necessary. | 4.1.1 | continual | CON, ES, LMAO, RSCH | TBD | | | | | | Depends on the number and location of sites as well as the temporal duration of the restoration project. |
| 3 | Evaluate the impacts and potential benefits of past and ongoing beach nourishment activities and identify and carry out any additional studies necessary. | 4.1.2 | ongoing | ES, LMAO, RSCH, CE, CI, CO | TBD | | | | | | |
| 2 | Develop higher-efficiency nest enclosures. | 4.2.1 | ongoing | ES, LMAO, RSCH | 20 | 10 | 5 | 3 | 2 | 0 | Compare new exclosures with current ones to determine effects on snowy plovers. |

| | | | | | | Cost Estimate (in $1,000 units) | | | | | |
|---|---|---|---|---|---|---|---|---|---|---|---|
| Priority No. | Action Description | Action Number | Action Duration | Responsible Parties | Total Costs | FY1 | FY2 | FY3 | FY4 | FY5 | Comments/Notes |
| 2 | Develop California least tern enclosures that prevent harm to snowy plovers. | 4.2.2 | as needed | ES, USMC, CDFG, CDPR, LMAO, RSCH | TBD | | | | | | Costs specific to sites with California least tern enclosures. Estimated cost for materials (fencing/posts): $7 per linear foot ($23 per meter). |
| 3 | Identify, prioritize and carry out investigations on control of predators. | 4.2.3 | as needed | ES, RW, LMAO, WS, CDFG, RSCH, CO, CI, P | TBD | | | | | | Cost dependent on number and types of studies identified. |
| 3 | Investigate predator management at the landscape level. | 4.2.4 | as needed | ES, RW, LMAO, WS, RSCH, CO, CI, P | TBD | | | | | | Costs dependent on number and types of studies identified. |
| 3 | Investigate techniques for identifying nest predators. | 4.2.5 | continual | LMAO, RSCH | TBD | | | | | | |
| 2 | Improve methods of monitoring population size. | 4.3.1 | ongoing | ES, LMAO, RSCH | TBD | | | | | | Dependent on costs of intensive monitoring of some sites. |
| 2 | Develop sampling methods for annually estimating reproductive success. | 4.3.2 | 2 years | ES, RSCH | 64 | 64 | | | | | Assumes time to compile and review data and develop methodology. |
| 3 | Develop methods to monitor plover survival rates. | 4.3.3 | ongoing | ES, LMAO, RSCH | TBD | | | | | | |

| | | | | | | Cost Estimate (in $1,000 units) | | | | | |
|---|---|---|---|---|---|---|---|---|---|---|---|
| Priority No. | Action Description | Action Number | Action Duration | Responsible Parties | Total Costs | FY1 | FY2 | FY3 | FY4 | FY5 | Comments/Notes |
| 3 | Identify brood habitat and map brood home ranges. | 4.4.1 | ongoing continual | ES, LMAO, RSCH, CO, CI, P | TBD | | | | | | Costs dependent on study design. May include radio telemetry. |
| 3 | Identify components of high-quality brood rearing habitat | 4.4.2 | 1 year | ES, LMAO, RSCH, CO, CI, P | 131 | 131 | | | | | Assumes study at 6 geographically representative sites for duration of breeding season. |
| 3 | Quantify wintering habitat needs along the Pacific coast. | 4.4.3 | 5 years | ES, RSCH, BRD, PRBO | 75 | 75 | | | | | Assumes study at 6 geographically representative sites during winter months. |
| 3 | Identify important migration stop-over habitat. | 4.4.4 | ongoing | ES, LMAO | TBD | | | | | | |
| 3 | Develop and implement a research program to determine causes of adult mortality. | 4.5 | ongoing | LMAO, RSCH | TBD | | | | | | Costs dependent on study design. |
| 3 | Compile information regarding number and types of banding injuries to plovers. | 4.6.1 | 1 year | ES, RSCH, PRBO, BRD, BBL | 32 | 32 | | | | | Assumes staff time to develop, distribute and compile information requests. |
| 3 | Review compiled information (see 4.6.1) and determine and implement an appropriate course of action. | 4.6.2 | 1 year | ES, RSCH, PRBO, BRD, BBL | 32 | | | | | | Assumes staff time to review compiled information, distribution and coordination with other responsible parties. |

| | | | | | | Cost Estimate (in $1,000 units) | | | | | |
|---|---|---|---|---|---|---|---|---|---|---|---|
| Priority No. | Action Description | Action Number | Action Duration | Responsible Parties | Total Costs | FY1 | FY2 | FY3 | FY4 | FY5 | Comments/Notes |
| 3 | Identify effects of oil spills on snowy plovers. | 4.7 | as needed | ES, RSCH, BRD, LMAO | TBD | | | | | | Typical range of cost for study is estimated between $25,000 - $100,000. |
| 3 | Monitor levels of environmental contaminants in snowy plovers. | 4.8 | as needed | ES, RSCH, BRD, LMAO | TBD | | | | | | Depends on number and type of samples. Cost estimate $700 per sample, but may vary depending on type of contaminant. |
| 3 | Design and conduct contaminants studies if monitoring of contaminants in action 4.8 indicates potential contaminants effects. | 4.9 | as needed | LMAO, ES, RSCH, BRD | TBD | | | | | | Depends on number of sites and samples analyzed. Cost estimates for studies range from $25,000 to $50,000 per site. |
| 3 | Identify, prioritize and carry out studies on the effects of human recreation on western snowy plovers. | 4.10 | ongoing | LMAO, ES, RSCH, PRBO, BRD | TBD | | | | | | Costs dependent on research needs identified. |
| 3 | Revise the population viability analysis when sufficient additional information is available | 4.11 | 1 year | ES, RSCH, PRBO, BRD | 25 | | | | | | Assumes cost to conduct modeling. |
| 2 | Develop and implement public information and education programs. | 5.1 | ongoing | ES, PA, LMAO | TBD | TBD | TBD | TBD | TBD | TBD | Depends on individual recovery unit strategies. See Appendix K (Information & Education Plan) for estimates of component expenses. |

| | | | | | Cost Estimate (in $1,000 units) | | | | | | |
|---|---|---|---|---|---|---|---|---|---|---|---|
| Priority No. | Action Description | Action Number | Action Duration | Responsible Parties | Total Costs | FY1 | FY2 | FY3 | FY4 | FY5 | Comments/Notes |
| 3 | Inform Federal, State and local planning agencies and local planning departments of threats to breeding and wintering snowy plovers and their habitats. | 5.2 | continual | ES, LMAO, CCC, CDFG, CDPR, ODFW, ODLCD, OPRD, WDFW, WDNR, WSPRC, CO/CI | TBD | | | | | | |
| 3 | Develop and maintain updated information and education materials on snowy plovers. | 5.3 | ongoing | ES, PA, LMAO, CO, CI | TBD | | | | | | Incorporate into ongoing management and Action 3.1 through 3.10. See Appendix K |
| 3 | Alert landowners and beach-goers about access restrictions within snowy plover habitats. | 5.4 | ongoing | ES, PA, LMAO, CO, CI | TBD | | | | | | Incorporate into ongoing management and Action 3.1 through 3.10. See Appendix K |
| 3 | Provide trained personnel to facilitate protective measures, provide public education, and respond to emergency situations. | 5.5 | continual | LMAO, CO, CI | TBD | | | | | | Need to secure funds for volunteer coordinator and staff to train volunteers. Incorporate into Action 3.1 through 3.10. See Appendix K. |
| 3 | Develop protocols for handling sick, displaced, injured, oiled, and dead birds or salvaged eggs. | 5.6 | 1 with periodic review | LMAO, CO, CI | 32.2 | 32.2 | | | | | Assumes staff time to develop protocol. |

| | | | | | | Cost Estimate (in $1,000 units) | | | | | |
|---|---|---|---|---|---|---|---|---|---|---|---|
| Priority No. | Action Description | Action Number | Action Duration | Responsible Parties | Total Costs | FY1 | FY2 | FY3 | FY4 | FY5 | Comments/Notes |
| 3 | Establish a distribution system and repository for information and education materials. | 5.7 | continual | ES, LMAO, CO, CI | TBD | | | | | | Incorporate into ongoing management and Action 3.1 through 3.10 and 7. See Appendix K. |
| 3 | Establish a reporting and distribution system for annual monitoring data. | 5.8 | annual | ES | 644 | 16 | 16 | 16 | 16 | 16 | Assumes time spent collecting and compiling data. |
| 2 | Develop and implement a tracking process for the completion of recovery actions and the achievement of delisting criteria. | 6.1 | continual | ES, RW, ARMY, BLM, CE, NASA, NAVY, NPS, USAF, USFS, USMC, CDFG, CDPR, ODFW, OPRD, WDFW, WDNR, WSPRC, LMAO | 688 | 64 | 16 | 16 | 16 | 16 | Assumes staff time to develop and implement tracking process. |
| 3 | Review progress toward recovery annually. | 6.2 | annual | ES, LMAO | 566 | 14 | 14 | 14 | 14 | 14 | Assumes staff time to compile and review data. |
| 3 | Assess the applicability, value and success of this plan to the recovery of the western snowy plover every 5 years. | 6.3 | every 5 years | | 258 | | | | | 32.2 | Assumes staff time to review every 5 years. |
| 3 | Prepare a delisting package for the Pacific coast population of the western snowy plover. | 6.4 | 6 months | ES | 64 | 64 | | | | | Assumes staff time to prepare delisting package. |

| | | | | | | Cost Estimate (in $1,000 units) | | | | | |
|---|---|---|---|---|---|---|---|---|---|---|---|
| Priority No. | Action Description | Action Number | Action Duration | Responsible Parties | Total Costs | FY1 | FY2 | FY3 | FY4 | FY5 | Comments/Notes |
| 3 | Prepare and implement a post-delisting monitoring plan. | 6.5 | 6 months | ES | 64 | 64 | | | | | Assumes staff time to prepare and implement post-delisting monitoring plan. |
| 1 | Dedicate sufficient U.S. Fish and Wildlife Service staff for coordination of western snowy plover recovery implementation. | 7 | continual | ES | 5,152 | 128.8 | 128.8 | 128.8 | 128.8 | 128.8 | Assumes staff time to coordinate recovery implementation |
| 3 | Develop a joint United States and Mexico effort to protect snowy plover populations and their habitat. | 8.1 | continual | ES, IA | TBD | | | | | | |
| 3 | Encourage research and monitoring of breeding and wintering snowy plovers in Baja California, Mexico by universities and authorities of Mexico. | 8.2 | continual | ES, IA, RSCH, BRD | TBD | | | | | | |
| 3 | Encourage development and implementation of public information and conservation education in Mexico. | 8.3 | continual | ES, IA, PA | TBD | | | | | | |

| | | | | | | Cost Estimate (in $1,000 units) | | | | | |
|---|---|---|---|---|---|---|---|---|---|---|---|
| Priority No. | Action Description | Action Number | Action Duration | Responsible Parties | Total Costs | FY1 | FY2 | FY3 | FY4 | FY5 | Comments/Notes |
| 3 | Coordinate with other survey, assessment, and recovery efforts for the western snowy plover throughout North America. | 9 | continual | ES, IA, RSCH, BRD | TBD | | | | | | |

Total Cost of Recovery through 2046: $149,946,000 plus additional costs that cannot be estimated at this time.

FOR IMMEDIATE RELEASE
March 13, 2013

## Snowy Plover Nesting Season Begins March 15

**Southern Oregon Coast –** The nesting season for the western snowy plover, a small shorebird that lays its eggs and raises its young in the open dry sand, begins on area beaches March 15 and runs through September 15. Some area beaches have access and recreational restrictions in place during this time to help protect the nests, eggs and chicks of these threatened birds.

After March 15, signs and ropes will mark snowy plover nesting areas. In the nesting areas, beachgoers will only have access to the wet sand portion of the beach – dry sand access will be closed. ATV use, dog walking and kite flying is also restricted on some beaches.

The dry sand closures will be in effect at Sutton Beach, Siltcoos Estuary, Oregon Dunes Day Use, Tahkenitch Estuary, Tenmile Estuary (northern Coos County), the North Spit of Coos Bay, Bandon Beach State Natural Area, and New River area beaches. The access restrictions affect approximately 18 miles of beach in Oregon.

"The number of fledgling plover chicks doubled from 2010 to 2011, going from 84 to 168 birds," said Kerrie Palermo, Wildlife Biologist with the Bureau of Land Management. "People honoring the closures, along with the habitat improvement and predator control projects the agencies are implementing, are getting us closer to recovering the snowy plover population."

The Pacific coast population of the western snowy plover was listed by the U.S. Fish and Wildlife Service as threatened in 1993. The primary threats to snowy plover survival are habitat degredation, urban development, European beachgrass introduction, and predators such as crows, ravens, foxes and skunks.

More information on plover habitat and beach restrictions can be obtained from the Forest Service at 541-750-7000, or the BLM at 541-756-0100. Visit http://www.fws.gov/oregonfwo/Species/Data/WesternSnowyPlover/default.asp to learn more about the western snowy plover.

# Mystery compound found to kill coho salmon

By Christopher Dunagan

Monday, January 21, 2013

SUQUAMISH — Stormwater runoff from highways appears to contain one or more unidentified compounds shown to be highly toxic to coho salmon and perhaps other salmon as well.

The problem has been studied only a few years. Now, experiments at Grover's Creek Hatchery in North Kitsap have confirmed that polluted stormwater has the ability to kill adult coho before they can spawn.

This "pre-spawn mortality," as it is called, could pose a serious threat to the ongoing salmon populations in many urban areas, said Nathaniel "Nat" Scholz, a biologist with NOAA's Northwest Fisheries Science Center.

The problem was first suspected in Seattle's Longfellow Creek, which receives a rush of stormwater whenever it rains. Observers noticed that many of the female coho that made it home to their natal streams were dying before they could lay their eggs, often within a few hours of a rainstorm. Leading up to their deaths, researchers noticed that the fish seemed confused, often going in different directions and turning onto their sides while swimming.

An extensive forensic analysis ruled out everything but toxic chemicals, Scholz said. Further investigations revealed that the more polluted a stream became, the more likely the fish were to experience pre-spawning mortality. Up to 90 percent of the females were dying in some streams following a rainstorm.

At first, heavy metals were suspected. After all, it has been shown in laboratory experiments that copper compounds can destroy the olfactory sense of smell in salmon. Adults exposed to copper presumably can fail to home in on their natal streams, while juveniles exposed to copper become highly vulnerable to predators, according to previous studies by Scholz and his associates.

But adult coho exposed to 10 times the level of metals found in the toxic stormwater failed to show the characteristic behavior of the dying salmon in Longfellow Creek and other urban streams.

Meanwhile, other studies demonstrated that 65 percent of coho embryos exposed to this toxic stormwater had severe physical abnormalities, such as malformed fins, bleeding on the brain and swelling around the heart, according to Julann Spromberg, who discussed the findings at a recent meeting of the Kitsap Poggie Club, a local fishing group. Typically, the malformed fish die at an early age, she said.

Still searching for the mysterious, deadly compound, NOAA researchers formed a partnership with the Suquamish Tribe to use the tribe's Grover's Creek Hatchery, which rears coho and gets a fair number of returns in most years.

The researchers collected stormwater from a highway during major rains last fall. The water first collected after a four-day dry period appeared the darkest and dirtiest. As the rains continued, the collected water looked to be less ominous.

These different samples of stormwater were placed into small tanks with clean water placed into identical tanks. The salmon were then exposed to the water for an hour or two.

To the surprise of the researchers, all of the coho exposed to the stormwater showed the behavior they had come to expect. The fish bumped into the sides of their tanks, showing no sense of direction and keeling over on their sides.

"They couldn't even figure out how to turn around, they were so out of it," Spromberg said. "There was something severely wrong with them."

Even the highway runoff that seemed the cleanest after days of rain killed the fish. On the other hand, coho exposed to water from a clean stream suffered no ill effects.

Scholz said typical highway runoff contains an enormous number of different compounds, and it is extremely difficult and costly to narrow down which ones may be affecting the fish. Because death comes so quickly, the cause must be a physiological or metabolic pathway, not any kind of disease progression, he said.

Many tissues were taken from fish in the Grover's Creek experiments in hopes of finding a problem in the heart, gills or perhaps other essential organs. The method involves testing for genetic markers to determine which organs are under stress. Results are still pending.

"The fish are telling us what is going on, given the high rates of mortality across many streams," Scholz said. "But, scientifically, this is a tricky challenge. We have to look at target organs and try to figure out why they are dying."

Scholz said the answer is likely to be one of two things. Either the mystery compound is two or more known chemicals working together synergistically — which means together they are worse — or the mystery compound is a single chemical that has never been identified for its extreme toxicity.

"We don't have evidence for either one," Scholz said. "It could be an unmonitored chemical contaminant or a group of chemicals working synergistically. We have chemists at the Northwest Science Center looking at what they can find in tires."

Because the Kitsap Peninsula is a "transitional" area between urban and rural development, researchers would like to extend their studies into a variety of local streams where the runoff comes from different types of development. Some areas have infiltrated much of the stormwater into the ground — either through old-fashioned stormwater ponds or with rain gardens and other kinds of low-impact development.

"What we want to know from the NOAA side of things is whether you can reduce pollution loading sufficiently to protect the fish," Scholz said.

Jon Oleyar, who counts salmon in Kitsap streams to estimate populations, says he has noticed the effects of pre-spawning mortality in urbanized sections of streams, such as lower Clear Creek near Silverdale and lower Dogfish Creek near Poulsbo — and other salmon may be affected as well.

"I've seen it in chinook, and I've seen it in chum, too," he said, "but I don't see a lot of it."

Chris May, manager of Kitsap County's Surface and Stormwater Management Program, said he is following the toxicity studies closely as new strategies are planned to deal with the problem.

One step Kitsap County has taken is to acquire three high-efficiency street sweepers, which actually vacuum up road dust and debris to keep it from washing into ditches and ultimately streams. The machines sweep about 700 miles a year, most frequently near stream crossings and along shorelines, he said.

The SSWM program monitors the amount of toxic chemicals found in 200 tons or so of material that gets swept up each year.

May said he hopes that street sweeping, stormwater management and other efforts can help prevent the problems of pre-spawn mortality observed in portions of King County and other urban areas.

*This story was changed from its original version to clarify previous studies on effects of copper.*

# Oregon DEQ
## Site Summary Report
## Former Weyerhaeuser North Bend Containerboard Mill
## North Bend, Oregon ECSI Nos. 528, 1083, and 1829
## September 7, 2006

## Introduction and Purpose

This document presents a summary of the environmental investigation and cleanup performed at the Weyerhaeuser Containerboard Mill property located in North Bend, Oregon. The purpose of this site summary report is to document the Oregon Department of Environmental Quality's (DEQ's) recommendation for a No Further Action (NFA) determination covering the recent hazardous substances investigation and removal actions completed at the main mill and the "Ingram Yard" sites.

Weyerhaeuser, the current owner of the property, entered the Voluntary Cleanup Program (VCP) under a Site-Specific Technical Consultation Cost Recovery Agreement on February 12, 2004 in order to obtain a NFA determination from DEQ for selected areas of the site.

This Site Summary Report and NFA recommendation does not include the mill's permitted industrial landfill (Solid Waste Disposal Permit #1142) or the mill's permitted industrial wastewater treatment system (NPDES Permit #101499; consisting of two settling ponds, an aerated stabilization basin, and a large former lagoon). These facilities will be closed under their respective permits in cooperation with DEQ's Solid Waste and Water Quality programs, possibly in the next few years.

## Site Description

Weyerhaeuser owns about 1,300 acres of land in the Jordan Point/North Spit area of North Bend. The parcels that are the subject of this document are located approximately one-half mile west of U. S. Highway 101 (Hwy 101) and approximately two miles north of downtown North Bend and include 1) the approximately 97-acre and 70-acre parcels located at 92770 Trans Pacific Lane, North Bend, Oregon, Tax Lots 100, (see http://www.ormap.org, Coos County, Map 25 13 4) and 200, (see http://www.ormap.org, Coos County, Map 25 13 3 & Index) (respectively), which collectively is referred to as the "main mill complex"; and 2) the approximately 200+ acre Ingram Yard property located about 1.5 miles west of the main mill complex on Trans Pacific Lane part of Tax Lot 200 (see http://www.ormap.org, Coos County, Map 25 13 & Index) (Figure 1).

The former mill complex consisted of a main mill/paper machine building, shipping warehouse and maintenance/operations buildings, several other buildings used for office space, shops, storage, and other purposes, and related improvements and infrastructure. The developed portions of the facility occupied the north central portion of the property, and the southern portions are undeveloped and consist of vegetated open spaces, stream channels, and shoreline/tidal flat areas along Coos Bay. Historically, the southern portion of the site was used for log storage. A general site plan showing the primary former facility features is shown in Figure 2. Most of the features shown on Figure 2 are no longer present because they have been dismantled/removed as part of mill decommissioning. Weyerhaeuser intends to remove most site structures to ground level. Surface features such as concrete slabs will be left in place.

Prior to construction of the mill, the area in the immediate vicinity of the mill was covered with low brush and grass. The vegetation was stripped and the area covered with several feet of dune sane to raise the elevation above high tide and flood levels. South of the building, toward Jordan Cove, large amounts of driftwood and vegetation were left in place and covered with fill sand to create a log storage yard.

The Ingram Yard property is vacant and undeveloped (Figure 1). The Ingram Yard property is bordered to the east by dune and forest areas and an industrial facility (Roseburg Forest Products, North Bend Chip Facility). It is bordered on the south by Coos Bay, on the west by the Henderson Marsh area, and on the north by Trans Pacific Lane. Because the Ingram Yard has been used in the past for industrial purposes (e.g., dredge spoils disposal, etc.), the Ingram Yard is slowly revegetating with a mix of native and non-native introduced plant species.

## Site History and Background

The mill site was originally developed as a sulfite process pulp and paper mill by the Menasha Wooden Ware Corporation (Menasha) in 1961, and Weyerhaeuser acquired the mill from Menasha in 1981. In 1995, Weyerhaeuser ceased pulp mill operations, and the facility was operated as a 100-percent recycle paper mill until it was closed in 2003. Since 2003, Weyerhaeuser has been decommissioning the facility and preparing the property for future alternative uses and possible sale.

Weyerhaeuser leased the property east of the main mill area between the railroad tracks and Coos Bay to a fish hatchery operation that existed from approximately 1980 to 1992. Structures and improvements associated with the former hatchery operation included the fish hatchery structure, four buildings, and an above-ground storage tank (AST) for diesel storage. The fish hatchery improvements have been removed, and the property is currently vacant and undeveloped.

The Ingram Yard was used as a livestock ranch and dairy prior to 1958, and as a log sorting and chipping yard from the late 1970s to early 1980s. Sand, boiler ash, and wood debris were also placed on the property during this period. Land spreading of decant-basin solids from the mill wastewater treatment facilities occurred at the Ingram Yard from 1985 to 1994. Dredge spoils from U.S. Army Corps dredging of Coos Bay were placed on the Ingram Yard property in 1972 and 1973.

Additional details concerning the site including the physical setting, hydrogeology, and operational history can be found in the document entitled *Level II Environmental Site Assessment, Former Weyerhaeuser Containerboard Mill* (PES, 2006).

## Regulatory History

This section summarizes the DEQ regulatory history related to hazardous substance releases at the facility, and excludes the history associated with the NPDES and Solid Waste permitted facilities, which will be addressed in a separate closure document.

In the following description, the main mill complex is referred to as site #1083. There are two other identification numbers that have been used in the past for specific areas within the main mill complex. These are referred to as #528 (for a small transformer oil release on the main mill complex) and #1829 (for releases associated with a former fish hatchery on the east side of the main mill complex).

In January 1984, DEQ was notified of a small transformer oil spill (about 5 gallons). DEQ staff were present to observe the cleanup, and concluded that adequate cleanup measures were taken to mitigate the release.

In 1988, the a portion of the main mill complex was added to DEQ's newly-formed Environmental Cleanup Site Information Database (ECSI) as Site #528 for Tax Lots 100 and 101 in Township 12S, Range 13W, Section 4 for the 1984 transformer-oil release.

During August 1990, an expansion joint on a fuel line north of the Recovery Plant (on the main mill complex) ruptured, resulting in oil spillage within the sand containment area surrounding the fuel tanks. As a result of this release, DEQ opened a second database entry for Tax Lot 200, T12S, R13W, Section 3 as ECSI #1083 in November 1990.

In 1994, DEQ recommended that a formal site screening be conducted to evaluate the potential for the site (ECSI #528) to pose a threat to human health and the environment due to hazardous substance releases. In August 1995, DEQ completed a Site Evaluation, and concluded that no further action was required regarding the 1984 transformer oil release.

In February 1996, the former fish hatchery site was added to the DEQ's database as ECSI #1829 due to diesel releases associated with fuel-refilling operations at the site. DEQ concluded that further evaluation was necessary, but that the priority for further evaluation was a low priority based on the limited impacts of the release.

In April 1996, DEQ's Site Assessment Section reviewed available documents regarding both the sites (ECSI #528 and #1083), and concluded that further action was necessary to fully characterize the extent and impact of hazardous substances either present or potentially present at the main mill complex. DEQ's priority for further action was considered "medium" (DEQ, 1996).

The facility was proposed to be included on the Confirmed Release List in July 1998, and was formally added to the list in January 1999. Once the remainder of the environmental cleanup and closure activities have been addressed at the site, primarily for the NPDES and Solid Waste permitted facilities, DEQ will provide a public comment period for a proposal to remove the site from the Confirmed Release List.

In February 2004, Weyerhaeuser joined DEQ's Voluntary Cleanup Program to obtain review of their investigation and cleanup activities as a part of their mill decommissioning.

A draft version of this Site Summary Report was made available for public comment during the period from May 1, 2006 until June 1, 2006. The comment period was extended until July 3, 2006 to accommodate a request for a public meeting from a group of 10 or more people. The public meeting was held on June 22, 2006, and was attended by about 24 individuals.

## Investigation and Remediation Summary

Weyerhaeuser evaluated environmental conditions within the main mill complex, including the southern portion of Jordan Point, and the Ingram Yard property as part of the facility closure and decommissioning process. Areas of concern were identified by reviewing data from past environmental assessment work (for both investigation efforts, and for multiple remediation and removal efforts), observations of current site conditions, DEQ's strategy recommendation (including a list of areas DEQ recommended for evaluation), Weyerhaeuser's knowledge of past practices, and the findings of a recent *Level I Environmental Site Assessment* (ESA) report (Delta, 2004). The list of areas of concern and a preliminary scope of work to investigate these areas were provided to and approved by DEQ during April and June 2005.

Table 1 provides details concerning releases and previous work completed in 14 areas of the mill complex that were the subject of the Level II assessment work.

Contaminants detected during investigative work over the years have included: mineral spirits, hydraulic oil, diesel, heavy-oil-range petroleum hydrocarbons (total petroleum hydrocarbons, or "TPH"), heavy metals, butylated tin compounds, polynuclear aromatic hydrocarbons, polychlorinated biphenyls, and dioxins. A summary of these detections can be found in tables 1 through 16 in the *Level II Environmental Assessment Report* (PES, 2006). With the exception of the Chip Truck Hydraulic Area, the results of the Level II Environmental Assessment indicated no cleanup was required for the remaining areas of the mill complex or the Ingram Yard, primarily due to previous remedial efforts.

As a result of their Level II investigation, Weyerhaeuser conducted additional soil-excavation work in the Chip Truck Hydraulic Lift Area (Area 4 in Table 1 and in Figure 2) during September 2005. Approximately 700 tons of hydraulic-oil-contaminated soil was removed from the site for disposal at Waste Management's Riverbend Landfill. Post-remediation sampling confirmed that contamination in this area no longer exceeded DEQ's screening levels.

## Risk Evaluation

The Level II Environmental Assessment report included an evaluation of the potential risks posed by residual contamination remaining at the main mill complex and the Ingram Yard. The major conclusions of this analysis were as follows:

- The land use for the main mill site currently is zoned industrial (zoning district code "IND") and it is not reasonably likely to change in the foreseeable future.

- Potable water is provided to the area by the Coos Bay-North Bend Water Board, and it is not likely that shallow water in the vicinity of the main mill complex or the Ingram Yard will be developed as a drinking-water source.

- Contaminant concentrations in soil and groundwater remaining at the site (i.e., post-remediation) were compared to human health risk-based screening tables (e.g., DEQ RBCs, 2005; EPA PRGs, 2004). For human health, the screening was based on occupational worker, excavation worker, and construction worker exposure scenarios for the soil ingestion, dermal contact, and inhalation pathways, and for the volatilization from groundwater into buildings pathway. No residual contaminants in soil or groundwater exceeded these screening values.

- Potential ecological impacts were evaluated for receptors (birds, mammals, invertebrates, and plants) on the main mill complex property, and for the Ingram Yard site. The Level II Environmental Assessment report concluded that ecological receptors are not exposed to residual contamination at the main mill complex because 1) post-remediation contamination is present at depth and not at the surface, and is limited in areal extent; and 2) there is little habitat on the main mill complex that would attract ecological receptors to the property.

- Potential ecological impacts also were evaluated for receptors at the Ingram Yard site. Because the property is largely undeveloped, and because there are potential ecological receptors nearby, Weyerhaeuser conducted additional sampling on the site. The results of the investigation indicated that there were low levels of contaminants present in surface soils on the property. The concentrations were then compared to DEQ's Screening Level Values (DEQ, 2001) for birds, mammals, invertebrates, and plants. No ecological screening values were exceeded for contaminants present at the Ingram Yard.

- DEQ does not have risk-based screening values for TPH in the heavy oil-range hydrocarbon range (i.e., hydraulic oil) for evaluating subsurface soil contamination in the vicinity of the south "lowerator" (Area 10 in Table 1 and in Figure 2; located at a depth greater than 5 feet), or for TPH in the mineral-spirits-range hydrocarbon range for residual contamination in the vicinity of the mineral-spirits release (Area 2 in Table 1 and in Figure 2).

- However, no specific "constituents" (e.g., polynuclear aromatic compounds such as naphthalene) in the soils in the "lowerator" area or in the post-remediation soils in the mineral-spirits release area exceeded screening levels. In addition, the hydraulic oil contamination in the "lowerator" the area is covered by an 8-inch thick concrete slab plus five feet of gravel. For these reasons, the Level II Environmental Assessment report concludes that these two areas do not currently pose a threat to human health and the environment (details provided in the Level II ESA report).

- The occurrence and amount of asbestos-containing transite siding buried in a fill area on south Jordan Point appears to be limited. Because the buried asbestos-containing material is considered a solid waste under DEQ's rules, any waste generated in the course of future site re-development should be properly managed and disposed at a DEQ-approved disposal facility.

Based on questions and comments received during the public comment period, DEQ re-examined the bioaccumulative potential (including their potential for bioconcentration and/or biomagnification) for residual contaminants in surface soils at the Ingram Yard site, and re-confirmed that they do not pose a threat to human health or ecological receptors at levels above DEQ's acceptable risk levels as outlined in OAR 340-122. However, they potentially could exceed applicable screening criteria[1] if they were disposed in waters of the State.

DEQ also conducted a more detailed analysis of the prey species and food sources for threatened or endangered (T&E) birds, including that protective of the snowy plover. According to our calculations, no adverse effects are likely to occur to upland birds from exposure to residual concentrations of dioxins present in surface soils at the Ingram Yard.

## Public Process

There was a 63-day public comment period from May 1, 2006 through July 3, 2006. Public notice was published in the Secretary of State's Bulletin and in a local newspaper (The World in Coos Bay).  Based on a written request by ten or more persons, a public meeting was be held in Coos Bay on June 22, 2006 to receive comments from interested parties. DEQ received two sets of formal comments from one individual (totaling 8 pages).

DEQ considered all public comments. As a result of public concerns, questions, and comments, DEQ is adding additional language to our NFA determination letter to notify future land owners that surface soils containing residual concentrations of dioxin from the Ingram Yard be managed carefully according to Solid Waste regulations, and not be disposed in waters of the State.

[1] DEQ is developing screening tables and guidance for evaluating bioaccumulative chemicals in sediments. A June 19, 2006 Technical Advisory Panel draft was available at the time this Site Summary Report was updated.

## Conclusions

Multiple site investigations completed at the former Weyerhaeuser Containerboard Mill identified 14 areas of potential environmental concern. Following an investigation in the summer of 2005, a total of about 700 tons of soil were removed for offsite disposal from one area with soil contamination that exceeded DEQ's screening levels. Investigation and post-remediation samples indicate little or no residual contamination exceeding DEQ screening levels in soil or groundwater with the exception of TPH-contaminated soils in the south "lowerator" area, and residual post-remediation TPH contamination in the mineral-spirits release area.

DEQ staff have evaluated the work completed at the site. Based on our evaluation, there is no apparent threat to human health or the environment posed by residual hazardous-substance contamination at the main mill complex and on the Ingram Yard parcel under current or reasonably likely future development scenarios.

## Determinations

DEQ considers the investigation and cleanup at the former Weyerhaeuser Containerboard Mill to be complete and recommends that, unless new or previously undisclosed information becomes available which warrants further investigation, no further action is required at the main mill complex and the Ingram Yard under ORS 465.200, et. seq.

However, the full extent of the hydraulic oil release in the vicinity of the south "lowerator" has not been determined due to the presence of a thick concrete slab and a railroad spur. Therefore, we recommend that a supplementary investigation (and subsequent remediation, if necessary) be conducted if the concrete slab is ever removed.

Also, there are low levels of residual TPH contamination below the concrete slab in the mineral-spirits release area. Therefore, if this area is exposed, any soils removed must be properly managed and/or disposed in accordance with DEQ rules.

In addition, the small amounts of transite siding in the fill area on south Jordan Point, if ever excavated in future site redevelopment activities, must be properly managed and disposed at a DEQ-approved disposal facility.

The monitoring wells at the facility associated with the hazardous-substance investigation and removal actions should be abandoned according to the Oregon Water Resources Department rules, unless they continue to serve a purpose for Weyerhaeuser.

Finally, while surface soils at the Ingram Yard site meet human health and ecological screening criteria, they contain low levels of potentially bioaccumulating chemicals and must not be placed in waters of the state.

| Table 1: Areas identified in DEQ Strategy Recommendation dated April 16, 1996 (DEQ ECSI # 1083) | | | |
|---|---|---|---|
| **Area** | **Previous work/data** | **DEQ identified data gaps** | **Scope of work** |
| 1 - Fuel Oil Release Area | Release from former reprocess fuel oil (RFO) or "cutter stock oil" AST. Soil excavation was conducted and soil and groundwater analyzed for TPH and BTEX. TPH in soil up to 57,200 mg/kg left in place near SE corner of excavation at 5 feet bgs. Groundwater samples east and west of source ND for TPH and BTEX. Release(s) in the RFO transfer area indicated by prior observations of soil staining. Site records indicate the area was paved over with asphalt to limit potential soil impacts. A broken pipe for the RFO storage area sump and apparently related surface staining near the boiler building was noted in December 2003. | In the fuel oil release area, future work should address residual PAH concentrations in soil. | Assessment of soils for TPH and PAHs. Evaluate need for potential groundwater assessment based on soil conditions. Consider excavation of impacted soils. |
| 2 - Mineral Spirits Release Area | Mineral spirits releases from USTs and AST system on north side of mill building. Soil excavation and soil and groundwater analysis conducted, and remediation system installed. TPH-impacted soil left in place due to adjacent structures. TPH and PAHs in groundwater based on groundwater monitoring results. Three wells (EW-1, MW-1, and MW-10) are still present in this area. | In the mineral spirits release area, future work should address residual TPH concentrations in soil and groundwater including potential downgradient (southeast) migration of contaminants. Analysis for PAHs and VOCs is appropriate. Existing structures impede groundwater sampling southeast of the source. | Redevelop and sample existing wells EW-1, MW-1 and MW-10. Further assess the extent of impacts in soil and groundwater as practical when adjacent structures are removed. Consider additional soil excavation after removal of adjacent structures. |
| 3 - Truck Scales and Carpenter's Shop Area | Three USTs (gasoline, diesel, and mineral spirits) of unknown size were removed from this area and no soil samples were collected during the removals. The gasoline and diesel USTs were located north of the truck scales and the mineral spirits UST was located north of the carpenter's shop. Soil and groundwater assessment revealed TPH impacts in soil, and TPH and PAH impacts in groundwater. Two wells (MW-07R and MW-09) are still present in this area. | In the truck scales and carpenter's shop area, future work should address residual TPH concentrations in soil and groundwater including appropriate characterization of soils in the vicinity of the former mineral spirits and gasoline/diesel USTs; and the presence of elevated TPH concentrations in groundwater (MW-7). | Redevelop and sample wells MW-07R and MW-09. Further characterize impacts to soil and groundwater including TPH, PAHs, and VOCs. |

| Table 1: Areas identified in DEQ Strategy Recommendation dated April 16, 1996 (DEQ ECSI # 1083) | | | |
|---|---|---|---|
| **Area** | **Previous work/data** | **DEQ identified data gaps** | **Scope of work** |
| 4 - Chip Truck Hydraulic Lift Area | Assessment work in this area has revealed elevated TPH concentrations in soil up to 100,000 mg/kg and a groundwater TPH concentration of 0.78 mg/L. | In the chip truck hydraulic lift area, future work should address PAH concentrations in soil and groundwater. | Further characterize impacts to soil and groundwater for TPH and PAHs. Excavate soils with TPH impacts up to 100,000 mg/kg in the chip truck hydraulic lift area. |
| 5 - Hog Fuel Hydraulic Lift Area | Assessment work in this area has revealed elevated TPH concentrations in soil up to 380 mg/kg and a groundwater TPH concentration of 1.0 mg/L. | In the hog fuel hydraulic lift area, future work should address PAH concentrations in soil and groundwater. | Further characterize impacts to soil and groundwater for TPH and PAHs. |
| 6 - Stream Channel Area | A former stream channel drained south-southeast from the maintenance shop, approximately 1,600 feet to Coos Bay. The northern portion has been culverted and paved over, but the southern 3/4 of the stream channel still exists. An earthen dam was constructed on the lower section of the channel to restrict potential releases of oil from discharging to the bay. A sediment/sludge sample collected upstream of the dam had a TPH concentration of 5,400 mg/kg (diesel and Bunker C ranges). Subsequent analyses revealed TPH concentrations up to 12,000 mg/kg downstream of the dam. | In the stream channel area, future work should address PAH concentrations in the vicinity of the current and former stream channel, as well as PCB and metal concentrations. | Further characterize impacts to the stream channel for TPH, and assess for PAHs, PCBs and metals. |

| Table 1: Areas identified in DEQ Strategy Recommendation dated April 16, 1996 (DEQ ECSI # 1083) | | | |
|---|---|---|---|
| **Area** | **Previous work/data** | **DEQ identified data gaps** | **Scope of work** |
| 7 - Anadromous Fish Hatchery | DEQ ECSI # 1829. ECSI report indicates surface and near-surface impact to soil from diesel AST. DEQ evaluation from "unsolicited report", but no specific information is included. | State based Preliminary Assessment recommended in 1996. Low priority site based on review of report conclusions. PES reviewed report that indicates soils with TPH impacts were excavated to non-detect levels. The results in the report should be sufficient for DEQ to make a NFA determination. Disposition of excavated soils that were stockpiled on-site is not known. | Review DEQ (and Weyerhaeuser?) files for more specific information regarding disposition of stockpiled soils. Assume no additional susurface assessment needed. Possible characterization of stockpiled soils. |
| 8 - Ash Bunkers | Ash bunkers/pits were located adjacent to boilers/powerhouse and used to accumulate and temporarily store ash. Overflow ash from the west bunker was stored on the ground surface on the west side of the bunker. Analytical testing of the ash has been performed. | Potential impacts to soils underlying/adjacent to the bunkers/pits from ash constituents (dioxins/furans and metals). Ground surface on the west side of the west bunker considered most likely location for potential "worse-case" impacts. | Assessment of soils for dioxins/furans and metals. |
| 9 - Paper Machine Floor Drains and Sumps | A floor drain system and several containment areas/sumps for hydraulic equipment, etc. are located on the ground floor of the main mill building below the paper machines. Oily water and oil staining of the floor drains and containment areas. | Potential impacts to fill/soil underlying the floor drains and containment areas for TPH. | Assessment of fill/soil for TPH and PAHs. |

| Table 1: Areas identified in DEQ Strategy Recommendation dated April 16, 1996 (DEQ ECSI # 1083) | | | |
|---|---|---|---|
| **Area** | **Previous work/data** | **DEQ identified data gaps** | **Scope of work** |
| 10 - "Lowerators" in shipping warehouse | Two elevators ("lowerators") were used to lower paper rolls from the upper floor of the paper machine building to the ground floor in the storage/shipping warehouse. The elevators had hydraulic lifts to raise/lower the elevators that were located beneath the elevators in sub-floor pits that have concrete walls and bases. One of these elevators was decommissioned approximately 15 years ago and the former pit was filled with gravel and capped with concrete to match the floor grade. The other elevator was recently dismantled as part of the mill decommissioning work and the elevator pit, which is approximately 10 feet deep, was found to contain water. After pumping to de-water the pit, the pit re-filled with water to approximately 6 to 8 feet below grade indicating that groundwater enters the pit. | Potential TPH impacts (from hydraulic oil) to surrounding fill/soil and potential impacts to groundwater. | Assessment of fill/soil and groundwater for TPH and PAHs. |
| 11 - Former Oil Shop, Mobile Shop, and Paint Shop | Former storage and use of petroleum products and wastes, solvents, and other chemicals used for maintenance and repair of vehicles. Former storage of paint and related materials in paint shop. Existing remnants of the shops include concrete slabs that were the former shop floors and a former service pit in the former oil shop that was filled with gravel and capped with concrete to match grade. | Potential impacts to to fill/soils underlying and adjacent to the former shops and beneath the service pit for TPH and solvents. Also potential for metals from used oil and paints | Assessment of fill/soils for TPH, PAHs, VOCs, and metals (RCRA 8). Evaluate need for potential groundwater assessment based on soil conditions. |
| 12 - Mobile Shop | Storage and use of petroleum products and wastes, solvents, and other chemicals used for maintenance and repair of vehicles. Drum storage in secondary containment areas on outside of mobile shop building. Surface staining around containment area. | Potential impacts to fill/soils underlying the containment areas from TPH and solvents. | Assessment of fill/soils for TPH, PAHs, VOCs and metals (cadmium, chromium and lead). |

| Table 1: Areas identified in DEQ Strategy Recommendation dated April 16, 1996 (DEQ ECSI # 1083) | | | |
|---|---|---|---|
| **Area** | **Previous work/data** | **DEQ identified data gaps** | **Scope of work** |
| 13 - South Jordan Point Debris/Fill Area | Areas of fill and debris that includes steel plates, wire, and asbestos-containing transite siding exist in the southern portion of Jordan Point. Debris is present on the surface and this material was encountered by Weyerhaeuser during trenching and installation of a rock wall for erosion control along the shorleine. Apparent filling in this area is evident in historical aerial photographs. In March 2005, Weyerhaeuser had a non-intrusive geophysical investigation of the area conducted to help delineate areas of fill/debris. The investigation identified several "anomoly areas" indicative of buried debris/fill. | Potential concerns associated with asbestos-containing transite siding. Documentation of fill/dedris areas for future land use/development. | Assessment of fill/debris areas to evaluate the locations, extent and types of material. Evaluate amount and composition of transite siding and other materials present. |
| 14 - Ingram Yard | The Ingram Yard has been used as a livestock ranch, dredge spoils disposal site (from Coos Bay dredging by U.S. Army Corps), and a log sorting and chipping yard. Sand, boiler ash, and wood debris have been placed on the Ingram Yard site and land-spreading of decant basin solids (sludge) has also occurred at the site. In 1996, a phase II investigation was conducted that included included review of existing analytical data for ash, sludge and dredge spoils, and sampling and analysis for metals, TPH, VOCs, PCB, and SVOCs. The quantity and distribution of of ash, sludge, and dredge spoils placed on the property were also assessed. | Potential impacts related to past placement of boiler ash, wood debris, and dredge spoils, and land spreading of decant basin solids. Dioxin/furans, metals, and tributyltin are a potential concern. | Review existing information and documentation. Assess shallow soil/fill for dioxins/furans, metals, and tributyltin. |

4277-S JOINT CLOSURE WORK PLAN

Jordan Cove Energy Project
Energy Projects Development LLC
125 Central Avenue, Suite 380
Coos Bay, OR 97420

Attention: Robert L. Braddock

**SUBJECT: Work Plan for Joint Program Regulatory Closure**
**Settling Basins, Petroleum Contaminated Soil, Asbestos Waste, and Mill Waste**
**Weyerhaeuser Mill Site and Ingram Yard Properties**
**Oregon Department of Environmental Quality**
**ECSI #1083, ECSI #4704, and NPDES #101499**
**Coos County, Oregon**

At your request, GRI has prepared this work plan for joint program regulatory closure related to the Weyerhaeuser Corporation (Weyerhaeuser) mill site (Mill Site) property at 92770 Trans-Pacific Parkway and the related Ingram Yard property in Coos County, Oregon. We understand Jordan Cove Energy Project (JCEP) presently owns the Ingram Yard property and plans to purchase the Mill Site property. The purpose of this work plan is to outline the program of anticipated steps that will be completed to address Oregon Department of Environmental Quality (DEQ) Water Quality and Land Quality program closure requirements in conjunction with site redevelopment activities. Solid Waste landfill closure at the Mill Site will be addressed under separate cover at a future time.

It is the intent of this work plan to provide that hazardous/regulated materials will be managed and disposed of according to state and federal laws and regulations and in compliance with associated permits.

## BACKGROUND

JCEP plans to construct industrial facilities at the Mill Site and at the Ingram Yard property located about 1/2 mile west. The locations of these areas are shown on the Location Map, Figure 1. The Mill Site is formally described as tax lots 25S-13W-4-100 and 25S-13W-3-200 (mill) and the Ingram Yard portion of tax lots 25S-13 W-0-200.

Ingram Yard and adjacent land will be developed with a new slip for ocean-going vessels. The slip construction will generate several million cubic yards (cy) of clean sand fill that will be used to raise site grades in and adjacent to Ingram Yard; site grade at the Mill Site will be raised to about elevation 40 ft NGVD. These activities are proposed to commence in 2013.

The Mill Site property has been owned and operated by Weyerhaeuser and is listed in the DEQ cleanup, leaking underground storage tank, hazardous waste, solid waste, and water discharge programs. Portions of the site have received environmental closure (Land Quality Program: Mill Site, #ECSI 1083; Ingram Yard, #ECSI 4704), and others are still under regulatory oversight and require periodic monitoring (Water Quality Program: industrial wastewater for Mill Site, National Pollution Discharge Elimination System

[NPDES] permit #101499). In 2006, DEQ issued a conditional "No Further Action" determination for the Mill Site and Ingram Yard, and it is the intent of this work plan to be consistent with the conditions outlined in that determination (DEQ, 2006).

GRI, JCEP, and Weyerhaeuser personnel met in April 2012 to review conceptual closure of the settling basins and landfills at the Mill Site. GRI, JCEP, and DEQ personnel also met in April 2012 to discuss closure of the existing settling basins, asbestos waste areas, residual areas under mill slab remnants with total petroleum hydrocarbons (TPH), and landfills (Cell 1, 2, and 3). The Cell 3 landfill has about 63,000 cy of capacity remaining (Thiel Engineering, 2004).

**MILL SITE**

**General.** JCEP plans to redevelop the Mill Site with a new industrial facility. Existing site grades will be raised a minimum of 3 ft with clean structural fill consisting of sand from the new slip to be excavated on the Ingram Yard property. Development over the existing mill wastewater system settling basins will require overexcavation of geotechnically unsuitable (highly organic) sludge in the basins and replacement with clean compacted structural fill. The approximate locations of the settling basins are shown on the Basin Detail Plan, Figure 2. Areas where structures will be seismically designed to minimize settlements will require ground improvement below existing site grades to a depth of about 35 ft to increase the density of the loose to medium dense sand fill. Methods of ground improvement have not been selected, but could include dynamic compaction or vibro compaction. These ground improvement methods are discussed in more detail below.

**Ground Improvement Considerations.** Dynamic compaction is a ground improvement technique that densifies soils and fills by using a drop weight. The drop weight, typically hardened steel plates, is lifted by a crane and repeatedly dropped on the ground surface. The mass of the drop weight and the drop height are determined by the specialty subcontractor based on the subsurface conditions and the resulting depth of the impact crater; too much compaction in a single drop can make removal of the weight difficult. Dynamic compaction is typically completed in a grid pattern; the spacing of the drop locations is determined by the subsurface conditions and foundation loading and geometry. Densification of granular soils using dynamic compaction is generally limited to a depth of about 30 to 35 ft. Following densification, the impact craters are filled with compacted clean granular structural fill material. An advantage of dynamic compaction for this site is that spoils are not generated, and there is limited risk of contaminated material being brought to the ground surface.

Vibro compaction is a ground improvement technique used to densify granular soils using a downhole vibratory probe to depths in excess of 100 ft, if necessary. The probe is lowered vertically into the soil, typically with a standard crane. After reaching the bottom of the treatment zone, the soils are densified as the probe is raised. Some settlement of the ground surface typically occurs as the underlying soils are densified. Vibro compaction in relatively clean sand results in limited spoil return to the ground surface. As a conservative assumption of this work plan, we have assumed vibro compaction or some other method of spoil-generating ground improvement may be selected.

**Settling Basins**

The mill was operated between 1961 and 2003 and required the use of two approximately 1-acre, 20-ft-deep, unlined settling basins at the locations shown on Figure 2. The basins connect in series and were used to treat facility wastewater by settling, evaporation, and infiltration. Leachate from the lined landfill Cell 3 continues to be discharged to the basins. Overflow fluids from the basins are collected in a sump and pumped to an off-site aeration basin west of Ingram Yard. Approximately 42,000 cy of sludge is present in the two unlined basins (GSI Water Solutions, Inc., 2012; Thiel Engineering, 2004). This volume will be reconfirmed (or re-estimated, as necessary) in summer 2012 by GRI to assist JCEP with cost estimating.

**Closure Plan:** A qualified contractor will be mobilized, and a dredge will be used to remove the basin sludge to a dewatering system. The dewatering system will be specified to reduce the 42,000 cy of sludge to approximately 2,500 cy of solids cake (about 3,000 dry tons). The solids cake will then be transported to an open area in the Cell 3 landfill for permanent disposal. Liquid from the dewatering process will be drained to the settling basins for reuse in dredging or drained to a sump and discharged to the off-site aeration basin as part of the existing wastewater conveyance system.

After completion of dredging and dewatering operations, the basins will be backfilled with approximately 50,000 cy yards of compacted structural sand fill. The solids cake placed in the Cell 3 landfill will be covered with a minimum 18 in. of clean sand as an interim measure pending final closure of the landfill. The surface of the solids cake area will be sloped to drain away from the center of the landfill.

Site observation during removal and disposal will be completed by an approved environmental firm, and a daily site visit report will be prepared. A summary report documenting the removal activities will be prepared and submitted to DEQ as technical basis for the closure of the settling basin system of NPDES #101499.

**Residual TPH**

Areas with residual TPH are known to exist in the mill site at the "lowerator" and mineral spirits release areas (DEQ, 2006), see Residual Mill Contamination, Figure 3. Ground improvement activities in these areas could potentially generate spoils that are impacted with TPH.

**Closure Plan:** Spoil from the ground improvement activities in the lowerator and mineral release area will be managed as petroleum-contaminated soil and transported off-site to an approved DEQ-regulated facility. Site observation during ground improvement activities will be completed by an approved environmental firm, and a daily site visit report will be prepared. A summary report documenting the removal activities will be prepared and submitted to DEQ as partial technical basis for the closure of the residual TPH areas of #ECSI 1083.

**Asbestos-Containing Material (ACM) Waste Area**

An area with ACM waste is located in the southern portion of the Mill Site (DEQ, 2006). The general and detailed locations of ACM are shown on Figures 3 and 4, respectively. The ACM areas encroach on Coos Bay and several wetland areas. Ground improvement activities in the ACM area will be limited to methods that do not generate spoil (likely dynamic compaction). Where the new sand fill encroaches on Coos Bay and the wetland shorelines, some excavation may be required to establish a toe trench for stability of the new fill perimeter. The toe trench excavations may encounter ACM; however, trench design will be optimized to reduce the footprint of excavation, thereby decreasing the volume of potentially hazardous material excavated.

**Closure Plan:** To reduce the potential for fiber release, a minimum of 3 ft of clean sand will be placed over the area with the ACM. Any ground improvement completed in the ACM area will likely be completed with dynamic compaction with wet working area (water mister).

Toe trench excavation will be completed by equipment operators and personnel with asbestos training using water misters to suppress potential airborne asbestos. Any ACM excavated will be double bagged in accordance with DEQ asbestos regulations and disposed of as allowed by permit in landfill Cell 3. ACM placed in Cell 3 will be covered with a minimum 18 in. of clean sand as an interim measure pending final closure of the landfill. The trench work area will be self-contained and interior drained to reduce the potential for construction runoff.

Site observation during ground improvement and toe trench activities will be completed by an approved environmental firm, and a daily site visit report will be prepared. A summary report documenting the removal activities will be prepared and submitted to DEQ as partial technical basis for the closure of the asbestos waste areas of #ECSI 1083.

## INGRAM YARD

### Wood Waste

Approximately 13,000 cy of non-hazardous log yard sort debris consisting of wood and barkdust waste is located in the southern portion of Ingram Yard in the area of the proposed slip (CH2M Hill, 1996). The location of the log yard sort debris is shown as Area 6 on the Ingram Yard Detail, Figure 5. This material was generated as part of the Mill Site operation and placed in Ingram Yard.

**Closure Plan:** The log yard sort debris will be managed as permitted non-hazardous solid waste. The debris will be excavated and removed by truck to the Mill Site landfill Cell 3 for permanent disposal. Site observation during removal and disposal will be completed by an approved environmental firm, and a daily site visit report will be prepared. A summary report documenting the removal activities will be prepared and submitted to DEQ as part of the Ingram Yard closure for case file #ECSI 4704.

### Sludge Waste

Approximately 116,000 cy of non-hazardous sludge waste is located in the north and central portion of Ingram Yard. The location of the sludge waste is shown as Areas 1 through 5 on the Ingram Yard Detail, Figure 5. This material was generated as part of the Mill Site operation and placed in Ingram Yard. The material has been characterized by PES Environmental, Inc. (2006) and GRI (2007). DEQ has indicated the material is suitable for upland industrial facility disposal provided the materials are not placed in the state waters (DEQ, 2006; 2012).

**Closure Plan:** The sludge will be managed as permitted non-hazardous solid waste. The sludge in the area of the slip and below the footprint of planned industrial facility on and adjacent to Ingram Yard will be excavated and placed in a new soil berm to be constructed adjacent to the rail line along the northernmost portion of Ingram Yard. The sludge in the soil berm will be capped with a minimum of 2 ft of clean sand from the slip excavation. Any excess sludge will be relocated by truck back to the Mill Site landfill Cell 3 for permanent disposal and capped with a minimum 18 in. of clean sand as an interim measure pending final closure of the landfill. Relocation of the sludge to the new soil berm or Cell 3 will provide a final disposal location consistent with the existing closure determination (DEQ, 2006).

Site observation during removal and disposal will be completed by an approved environmental firm, and a daily site visit report will be prepared. A summary report documenting the removal activities will be prepared and submitted to DEQ as part of the Ingram Yard closure for case file #ECSI 4704.

## CONCLUDING REMARKS AND LIMITATIONS

We recommend this work plan be submitted to the DEQ Eugene office to the attention of Bill Mason for his review and comment.

The information presented in this work plan is based on our present understanding of the site environmental conditions, regulatory constraints, and site redevelopment plan. No other warranty or representation, either expressed or implied, is included or intended.

Please contact the undersigned if you have any comments or questions.

Submitted for GRI,

George A. Freitag, CEG
Associate

RE: No Further Action Determination
Former Weyerhaeuser Containerboard Mill
North Bend, Coos County, Oregon
Tax Lots #25S-13W-4-100, 25S-13W-3-200,
and the Ingram Yard portion of 25S-13W-0-200
ECSI Site ID No. 1083

Dear Mr. Scheideman:

The Oregon Department of Environmental Quality (DEQ) has completed a review of the document entitled *Level II Environmental Assessment* dated May 26, 2005 and submitted to DEQ on your behalf by PES Environmental, Inc. The document focuses on the former Weyerhaeuser North Bend Containerboard Mill property consisting of tax lots numbers 25S-13W-4-100 and 25S-13W-3-200 (the "Main Mill Complex"), and the Ingram Yard portion of 25S-13W-0-200 as illustrated in the attached site map. The work described in the report was based on an investigatory scope of work recommended by your consultant and agreed to by DEQ after Weyerhaeuser joined our Voluntary Cleanup Program as described in a voluntary agreement signed February 12, 2004.

DEQ has determined that no further action is required to address environmental contamination at the Main Mill Complex and Ingram Yard properties. This determination is based on the regulations and facts as we now understand them as outlined in our final Site Summary Report dated September 7, 2006.

This decision is based on a determination that the site will remain in commercial/industrial use. Any zoning or use changes resulting in residential use of this property might not meet the protective criteria set forth in DEQ Cleanup rules, and additional assessment or cleanup could be required by DEQ.

This no further action determination does not include the mill's permitted industrial landfill (Solid Waste Disposal Permit #1142) or the mill's permitted industrial wastewater treatment system (NPDES Permit #101499; consisting of two settling ponds, an aerated stabilization basin, and a large former lagoon). These facilities will be closed under their respective permits in cooperation with DEQ's Solid Waste and Water Quality programs.

Residual contamination remains at the Main Mill Complex and Ingram Yard sites. DEQ approves leaving this contamination because the contamination is not present at concentrations that pose an unacceptable risk to human health, safety, welfare and the environment. DEQ's approval to leave contamination on the site was based on present and reasonably likely future conditions, as described in the reports named above. Any residually contaminated soil or sediment excavated during future site activities or development must be properly managed and disposed in accordance with DEQ regulations and policies. In particular, we note the following requirements (locations are illustrated in an attached figure):

1. There are low levels of residual total petroleum hydrocarbon (TPH) contamination below the concrete slab in the mineral-spirits release and south "lowerator" areas. Therefore, if these areas are exposed, any soils removed must be properly managed and/or disposed in accordance with DEQ rules;
2. The small amounts of transite siding in the fill area on south Jordan Point, if ever excavated in future site redevelopment activities, must be properly managed and disposed at a DEQ-approved disposal facility; and
3. While surface soils at the Ingram Yard site meet human health and ecological screening criteria, they contain low levels of potentially bioaccumulating chemicals and must not be placed in waters of the state. Soils and/or sediments containing residual contamination must be managed and/or disposed in accordance with DEQ rules.

In addition, we have the following recommendations:

1. The full extent of the hydraulic oil release in the vicinity of the south "lowerator" has not been determined due to the presence of a thick concrete slab and a railroad spur. Therefore, we recommend that a supplementary investigation (and subsequent remediation, if necessary) be conducted if the concrete slab is ever removed; and
2. The monitoring wells at the facility associated with the hazardous-substance investigation and removal actions should be abandoned according to the Oregon Water Resources Department rules, unless they continue to serve a purpose for Weyerhaeuser.

DEQ concludes that based on the information presented to date, the Main Mill Complex and Ingram Yard parcels associated with the former Weyerhaeuser North Bend Containerboard Mill site are currently protective of public health and the environment and requires no further action under the Oregon Environmental Cleanup Law, ORS 465.200 et seq., unless new or previously undisclosed information becomes available. We will update the Environmental Cleanup Site Information System (ECSI) database to reflect this decision.

DEQ recommends keeping a copy of all of the documentation associated with this investigation and remedial action with the permanent facility records.

If you have any questions about this letter, please contact Bill Mason, the DEQ remedial action project manager for this site, via email at mason.bill@deq.state.or.us or by phone at (541) 687-7427.

Sincerely,

Paul S. Rosenberg

Paul S. (Max) Rosenberg, Manager
Environmental Cleanup Program

## News Release

### *Western Snowy Plover Nesting Season Begins on Oregon Coast*

**Media Contacts:**

Daniel Elbert, (541) 867-4558

*Beachgoers are asked to respect restrictions in sensitive nesting areas*

The nesting season for western snowy plovers returns to the Oregon coast this month, and 2013 promises to deliver another banner year for this threatened species as conservation actions that have led to a record number of breeding adults resume. Beachgoers have the opportunity to actively participate in this recovery success story by honoring access restrictions to a small portion of beaches along the Oregon coast.

Beginning March 15, signs and ropes will be used to inform the public of sensitive western snowy plover nesting areas, and to direct the public to non-sensitive areas where recreational activities are permitted. At these marked beach areas, beachgoers will still have access to the wet sand portion of the beach to enjoy passive recreational activities such as walking and horseback riding. All recreational activities within the dry sand areas, however, will be prohibited. On plover nesting beaches the following recreational activities will also be prohibited on the wet sand: operating a motorized or non- motorized vehicle or flying apparatus (e.g., flying a kite) and having a dog, leashed or unleashed. These access restrictions will protect the nests, eggs and chicks of breeding plovers, which are highly sensitive to repeated disturbance. Access restrictions will be in effect through September 15, but may be lifted early if there is no more nesting by July 15.

Dry and wet sand restrictions will be in effect at Sutton/Baker Beach, on the beach from Siltcoos Estuary to Tahkenitch Estuary and from just south of the Douglas/Coos County line south to Tenmile Estuary (northern Coos County), the North Spit of Coos Bay, Bandon Beach State Natural Area, and New River area

beaches. These access restrictions affect approximately 48 miles along the 230 miles of sandy shore in Oregon. For more detailed information on specific locations of these areas, please consult the following webpage: http://www.oregon.gov/oprd/NATRES/docs/plover/DogFriendlyBeaches_web2013.pdf (http://www.oregon.gov/oprd/NATRES/docs/plover/DogFriendlyBeaches_web2013.pdf)

"In 2012, monitors found 231 nesting plovers along the Oregon Coast – a significant increase from a population low of 28 nesting plovers as recently as 1992," said Laura Todd of the U.S. Fish and Wildlife Service. "People who share the beach and honor the plover area access restrictions have played a huge role in getting us closer to recovering the western snowy plover."

The Pacific coast population of the western snowy plover was listed by the U.S. Fish and Wildlife Service as threatened in 1993. It is also listed as threatened under state law. The primary threats to snowy plover survival are habitat degradation, urban development, introduced European beach grass and predators such as crows, ravens, foxes and skunks.

More information on plover habitat and beach restrictions can be obtained from the U.S. Fish and Wildlife Service, 541-867-4558 ; Oregon Parks and Recreation Department, 541-888-9324 ; U.S. Forest Service, 541-750-7000 ; or the Bureau of Land Management, 541-756-0100 .

# *Final* North Spit Plan

**An update to the Coos Bay Shorelands Plan of 1995**

December 2006

BLM

Coos Bay District

Umpqua Field Office

U.S. DEPARTMENT OF THE INTERIOR
BUREAU OF LAND MANAGEMENT

As the Nation's principal conservation agency, the Department of the Interior has responsibility for most of our nationally owned public lands and natural resources. This includes fostering the wisest use of our land and water resources, protecting our fish and wildlife, preserving the environmental and cultural values of our national parks and historical places, and providing for the enjoyment of life through outdoor recreation. The department assesses our energy and mineral resources and works to assure that their development is in the best interest of all our people. The Department also has a major responsibility for American Indian reservation communities and for people who live in Island Territories under U.S. administration.

# FINAL NORTH SPIT PLAN

December 2005

An update to the Coos Bay Shorelands Plan of 1995

# Executive Summary

## Introduction

In 1995, the Bureau of Land Management completed the Coos Bay Shorelands Final Management Plan to guide the use of BLM lands on the North Spit of Coos Bay. Under that plan and its associated Environmental Assessment (EA), the BLM established specific management objectives to provide for public use and natural resource conservation. Since then, changes in land ownership, environmental conditions and the passage of time necessitated a plan update. The North Spit Plan (the Plan) was prepared to reflect the current situation. Any proposed actions outside the scope of the previous Environmental Assessment will require a new EA. This summary provides a brief outline of the Plan and describes management objectives and actions. The Plan focuses exclusively on comprehensive management of the 1,864 acres of BLM land on the North Spit (the Spit). The remainder of the Spit is managed by other federal agencies, state agencies, and private interests.

Prepared by an interdisciplinary team of specialists, the North Spit Plan:

- describes the resources on the North Spit;
- addresses changes that have occurred since the 1995 Shorelands Plan was completed;
- clarifies management direction for BLM lands on the Spit;
- reports accomplishments; and
- describes ongoing management actions.

Overarching goals are to:

- provide a broad range of recreational opportunities on the Spit while managing for the protection, maintenance, and rehabilitation of the area's natural systems;
- protect and interpret the Spit's biological, cultural and natural resources; and to
- involve and foster open communication among all interested parties during the development and implementation of the North Spit Plan.

## Background

The North Spit of Coos Bay is a large, isolated peninsula northwest of the communities of Coos Bay, North Bend, and Charleston in Coos County, Oregon. The Spit supports a unique assemblage of habitats in a relatively confined area including estuarine, fresh water wetlands, mudflats, and forested uplands. The importance of this natural area is amplified by its proximity to one of the largest urban areas on the Coast. Consequently, the Spit experiences considerably high recreational use and pressure for industrial development.

In 1995, in recognition of the Spit's high ecological and recreational values, portions of it were given special designations by BLM to guide management and use. Approximately 725 acres of the Spit are classified as an Area of Critical Environmental Concern (ACEC). Areas of Critical Environmental Concern are public lands where special management attention is required to protect important historic, cultural, or scenic values, fish and wildlife resources, or other natural systems or processes. The Spit is also a BLM Special Recreation Management Area (SRMA). SRMAs are defined as areas where specific recreational activities and experience opportunities will be provided on a sustained yield basis. The North Spit Plan provides for the preservation of ACEC and SRMA values through specific and compatible management actions related to recreational access, cultural and historic preservation, wildlife and plant conservation and management, and educational and interpretive opportunities.

# Public Scoping

Prior to drafting the North Spit Plan, public comments on North Spit management were solicited via letters, presentations, public service announcements, and newspaper notices. Thirty-six people responded and provided 56 specific comments. BLM determined from the comments the following general areas of concern:

Public access to the jetty and beaches
Western snowy plover management
Development of lands
All-terrain vehicle use
User fees
Protection of resources
Land exchanges
Flexibility of management
Boat dock use
Firearm use

Responses to these concerns are presented in the Plan's introduction and relevant issues are further discussed elsewhere in the document.

# Plan Format

**Part One** describes BLM's planning framework. In the BLM planning system there are three levels or tiers:

1. National and State Level: Laws, regulations, directives, and policies
2. District Level: Coos Bay District Resource Management Plan (May 1995)
3. Field Office Level: Activity Plans (site-specific plans such as the North Spit Plan)

Each of these levels is discussed in terms of its relevancy to the North Spit Plan.

**Part Two** reviews the original 1995 Shorelands Plan and outlines the status of its management actions. The 1995 Coos Bay Shorelands Plan identified issues, concerns, and opportunities on the Spit, and included specific management actions pertaining to each of the following subjects:

- Education and Interpretation
- Land Tenure and Cooperative Agreements
- Law Enforcement
- Recreation
- Vegetation
- Wildlife Habitat

Management actions listed in the 1995 Shorelands Plan were reviewed and updated (Table 2 of the Plan). The actions fall into four categories: accomplished, accomplished in part, not accomplished, and ongoing. Actions in the the Shorelands Plan that were not accomplished include those where land exchanges have removed or precluded lands from BLM jurisdiction and therefore are no longer applicable to BLM management of the Spit.

Other changes to note include those pertaining to the threatened Western snowy plover. The 1995 Shorelands Plan proposed several actions pertaining to snowy plovers and ocean beach access that were never implemented (Table 2, Management Action 5). Changes to management actions are a result of a revised public access strategy implemented subsequent to the grounding of the New Carissa in 1999. The strategy pertains to the management of public lands on the Spit and allows for public use while protecting plovers and promoting their recovery (USDI FWS 2000).

Strategy details are described in Part Three under Species of Special Management Concern and are summarized in Table S-1.

The Shorelands Plan made some recommendations that were not listed as actions. Errors are noted and additions or changes to these recommendations are listed and explained.

**Part Three** describes the cultural, natural, and recreational resources on the Spit. Resources are grouped into five categories:

- Physical, including Water, Geology, Soils, Minerals, Coal Bed Methane, Oil and Gas
- Biological, including Vegetation, Wildlife, and Fisheries
- Cultural and Historical
- Recreational
- Visual

**Part Four** presents management actions on BLM-administered lands for the next ten years. The remainder of this summary focuses on Part Four as it brings the reader up to date on management objectives, accomplishments, and ongoing and proposed activities.

# North Spit Management, 2005

Table S-1 summarizes management objectives and actions for BLM lands on the North Spit. The objectives and actions reflect the goal of the North Spit Plan to conserve the natural, cultural, and recreational values of the Spit. Due to the interrelationship of the various resources at the Spit, many actions apply to more than one objective. Objectives and actions in the North Spit Plan are consistent with BLM policies, state and federal regulations, ACEC planning documents, and the 1995 Shorelands Plan. For the North Spit Plan, objectives and proposed actions were reviewed and revised based on current conditions and needs, and will be implemented as funding allows. Objectives correspond to the resources described in Part 3 as well as to other BLM programs such as land tenure, environmental education and interpretation, site protection and administration, and monitoring and research. With the exception of the latter, the objective and actions for each resource or program are presented in alphabetical order, starting with Cultural Resources. The objective for Monitoring and Research is placed at the end because several of the resources and programs have actions under this heading.

Monitoring is used to: 1) ensure that the management goals, objectives, and actions are being followed (implementation monitoring); 2) verify if the actions are achieving the desired results (effectiveness monitoring); and 3) determine if the underlying assumptions of the Plan's goals and objectives are sound (validation monitoring). Ongoing or proposed monitoring actions are included for Cultural Resources, Environmental Education and Interpretation, Geology, Recreation, and Vegetation and Wildlife Resources.

Updated maps, tables, and appendices are presented to clarify information presented in the Plan. They include detailed descriptions, lists, and chronologies of key interest including site names, ownership boundaries, an update of 1995 management actions, wildlife and plant lists, and land tenure history. A glossary and a list of acronyms are presented to assist the reader with unfamiliar terms.

**Table S-1. Summary of Management Objectives and Actions Accomplished, Ongoing, and Proposed for the North Spit. The North Spit Plan provides more detailed explanations and supporting references. See Part 4 for a complete description of the actions.**

| Management Objectives | Actions Accomplished | Actions Ongoing | Actions Proposed |
|---|---|---|---|
| **CULTURAL RESOURCES**<br><br>**1:** Preserve important cultural resources on the Spit. | • A report was completed by noted historian Stephen Dow Beckham detailing the history of federal activities on the North Spit. | • Continue to preserve remaining historic cultural resources. | • Work with the Confederated Tribes of the Coos, Lower Umpqua, and Siuslaw Indians and the Coquille Indian Tribe to assure continued protection and preservation of prehistoric resources.<br><br>• Remove damaged chain link fence from the perimeter of the World War II Quonset huts. |
| **ENVIRONMENTAL EDUCATION and INTERPRETATION**<br><br>**2:** Promote awareness and appreciation for the Spit's many resource values and recreational opportunities, and support a minimum impact land use ethic through educational programs such as *Leave No Trace* and *Tread Lightly*. | • A brochure was developed to provide visitors with a map of the Spit and inform them of regulations and opportunities.<br><br>• Interpretive signs and a kiosk were developed and installed. Seasonal interpreters were hired to educate the public about seasonal closures and recreational opportunities. | • Continue to host field trips for schools at the Spit for students to learn about the area.<br><br>• Continue to work cooperatively with the interagency snowy plover working team on issues pertaining to public education and outreach. | • Develop an environmental education prospectus for the District and implement its recommendations on the North Spit.<br><br>• Utilize seasonal or volunteers to contact visitors and disseminate information.<br><br>• Conduct special educational opportunities and events that involve the public.<br><br>• Interpret cultural or paleo-environmental history of the Spit in coordination with interested Indian tribes and the Coos Bay District Archaeologist.<br><br>• Rotate or replace interpretive displays as needed.<br><br>• Use the draft Western Snowy Plover Outreach Plan when planning plover outreach on the Spit.<br><br>• Raise public awareness about the environmental and recreational values of riparian and wetland areas on the Spit. |
| **LAND TENURE ADJUSTMENTS**<br><br>**3:** Prioritize land tenure adjustments based on natural resource values and recreational opportunities on non-BLM parcels, consolidate BLM properties, and safeguard public investments. | • The 1995 Shorelands Plan identified four potential land acquisitions and one disposal. Three acquisitions were accomplished. | • In accordance with the RMP, some BLM lands on the Spit within zoning districts 3-EWD, 4CS, and 6WD as delineated by the Coos County Comprehensive Plan could be offered for exchange, sale, or lease. A land disposal is currently in progress for an 80 acre BLM parcel north of the Roseburg Chip Facility along the Trans Pacific Lane.<br><br>• Several utility and access rights-of-way were issued and are currently in use. Future applications for leases, permits, and right-of-ways will be reviewed and authorizations issued on a case-by-case basis. | • Consider land tenure adjustments to ensure access to public lands as appropriate to meet objectives. Appendix 3 contains a chronological history of the land tenure adjustments affecting public lands on the Spit. |

| Management Objectives | Actions Accomplished | Actions Ongoing | Actions Proposed |
|---|---|---|---|
| **RECREATION**<br><br>**4:** Manage the North Spit SRMA to provide for a range of recreation opportunities that contribute to meeting traditional as well as projected recreation demand within the region while protecting the area's natural, cultural, and scenic resources. | • Signs were placed at the ocean beach access points along the Foredune Road; other signs and maps were placed at various locations to inform visitors of regulations and recreational opportunities.<br><br>• Roads and trails that were not designated as open were closed using logs, root wads, and signs. Many of these closed routes are disappearing through natural revegetation.<br><br>• A sign strategy was developed to assist BLM in providing information to the public on regulations, recreational opportunities, and natural resources on the Spit. | • Continue to provide motorized access on the Spit to support the area's long-standing traditional recreation uses while protecting natural, cultural and scenic resources.<br><br>• Retain a recreation setting compatible with the area's Rural and Semi-Primitive Motorized ROS classification.<br><br>• Provide press releases related to seasonal access restrictions.<br><br>• Clear sand and debris from the boat ramp each spring prior to reinstalling the docks for the summer season.<br><br>• Continue to maintain the docks.<br><br>• Continue to allow primitive camping on BLM lands on the Spit except where signed to protect sensitive plants and wildlife.<br><br>• Continue to permit hunting and shooting on BLM lands on the Spit in conformance with applicable state and federal laws and regulations. These regulations prohibit shooting adjacent to and across public roadways and within developed recreation sites. | • Place improved signs along the sand roads and at ocean beach access points. Advise visitors the beach access points may be blocked and to look before driving over the foredune.<br><br>• Remove dilapidated fences and fence posts from the intersection of the Foredune Road and Trans Pacific Lane, the WWII bunker fence, and from the southern interior.<br><br>• Establish trails for pedestrian and equestrian use within the North Spit interior. Develop and support local partnerships to assist in maintaining and managing this trail system.<br><br>• Create and maintain connections between trails on BLM, the Forest Service, OPRD and Weyerhaeuser lands.<br><br>• Construct a small equestrian and hiking staging area to provide parking and visitor information at the portal to the trail system.<br><br>• Implement completed sign strategy developed to improve communication with Spit visitors. Include information about wildlife viewing opportunities at the kiosk proposed for the boat ramp. |
| **SITE PROTECTION and ADMINISTRATION**<br><br>**5:** Provide and maintain adequate visitor facilities, services, signing, and programs that are appropriate for the area's recreation opportunity setting and that serve to protect the Spit's sensitive resources. | **Fire Management**<br>See Actions Ongoing.<br><br>**Hazardous Materials Management**<br>See Actions Proposed.<br><br>**Law Enforcement**<br>See Actions Ongoing.<br><br>**Facility Management**<br>See Actions Ongoing.<br><br>**Road Maintenance and Improvement**<br>None at this time. | **Fire Management**<br>• BLM contracts with the Coos Forest Protection Association for fire response, including the lands on the Spit.<br><br>**Hazardous Materials Management**<br>See Actions Proposed.<br><br>**Law Enforcement**<br>• BLM Law Enforcement Officers enforce federal regulations on BLM lands. BLM may continue to contract with the Coos County Sheriff's Department and contribute funds to OPRD for seasonal assistance with beach patrol.<br><br>• BLM Law Enforcement Officers enforce Federal and State firearm regulations and encourage shooter safety on the Spit.<br><br>**Facility Management**<br>• Maintain existing facilities at the boat launch recreation area.<br><br>**Road Maintenance and Improvement**<br>None at this time. | **Fire Management**<br>None at this time.<br><br>**Hazardous Materials Management**<br>• Finish the Spit Life Guard Station Environmental Site Characterization.<br><br>**Law Enforcement**<br>None at this time.<br><br>**Facility Management**<br>• Consider placing alternative toilet facilities at high use areas.<br><br>**Road Maintenance and Improvement**<br>• Consider raising and widening the Re-route Road to minimize the risk of vehicular collisions. |

| Management Objectives | Actions Accomplished | Actions Ongoing | Actions Proposed |
|---|---|---|---|
| **VEGETATION and WILDLIFE RESOURCES**<br><br>**6:** Conserve, enhance, or restore natural habitats, with an emphasis on habitats that support special status plant and wildlife species. | <u>**Vegetation**</u><br>• Plant communities were mapped and digitized.<br><br><u>**Special Status Plant Species and Communities**</u><br>• Pink sandverbena was reintroduced.<br><br>• A permanent vehicle re-route was constructed to protect the Point Reyes bird's-beak population on the bay side.<br><br><u>**Exotic Plants and Noxious Weeds**</u><br>• Gorse was removed from the Coast Guard Lifesaving station.<br><br>• Scotch broom was cleared from HRAs.<br><br><u>**Wildlife**</u><br>None at this time.<br><br><u>**Special Status Wildlife Species**</u><br>Nest boxes were installed for purple martins. | <u>**Vegetation**</u><br>• Coordinate with other agencies and institutions to restore degraded and disturbed plant communities.<br><br><u>**Special Status Plant Species and Communities**</u><br>• Facilitate the recovery of the pink sandverbena by collecting seeds for dispersal to other sites along the coast.<br><br>• In cooperation with the Port and the DSL maintain protective barriers around the Point Reyes bird's-beak population.<br><br>• Continue inventory and management for SSS.<br><br><u>**Exotic Plants and Noxious Weeds**</u><br>• European beach grass is removed annually from plover areas.<br><br><u>**Wildlife**</u><br>None at this time.<br><br><u>**Special Status Wildlife Species**</u><br>• Continue to implement snowy plover conservation actions:<br>1. Closing the upper, dry sand portion of the ocean beach to all public access from the FAA Tower south to the BLM boundary during the Western snowy plover nesting season (March 15- September 15 annually). The lower, wet sand beach is restricted to motorized use as authorized by OPRD. Inland snowy plover nesting areas on BLM land are also signed closed to all use during the nesting season, and are open to nonmotorized use the remainder of the year.<br>2. Removing beachgrass from the inland snowy plover areas to maintain open, sandy habitat suitable for nesting plovers.<br>3. Implement predator control to protect the plover population from further declines caused by predation.<br>4. Monitor plover nesting to gauge the success of management actions and progress toward plover recovery.<br><br>• Continue to implement recovery plans for other species as necessary. | <u>**Vegetation**</u><br>• Refine the classification of plant associations on the Spit.<br><br>• Conduct a complete inventory of all plant species.<br><br><u>**Special Status Plant Species and Communities**</u><br>On the North Spit Area of Critical Environmental Concern:<br>• Implement beach and dune ecosystem restoration.<br><br>• Establish additional special status plant populations.<br><br>• Develop opportunities to increase the amount of habitat suitable for rare species and to link isolated populations.<br><br>• Collect special status plant seeds for future use.<br><br>• Identify opportunities to restore rare plant communities.<br><br><u>**Exotic Plants and Noxious Weeds**</u><br>• Continue treatments to remove noxious and exotic species. Restore treated areas with native seeds and plants.<br><br>• Use best management practices to prevent the further spread of exotic plants and noxious weeds.<br><br><u>**Wildlife**</u><br>• Survey for great blue herons and great egret rookeries.<br><br>• Conduct wildlife inventories at selected wetlands.<br><br>• Survey for nesting raptor species.<br><br><u>**Special Status Wildlife Species**</u><br>• Develop and implement survey protocols to locate special status species.<br><br>• Actively manage habitats to promote the conservation of special status species and raptors. |
| **WATER RESOURCES**<br><br>**7:** Maintain wetland areas in a condition supportive of a healthy aquatic ecosystem. | • BLM participated in the creation of wetlands on BLM adjacent to Weyerhaeuser's Overlook wetlands site. | None at this time. | • Support wetland mitigation projects consistent with the Henderson Marsh Mitigation Plan. |

| Management Objectives | Actions Accomplished | Actions Ongoing | Actions Proposed |
|---|---|---|---|
| **MONITORING and RESEARCH**<br><br>**8:** Facilitate improved management of the Spit through monitoring to learn more about the natural and cultural resources of the area and to assess the effects of management actions. | **Cultural Resources**<br>None at this time.<br><br>**Environmental Education and Interpretation**<br>See Actions Ongoing.<br><br>**Geology**<br>None at this time.<br><br>**Recreation**<br>See Actions Ongoing.<br><br>**Vegetation and Wildlife Resources**<br>See Actions Ongoing. | **Cultural Resources**<br>None at this time.<br><br>**Environmental Education and Interpretation**<br>• Evaluate the effectiveness of educational brochures and signs.<br><br>**Geology**<br>None at this time.<br><br>**Recreation**<br>• Continue to use traffic and trail counters and field staff observations to monitor visitor use and to report findings in the Recreation Management Information System.<br><br>• Continue to monitor camping on BLM lands on the Spit.<br><br>**Vegetation and Wildlife Resources**<br>• Monitor noxious weed species to document existing population areas, effectiveness of management actions for removal, and the spread of these species to new sites.<br><br>• Evaluate and explore effective management strategies to meet recovery goals for the Western snowy plover. Monitor human and natural disturbance effects on breeding plovers.<br><br>• Continue to support the Oregon Natural Heritage Information Center in its efforts to monitor Western snowy plover reproductive success.<br><br>• Continue to monitor great blue heron and great egret rookeries.<br><br>• Continue to monitor selected special status species on the Spit.<br><br>• Continue to monitor the condition of riparian-wetland vegetation. If signs of excessive disturbance caused by unauthorized motorized recreation become evident, adjust patrols, signing and barriers to reduce or prevent impacts | **Cultural Resources**<br>• Monitor stability of important cultural resources and propose actions to continue their preservation.<br><br>**Environmental Education and Interpretation**<br>• Evaluate the effectiveness of environmental education programs and interpretive materials on a regular basis, and make modifications as necessary.<br><br>**Geology**<br>• Track elevation changes on the ocean foredune and monitor the effects of weather and beach grass removal on foredune erosion.<br><br>**Recreation**<br>• Monitor the condition of beach access routes.<br><br>**Vegetation and Wildlife Resources**<br>• Monitor special status species' population status and trends. Pursue collaborative efforts to study SSS reproductive ecology, threats, habitats, and effects of management treatments and practices.<br><br>• Monitor the status and trends of globally ranked plant communities within the North Spit ACEC.<br><br>• Seek collaborative opportunities to survey migratory shorebirds and waterfowl to establish population status and trends. |

# INTRODUCTION

The North Spit of Coos Bay (the Spit) is a sandy, vegetated point of land separating the waters of Coos Bay from the Pacific Ocean (Map 1). It is northwest of the communities of Coos Bay, North Bend, and Charleston in Coos County, Oregon. The Bureau of Land Management (BLM) administers 1,864 acres of public domain lands on the Spit, primarily acquired from the Army Corps of Engineers (COE) in 1984. It is comprised of narrow, sandy beaches on the Pacific Ocean side and a combination of sand beaches, mudflats, and salt marshes on the bay side. The interior of the Spit is characterized by stabilized and shifting sand dunes, fresh water wetlands, and upland stands of shore pine and Sitka spruce. Non-native European beach grass and Scotch broom dominate much of the deflation plain.

The diverse natural resources and recreational opportunities found on the Spit attract a variety of people and present unique management challenges for state and federal agencies. The North Spit Plan combines background and current information on the Spit's major resources and recreational values, defines management objectives for those resources, and outlines BLM's planned actions to meet those objectives.

## Purpose and Scope

The North Spit Plan provides updated direction for comprehensive management of the North Spit. Prior planning efforts by BLM for the Spit include the Coos Bay Shorelands Draft Management Plan (USDI BLM 1989) and the Coos Bay Shorelands Draft Management Plan and Environmental Assessment (USDI BLM 1994). The Final Supplemental Environmental Impact Statement on Management of Habitat for Late Successional and Old Growth Forest Related Species Within the Range of the Northern Spotted Owl and its Record of Decision (i.e. the Northwest Forest Plan; Interagency 1994) and the Coos Bay District's Resource Management Plan and Environmental Impact Statement and its Record of Decision (RMP; USDI BLM 1995) were incorporated into the Coos Bay 1995 Shorelands Final Management Plan (1995 Shorelands Plan; USDI BLM 1995). The purposes of the North Spit Plan are to address changes that have occurred since the 1995 Shorelands Plan was completed; clarify management direction for BLM lands on the Spit; report accomplishments; and describe ongoing management actions described in the 1989 plan. The 1994 Environmental Assessment (EA) associated with the 1995 Shorelands Plan remains valid. In the future, site specific EAs will be prepared when necessary to evaluate the effects of any new ground disturbing activities.

Lands on the Spit are owned and managed by several public agencies and private interests. BLM has no authority over lands not under its jurisdiction; hence management actions proposed in the North Spit Plan pertain only to the BLM-administered lands on the Spit. When necessary, BLM works with adjacent landowners per written agreements to accomplish joint management goals. The COE administers 245 acres on the Spit and their primary mission is to maintain the North Jetty (the Jetty) at the entrance to Coos Bay. The COE allows public access on their lands; however the Jetty itself was not designed for public use. The US Forest Service (FS) manages the Oregon Dunes National Recreation Area (ODNRA) to the north of the Spit. Many developed and undeveloped recreational opportunities are available in that area. The Oregon Parks and Recreation Department (OPRD) manages the Pacific Ocean beaches below the high tide line. The OPRD management guidelines for the Spit are described in the Draft Ocean Shore Management Plan and Habitat Conservation Plan for the Western snowy plover (Oregon Natural Heritage Information Center [ORNHIC] and OPRD 2004). The Division of State Lands (DSL) manages lands below the mean low tide, including submersed lands. The primary access to the bay side of the Spit is currently through lands owned by the Oregon International Port of Coos Bay (the Port). Coos County's zoning designations for the Spit are Conservation Shorelands, Natural Shorelands, Water-dependent Development Shorelands, and Development Shorelands (Coos County 1986). Privately owned lands include: a Roseburg Forest Resources chip facility and a Weyerhaeuser Company cardboard plant that is currently closed. In the past, BLM and Weyerhaeuser worked together on wetland mitigation plans and actions, including wetlands creation. State (the Oregon Department of Fish and Wildlife [ODFW]) and federal (the US Fish and Wildlife Service [FWS]) agencies provide regulatory oversight for the fish and wildlife resources found on the Spit.

# Vision and Goals

BLM's vision is to manage the public lands on the Spit as a predominately natural landscape by conserving botanical, cultural, and wildlife resources while providing recreational, educational, and interpretive opportunities for the benefit of local and regional visitors and economies. The two overarching goals of the North Spit Plan are:

- To provide a broad range of recreational opportunities on the Spit while managing for the protection, maintenance, and rehabilitation of the area's natural systems and cultural resources.

- To involve and foster open communication among local, regional, and national publics, and with other agencies and units of the government during the development of the North Spit Plan and as management of the Spit continues into the future.

# Plan Development and Public Involvement

## Scoping

As required under BLM's planning regulations (43 FR 1600), an interdisciplinary team of BLM specialists brought their professional expertise and experience to bear on the issues and concerns of managing the Spit (see below). Regulations also require public involvement and comment through the planning process. To this end, in 2003, BLM conducted public scoping to better understand the concerns regarding management of BLM-administered lands on the Spit. Public input was solicited via letters, presentations, public service announcements, and newspaper notices. Thirty-six people responded and provided 56 specific comments (Table 1).

## Additional Public Involvement

The BLM conducted a formal comment period on the DRAFT North Spit Plan from August 1 through August 31, 2005. Public input was solicited via letters, newspaper notices, and through fliers handed out in the field. Comments are listed by categiry in Table 2. Some of the comments BLM received during and after the official comment period for the DRAFT Plan made it clear there was misinformation circulating concerning restrictions to assecc activities on the North Spit. BLM held a public forum on October 20, 2005, to clarify information and to listen to the public's interests and recommendations related to recreation and natural resources. Three new action items are presented in this Final North Spit Plan as a result of the public forum. The items are improving information available about the North Spit, possibly placing picnic tables at the boat launch facility and investigating the possible opening of the Foredune Road to motorized use from the South Dike Road intersection to the USFS boundary to the north.

**Table 1. Summary of public comments received during 2003 scoping for the North Spit Plan and BLM response.**

| 2003 Public Comment | BLM Response |
|---|---|
| Availability of Jetty access for COE | The COE's right-of-way over BLM lands for Jetty work is not affected by the North Spit Plan. |
| Concern about plover decisions including road and beach closures | BLM will cooperate with OPRD, ODFW, and the FWS regarding plover habitat and nesting season restrictions. |
| Develop commercial ocean front property | BLM does not have the authority to develop commercial property. |
| Opposes all-terrain vehicle use | Motorized travel off of designated routes on BLM lands on the Spit is prohibited. Route designation occurred in the 1995 Shorelands Plan, page 11. |
| Opposes development | No development by BLM is planned at this time. |
| Opposes fees | No fees are planned. |
| Opposes land exchange/wants free land | BLM does not have authority to give away the public lands. Land tenure adjustments will be assessed as necessary under NEPA. |
| Protect natural and cultural resources | BLM will continue with ongoing protection efforts. |
| Remain flexible with land use; work with the Port | BLM promotes good working relations with the Port and other partners. |
| Replace boat docks | Docks will be repaired and replaced as necessary. |
| Restrict target shooting | BLM, county, and state law enforcement will enforce safe use of firearms. |
| Retain bay and ocean beach access | Pedestrian and equestrian access to BLM lands will remain except for beach access in designated areas during the plover nesting season. Motorized access will remain available on the three designated open routes. |
| Storm water drainage issues | BLM will investigate these issues with the Port. |
| Supports day use fees | No fees are planned. |
| Supports off-road vehicle (ORV) use | ORVs are permitted on the designated open routes on BLM lands. |

**Table 2. Additional Public Input.**

| Comments on the DRAFT North Spit Plan | No. of Comments during Comment Period for Draft Plan | No. of Comments from Public Forum | BLM Response |
|---|---|---|---|
| Bicycle trails - supports | 1 | | Bicycles are permitted on the Spit, however the loose sand makes bicycling difficult without paved trails. There are no plans to pave any trails at this time. |
| Bicycle trails - against | 1 | | BLM will continue to support multiple use activities. |
| Build a boat ramp | 1 | | This was completed in 1993. See Map 3 for location. |
| BLM should re-do the 2000 Biological Opinion for the western snowy plover | 2 | | BLM is planning to reinitiate consultation to update the 2000 Biological Opinion, based on additional information on visitor use and to clarify areas and activities under BLM's jurisdiction. |
| Build a retaining wall at Half Moon Bay | 1 | | This is on COE property and this Plan only addresses BLM-administered lands. |
| Cannot ride from Saunders Lake to the north jetty | | 1 | BLM will investigate the possible opening of the Foredune Road north to the USFS boundary, as a Recreation Action item. |
| Concern about losing hunting grounds | | 1 | BLM proposes no changes to legal hunting on the spit. |
| Equestrian trails - supports | 59 | 3 | BLM will continue to work with local volunteer groups to identify and maintain trails. |
| Equestrian and pedestrian trails - against | 1 | | BLM will continue to support multiple use activities. |
| Grade area by paved road and South Dike Road intersection; add a sani-can | | 2 | This parcel is being considered for sale at this time. The COE has a right-of-way for the area. It is possible BLM may create a small trailhead staging area there, pending current negotiations. |
| Improve information available about the North Spit | | 10 | BLM staff is working on this now and it was added into the action items. |
| Keep it the way it is | 2 | 10 | No additional development or access restrictions by BLM are planned at this time. |
| Keep access to bay regardless of land sales | | 1 | BLM only has jurisdiction on BLM lands. |
| Keep access to bay side open | | 1 | This is Port land, not BLM |

**Table 2. Additional Public Input. (continued)**

| Comments on the DRAFT North Spit Plan | No. of Comments during Comment Period for Draft Plan | No. of Comments from Public Forum | BLM Response |
|---|---|---|---|
| Bicycle trails - supports | 1 | | Bicycles are permitted on the Spit, however the loose sand makes bicycling difficult without paved trails. There are no plans to pave any trails at this time. |
| Bicycle trails - against | 1 | | BLM will continue to support multiple use activities. |
| Build a boat ramp | 1 | | This was completed in 1993. See Map 3 for location. |
| BLM should re-do the 2000 Biological Opinion for the western snowy plover | 2 | | BLM is planning to reinitiate consultation to update the 2000 Biological Opinion, based on additional information on visitor use and to clarify areas and activities under BLM's jurisdiction. |
| Minimize signs, gates, fences and maps | | 1 | BLM plans to remove some fences and possibly one gate. Signs are needed for safety and to inform those not familiar with the area. |
| Mitigation plan concerns (Henderson Marsh) | | 1 | The wording in the draft was changed to clarify the issue. |
| Monitor effectiveness of signs and information; coordinate with USFS; use volunteers | | 3 | This is standard procedure for BLM and it will continue for the North Spit. |
| Picnic tables should be installed at the boat ramp | 1 | 5 | This will be considered and was added as an Action item. |
| Plan departs from its underlying EA | 1 | | There are no additional ground disturbing actions in the Plan, or additional environmental impacts, thus NEPA is not required. |
| Planning – Evidence suggests its preparation could be in violation of NEPA, FLPMA, and the Federal Advisory Committee Act | 1 | | There are no ground disturbing actions in the Plan, thus additional NEPA is not required. The trail work was conducted under a volunteer agreement and it implemented MA13 in the 1995 Shorelands Plan, thus it would not be a FACA violation. |
| Plan proposals cultivate conflict. They erode traditional uses, further segregate uses, and elevate some uses above others. | 2 | 1 | The Plan makes no changes to the existing motorized and non-motorized (segregated use) access designations that have been in effect since 1985 when BLM amended the Master Framework Plan for the Coos Bay District and in 1995 with the Coos Bay District RMP and the Coos Bay Shorelands Plan. Traditional uses are not restricted and BLM welcomes volunteer groups to help us maintain trails. |
| Plan relies on irrelevant and inaccurate data (SCORP, Oregon State Parks Surveys) | 1 | | The SCORP is the best available survey resource for recreational activities and is used to assess current uses, trends and demand at the state level and subregional level. The Ocean Shore Plan survey is also relevant as it included a subsurvey from Ten Mile Creek to Coos Bay, including the North Spit. BLM also utilizes three traffic counters on the spit. |

**Table 2. Additional Public Input. (continued)**

| Comments on the DRAFT North Spit Plan | No. of Comments during Comment Period for Draft Plan | No. of Comments from Public Forum | BLM Response |
|---|---|---|---|
| Bicycle trails - supports | 1 | | Bicycles are permitted on the Spit, however the loose sand makes bicycling difficult without paved trails. There are no plans to pave any trails at this time. |
| Bicycle trails - against | 1 | | BLM will continue to support multiple use activities. |
| Build a boat ramp | 1 | | This was completed in 1993. See Map 3 for location. |
| BLM should re-do the 2000 Biological Opinion for the western snowy plover | 2 | | BLM is planning to reinitiate consultation to update the 2000 Biological Opinion, based on additional information on visitor use and to clarify areas and activities under BLM's jurisdiction. |
| Plan will cost BLM money and work the agency cannot afford | 1 | | The Coos Bay District BLM receives funding to support outdoor recreation on the public lands from a variety of appropriated funding sources. The minimal improvements proposed in the Update are well within the fiscal constraints of the Coos Bay District recreation and maintenance budget. In addition, group volunteer agreements assist in long term maintenance of trails and other projects. |
| Shooting - concerned you cannot shoot a firearm across a trail | 1 | | BLM trails and the unmaintained sand roads are not considered public roads, thus shooting is not restricted. |
| Shooting - restrict firearms | 1 | | BLM staff will track this as an issue identified by the public. |
| Shooting (firearms) safety concerns | 5 | | BLM will track this as an issue identified by the public. BLM will also include firearm safety messages in North Spit information. |
| Supports crab dock construction | 2 | 4 | This popular suggestion is hampered by funding constraints. Estimates to construct a crab dock are several hundred thousand dollars. The location is questionable with known sand and wood debris deposition, and so there are no plans for construction. |
| Supports OHV trails | 2 | 2 | This triggered a new action item in the Recreation section that will investigate the possibility of opening the Foredune Road north to the USFS boundary. |
| Weeds Program – use "Casoron" herbicide; Policy questions | | 1 | BLM is not authorized to use certain chemicals on public lands. Beach grass is not listed as "noxious," therefore, BLM cannot use "Caroson." BLM weed policy is set at the national level and cannot be changed at the field level. |

Comments received which are outside the scope of this planning document:

- It could lead to prolonging the Coos Bay District RMP revision process
- Its ties to the New Carissa DARP are obvious and the DARP is itself a NEPA/FLPMA concern
- The ACEC designation on the North Spit should be eliminated
- BLM is over emphasizing Policy 6840
- The Draft should note that the ocean beach was declared a road in 1913 and the Coos County Board of Commissioners declared a county road across the north spit at the old ferry crossing and up the beach to Tenmile Creek in 1856.

## BLM Interdisciplinary Team Members

| | |
|---|---|
| Tim Barnes | Geologist |
| Nancy Brian | Botanist |
| John Colby | Hydrologist |
| Linda Petterson | Realty Specialist |
| Sharon Morse | Interpretive Specialist |
| Steve Samuels | Archaeologist |
| Madeleine Vander Heyden | Wildlife Biologist, ACEC Manager |
| Dan VanSlyke | Fisheries Biologist |
| Tim Votaw | Hazardous Materials Coordinator |
| Dave Wash | Outdoor Recreation Planner |
| Nancy Zepf | Outdoor Recreation Planner |

This plan consists of four parts: Part One describes BLM's planning framework; Part Two reviews the original 1995 Shorelands Plan and outlines the status of its management actions; Part Three provides current information on the cultural, natural, and recreational resources on the Spit; and Part Four presents management actions on BLM-administered lands for the next ten years.

# PART 1 – PLANNING FRAMEWORK

Part One describes BLM's planning framework. In the BLM planning system there are three levels or tiers which are described below:

1. National and State Level: Laws, Regulations, and Policy
2. District Level: Coos Bay District Resource Management Plan (May 1995)
3. Field Office Level: Activity Plans (site-specific plans such as this one)

These levels are described in detail below.

## National and State Level

The management actions put forth in the North Spit Plan are guided by public laws, Executive Orders, regulations, and directives of the Secretary of the Interior. BLM policy must be consistent with these higher authorities as they provide a framework to ensure that management actions will maintain, enhance, or rehabilitate the natural resources present on the Spit while providing for public access. Pertinent federal laws, regulations and policies are summarized below.

- *Federal Land Policy and Management Act (FLPMA)* — Directs the BLM to plan for and manage the public lands in a manner that "protects the quality of scientific, scenic, historical, ecological, environmental, air and atmospheric, water resource, and archaeological values; that, where appropriate, will preserve and protect certain public lands in their natural condition; that will provide food and habitat for fish and wildlife and domestic animals; and that will provide for outdoor recreation and human occupancy and use by encouraging collaboration and public participation throughout the planning process. In addition, the public lands must be managed in a manner that recognizes the Nation's need for domestic sources of minerals, food, timber, and fiber from the public lands."

- *National Environmental Policy Act (NEPA)* — Requires environmental analysis prior to surface disturbing activity on federal lands.

- *National Historic Preservation Act (NHPA)* — Protects important historic properties.

- *Endangered Species Act (ESA)* — Protects flora and fauna listed as threatened or endangered and at risk of extinction.

- *Code of Federal Regulations, Title 43, 8300 — Recreation Management*
  Recreation regulations guiding the inventory, planning, and management of recreational resources, including off-highway vehicle management on the public lands.

- *Executive Orders 11644 and 11988, Use of Off-Road Vehicles on Public Lands* —
  Provides a uniform federal policy for the management of off-highway vehicles on lands administered by the Departments of Interior, Agriculture, Defense and Tennesee Valley Authority.

- *Executive Order 11990, Protection of Wetlands, and BLM Manual 1737, Riparian-Wetland Area Management* — Describes the policies, responsibilities, and guidance for the identification, protection, restoration, and maintenance of fresh, brackish, and saline wetlands.

- *Special Status Species Policy (SSSP)* — Directs the BLM to conserve special status species (SSS) and the ecosystems upon which they depend so as not to contribute to the need to list these species under the ESA (USDI BLM 2001a).

# District Level

The Coos Bay District operates under its Resource Management Plan (RMP) and its Record of Decision as supplemented and amended (USDI BLM 1995a., 1995), which is in conformance with the Final Supplemental Environmental Impact Statement on Management of Habitat for Late Successional and Old Growth Forest Related Species Within the Range of the Northern Spotted Owl and its Record of Decision as supplemented and amended (i.e., the Northwest Forest Plan; Interagency 1994). The RMP addresses the designation and management of special areas such as the Spit to protect their unique natural, cultural, and recreational values.

The RMP made four specific designations for lands on the Spit:

- Area of Critical Environmental Concern (ACEC)
- Special Recreation Management Area (SRMA)
- Motorized Access Limited to Designated Roads and Trails
- Visual Resource Management Classes II, III and IV

## The North Spit Area of Critical Environmental Concern

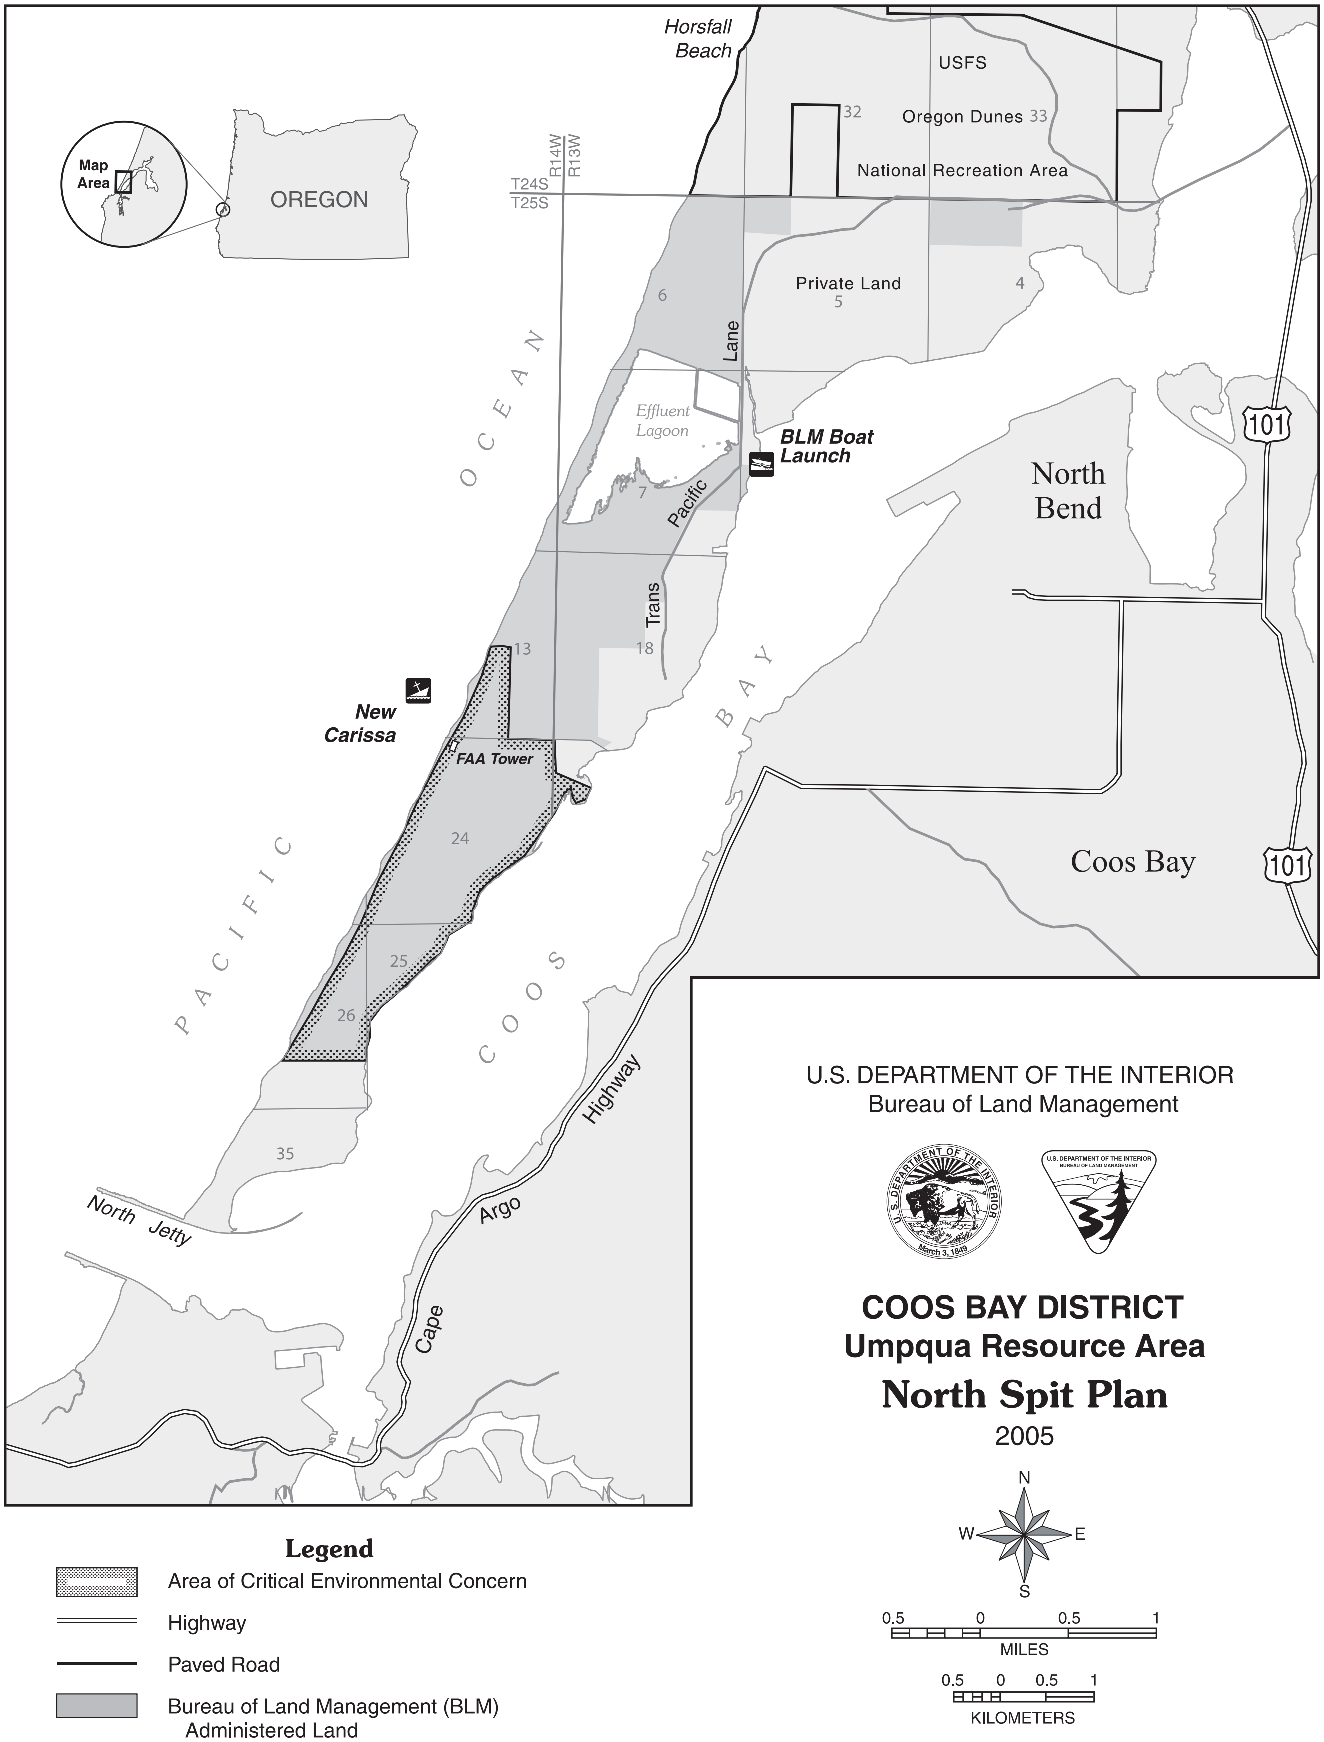
Areas of Critical Environmental Concern (ACECs) are public lands where special management attention is required to protect important historic, cultural, or scenic values, fish and wildlife resources, or other natural systems or processes (43 CFR 1601.0-5). The District RMP designated 580 acres of the Spit as an ACEC primarily for the conservation of its outstanding biological values (USDI BLM 1995; Map 2). An additional 145 acres were obtained from private ownership, raising the ACEC's total to 725 acres.

Prior to 1995, the Audubon Society, FWS, ODFW, The Nature Conservancy, and the COE (USDI FWS 1980) recognized the Spit's high value for wildlife and expressed concern for its conservation. As one of the largest undeveloped spits on the Oregon Coast, its close proximity to a populated urban area was creating a high demand for resources and recreational use (Wilson-Jacobs 1983; USDI BLM 1980). Although adjacent private lands provided important natural areas they were under development pressure, and management objectives for the adjacent ODNRA focused primarily on motorized recreation. Consequently, protecting and preserving natural resources under BLM management was determined imperative to the conservation of the Spit's rich biological community (USDI BLM 1994). The Spit was also designated as an ACEC for its cultural and historic resources, and its scenic value to the communities of North Bend and Coos Bay (USDI BLM 1994).

In 1992, three broad objectives were identified by an interdisciplinary team tasked with developing a management strategy for the North Spit ACEC: 1) no net loss of wetlands; 2) maintain and enhance threatened and endangered species habitat; and 3) maintain and enhance a diversity of habitats for animals and plants (USDI BLM 1992). In addition, cultural and historic values would be preserved, and educational and interpretive information provided to the public. In accordance with BLM policy, recreational and other uses would be managed to provide for visitor access and enjoyment while leaving all other ACEC values unimpaired (USDI BLM 1988). The North Spit Plan incorporates these objectives and goals by providing for the preservation of ACEC values through specific and compatible management actions related to recreational access, cultural and historic preservation, wildlife and plant conservation and management, and educational and interpretive opportunities.

## Special Recreation Management Area

The designation of the North Spit as a Special Recreation Management Area (SRMA) in the District RMP formally recognized the high recreational value of the Spit's public lands. SRMAs are defined as areas "…where a commitment has been made to provide specific recreation activity and experience opportunities on a sustained yield basis." Through the SRMA designation in the



## Area of Critical Environmental Conern - Map 2

M05-12-05

RMP, the BLM has made a long-term commitment to manage the physical, social, and managerial settings on the North Spit to sustain recreational activities and experience opportunities.

In addition to SRMA designations, the RMP identified recreation management objectives for the entire Coos Bay District. Specific objectives from the RMP that direct recreation management are:
- Manage scenic, natural, and cultural resources to enhance visitor experience expectations and to satisfy public land users.
- Support locally-sponsored tourism initiatives and community economic strategies by providing recreation projects and programs that benefit both short- and long-term implementation.
- Manage off-highway vehicle use on BLM-administered land to protect natural resources, provide visitor safety, and minimize conflicts among various users.
- Continue to provide non-motorized recreation opportunities and create additional opportunities where consistent with other management objectives.

The BLM planning process defers the specific details on how these resources are to be managed to the activity planning stage, in this case through the Coos Bay Shorelands Management Plan and subsequent updates such as this document.

## Motorized Access – Limited to Designated Roads and Trails

In 1972, Executive Order 11644 established a unified federal policy for motorized vehicle management on public lands administered by the Departments of the Interior and Agriculture, the Secretary of the Defense and the Tennessee Valley Authority. This Executive Order required each respective agency to develop and issue regulations and administrative procedures to provide for the designation of specific areas and trails where motorized use would be permitted and where it would be prohibited. As directed, each of these agencies developed regulations through the Code of Federal Regulations to govern the designation and management of off-highway vehicles.

On the public lands of the North Spit, administered by the Secretary of the Defense through the US Army Corps of Engineers, off highway vehicle management has been directed by the Rules and Regulations Governing Public Use of Water Resource Development Projects Administered by the Chief of Engineers (36 CFR Part 327). Through these regulations, the operation of a vehicle off authorized roadways is prohibited except at locations and times designated by the District Commander. Since no designation had been made by the Corps of Engineers on the North Spit, these parcels were effectively closed to off-highway vehicle use prior to these lands being transferred to the BLM.

The BLM's management of off-highway vehicles is directed through the Federal Land Policy and Management Act and the Code of Federal Regulations in 43 CFR to designate areas and trails as open, limited, or closed to motorized access through the resource management planning process. The public lands on the Spit were designated through the Coos Bay District RMP as Limited to Designated Roads and Trails. The individual roads and trails were then inventoried and designated as open or closed through the Coos Bay Shorelands Plan of 1995. The four roads/trails designated as open by this plan were the South Dike Road, the Foredune Road, the Re-route Road, and the Bay Side Road (Map 3). The remaining trails were designated as closed to motorized use.

# Field Office Level

The North Spit is managed by the Umpqua Field Office of the Coos Bay District. At the field office level, site specific plans are developed to guide management activities. A chronology of planning efforts for the Spit includes:

- The Coos Bay Shorelands Draft Management Plan (USDI BLM 1989);
- The Coos Bay Shorelands Draft Management Plan and Environmental Assessment (USDI BLM 1994; EA No. OR120-93-07);
- The Coos Bay 1995 Shorelands Final Management Plan (USDI BLM 1995b), and lastly;
- The North Spit Plan, 2005.

2005

# Land Ownership and Landmarks - Map 3

# PART 2 – THE COOS BAY SHORELANDS FINAL MANAGEMENT PLAN, 1995

Part Two reviews the original 1995 Shorelands Plan and outlines the status of its management actions. In 1995, the Coos Bay Shorelands Plan was approved to guide management of lands on the Spit. It identified issues, concerns, and opportunities on the Spit, and included specific management actions pertaining to each of the following subjects:

- Education and Interpretation
- Land Tenure and Cooperative Agreements
- Law Enforcement
- Recreation
- Vegetation
- Wildlife Habitat

Management actions listed in the 1995 Shorelands Plan were reviewed and updated (Table 3). The actions fall into four categories: accomplished, accomplished in part, not accomplished, and ongoing. Actions in the plan that were not accomplished include those where land exchanges have removed or precluded lands from BLM jurisdiction, consequently these actions are no longer applicable to BLM management of the Spit. All ongoing and planned actions are listed in Part Four of the North Spit Plan.

In the case of Western snowy plover management, actions have evolved through a multi-agency process. The 1995 Shorelands Plan proposed several actions pertaining to snowy plovers and ocean beach access that were never implemented (Table 3, Management Action 5). Changes to management actions are a result of a revised public access strategy implemented subsequent to the grounding of the New Carissa in 1999. The strategy pertains to the management of public lands on the Spit and allows for public use while protecting plovers and promoting their recovery (USDI FWS 2000). Strategy details are described in Part Three under Species of Special Management Concern.

The following actions described in the text of the 1995 Shorelands Plan (Actions 4, 7, 11, 12, 13, 16, and 20) were not incorporated into the original Management Action Chart. Action 4 – Bay Beach Access is not BLM land; Action 7 –Campground Construction - No construction will be developed; Action 11RV Dump Station – no RV dump station will be installed; Action 12 – Equestrian Staging Area – No area to be developed at this time; Action 13 – Non-motorized trails – trails will be available but not maintained; Action 16 – Barrier-free interpretive loop – No loop will be developed; Action 20 – Coos Head – no day use site will be developed.

## Text Changes

The 1995 Shorelands Plan made some recommendations that were not listed as actions. Errors, additions, or changes to these recommendations are as follows:

1. Page 10, first paragraph – "The BLM will petition to Oregon State Parks to prohibit the following activities on the CBS (Coos Bay Shorelands) ocean beaches: removing surfcast kelp and driftwood, allowing dogs to run free, and falcon flying." This action is no longer under consideration as the ocean beaches are under the OPRD's jurisdiction.

2. Page 10, second paragraph related to the potential discovery of a plover nest on the Foredune Road – Delete: "In addition, the road will be seasonally closed for 200 feet from the nest site until chicks have left the nesting area, or rerouted temporarily to avoid active nests." The road

is currently re-routed every six months. Other actions that may occur to protect nesting plovers will be done in cooperation with the FWS and other agencies as required.

3. Pages 11, OHV Access – There are seven bullets describing allowable motorized access.The three items below are no longer applicable.

   - Remove – “Wet sand along the ocean beaches year round.” Wet sand is under the jurisdiction of OPRD.
   - Remove – “260-acre open sand area (by permit only…)”. This management action was inconsistent with the regulations and policies that were in effect in 1995 and was inconsistent with the land use allocations identified in the Coos Bay District RMP of 1995. An activity level plan, such as the Shorelands Plan, was not sufficient for changing the OHV designation status of this 260 acre parcel from Limited to Open. This statement was removed through a plan maintenance action in 2000. This area remains a Limited Area as per the Record of Decision in the RMP.
   - Remove – “80-acre parcel near the Roseburg Chip Facility (by permit only…).” This management action was inconsistent with the regulations and policies that were in effect at that time and was inconsistent with the land use allocations identified in the Coos Bay District RMP of 1995. An activity level plan, such as the Shorelands Plan, was not sufficient for changing the OHV designation status of this 80 acre parcel from Limited to Open. This statement was removed through a plan maintenance action in 2000. This area remains a Limited Area as per the Record of Decision in the RMP.

4. Pages 13, 14 – Management Action 5 – Ocean Beach Access:BLM was to petition OPRD to enact restrictions on the ocean beach. There are 14 action items, including rationale. Remove all actions as the wet sand beach is under the jurisdiction of OPRD.

5. Page 16 – Management Action 12 – Equestrian Staging Areas.Equestrian use in the Central Coast Region of the Oregon Coast has increased by 39% since the last Shorelands Plan was written. The Spit has become one of the more popular equestrian riding areas in the region and a need has been identified to provide an adequate staging area for the off-loading/loading of horses.

6. Page 16 – Management Action 13 - Non-Motorized Trails.The BLM proposed the designation of approximately 12 miles of hiking/equestrian trails in the 1995 Shorelands Plan. The BLM will implement this action and will identify a trailhead/staging area. The agency may develop new trail segments and will establish local partners to assist in the management and maintenance of the trail system (see Recreation, Part Three).

**Table 3. Management actions as described in the Coos Bay Shorelands Final Management Plan (USDI 1995) and their current status.**

| Management Action | Status | Comments |
|---|---|---|
| Biological mapping of plant communities and wildlife habitats. | Accomplished. | Plant communities were mapped and preliminary information reported for plant alliances and vegetation classes based on the Oregon Dunes NRA assessment (Christy et al. 1998). Information on wildlife habitats may be obtained from the mapped plant alliances. |
| Cadastral survey (to determine mean high tide on the bay side). | Not accomplished. | This action was originally proposed in relation to the Point Reyes bird's-beak. The plant has been protected by re-routing vehicles around it and placing root wads to protect the area as authorized by the management agency (Port and DSL). Additional maintenance actions on state lands will be conducted per written agreements from the appropriate agency. |
| Land tenure adjustments (Page 10 in 1995 Shorelands Plan). | Accomplished, in part. | Priorities 2, 3, and 4 have been accomplished. If Priority 1 is accomplished, the bay side access road will come under BLM jurisdiction and will be designated as open for motorized access. |
| MA-1. North Dike road improvement and turnaround construction. | Not accomplished. | This road is owned by Weyerhaeuser. |
| MA-2. Extension of Trans Pacific Parkway (now called Trans Pacific Lane) for 1/3 mile to day-use facility. | Not accomplished. | The area proposed for the road extension belongs to the Port. If the lands are acquired by BLM, the extension would not be paved, nor would a day use area be built. The road would be designated as open for motorized access. |
| MA-2. Bay Side road construction, includes post and cable installation. | Accomplished, in part. | This area is under the Port's jurisdiction. Post and cable installation and a road reroute to protect the Point Reyes bird's-beak was completed and will be maintained. |
| MA-3. Petition DSL to prohibit motor vehicles on 1/2 - 3/4 mile section of bay beach around salt marshes. | Not accomplished. | BLM's re-route has been effective thus precluding the need for the prohibition (see above). |
| MA-5. Petition to OPRD to close dry sand portion of ocean beaches, south of effluent pond between March 15 and Sept 15 (Western snowy plover nesting season). | Not accomplished. | Because much of the dry sand portion of the ocean beach is under BLM jurisdiction, the annual closure request to OPRD is not necessary. However, changes in plover management are reflected in a different closure area: BLM closes the dry sand from the FAA (Federal Aviation Administration) tower (not the effluent pond) south to within one mile of the Jetty. |
| MA-5. Petition OPRD to close ocean beaches from south end of effluent pond to Forest Service boundary. | Not accomplished. | This did not occur and is not necessary for the protection of snowy plovers. BLM will cooperate with OPRD when the final Ocean Shores Management Plan is completed (OPRD 2004). |

| Management Action | Status | Comments |
|---|---|---|
| MA-5. Petition OPRD to close ocean beaches from 30 minutes after sunset to 30 minutes prior to sunrise. | Not accomplished. | BLM will cooperate with OPRD's final Ocean Shores Management Plan when it is completed (OPRD 2004). |
| MA-5. Signs indicating designated access routes to ocean beaches, south of effluent pond. | Ongoing. | Signs are maintained as necessary. |
| MA-5. Signs indicating non-authorized access points to ocean beaches south of effluent pond. | Not accomplished. | Non-authorized access points to the ocean beach were not signed. Signs indicating authorized access points were placed. |
| MA-5. Informational signs explaining beach access. | Ongoing. | Signs are in place. New OPRD signs will be used in the future. |
| MA-5. News releases and updates on ocean beach access. | Ongoing. | Information is provided to the media as needed. |
| MA-5. Public meetings discussing beach access. | Ongoing. | Meetings primarily occur through OPRD'S planning effort and North Spit Plan public scoping. BLM accepts public comments and suggestions at any time. |
| MA-6. 260-acre and 80-acre open sand areas open to OHVs by permit only. | Not accomplished. | No permits were requested. Motorized access is permitted on sand roads designated as open. This policy was inconsistent with the OHV designations created in the RMP. |
| MA-6. Signs marking perimeter of open sand areas. | Not accomplished. | Motorized access remains open on designated sand roads. This action was inconsistent with the OHV designations created in the RMP. |
| MA-8. Pack-in camping permitted throughout the CBS with length of stay not to exceed 14 days. | Ongoing. | Allowed except in designated snowy plover areas during the nesting season. |
| MA-8. Vehicles remain within 100 feet of designated roads. | Ongoing. | Allowed except where signed to protect natural resources. |
| MA-10. MA-10. Placement of garbage cans and vault toilets at day-use facility (near anadromous facility). | Not accomplished. | The area is not under BLM jurisdiction. No new developments are planned on BLM lands. The correct name of the anadromous plant is the North Bay Aquaculture Facility and it is owned by the Port. |

| Management Action | Status | Comments |
|---|---|---|
| MA-10. Maintenance of vault toilets and garbage cans at day-use facility. | Not accomplished. | The area is not under BLM jurisdiction. |
| MA-14. Firearms policy. | Not accomplished. | Federal and state regulations cover the discharge of firearms in developed and undeveloped areas. Enforcement occurs through federal, state, and county patrols. |
| MA-15. Development and installation of Watchable Wildlife signs along bay and at north dike day-use facility. | Not accomplished. | These areas are not under BLM jurisdiction. Wildlife information may be provided at the proposed boat launch information kiosk. The potential remains for a "Watchable Wildlife" site to be developed. |
| MA-17. Closing of non-designated roads and trails using logs or root wads. | Ongoing. | BLM will maintain vehicle barriers to the interior of the Spit as necessary to deter resource damage from unauthorized motor vehicle use. |
| MA-18. Management of European beach grass. | Ongoing. | Occurs within the snowy plover Habitat Restoration Areas. |
| MA-19. Noxious weed control. | Ongoing. | Occurs under BLM's weed management program. |
| MA-21. Timber, standing or down, cutting prohibited. | Ongoing. | Dependent upon standard Bureau procedures including NEPA compliance and Small Sales Permits. |
| MA-22. Development of interagency, inter-tidal agreement to manage salt marshes within the Coos Bay estuary. | Not accomplished. | These areas are not under BLM jurisdiction. Any work done in the salt marshes necessitates permits from the appropriate agencies prior to the start of the project. No new projects are proposed. |
| MA-23. Salt marsh restoration (depends on rate of natural re-vegetation of salt marsh). | Not accomplished. | See above. |
| MA-24. Introduction of pink sand verbena. | Accomplished. | Pink sand verbena seeds are collected for dispersal at other coastal sites. |
| Monitoring of dry sand closure during Western snowy plover nesting season. | Ongoing. | Occurs in compliance with FWS' Biological Opinion. |

| Management Action | Status | Comments |
|---|---|---|
| Monitor permanent traffic counters. | Ongoing. | Traffic counters are maintained and data collected.  Counters may be moved to different locations as warranted. |
| Monitor salt marsh bird's-beak population. | Ongoing. | The correct name is Point Reyes bird's beak.  No additional protections are required, however BLM will maintain the existing vehicle re-route and root wad barrier on the bay side of the Spit, as permitted by DSL. |
| Monitor Western snowy plover nesting exclosure and brood success. | Ongoing. | Cooperative effort with ORNHIC, OPRD, ODFW, FWS, and COE. |
| Monitor great blue heron and great egret rookery. | Ongoing. | The rookery was abandoned in 2000.  Surveys will be conducted to locate additional rookeries on BLM lands.  A new rookery was discovered in 2002 on ODNRA lands and in 2004 on the northeast side of the Spit on BLM. |

# Part 3 –North Spit Resources

## Introduction

Part Three describes the cultural, natural, and recreational resources on the Spit. Management actions are listed in Part Four. Resources are grouped into five categories:

- Physical, including Water, Geology, Soils, Minerals, Coal Bed Methane, Oil and Gas
- Biological, including Vegetation, Wildlife, and Fisheries
- Cultural and Historical
- Recreational
- Visual

### Physical: Water Resources

#### *Climate*

The Central Oregon Coast has a temperate maritime climate characterized by cool, dry summers and mild, wet winters. Rainfall occurs primarily from November through March and averages 63 inches per year at the North Bend Municipal Airport near the Spit. The average annual maximum and minimum temperatures at the North Bend Municipal Airport for the period January 1931 to December 2004 are 60ºF and 45ºF respectively. Temperatures above 90ºF or below 20ºF are rare (Western Regional Climate Center 2004).

Prevailing winds are from the north-northwest in the summer and from the south-southeast in the winter (Oregon Climate Service 2004). Summer days are characterized by foggy mornings, sunny afternoons, and cool evenings. Afternoon northwesterly winds are quite cool. Precipitation is light and spotty; however, fog or low overcast clouds may persist all day, and fog drip may contribute to available moisture. Winter weather is characterized by frequent rains with intermittent clearing periods. Snow may fall on the beach every few years when Arctic air meets an onshore flow of moist air.

#### *Groundwater*

The groundwater supply in the Coos Dune Sheet aquifer is large. The Coos Bay – North Bend Water Board has 18 freshwater production wells just north of the BLM-administered lands on the Spit. Although these 90 to 120 foot deep wells can produce up to 4 million gallons per day (Mgal/d), they are currently not being used (Schab 2004). According to Jones (1992), model simulations indicate that 10 Mgal/d could be pumped with minimal risk of seawater intrusion into the dune aquifer. The model also indicates that a maximum of 17 Mgal/d could be pumped without causing intrusion, but the risk associated with pumping this quantity over time is uncertain.

Both the Water Board and the Weyerhaeuser Company monitor groundwater levels and groundwater quality (Souza 2004). The Water Board maintains 55 monitoring wells in the dunes between the Spit and Tenmile Creek. Eight of the wells are sampled for chlorides and the remainder of the wells are used to measure static water levels. The production wells mentioned previously are monitored monthly for seven water quality parameters.

Between 1982 and 1997, several groundwater monitoring wells were installed near the Weyerhaeuser containerboard mill and the former effluent lagoon, and on adjacent property managed by the Bureau of Land Management. The wells were installed for environmental assessment, and permit-required characterization and water quality monitoring related to wastewater discharge an solid waste disposal.

Weyerhaeuser currently has 9 serviceable groundwater monitoring wells in or adjacent to the former effluent lagoon. Twenty-five other wells in the same area were decommissioned between October 2004 and January 2005 to reduce maintenance and eliminate potential risks related to the integrity of wellheads and surface seals.

Weyerhaeuser also has 13 serviceable groundwater monitoring wells in the vicinity of the former containerboard mill on the Spit. Seven additional wells in the same area were decommissioned in October 2004 (Souza 2005)

### *Wetlands*

Vegetation mapping using 1999 aerial photographs and ground-truthing indicates that roughly 27% (669 acres) of the North Spit is open water or supports vegetation indicative of semipermanently flooded, seasonally flooded, and saturated areas. The US Fish and Wildlife Service's National Wetlands Inventory (NWI) identifies several wetland types on the Spit. Marine, intertidal habitats of high salinity are found along the Pacific Ocean shore, and intertidal and subtidal estuarine wetlands of moderate salinity are located on the bay side of the Spit. Freshwater, nontidal (palustrine) wetlands are scattered in low lying portions of the deflation plain east of the ocean and foredune.

The goals of the NWI is to classify and map the nation's wetlands and evaluate wetland status and trends. National Wetlands Inventory maps covering the Spit were published in 1989 and contain information on the location and classification of wetlands. This information is overlaid on the Charleston and Empire 7.5 minute (1:24,000) US Geological Survey topographic maps. The NWI maps were based on interpretation of visible hydrologic features and wetland vegetation using high-altitude aerial photographs (1:58,000) taken in August and September 1982. Because dynamic systems like the Spit wetlands vary seasonally and annually, these maps likely differ from current conditions.

Wetlands mapped by the NWI must have one or more of the following three attributes: (1) at least periodically, the land supports predominantly hydrophytes (plants adapted to live in anaerobic (oxygen free) soil conditions; (2) the substrate is predominantly undrained hydric soil (soil that formed under conditions of saturation, flooding, or ponding long enough during the growing season to develop anaerobic conditions in the upper part); and (3) the substrate is nonsoil and is saturated with water or covered by shallow water at some time during the growing season of each year (Cowardin et al. 1979).

The NWI maps were not intended to delineate regulated wetlands. Delineation is defined as a determination of wetland presence that includes marking the wetland boundaries on the ground and/or on a detailed map prepared by a professional land surveyor or similar accurate methods (Oregon Administrative Rules 141-090-0020). Delineation of jurisdictional (regulated) wetlands is determined by on-the-ground examination of hydrology, vegetation, and soils (USDOD 1987). It requires that specific vegetation, soils, and hydrology attributes be found to make a positive wetland determination.

**Palustrine Wetlands.** Seasonal precipitation that infiltrates into the relatively porous dune sheet recharges groundwater and sometimes appears as standing water in relatively small, freshwater deflation plain wetlands east of the foredune. The 1989 NWI maps covering the Spit show roughly 300 acres of unconsolidated shore, emergent, scrub-shrub, and forested wetlands scattered throughout BLM-administered land. Unconsolidated shore habitats include beaches, bars, and flats with less than 30% areal vegetative cover other than pioneering plants. Emergent wetlands (marshes) are characterized by erect, rooted, herbaceous hydrophytes. This vegetation is present for most of the 335 day growing season (USDA FS 1993) and these wetlands are usually dominated by perennial plants. Scrub-shrub wetlands are dominated by woody vegetation less than 6 meters (20 feet) tall, and forested wetlands have woody vegetation that is 6 meters tall or taller. Swamps are wetlands dominated by trees or shrubs. A shrub swamp often occurs as a transitional phase between habitats evolving from a marsh to a swamp.

Temporarily and seasonally flooded unconsolidated shore, emergent, and scrub-shrub habitats were mapped on the Spit. Temporarily flooded areas occur where the surface water is present for brief periods during the growing season, but the water table usually lies well below the soil surface. Seasonally flooded wetlands have surface water present for extended periods, especially early in the growing season. Surface water is absent by the end of the growing season in most years.

Deflation plain wetlands are a direct result of foredune establishment (USDA FS 1993). Over the past several decades, the foredune has essentially cut off the supply of wind blown sand to the inland open sand dunes. Winds continue to move the remaining inland dune sands toward the bay, stripping sand from the eastern edge of the deflation plain and further exposing the water table. This deflation also occurs further inland in troughs among dunes. Rapid plant succession follows exposure of the water table and early seral stage wetlands (e.g.: grass, sedge, rush, low shrub) progress toward later seral stages (tall shrub, shore pine). Because the surface of the deflation plain is at the summer ground water level, only plants tolerant of perennially wet soils can survive.

**Estuarine Wetlands.** Based on the 1989 NWI maps, roughly 300 acres of intertidal, estuarine wetlands are located on the bay side of the Spit south of the North Bay Aquaculture Facility. A majority of these habitats (nearly 265 acres) are classified as aquatic bed and unconsolidated shore wetlands that are regularly flooded (tidal water floods and exposes the land surface at least once daily) and irregularly flooded (tidal water floods the land surface less than daily). Aquatic bed habitats are dominated by plants that grow principally on or below the surface of the water for most of the growing season in most years. Approximately 35 acres of regularly and irregularly flooded, emergent wetlands (marshes) border the beach on both sides of the dredge disposal lobe. Vegetated marshes develop on deposits of fine sediment in low velocity areas of the estuary. Additional deposition in areas of established vegetation alters site characteristics and suitability of the habitat for different plant species (Coats 1995).

**Marine Wetlands.** Marine, intertidal habitats are found along the high energy Pacific Ocean shore. Two habitats are recognized by the NWI: unconsolidated shore (beach) that is regularly flooded (inundated daily), and unconsolidated shore that is irregularly flooded (inundated less than daily).

**Henderson Marsh Mitigation Plan.** Although not a signatory party, BLM has been involved with the Henderson Marsh Mitigation Plan (HMMP) because the original plan identified sites on federal lands to be used for wetland mitigation.

Historically the lands known as Henderson Marsh were owned by private individuals and used for grazing. Menasha Woodenware Corporation acquired the land and, in 1959, developed plans for a paper mill which required the construction of a waste water treatment lagoon. The original plan was to place the lagoon in Henderson Marsh. Through the intervention of state and federal wildlife management agencies, the lagoon was sited on federal land in the deflation plain southwest of Henderson Marsh (Map 3). Menasha agreed to hold the lands in Henderson Marsh available for waterfowl management, including public hunting, and to construct and maintain dikes, spillways, and tidegates to improve waterfowl habitat.

In 1978, plans were developed to fill a significant portion of the Henderson Marsh. Because filling required compensation for wetland losses, a task force was formed in 1979 to create a mitigation plan. In 1981, Weyerhaeuser purchased the Menasha holdings on the Spit including Henderson Marsh. The HMMP was finalized in 1984 and signed by Weyerhaeuser, the Oregon Department of Fish and Wildlife, and the US Fish and Wildlife Service. The HMMP allows for the filling of 160 acres of freshwater and saltwater wetlands and identifies mitigation actions on public and private lands to compensate for the loss of these wetlands.

BLM has provided technical advice to Weyerhaeuser on mitigation projects, and participated in the development of a wetlands monitoring protocol. In addition, a limited amount of open water pond and wetland habitat was constructed on federal land for mitigation. A weir and reverse tidegate system was installed in upper Jarvis Creek when the Trans Pacific Lane was built to create a brackish water regime west of the road corridor and hold open water to a larger surface area. This area immediately north of the effluent lagoon is permanently flooded and classified as a subtidal, estuarine wetland on the Empire NWI map. Approximately 5 acres of estuarine and 24 acres of freshwater habitat were created or enhanced by installing the water control structure. Another 6 acres of ponds were created further north on BLM-administered land.

## Physical: Geology and Soils

### *Eolian and Oceanic Processes*

Two separate, but interrelated, geomorphologic forces on the earth's surface occur to form and shape a sediment dominated beach and its associated dunes. These processes are oceanic and eolian (wind). The oceanic process is the mechanism that delivers eroded sediment to the beach front. The eolian process is the mechanism that mobilizes unincorporated beach sediment inland. The oceanic process creates, molds, and removes beaches, spits, and headlands. The eolian process creates and mobilizes the ridges, dunes, dune fields, and deflation plains.

**Eolian Process.** Numerous dune fields exist along the Oregon Coast, including the Coos Bay Dune Sheet, located north of Coos Bay. Components needed for dune formation are abundant loose sand, wind, and a favorable terrain. Other ingredients that play important roles in dune-

***North Spit deflation plain.***

forming include water and vegetation. Human alteration of these components influence the sand migration process (Lund 1973). The coastal dune fields are within two miles of the ocean shore with most immediately adjacent to sand beaches.

Three episodes of dune advance in the Coos Bay dune sheet and other dune fields are documented (Cooper 1958). The earliest is represented today by a strip of thoroughly vegetated dunes that in most places achieved the greatest landward advance. The second advance generally fell short of the first, and its present condition ranges from complete stabilization to still vigorous activity. The third episode is represented by the large areas of active dunes that until recently had open access to the ocean beaches that supplied them with sand. The landward edges of these dune fields are well defined by the presence of precipitation ridges with steep slip faces that slowly invade and bury adjacent vegetation, including forested areas. The precipitation ridge often blocks stream drainage, creating ponds and lakes (Komar 2000).

The eastern face of the migrating dune, called the precipitation ridge (Cooper 1958) will migrate several feet a year by the accumulation of sand along a slope on the inner boundary of the active dune belt. Because both winter and summer wind patterns are landward, sand supply is provided year-round (Lund 1973). This migration of sand is sufficient to cover existing forests as well as other vegetation (Lund 1973; Komar 2000). Along the dune field north of Coos Bay, dune advancement has been measured at 6 to 18 feet per year (Alt and Hyndman 2001).

Water and vegetation reduce the rate at which sand shifts (Lund 1973). In many areas dunes are being actively molded by winds while in other areas vegetation now covers formerly mobile dunes (Komar 2000). Where eolian sand moving across a smooth surface meets an obstruction, the carrying velocity is lost behind the obstruction. This causes the sand to be deposited. Such evidence can be seen in summer at many places along the dry sand part of the beach where sand is accumulating on the lee side of a log or some other object. Native vegetation and natural debris have naturally stopped enough sand to create a low beach ridge, but much of the sand was able to move past the ridge and enter the dune-building activity behind the shore (Lund 1973).

However, as described by Lund (1973):

> *"... with the introduction of European beach grass on the West Coast, the conditions along the shore underwent a pronounced and rapid change, and in the past 25 or 30 years a foredune has built up along the shore that has effectively shut off movement of sand from the beach at all but a few places along the Oregon coast..."*

The newly created foredune is a ridge of coalesced (grown together) hillocks superimposed on an earlier, low beach ridge. The hillocks nearest the beach stop most of the sand and continue to grow while the ones farther from the beach stay about the same size or grow slowly. During winter storms, waves reach the base of the foredune ridge and erode it back to an abrupt edge. Thus in places, banks several feet high are formed which block the inland migration of sand, increasing the effectiveness of the foredune as a barrier (Lund 1973). The Spit foredune is representative of the stabilizing affects of European beach grass (Beckham 2000).

With the foredune stopping the supply of sand to the dunes along most of the Oregon coast, the interior dunes are now consuming themselves. As the dune field narrows at the expense of the western sand supply, a deflation plain forms and expands. The deflation plain is caused by the vertical removal of loose sand to the point that the summer groundwater table is reached. The saturation of the sand makes it harder for wind to move it, increasing its stability in wind velocities. As erosion stops, vegetation propagates in the deflation plain. This zone at the western edge of the active dune belt or field thereby demarks the end of dune activity (Lund 1973). However, when stabilizing vegetation is removed from the dunes, the mobilization of sand can be reinitiated (Komar 2000).

**Oceanic Process.** Oceanic processes supply material to the beach front, circulate the sediment within the littoral (situated near a shore) cell, and are the cause of beach and dune alteration.

Along the Oregon Coast, waves tend to arrive from the southwest during the winter and from the northwest during the summer, corresponding to prevailing wind directions. As a result, there is a seasonal reversal in the direction of littoral drift (migration of sand within the oceanic process); north during the winter, south during the summer. The net littoral drift is the difference between these northward and southward sand movements (Komar 2000).

In general and with few exceptions, net littoral drift is zero due to the large rocky headlands that extend sufficiently into deep water to prevent sand and coarse sediment migration. On many coasts, sand spits grow in the direction of littoral drift. However, sand spits are documented in both north and south directions within zero net drift littoral cells (Komar 2000). Human made features such as jetties impact this sand migration, causing deposition behind the jetties, with accompanying erosion from other areas of the beach front. The Spit grew as sand accumulated southward (Beckham 2000).

The erosion mechanism of the oceanic process is aided by a number of systems, individually or in combination, such as raising ocean levels, storm energies, upland landslides, and rip current embayments (landward erosion of the beach, forming steeper sloped scallops in the beach front). It is estimated that currently the Oregon Coast is retreating by two feet per year (Orr and Orr 2000). The oceanic processes that supply sediment to create beaches, spits, ridges and dunes (foredunes) also supplies the energies needed to destroy and reshape these features.

Breaching and overwashes are common on spits and barrier islands along the East and Gulf Coasts of the United States, where the sea level is rising with respect to the land. Natural breaching of well established spits along the Oregon Coast is not common. The Northwest Coast is rising tectonically, and this probably accounts for the rarity of spit breaching (Komar 2000). However, northwest spit erosion was documented on the Siletz Spit where the foredune retreated a hundred feet within three weeks during winter storms in 1973 (Komar 2000).

Other events may deliver a series of waves related or unrelated to plate subsidence. These tsunamis, whether from a Cascadia Event, other distant plate movements, or submarine landslides, may deliver waves with sufficient height and energy to overtop the spit, relocating sand and dunes and creating breaches. Such effects were witnessed on the New River Spit from tsunamis delivered by the 1964 Good Friday Earthquake in Alaska (Komar et al. 1999). Large portions of the North Spit are within the tsunami runup boundary (Priest 1995a and 1995b).

European beach grass trapped the migrating sand causing the creation and elevation of the foredune thus greatly increasing the Spit's stability (Beckham 2000). The Spit's existence, alterations, and dynamics were created and are maintained by the manipulation of oceanic and eolian processes common to the Northwest Coast, and actions that alter these processes may potentially impact Spit dynamics. Grass removal may compromise the stability of the Spit, exasperating erosional conditions and potentially leading to overwash where dune elevations are sufficiently lowered.

## Physical: Minerals

### *Silica*

Historical investigations have been made as to the silica value of Spit sands. Production of silica sands from the Spit, used in glass manufacturing, was documented at 25,000 tons per year (Geitgey 1990). Preliminary studies indicate that the Spit may have mineral potentials for glass and foundry sands, (and other minerals), however current economics may not be sufficient for their development.

## Physical: Coal Bed Methane, Oil and Gas

Coal Bed Methane (CBM) is a relatively recent resource, with development occurring within the last 20 years. Although considered an unconventional resource, it currently reflects 8% of the country's reserves. Potential economic reserves lie between 1,000 and 4,000 feet below the ground. Surface coals have lost the CBM to atmospheric escape. Coal extraction can be developed after methane extraction; however, the depth, with current economics and technology, is usually beyond resource development. Removal of CBM does not reduce the energy capability of the coal bed.

The coal bed methane is held within the molecular structure of the coal, kept below vapor pressure by water confinement. This is different than natural gases and oils, which are formed from mature organics, separated from the source rock, and migrate to a trapping structure. In CBM extraction, the drilling first encounters water within the coal seam. As this water is removed, the pressure is reduced, releasing the methane from the coal seam. This is then collected from a wellhead system (Pappajohn 2002).

Geologic mapping indicates that the Spit is located within the Coos Basin, which includes numerous coal and organic bearing formations. It is inferred that the Spit is underlain by the Coaledo Formation, consisting of coal bearing sediment beds (Madin et al. 1995). Currently, mineral leases have been granted by DSL for the exploration and mineral extraction of submerged lands adjacent to the Spit. While speculative, the potential for oil and gas development does exist under the Spit. Historically, oil and gas leases were issued on the Spit (Fritz 1992).

The BLM has a well developed mineral leasing program, and the Spit lands maintain a "No Surface Occupancy" (NSO) and "Controlled Surface Use" (CSU) for leaseable minerals. The lands have been withdrawn from location and entry for locatable and salable minerals. Leaseable, locatable, and salable minerals are difficult to list because the history of the law has resulted in a definition of minerals that includes economics of minerals. As an example, sand can be considered as a "salable" material, sold by competitive and noncompetitive sales by the unit for construction. Sand can also be claimed under the locatable laws because of the economically valuable silica component of sand, provided the silica content is sufficient to meet an "uncommon" mineral definition.

## Biological: Vegetation

### *Botanical Surveys*

Inventory of the flora of the Spit is incomplete (Appendix 1). Only four botanical surveys were conducted on the Spit. In 1989, an informal vascular plant survey was conducted for a small portion of the western shore of the Spit between the North Bay Aquaculture Facility and the site of the 1892 US life-saving station (Stansell 1989). In 1998, a sedge (Carex spp.) survey was conducted as part of a Challenge Cost Share project (Zika et al.1998). In 2003, BLM staff prepared a preliminary map of the vegetation alliances (see below). A vegetation alliance is a plant association based on the National Vegetation Classification System, a hierarchical classification designed to standardize vegetation classification in the United States. In 2004, BLM staff conducted a survey of the 80 acre BLM parcel located south of the Trans Pacific Lane (Sperling 2004).

The vegetation alliances of the Spit were mapped using June 1999 aerial photography and ground-truthing. Alliance polygons were digitized and represent vegetation classes as defined by the National Vegetation Classification Standard (The Nature Conservancy 1994). They are similar to the plant associations found in the ODNRA (Christy, Kagan, and Wiedemann 1998). The five vegetation classes on the Spit and their overall percentage are as follows: forest (25%), woodland (2%), shrubland (17%), dwarf-shrubland (trace %), and herbaceous (32%). Approximately 24% of the Spit is not vegetated, but is characterized by open sand, disturbed areas, blacktop, and open water.

Further refinement of the vegetation map is needed, however some characteristics can be described. The Spit forest and woodland areas commonly include shore pine (*Pinus contorta* ssp. *contorta*) and Sitka spruce (*Picea sitchensis*). The shrubland is characterized by salal (*Gaultheria shallon*), evergreen huckleberry (*Vaccinium ovatum*), willow (*Salix* spp.), wax myrtle (*Morella californica*), sword fern (*Polystichum munitum*), European beach grass (*Ammophila arenaria*), rhododendron (*Rhododendron macrophyllum*), coyote brush (*Baccharis pilularis*), and Scotch broom (*Cytisus scoparius*). The dwarf-shrubland is composed of bog blueberry (*Vaccinium uliginosum*) and tufted hairgrass (*Deschampsia caespitosa*). The herbaceous community includes salt rush (*Juncus lesueurii*), slough sedge (*Carex obnupta*), Pacific silverweed (*Argentina egedii*), seashore lupine (*Lupinus littoralis*), beach morning-glory (*Calystegia soldanella*), beach silver-top (*Glehnia littoralis*), American bluegrass (*Poa macrantha*), American dunegrass (*Leymus mollis*), floating-leaved pondweed (*Potamogeton natans*), and European beach grass (*Ammophila arenaria*). The salt water marsh is a type of herbaceous community and is characterized by pickleweed (*Salicornia virginica*), fleshy jaumea (*Jaumea carnosa*), and salt grass (*Distichlis spicata*).

### *Botanical Resources*

The Spit marks the southern limit of the subarctic beach flora and the northern limit of the dry Mediterranean beach flora (USDI BLM 1994). It has approximately 75 nonvascular and over 140 vascular plant species (Appendix 1). Additional species will undoubtedly be discovered as the area is botanically explored and a systematic survey is conducted. As a comparison, about 260 vascular plant species are reported from the adjacent ODNRA (Christy, Kagan, and Wiedemann 1998).

Four sites within the ODNRA (South Horsfall Campground, Tenmile Creek Research Natural Area, Umpqua Lighthouse State Park, and Eel Creek) located directly north of the Spit have been identified as having ecological cells and special species unique to the Coast Range Ecoregion (Natural Heritage Advisory Council 2003). Similar cells and species are present at the Spit.

One globally significant community on the Spit is the unstabilized coastal dune wildrye and beach pea vine (*Leymus mollis* ssp. *mollis – Lathyrus japonicus*) community. The Natural Heritage Program uses a prioritization system for determining global significance of plant communities (Kagan et al. 2004). Globally, species are ranked from 1-5 based on the number, quality, and condition of the occurrences; the narrowness of range; the trends in populations and habitats; and the threats to and the fragility of the element being assessed. The wildrye and beach pea vine community is a G1 plant community that is considered critically imperiled globally with typically five or fewer occurrences (Kagan et al. 2004). This community type was likely much larger on the Spit prior to the 1930s. Currently, only isolated patches remain and are threatened by invasion of European beach grass. The occurrence of this unique plant community on the federally managed lands on the North Spit is important to the conservation of the community. The District's RMP calls for recognition, protection, and restoration of unique special habitats (USDI BLM 1995).

### *Special Status Species*

Twenty-two special status plant species within the Bureau sensitive and assessment categories are located on BLM lands on the Spit. These include nine vascular plant species and thirteen nonvascular plant species (Table 4). Populations of the two vascular Bureau sensitive species, the pink sand verbena (*Abronia umbellata* ssp. *breviflora*) and the Point Reyes bird's-beak (*Cordylanthus maritimus* ssp. *palustris*), are discussed below.

Pink sand verbena is a federal species of concern, is listed as endangered by the State of Oregon, and is a Bureau Sensitive species. This annual herb historically occurred from British Columbia, Canada, to Marin County, California. It is believed to be extirpated from Washington; two plants were observed in 2000 on Vancouver Island. Habitat for pink sand verbena includes sandy beaches above the high tide line and possibly dunes further inland. The primary threats to pink sand verbena are loss of habitat from the encroachment of European beach grass and disturbance from OHVs. In 1993, a population of this species was established on the Spit on COE land within a Western snowy plover Habitat Restoration Area (HRA). The practice of removing European beach grass each year to promote open sand habitat for nesting plovers has benefited the pink sand verbena. The population has gradually increased in number and aerial extent. In 2003, over 111,500 reproductive plants were documented within the COE lands. The population now extends onto neighboring lands outside of the HRA enclosure.

***Pink sand verbena.***

Point Reyes bird's-beak is a federal species of concern, is listed endangered by the State of Oregon, and is a Bureau Sensitive species. Historically, this annual, hemi-parasitic herb occurred along a 900 mile section of coastline, from Netarts Bay, Oregon, south to Morrow Bay, California. Today, it is known only from Netarts Bay, Yaquina Bay, and Coos Bay. The primary threat to the Point Reyes bird's-beak is habitat loss from development, OHVs, and water pollution from petroleum spills. A population of the species is located on the bay side on lands managed by the Port and BLM (Map 3). The 2001 population at Spit was estimated at about 20,000 plants.

**Table 4. Bureau sensitive and assessment plant species documented (D) and suspected (S) on the North Spit by scientific name, common name or group, presence, status, and habitat. Bureau tracking species are noted in Appendix 1. Note: BA = Bureau assessment, BS = Bureau sensitive, SE = State Endangered, and SoC = Federal Species of Concern.**

| Scientific Name<br>(Common Name or Group) | Presence | Status | Habitat |
|---|---|---|---|
| **Vascular Plants** | | | |
| *Abronia umbellata* ssp. *breviflora*<br>(pink sandverbena) | D | BS, SoC, SE | Coastal beaches and dunes |

| **Nonvascular Plants** | | | |
| *Bryoria pseudocapillaris* (Lichen) | D | BS | Rock, conifer bark, and Sitka spruce in exposed coastal headlands |
| *Bryoria spiralifera* (Lichen) | D | BS | Shore pine and Sitka spruce in coastal habitats, often with *Ramalina menziesii* |
| *Bryoria subcana* (Lichen) | S | BA | Bark and wood of Sitka spruce, Western hemlock, Douglas-fir, and hardwood forests along coastal bays, streams, and dune forests within 30 miles of ocean |
| *Diplophyllum plicatum* (Liverwort) | D | BA | Tree boles of old-growth western hemlock, western red cedar, and Douglas-fir |
| *Erioderma sorediatum* (Lichen) | D | BA | Ericaceous shrubs in coastal forests, documented at North Spit and Eel Creek Campgrounds (ODNRA) |
| *Heterodermia leucomelos* (Lichen) | D | BA | Spruce and shore pine branches on forested headlands in the coastal fog zone |
| *Leioderma sorediatum* (Lichen) | D | BA | Thin moss mats on rhododendron and huckleberry branches near coast, documented at North Spit and Eel Creek Campground (ODNRA) |
| *Ramalina pollinaria* (Lichen) | S | BA | Coastal, reported from New River ACEC |
| *Rhizopogon exiguous* (Fungi) | S | BS | Coastal, known site at Mapleton, hypogenous fungi in coniferous forests |
| *Sulcaria badia* (Lichen) | S | BA | Hardwood, conifer bark, and spruce branches in lowlands, valley fringes, and coast, 300-600 m |
| *Teloschistes flavicans* (Lichen) | S | BA | Coastal forests, shore pine and Sitka spruce |
| *Thaxterogaster pavelekii* (Fungi) | S | BS | Coastal forests in Washington, Oregon, and California |
| *Triquetrella californica* (Moss) | S | BA | Exposed to shaded soil, rocks, or sand in coastal shore pine and Sitka spruce |

## *Exotic and Noxious Weed Species*

Approximately 24 exotic or non-native plant species occur on the Spit (Appendix 1). Additional exotic species are expected as the area is botanically explored and a systematic survey is conducted. Exotic plants are those that did not occur before the arrival of European culture, are not indigenous to a given area, occur as a result of introduction, or have escaped from gardens and become naturalized. Some exotic species are pioneer plants that are normally limited to a single generation before a dense cover of other native plants develop. Others, like European beach grass, colonize or invade a habitat by vegetative reproduction and exclude native species. Invasive plants displace native vegetation and consequently may diminish habitat quality for wildlife. Invasive weedy species at the Spit are found primarily in terrestrial habitats.

The history of European beach grass exemplifies the impact of an exotic species. During 1891-93, rooted plants were hand planted by the COE in an effort to reclaim the Spit (Beckham 2000). Between 1910 and 1934, additional plantings were also made along the southwestern Oregon coast (McLaughlin and Brown 1942). European beach grass now covers approximately 19% of the Spit. It is found in pure stands, intermixed with other herbaceous species, and as an understory associate within forest and woodland communities. European beach grass reduces the native plant richness (the number of species) by as much as half (Barbour and Johnson 1988). It has the ability to out compete native foredune plant species (Barbour, Dejong, and Paulik 1985) by altering the habitat (Pickart, Brown, and Avery 1990). Blowing sand is trapped, burying other species and precluding resource competition. European beach grass can withstand sand burial of up to one meter per year. In fact, sand burial promotes leaf elongation and underground stem development (Ranwell et al. 1959). Runners in the root system are the primary means of beach grass reproduction. Despite high seed production of up to 20,000 seeds per plant per year, most beach grass seedlings die within a few weeks of germination (Huiskes 1979). Significant differences are seen when comparing areas dominated by European beach grass with those covered by native dune species, such as American dunegrass. Foredunes dominated by European beach grass are steep and give way to a series of dunes and swales parallel to the coast. In contrast, dunes dominated by American dunegrass rise gradually and lead to dunes and swales perpendicular to the coast (Barbour and Johnson 1988).

Some exotic plant species are designated as noxious weeds by the state's Noxious Weed Control Program. Noxious weeds are considered injurious to public health, agriculture, recreation, and wildlife on any public or private property by the (Oregon Department of Agriculture 2003). The seven noxious weeds present or suspected at Spit include: Scotch broom (*Cytisus scoparius*), French broom (*Genista monospessulana*), common gorse (*Ulex europaeas*), Himalayan blackberry (*Rubus armeniacus*), English ivy (*Hedera helix*), Canadian thistle (*Cirsium arvense*), and bull thistle (*C. vulgare*). Methods to remove noxious weeds on the Spit may include herbicides, mechanical means, hand cutting and pulling, and the application of fire.

### *Timber and Special Forest Products*

The Spit was designated as a non-commercial forest in the RMP. Consequently, no commercial timber management occurs on the Spit. No commercial harvest of Special Forest Products is permitted within the North Spit ACEC unless the harvest benefits the ACEC or clearly does not impact any special status plants or animals (USDI BLM 2003b).

## Biological: Wildlife

The BLM is responsible for managing habitats of all existing native vegetation and wildlife species on BLM land. Therefore, wildlife management on the Spit focuses on the management of habitats for native wildlife species (Appendix 2), with special emphasis on the protection of rare habitats and sites important to special status species (Table 5; see below).

### *Wildlife Habitats*

A mosaic of habitats supports an abundant and diverse array of wildlife on the Spit. The interspersion of coastal environments and upland late-seral forest combined with the relative isolation of the Spit creates a very rich and productive wildlife area heavily used by shorebirds, waterfowl, raptors, and many other species (Northwest Biological Consulting; Appendix 2). Although not all the habitats described below are under BLM administration, wildlife species cross jurisdictional boundaries as they travel among habitats to forage or nest. Additionally, species using the Coos Bay estuary may be directly affected by adjacent uplands management, including recreational use of the Spit.

**The Coos Bay Estuary.** Including saltmarshes, open water, mudflats, and sandflats, estuaries are among the most productive environments in the world due to the dynamic interaction of riverine and marine systems (Buchanan et al. 2001). As interfaces between salt and freshwater and between terrestrial and aquatic habitats, they receive large influxes of nutrients from watersheds, marshes, and tidal action. Consequently, the habitats found in this environment support a rich wildlife community. The estuary supports some of the highest numbers of dabbling ducks using Coos Bay (Varoujean 1985) and a March 1992 aerial survey placed Coos Bay with the third highest waterfowl count on the Oregon coast (Oregon Wetlands Joint Venture 1994).

Salt marshes are an important component of estuarine ecosystems, providing roosting areas for shorebirds and gulls, and haul-out areas for harbor seals. Raptors, including bald eagles, falcons, and hawks, hunt over the salt marsh, and use logs as resting or hunting perches (USDI BLM 1994). Approximately 90% of the salt marshes associated with the Coos Bay estuary were eliminated following European settlement (Buchanan et al. 2001), thus accentuating the value of the remaining marshes.

The open water habitats of the Coos Bay estuary include both shallow and deep water habitats used by many species of wildlife (USDI FWS 1980). Waterfowl and seabirds forage on fish and invertebrates, their numbers and species diversity varying throughout the year but highest during the spring and fall migrations. Bald eagles and osprey feed on fish and waterfowl using the Bay, and peregrine falcons hunt waterfowl and shorebirds during their spring and fall migration.

Harbor seals and California sea lions forage within the bay throughout the year and use the dredge material islands as haul-out sites. Occasionally they may be found resting on the Spit's beaches. Although foraging seals do not appear to be affected by activities on the Spit, they are very sensitive to disturbance on their haul-out sites.

***Snowy Plover with chick.***

**Table 5. Special status wildlife species documented (D), suspected (S) and potentially (P) on the North Spit by name, presence, status, and habitat. Note: BA = Bureau assessment, BAO = Bureau assessment Oregon only, BS = Bureau sensitive, BSO = Bureau sensitive Oregon only, FE = Federally Endangered, FT = Federally Threatened, and FC = Federal Candidate.**

| NAME | Presence | Status | Habitat |
|---|---|---|---|
| ***AMPHIBIANS*** | | | |
| California Slender Salamander<br>*Batrachoseps attenuatus* | S | BAO | Late seral forests, large down logs |
| ***REPTILES*** | | | |
| Northwestern Pond Turtle<br>*Clemmys marmorata* | D | BSO | Lentic water (ponds, slow sections of rivers) Nests in open areas adjacent to water, can overwinter in forest |
| ***BIRDS*** | | | |
| Arctic Peregrine Falcon<br>*Falco peregrinus tundrius* | D | BS | Cliffs, may perch in trees |
| American Peregrine Falcon<br>*Falco peregrinus anatum* | D | BS | Cliffs, may perch in trees |
| Cacklin Goose<br>*Branta canadensis leucopareia* | D | BS | Coastal grasslands |
| Dusky Canada Goose<br>*Branta canadensis occidentalis* | D | BSO | Open grasslands, wet meadows |
| Bald Eagle<br>*Haliaeetus leucocephalus* | D | FT | Large trees for nesting/perching, near water |
| Bobolink<br>*Dolichonyx oryzivorus* | D | BAO | Grasslands, open areas |
| Brown Pelican<br>*Pelecanus occidentalis* | D | FE | Forages off shore, uses jetties and beaches to roost |
| Marbled Murrelet<br>*Brachyramphus marmoratus* | D | FT | Late-seral forest, remnant large trees |
| Oregon Vesper Sparrow<br>*Pooecetes gramineus affinis* | D | BSO | Grassland |
| Purple Martin<br>*Progne subis* | D | BSO | Large remnant trees and snags, near water, edges |
| Streaked Horned Lark<br>*Eremophila alpestris strigata* | D | FC | Coastal dunes; open ground with short grass or scattered bushes |
| Trumpeter Swan<br>*Cygnus buccinator* | P | BAO | Marsh, wet meadows, bogs, ponds |
| Upland Sandpiper<br>*Bartramia longicauda* | D | BSO | Coast; open grasslands |
| Western Snowy Plover<br>*Charadrius alexandrinus nivosus* | D | FT | Beaches and inland areas of open sand |
| White-tailed Kite<br>*Elanus leucurus* | D | BAO | Pastures, open grasslands; typically low elevations |
| ***MAMMALS*** | | | |
| Fisher<br>*Martes pennanti* | P | FC | Closed or multi-canopy forest, snags, dead parts of live trees, large live branches |
| Townsend's Big-eared Bat<br>*Corynorhinus townsendii* | P | BSO | Breed in caves and mines, bridges for night roosts |
| ***INVERTEBRATES*** | | | |
| Salamander Slug<br>*Gliabates oregonius* | P | BSO | Moist coniferous forest with leaf litter |
| Spotted Tail-dropper<br>*Prophysaon vanattae pardalis* | P | BSO | Moist, mature forests |
| Newcombs Littorine Snail<br>*Algamorda newcombiana* | *P* | BSO | Saltwater at edge of bays and estuaries |

Mudflats and sandflats are found on the Spit's bay side. These areas are tidally-inundated, and support an abundance of marine invertebrate species, including many of the most productive shellfish beds on Oregon's south coast (Northwest Biological Consulting 1980). These sandflats and mudflats also provide foraging habitat for a variety of birds and mammals. Resident and migrant shorebirds congregate there, especially during low tides, to forage on the invertebrates in the shallow waters and exposed mudflats (Varoujean 1985). Coos Bay is one of the six most important areas for shorebirds between San Francisco Bay and British Columbia (Oregon Wetlands Joint Venture 1993) and the Spit's mudflats consistently support the greatest number of wading birds in the Coos Bay estuary (Varoujean 1985). The concentration of shorebirds and wading birds in these habitats provide prey for bald eagles, northern harriers, and peregrine falcons, and ravens, gulls, raccoons, mink and skunks forage in the shallow waters and exposed flats for shellfish, invertebrates and carrion.

**Jetties.** The Jetty and the training jetty on the southern tip of the Spit provide roosting habitat for gulls and cormorants, and shorebirds (e.g., turnstones and surfbirds) forage on invertebrates inhabiting the rocks (Map 3). Flocks of California brown pelicans, a federally-listed endangered species, use the jetties for roosting and feeding (Northwest Biological Consulting 1980).

**Beaches and Sand Dunes.** Aquatic and terrestrial invertebrates, fish, and carrion found on the beach provide a rich food source which attracts a variety of wildlife species. Shorebirds are among the most abundant groups using the beach habitats, and are an important food source for raptors, particularly peregrine falcons during their fall and spring migration along the Oregon coast (Wilson-Jacobs 1983). Shorebirds forage primarily on the beaches and mudflats and eat insects, shellfish, and other marine invertebrates. The threatened Western snowy plover also nests on the upper beach, laying its eggs in small hollows (scrapes) above the high tide line and behind the foredune. After hatching, the flightless chicks forage in the vicinity of the nest sites until they fledge. In combination with the inland sandy sites east of the foredune, the Spit provides nesting habitat for the largest breeding population of coastal snowy plovers in Oregon (USDI FWS 1993). Larger birds such as gulls, terns, ravens, and crows feed opportunistically along the shoreline on a variety of shellfish, carrion, insects, eggs, and chicks, and often rest in large flocks at the ocean's edge. In addition to peregrine falcons, several other raptors occur on the Spit, including bald eagle, osprey, northern harrier, and turkey vulture. Most raptor species forage opportunistically on both live animals and carrion found on the beach. Terrestrial mammals that forage along the beach for shellfish, carrion, and invertebrates include raccoons, mink, skunks, gray foxes, opossums, and various small rodents. Although less frequently than other animals, black bears, bobcats, Roosevelt elk, and black-tailed deer feed on the beach too, and drift logs washed up onto the beach are used as foraging and resting perches for falcons and as windbreaks by roosting shorebirds (Buchanan et al. 2001).

Inland sand dunes with little or no vegetation are used extensively by certain species of terrestrial insects, primarily beetles, centipedes, and millipedes. Flying insects found just off the surface of the sand are common and fed upon heavily by barn swallows. The small amount of hiding cover in the open sand renders prey species vulnerable, thus making these areas valuable foraging habitat for many predators, including raptors (e.g., northern harriers and kestrels), gray foxes, coyotes, and other species that eat insects, rodents and reptiles. Crows, ravens, turkey vultures, and other birds use the dunes for resting and foraging, and burrowing owls have been documented foraging and roosting in the open sand during the winter (USDI BLM 1994).

In contrast to the homogeneity of the open sand dunes, stabilized sand communities are quite variable, ranging from sparsely vegetated areas with scattered beach grass hummocks, to habitats with more developed plant communities dominated by dense beach grass containing scattered clumps of shrubs and conifers (see Botanical Resources). The amount of cover and available prey or plant foods determine which species occur in these habitats. Black-tailed deer and rabbits occur throughout these communities, and passerine bird species feeding on plant seeds and insects take cover in the dense shrubbery. Mammalian predators such as skunks, foxes, coyotes, raccoons, mink, and bobcats prey on small mammals, birds, eggs, reptiles, and insects in and under logs deposited by winter storms.

Sparsely-vegetated hummock areas are used for foraging throughout the year by northern harriers, red-tailed hawks and bald eagles (USDI BLM 1994) and shrubs and logs are used as perch sites. Raptors use all of the stabilized sand habitats, but the sparsely-vegetated areas are believed to provide better hunting because small mammals and reptiles are more vulnerable to attack by aerial predators.

**Freshwater Wetlands and Ponds.** The freshwater wetlands of the deflation plain support a diverse wildlife community and are some of the most productive habitats on the Spit (Wilson-Jacobs 1983). Ranging from areas dominated by grasses and sedges to tall shrub thickets, the wetlands are used by many wildlife species to fulfill all or a portion of their habitat requirements. Wetlands provide critical breeding and rearing habitat for amphibians, including red-legged frogs and numerous invertebrates provide prey for various species of wildlife.

The structurally diverse low shrub and thicket habitats contain the highest number of species in the wetland environment (USDA FS 1972). Muskrats, voles, rabbits, and other small mammals find food and shelter in the diverse vegetation and vertical structure of these areas. Predatory mammals (including shrews, mink, skunks, bobcats, foxes, and coyotes) forage on invertebrates, amphibians, birds, and small mammals, and during the spring and summer, bats forage extensively on flying insects.

A combination of structurally complex habitat features and an abundant variety of available food sources support a variety of bird species. Waterfowl, shorebirds, passerines and raptors nest or forage in the freshwater wetlands, and migratory birds rest and feed there while traveling. Approximately one-third of all North American bird species depend upon wetlands during some part of their life, and approximately three-quarters of these species are non-game birds whose ecological significance is poorly understood (USDI FWS 1984).

Ponds provide areas of open water adjacent to the more heavily vegetated freshwater shrublands and thickets, and support a community of aquatic invertebrates, fish and amphibians. Many of the species inhabiting the ponds are important food sources for other animals. Although the inland open water sites of the Spit are not considered high quality nesting habitat for most species of waterfowl, they are used for foraging by a variety of migrating waterfowl during the spring, fall, and winter (Thornburgh 1991).

**Forests.** The shorepine and Sitka spruce forests found on the eastern edge of the deflation plain constitute the habitat with the greatest structural complexity on the Spit; on the adjacent ODNRA, this type of habitat supported the greatest diversity of wildlife species (USDA FS 1972). The trees, snags and down logs not found in other plant communities on the Spit provide important breeding, foraging, and cover habitat for a variety of wildlife species. Upland amphibians (e.g., the western redback salamander and ensatina) seek cover in down logs, and many bird species (including raptors, woodpeckers, and passerines) nest and forage in these habitats. In past years, the stand of late-seral Sitka spruce on BLM land contained the largest mixed heronry of great blue herons and great egrets on Coos Bay (Northwest Biological Consulting 1980). That heronry was abandoned in 2000 for unknown reasons. Two new rookeries were subsequently discovered: one on the ODNRA in 2002 and one on BLM in 2004. It is possible that these heronries may contain birds from the abandoned site. Coos Bay is the most northerly nesting site for great egrets.

### *Wildlife Species of Special Management Concern*

The interface of the marine, freshwater, and terrestrial environments described above provides habitat for many special status wildlife species (SSS Table 5). Several are dependent upon snags, large trees, and coarse woody debris: habitat elements characteristic of older forests that have become limited in availability and distribution throughout Western Oregon. Others are associated with wetlands, or habitats uniquely identified with areas of open sand and coastal grasslands. In addition to SSS, special management provisions are in place for the conservation of other species collectively termed Buffer Species. Specifically, BLM is directed to establish protective buffers around the nests of great blue herons, great egrets, and certain raptor species such as ospreys, red-tailed hawks, sharp-shinned hawks, and Cooper's hawks (USDI BLM 1995a). Depending upon the species, up to 15 acres may be delineated near nest sites to minimize human disturbance, and nest platforms, boxes and other structures may be constructed where natural availability is low. Management for great blue herons and great egrets includes monitoring known rookeries and surveying appropriate habitat for new ones.

Little is known about the distribution and abundance of most of these species on the District; consequently much of the information related to wildlife on the Spit is based on literature pertaining to wildlife-habitat associations and incidental observations. As discussed above, in the absence of site-specific information, recreational and other activities are managed to minimize effects to wildlife habitats thus minimizing potential impacts to species. When assessing the effects of a proposed project, species are assumed present given the availability of suitable habitat. Special status species that are designated as "potentially" present on the Spit are those for which suitable habitat is present but no individuals have been documented (Table 5). One such species is the Pacific fisher, a Federal Candidate for listing under the ESA. Consequently, there is heightened concern for their population status and conservation needs.

In Oregon, fishers appear to have been extirpated from their historical range with the exception of two small disjunct populations in the Siskiyou Mountains and in the southern Cascade Range (Aubry and Lewis 2003). Although possible, the presence of fisher on the Spit is unlikely given the rarity of the species and the lack of large, well-connected tracts of mature forest with continuous canopies. Most forested areas on the Spit are interspersed with areas of open sand and research indicates that fishers are reluctant to cross openings greater than 25 meters (Powell and Zielinski 1994). Furthermore, fishers on the Spit would be separated from Coast Range populations by Highway 101, human developments, and fragmentation of mature forest. It is uncertain the extent to which fishers can recover from extirpation given that their populations are isolated and their apparent inability to colonize unoccupied areas (Aubry and Lewis 2003).

The Coos Bay District wildlife sightings database contains several fisher observations in Coos County; none of these sightings were in the vicinity of the Spit. Remote camera surveys for fisher in other parts of the District between 1994 and 1997 failed to detect fishers. Efforts are underway to further refine the species' distribution in Oregon.

Several other species of interest are discussed below.

**Marbled Murrelet and Bald Eagle.** The occurrence of large diameter trees with large branches in close proximity to the ocean renders the Spit suitable for marbled murrelets and bald eagles. Limited surveys for murrelets were initiated in 2005, and surveys for bald eagles conducted in the area by the Oregon Cooperative Wildlife Research Unit have not documented nesting eagles on BLM land. The area is suitable for roosting and hunting, and eagles are occasionally seen foraging on Spit beaches.

**Purple Martin.** Purple martins are the largest members of the swallow family in North America. They forage above many types of open habitats, particularly near water and nest in snags with cavities. They were once much more common in Oregon prior to the removal of snags by logging and competitive exclusion from the remaining snags by introduced European starlings (Sharp 1996). Oregon nest sites include snags in forest clearcuts and burns and snags in coastal dunes (Rodenkirk 2003). Suitable nest trees occur on the Spit, many located near ponds and wetlands in close proximity to the bay and ocean beaches. In addition to natural structures, purple martins readily nest in bird houses. Currently, there are 24 nest boxes on pilings in the bay near the boat launch facility (Map 3). Twenty-one of these boxes were used by purple martins in 2004. The boxes are maintained and monitored yearly.

**Peregrine Falcons.** The American peregrine falcon (*Falco peregrinus anatum*) and the Arctic peregrine falcon (*Falco peregrinus tundrius*) require cliffs for nesting but may be found perching in trees while hunting or migrating. Whereas the Arctic peregrine is an occasional winter migrant, the American peregrine nests on the Coos Bay District and may occasionally be seen on the Spit while hunting or migrating.

**Northwestern Pond Turtle.** One of two freshwater turtles of the Pacific Northwest, the northwestern pond turtle is in decline in Oregon because mortality exceeds reproduction for a number of reasons. Threats include habitat loss and degradation, which in conjunction with predation and disease, has led to small disjunct populations with low recruitment rates (Marshall et al. 1996). Western pond turtles may inhabit a variety of aquatic habitats providing that suitable sites are available for basking (e.g., logs, rocks, and islands) and there is sufficient aquatic and emergent vegetation. Mud substrates and leaf litter are important components for breeding and hibernating, as are shallow bank margins for traveling between the water and the adjacent upland (O'Neil et al. 2001). A western pond turtle was documented on the adjacent ODNRA. Wetlands on BLM land likely contain western pond turtles.

**Western Snowy Plover.** The coastal population of the Western snowy plover uses sandy beaches along the Pacific Coast from southern Washington to Baja California for breeding and wintering. It receives the highest priority for management on the Spit due to its low population numbers and the significance of the Spit as nesting habitat. In 1993, the coastal population of the Western snowy plover was listed as a Federally threatened species due to declining population numbers and loss of nesting habitat (USDI FWS 1993).

In February 1999, the ocean freighter New Carissa grounded on the Spit and began leaking oil. To ensure public safety, the Spit was closed through an emergency order to public access. At the end of 1999, two portions of the New Carissa wreck remained mired, releasing oil and depositing tar balls (Map 3). To address concerns related to impacts on snowy plovers, BLM, FWS, ODFW, and COE collaborated on a Biological Assessment to allow public use of the Spit while protecting plovers and promoting their recovery (USDI BLM 2000). The following ongoing actions are a result of the subsequent Biological Opinion for management of federal lands on the North Spit of Coos Bay (USDI FWS 2000).

**Public Access and Snowy Plovers.** From the FAA Tower south to the BLM boundary, the upper, dry sand portion of the beach is closed to all public access during the Western snowy plover nesting season (March 15- September 15 annually; Map 3). The area is clearly marked with ropes and signs. Restrictions on motorized use of the adjacent lower, wet sand area are authorized by OPRD. Inland snowy plover nesting areas on BLM land are also signed closed to all use during the nesting season, and are open to nonmotorized use the remainder of the year.

**Habitat Restoration Areas.** Approximately 170 acres of the inland Spit area are managed for snowy plovers; 100 acres by COE and 70 acres by BLM. The Habitat Restoration Areas (HRAs) were largely unsuitable for plovers prior to restoration due primarily to the presence of European beach grass. BLM annually removes beach grass to create suitable open, sandy habitat for snowy plovers. No new HRAs are currently planned.

**Predator Control.** In 2000, the BLM led a multi-agency effort to produce an EA on predator control throughout the range of the coastal population of snowy plovers (USDA FS and USDI BLM 2002). The selected action consists of an integrated predator damage management program to protect the plover population from further decline. Actions were initiated in 2003 and include an expanded assessment to determine and reduce the predator species responsible for nest, chick, and adult predation. The Animal Plant and Health Inspection Service (APHIS) conducts these activities. Targeted species include American crows, common ravens, and small mammalian predators. Most traps are located in areas closed to the public (e.g., the HRAs and the upper beach), clearly signed, and unlikely to cause injury to domestic animals and humans.

**Population Monitoring.** The Oregon Natural Heritage Information Center monitors plover nesting. Intensive surveys are conducted throughout the six month nesting season to determine population size and reproductive success. All chicks are banded for identification and an attempt is made each year to locate them to assess survivorship and track their productivity. From this information, it was determined that the Spit contains the most productive snowy plover population segment on the Oregon Coast. Since 1990, the Spit has produced over 40% of all plovers fledged each year in Oregon (Lauten et al. 2003). Through intensive monitoring, the success of management actions can be assessed and progress toward plover recovery determined.

**Designated Snowy Plover Critical Habitat.** On December 7, 1999 the FWS published a Final Rule designating critical habitat for the Pacific coast population of the Western snowy plover (USDI FWS 1999). Critical habitat on the Spit includes the ocean beach from Horsfall to the Jetty and all of the federal lands at the south end of the Spit.

**Other Planning Efforts for the Snowy Plover.** The FWS is preparing a final recovery plan for the Pacific Coast population of the western snowy plover in Washington, Oregon, and California. OPRD has a leading role in managing plover habitat in Oregon. To guide beach management, it is preparing management and conservation plans (ORNIC and OPRD 2004; OPRD 2004). BLM will implement the final plans on BLM lands.

## Biological: Fisheries

No fish surveys have been conducted on BLM lands on the Spit. Potential fish-bearing waters on BLM lands occur above the mean high tide. They include natural ponds and a created mitigation pond and wetland to the north of the effluent lagoon (see Water Resources). These areas are likely to contain introduced largemouth bass, other sunfish species, such as bluegill, and threespine stickleback. There are no SSS fish species on BLM land on the Spit due to lack of suitable habitat.

## Cultural and Historical Resources

### *Social and Historical Setting*

Before the introduction of European beach grass, the North Spit of the Coos River was highly unstable and subject to major changes during the heavy winds of summer and winter (Beckham 2000). At least two river channels cut through the Spit, turning a portion of the area into an island during much of the year (Pullen 2004). Despite these changes, historical records indicate the area was heavily utilized prehistorically.

The North Spit of Coos Bay was an ideal place for a wide variety of food procurement for native peoples. The Coos Indians built fish weirs along the shore to catch salmon, gathered clams and crabs at low tide, hunted for deer, elk, and waterfowl in the Spit's marshes, and gathered various types of berries that grew abundantly along the edges of the marshes (Peterson and Powers 1977; Zenk 1990).

In the 1940s, John Harrington was able to obtain information about villages on the Spit while interviewing elders of the Coos Indian tribe. Prior to the changes introduced by American exploration and settlement, there were at least half a dozen villages along the inner shoreline of the Spit, although their locations are not precisely known (Zenk 1990). There are also undoubtedly native burial sites or cemeteries on the Spit, as the Coos people usually buried their dead within or adjacent to their villages (Zenk 1990).

Between 1820 and 1850, British and American trappers camped up and down the coast. Documented parties camped on the Spit in 1826 and again in 1828 (Beckham 1986, 2000; Peterson and Powers 1977). Between this time and the beginning of Euro-American settlement in 1851, the Native population of the area was decimated by the spread of infectious diseases (Boyd 1999). In 1855, violence between settlers and Native Americans flared to the south along the Rogue River, resulting in a response by the US Army. Along with other southwest Oregon coastal groups, the Coos people were forcibly removed from their homes and relocated, first to Fort Umpqua near Reedsport, and then to a new reservation at Yachats in 1860 (Zenk 1990). In 1875, some of the survivors of this relocation were moved to the Coast reservation at Siletz, while others, refusing to be moved again, returned to their ancestral homelands around Coos Bay (Zenk 1990).

Located adjacent to the largest estuary between the Columbia River and San Francisco, the Spit served as an important transportation link between Coos Bay and settlements on the Lower Umpqua during the late 1800s. Wagons and stagecoaches traveled down the beach during low tide from Winchester Bay to a point across from Empire, where, weather permitting, scows carried the passengers across the bay (Beckham 1986, 2000). In the 1880s, Fred Jarvis took over the Coos-Umpqua stage route and established what is known as the Jarvis Landing Beach Road on the Spit.

As the industrial capacity of the fledgling coastal towns increased, so did the need to improve the harbor and the bar at the mouth of the bay. Roads were almost non-existent, and the only markets for fish, lumber, farm produce, and coal lay far to the south in San Francisco. However, traversing the Coos Bay bar was often a dangerous enterprise, and when the weather closed in, it could be months before safe passage was assured. This was an untenable situation for a community focused on water transportation for its goods. In 1880, the COE was awarded a contract to construct a jetty near Barview. By the fall of 1881, the jetty cribs extended 1,384 feet into the bay (Beckham 2000). Throughout the rest of the 1880s, the COE monitored the jetty and realized that further work was needed before the harbor mouth could be stabilized.

In 1890, at the southern tip of the North Spit the COE began construction of the North Jetty, a rock sea wall nearly two miles long (Beckham 2000). Government Works, a village of laborers and engineers, was built on pilings along the inner shoreline near the North Jetty construction site. An aggressive program of sand stabilization was begun by the COE along with jetty construction. Nearly 1,000 acres of European beach grass eventually was hand-planted to stabilize the dunes (Beckham 2000).

In 1892, a US life-saving station was built on the Spit to rescue sailors stranded by adverse weather conditions (Map 3). It was located on the bay side about two miles north of the harbor entrance. Between 12 and 16 families lived at the station during its peak use. The facility included a dock, workshops, and two crew buildings (Beckham 2000).

The ocean took a heavy toll on the Jetty. During the 1920s, Congress funded the construction of a South Jetty and the reconstruction of the North Jetty (Beckham 2000). Major reconstruction work was again completed on the North Jetty during 1939 and 1940, when a railroad was used to transport materials (Beckham 2000). The railroad route came around Jordan Cove and down the bay side, cut across the Spit at the dike road (along the south edge of the effluent pond), turned south through an unstabilized dune field and followed the foredune south around the southern tip of the Spit and ended at Government Works.

Concrete bunkers were erected along the Spit during World War II, in hopes of slowing the anticipated Japanese invasion of the West Coast. There were no recorded conflicts during WWII in the Coos Bay area.

### *Prehistoric Sites*

Although considerable documentation supports the presence of numerous Native American sites on the Spit, only two sites are officially on record with the Oregon State Historic Preservation Office. Site 35CS26 was located between Jordan Cove and the North Slough. Site 35CS27 was reportedly along the inner shoreline on the southern end of the spit, but was never specifically located. A recent intensive survey of this shoreline failed to reveal any evidence of this site (Pullen 2004).

The Coos Indians unquestionably used the Spit for various activities. However, this area is very unstable and any remaining evidence could have been destroyed either by erosion or shifts in the river channel, or could have been covered by sand movement. Continued dumping of dredge spoils along the shoreline has further clouded the identification of prehistoric middens, as both types of deposits are largely composed of shells. Although there is little evidence of extant prehistoric archaeological deposits on BLM-administered land, the instability of the sand dunes on the Spit may uncover cultural sites in the future.

### *Historic Sites*

Preservation and identification of historic sites is constrained by the potential for dynamic changes to the Spit landforms. Campsites used by trapping expeditions during the 1820s probably left little evidence, long since removed. However, the four month-long camp (Camp Castaway) created by the US Army survivors of the beached vessel *Captain Lincoln* in 1852 (Beckham 2000; Dodge 1898; Peterson and Powers 1977) may have left more substantial evidence.

The sand road across the Spit used by the Coos-Umpqua stage route isn't likely to have any remnants as the effluent ponds and South Dike Road have substantially altered the land surface on that part of the Spit. Initial Jetty construction transported jetty materials (piling and rock) via barge from Empire to Government Works. Subsequent reconstruction efforts involved creation of a railroad. Evidence of this railroad line has been found both under the present day Foredune Road and in open dunes near the intersection of the South Dike and Foredune Roads.

Other remnants of construction and reconstruction of the Jetty are likely to be concentrated in the area occupied by Government Works (Beckham 2000). Today, this area has largely been reclaimed by the Coos River, and is known as Half Moon Bay (Map 3).

The life-saving station retains historic interest, although most structures have been removed. Remnants of the dock remain, as do building foundations, walkways and other landscape improvements. Because there were numerous fatal shipwrecks during the station's operation there exists a possibility that a cemetery exists on the "tree island" just west of the station. This is a likely location for the cemetery because prior to sand stabilization by introduced European beach grass, this area was the only portion of the Spit with sufficient elevation to withstand winter storm wave action (Beckham 2000). Today, this "tree island" is densely vegetated and cultural site locations are unknown.

Nearby, three World War II vintage Quonset huts remain open to the public. These structures are over 50 years old, and therefore may be considered for inclusion onto the National Register of Historic Places.

## Recreational Resources

The diversity of environments and landforms (dunes, wetlands, seasonal ponds, extensive ocean and bay beaches, forests, and meadows) that make the Spit valuable for wildlife also place these lands in demand for outdoor recreation. The value to these public lands for outdoor recreation is further amplified by its close proximity to one of the largest population centers on the Oregon Coast, Coos Bay/North Bend. Most of the private and Port of Coos Bay property on the Spit is zoned for development. It is reasonably foreseeable that these private and Port of Coos Bay parcels will eventually become closed to public access and recreation as further development occurs on the bay front. The public lands managed by the BLM on the Spit are destined to become the largest and most accessible tract of public green space available for the Coos Bay area communities.

In 1992, the BLM developed a boat launch facility and courtesy dock to provide access to the Coos Bay estuary on the Spit. This recreation complex includes a paved parking lot, flush restrooms, interpretive wayside exhibits, and facilities for a volunteer host. The boat launch facility was developed with funding from the Oregon State Marine Board (OSMB), Oregon Department of Fish and Wildlife, Coos County, and the Northwest Steelheaders.

In recognition of the site's value for outdoor recreation, the Spit was designated as a Special Recreation Management Area (SRMA) in the Coos Bay District Resource Management Plan in May 1995. Through the SRMA designation, the BLM made a long-term commitment to manage the Spit to sustain outdoor recreation and the experience opportunities these activities depend upon in a manner that is compatible with the conservation of the areas' wildlife and cultural resources. Recreation management projects completed by the BLM on the Spit include:

- Designation of routes and trails as open, limited, and closed for off-highway vehicle use through the 1995 Coos Bay District RMP and Coos Bay Shorelands Plan of 1995.
- Installation of visitor management signs within the Spit interior to manage OHV recreation and to protect wetland and snowy plover nesting habitat.
- Providing BLM law enforcement and Coos County contract law enforcement support as well as funding a visitor assistance/biological technician position to implement visitor services and resource protection patrols throughout the year.
- Inventory and preliminary planning for a 12-14 mile hiking and equestrian trail system.

## Visitor Use

In the BLM's national recreation tracking data base, the Recreation Management Information System (RMIS), the North Spit reported 27,100 visits and 9,774 visitor days for the period of October 1, 2003 to September 31, 2004. These estimates were developed using electronic, seismic and laser counters at key locations. The counter numbers are recorded weekly in summer and monthly in winter. While counters may not be 100% accurate, they are a standard, valid method to collect visitor use data. There are counters at the boat ramp, one nearer to the jetty, and one on the South Dike Road. Visitor numbers from the counters show that in FY 2003, about 7,250 people used the restrooms at the boat launch, 13,100 vehicles entered the boat ramp, and about 420 boats were launched. Data from the counter near the Jetty shows the average number of vehicles per month at 200, or about 2, 460 vehicles per year. Using a visitor/vehicle estimate of 2.5 (based on a visitor survey in the summer of 2000), approximately 6,150 people travel the sand road out to the Jetty each year by 4-wheel drive or ATV.

**Recreation Demand and Trend.** Every five years, state park and recreation departments around the United States are required to conduct a statewide assessment of outdoor recreation demand, needs and trends to qualify for Federal Land and Water Conservation Fund Act grants. The Oregon Statewide Comprehensive Outdoor Recreation Plan for 2003-2007 (SCORP) offers the best view into outdoor recreation demand within the state on a region by region basis. BLM Manual 8332.08 – Recreation Area Management Plans encourages the use of SCORP data to obtain statewide and regional trends. The SCORP is the product of extensive phone and mail-in surveys of Oregon households as well as out-of-state residents from Washington, Idaho and California. Based on this statistically valid study, a number of observations can be made about the recreation potential on the North Spit:

- The North Spit offers good opportunities for six of the top ten highest demand recreation activities in the state. In ranking order these are: 1. Running/Walking for Exercise; 2. Walking for Pleasure; 3. Bird Watching; 4. Nature/Wildlife Observation; 5. Sightseeing; and 10. Ocean Beach Activities.
- Statewide, ocean beach-related activities rose significantly from 4.45 million user occasions in 1987 to 7.6 million user occasions in 2001. For the North and Central coastal regions, "beach activities" were the #1 growth activity from 1987 to 2002 (an increase of 2.7 million user occasions). On the South Coast, "beach activities" were the #2 growth activity during this same time period (an increase of 0.4 million user occasions).
- The #1 growth activity in the South Coast region was ATV recreation – up 144% (185,181 annual user occasions) from the 1987 survey estimates. This growth reflects the sharp increase in ATV sales over the last decade and the corresponding growth in off-highway vehicle recreation in the Oregon Dunes National Recreation Area – the premier dune riding location in the Pacific Northwest.
- The SCORP also identified the highest recreation priorities for the state on a region by region basis. Within the South Coast Region, residents responded that one of their top three recreation management priorities was to "Conserve Coastal Areas and Preserve Coastal Access for Recreation."

Ocean shore related recreational use was further studied by the Oregon Department of Parks and Recreation in 2001 as part of the Ocean Shore Management Plan. The Ocean Shore Recreational Use Study conducted by Oregon State University examined activities and management preferences of actual beach users during the summer of 2000. While the BLM does not directly manage the thin strip of land that comprises the Ocean Shore Management Area, it does manage the dry sand and foredune adjacent to this area. Therefore, the data provides a good perspective into actual user behavior, values and activities within the ocean shore areas managed by both the BLM and OPRD.

- Within the South Coast Region, from the Umpqua River to the California border, the top 10 recreational activities among those surveyed were: Walking 93.2%, Scenic Enjoyment 81.9%, Picnicking 56.7%, Exercise 51.2%, Beachcombing 38%, Recreation Activities Involving Dogs 35.2% (highest rate on the coast), Driftwood Collection 26.4%, Birding 24.3 %, Kite Use 22.4% and Camping 16.8%.
- On a much more localized level, within Segment 5 of the South Coast Region- the 15 mile section from Ten Mile Creek to Coos Bay, the top activities were: Vehicle Use 54% (highest rate in the study), Relaxing 21%, Walking 16%, and Recreation Activities Involving Dogs 4%. The high rate of OHV use in this study is partially due to the fact that nearly 2/3 of this survey unit is within the popular riding areas offered in the ODNRA.

The Spit directly supports or provides immediate access to a wide variety of outdoor recreation activities, including most of the high demand activities identified in the SCORP and Ocean Shore studies. These activities include: hiking, walking/running, horseback riding, motorized boating, primitive dispersed camping, motor-vehicle touring/sightseeing, 4-wheel drive and ATV trail riding, picnicking and social gatherings, waterfowl and deer hunting, backpacking, berry and mushroom picking, outdoor photography, dog exercise and training, recreational shooting, ocean and bay shore fishing, crabbing, clamming, birding and wildlife viewing, surfing, sea kayaking, canoeing, and wind surfing.

The Spit has been an important local recreation resource for generations, supporting traditional uses such as beach combing, fishing, crabbing, clamming and surfing. Motorized use is a key element in supporting these activities on the spit.

Since the 1995 Shorelands Plan was written, a number of new outdoor recreation activities have made an appearance in the region and are likely to find a place on the Spit. These include kite sailing, paint ball, geo-caching, sand boarding, and long distance hiking on the Oregon Coast Trail, to name a few. The public lands are generally open to any and all new recreation activities, unless and until adverse resource impacts occur or serious visitor conflicts develop.

### *Recreation Opportunity Spectrum*

The concept of managing recreation opportunities and visitor experiences is a dominant theme throughout the objectives presented in the Coos Bay RMP. However, the actual details of which opportunities would be provided for and where they would occur are not well defined. The classification and management of recreation opportunities is typically accomplished through a planning process known as the Recreation Opportunity Spectrum or ROS.

The ROS provides a conceptual framework for the inventory, planning and management of the recreation resource setting and recognizes that people differ in their needs and in the outdoor experiences they desire. The ROS is used to classify lands into a range of recreation opportunity classes based on the physical, social, and managerial setting inherent in the landscape. Six opportunity classes are identified in this planning framework and range from the Primitive at one end of the spectrum to Urban at the other.

**Recreational Opportunity Spectrum**

Applying this recreation planning framework to the current physical, social and managerial setting that exists on the Spit provides for two distinct recreation opportunity settings – Rural and Semi-Primitive Motorized. A strong theme heard from the public during the scoping process for this plan update was for the Spit to remain essentially unchanged from its current condition. The ROS is an excellent tool to ensure that landscapes and recreation settings do not undergo incremental changes that degrade the quality of the recreation opportunity that the place provides.

**Rural Setting.** The immediate area surrounding the developed North Sit Boat Ramp and the public lands within 100 feet of the paved section of the Trans Pacific Parkway fit well within the setting descriptions and management parameters common to a Rural ROS setting. The characteristics that comprise this setting include:

- The natural environment is culturally modified. The setting backdrop may range from locations where cultural alterations are not obvious to the casual observer to places where alterations are a dominant aspect of the landscape.
- For the visitor, self reliance on outdoor skills is of little importance in this setting and there is an expectation that recreation activities will involve very little challenge or risk.
- The opportunity to observe and affiliate with other users may be important to visitors in this setting. Interactions between users and evidence of other visitors may be high at times.
- The convenience of facilities to support outdoor recreation is expected by visitors.
- There are obvious and prevalent on-site controls (i.e., gated roads, barriers, fences, and regulatory signs).
- Access and travel facilities are designed to accommodate conventional motorized vehicle access.

Management objectives in this setting are intended to provide an environment that is natural appearing while providing easy access to recreation opportunities. Objectives for recreation management within a Rural ROS setting include the following:

- Access to recreation opportunities for people with disabilities is "easy" and meets Americans with Disabilities Act (ADAAG) standards.
- Some facilities are designed primarily for user comfort and convenience. Synthetic materials may be used in fabricating facilities, but more harmonious materials may also be incorporated. Facility designs can be more complex and refined than in more primitive settings.
- Moderate to heavy site modifications are allowed in order to provide for outdoor recreation facilities.
- Interpretation may be accomplished through the use of complex wayside exhibits and some personalized services.

**Semi-Primitive Motorized Setting.** The majority of the North Spit, except for the developed recreation complex at the boat ramp and the areas immediately adjacent to the Trans Pacific Lane, would best be characterized by a physical and social setting comparable to a Semi-Primitive Motorized ROS classification. The characteristics common to this ROS setting includes the following:

- The overall setting is characterized by a predominantly natural appearing environment.
- Visitors have a moderate probability of experiencing solitude, closeness to nature, and tranquility.
- The concentration of users is low, but there is often evidence of other visitors on trails.
- Motorized access may require the use of 4-wheel drive vehicles and may impose a high degree of self-reliance, challenge and risk
- Visitors encounter a minimum of subtle on-site controls and restrictions.

In addition to these general characteristics, the North Spit possesses several other factors that further support this more primitive recreation setting classification. These are:

- The necessity to use 4-wheel drive to access the sandy interior roads, ocean shore and bay beaches combined with the dynamic nature of traveling in an environment that frequently changes due to the effects of tide, storms and wind.
- The dense coastal vegetation and rolling topography provide effective screening between the interior trails and the motorized network. In addition, the vegetation and pounding surf tends to absorb many of the sounds generated by human activity on the Spit. These physical factors make for a recreation setting that provides an experience of isolation within a relatively small area.
- The inherent challenges common to a semi-primitive setting impose limitations that help to keep visitor use numbers relatively low. Due to this factor, this management setting is more compatible with the BLM's wildlife management goals for the North Spit by protecting sensitive species habitat from over use and excessive impact.

In keeping with this ROS classification, recreation development and management would be constrained within the following parameters:

- Recreation facilities, when developed, are primarily for the purpose of resource protection.
- Facilities are rustic and rudimentary and make use of undimensioned native materials rather than synthetic materials.
- Access for people with disabilities is "difficult" and challenging.
- Interpretation, when it occurs, is accomplished through very limited on-site facilities, maps, brochures and guidebooks.

The Oregon Statewide Trail Plan showed that users who engaged in trail-based outdoor recreation activities, both motorized and non-motorized, strongly preferred to participate in these activities in settings at the more primitive end of the opportunity spectrum (e.g., semi-primitive motorized to primitive). This quality was also brought out in the public scoping that was done for this plan update by the large number of comments stating that people wanted the North Spit to "stay the same."

### *Adjacent Recreation Resources*

The BLM public lands on the Spit are surrounded by regionally and nationally significant outdoor recreation resources. The most notable of these is the Oregon Dunes National Recreation Area managed by the US Forest Service. This vast recreation area extends for 40 miles along the Oregon Coast and supports a wide variety of human-powered as well as off-highway vehicle recreation opportunities. The segment of the ODNRA, north of the Spit, supports extensive opportunities for OHV recreation and attracts over 400,000 visitors per year. In the area immediately between the Horsefall Beach OHV staging area and BLM public lands, the Forest Service offers a non-motorized setting favoring hiking and equestrian opportunities.

In 2001, Weyerhaeuser created a wetland adjacent to the Trans Pacific Lane as a mitigation measure under the Henderson Marsh Mitigation Plan (see Water Resources). A hiking trail and parking lot was created at the site along with interpretive signs, a picnic area and an overlook (Map 3).

On the ocean side of the Spit, the Oregon Parks and Recreation Department administers the Ocean Shore Management Unit and the Oregon Coast Trail. One of the more popular sightseeing destinations on the North Spit, the wreckage of the New Carissa, is located within the Ocean Shore Management Unit and can be seen from a viewpoint along the Foredune Road.

### *Motorized Access*

The public lands on the North Spit were never legally open to cross country off-highway vehicle travel. Under the management of the US Army Corps of Engineers, these lands were officially closed, except for access via established roadways, by the Code of Federal Regulations 36 CFR.

***Bay side camping.***

After the BLM acquired these lands in 1984, the agency prepared the North Spit Plan Amendment to the Master Framework Plan (MFP) and placed these lands under an interim designation of Limited to Designated Existing Roads and made limited OHV use legal on the North Spit for the first time. The December 1985 MFP makes reference to the off highway vehicle opportunity presented by the dunes, but defers this decision until a full analysis of the impacts could be conducted. The full analysis of impacts and final motorized vehicle designations for the Coos Bay District, including the North Spit, did not take place until the Coos Bay District RMP was completed ten years later in 1995.

During the RMP planning process, a range of alternatives for motorized vehicle access were analyzed after extensive public participation through the Final Coos Bay District Proposed Resource Management Plan/Environmental Impact Statement. Through the Record of Decision and Resource Management Plan that followed the EIS, all of the 1,660 acres in the Coos Bay Shorelands SRMA were formally designated as Limited to Designated Roads and Trails in May 1995. This more controlled alternative was chosen over a Limited to Existing Roads and Trails designation to make this activity more manageable, control route proliferation and to ensure the conservation of sensitive resources on the Spit.

The decision on which roads and trails would be open for use was later resolved through the Coos Bay Shorelands Plan of 1995 when the individual roads and trails were inventoried and then designated as open or closed. The four roads/trails designated as open by this plan were the South Dike Road, the Foredune Road, the Re-Route Road, and the Bay Side Road (Map 3). The remaining trails were then designated as closed to motorized use.

The Coos Bay Shorelands Plan included two management actions that stated OHV use in the sand dune areas on the Spit would be allowed to occur under a permit. Implementation of this permit concept would have made these areas defacto open areas and would have been in conflict with the land use allocation handed down by the Coos Bay District Resource Management Plan. Because this management action was inconsistent with the BLM's own policy and regulations and the Record of Decision for the RMP, these management actions were removed from the Coos Bay Shorelands Plan through a plan maintenance action in 2000.

On the lands immediately adjacent to the BLM parcels on the Spit, OHV recreation is prohibited on the beach between the northern BLM boundary and the Bull Run Sand Road north of Horsfall Beach from May 1 to September 30 to provide for a non-motorized recreation setting. The foredune and forest lands in the ODNRA south of the Horsfall Beach Road to the BLM boundary are closed year-round to OHV use to provide for non-motorized recreation and to protect sensitive resources. The COE lands on the North Jetty are still closed to OHV use, except for motorized use on established roadways. The Oregon Department of Parks and Recreation Department has closed the ocean beach adjacent to BLM to all ATV use and closes the ocean shore to motorized use from March 15 to September 15. On the private parcels and on Port of Coos Bay lands, use is controlled and limited to established roadways where access is allowed.

While OHV cross country use on the North Spit has been officially controlled by federal and state regulations for a long time, actual enforcement of these restrictions is relatively recent. The listing of the snowy plover in 1993 and the grounding of the New Carissa and the subsequent emergency closure in 1999 promoted the agency to place more resources and management focus toward controlling this use on the Spit.

The BLM has placed most of its enforcement efforts in those areas on the Spit with the highest resource values (e.g. snowy plover nesting habitat and interior wetlands). Compliance with OHV designations in these areas has been goodin the interior of the Spit. Compliance varies on the beach and in plover areas. This is not the case in the 80 acre dune area located next to the Roseburg chip facility. This area is used as a defacto "open area" by people who choose not to use the legal and managed OHV open areas, located 1.5 miles away, in the ODNRA.

***New Carissa 2002.***

## Visual Resources

The public lands on the south shore of the North Spit are a dominant visual resource element in the overall scenic backdrop of the Coos Bay estuary. The quality of visual resources directly influences a community's potential for tourism, high-end real estate development, and the area's desirability for business and residential relocation.

Visual resources on the public lands are managed through the BLM's land use planning process. Through this inventory and classification process, public lands are placed in one of four visual resource management classes. These management classes range from the total preservation of the existing landscape in Class I, to allowing major modifications of the landscape character in Class IV (Map 4). The lands on the North Spit were classified in the Coos Bay District RMP as follows:

- Class II. The public lands in the northwest corner of the ACEC and within the SRMA in T25S, R14W, Section 13 and T25S, R13W Section 18 were given this fairly protective classification to preserve the quality of the recreation setting. Objectives for Visual Resource Management in this area are to retain the existing character of landscape. Changes in any of the basic elements (form, line, color, texture) caused by a management activity should not be evident in the characteristic landscape. Contrasts are seen, but must not attract attention.

- Class III. Within two parcels adjacent to the Trans Pacific Lane in T25S, R13W in Sections 5 and 4, public lands were classified as Class III. Objectives for VRM management in these parcels would be to partially retain the existing character of landscape. Contrasts to the basic elements caused by a management activity are evident, but should remain subordinate to the existing landscape.

- Class IV. The majority of the public lands on the North Spit are VRM Class IV. VRM objectives in these areas allow for major modifications of the existing character of the landscape. Contrasts that are created by management activities may attract attention and be a dominant feature of the landscape in terms of scale, but should repeat the form, line, color, and texture of the characteristic landscape.

# PART 4 –NORTH SPIT MANAGEMENT, 2005

## Introduction

Part Four presents management actions on BLM-administered lands for the next ten years. Management actions are described in alphabetical order except for Monitoring and Research which is found at the end of the section. There are no management actions for fish on BLM lands on the Spit. Geology management actions are located under Monitoring and Research.

The aim of the North Spit Plan is to conserve the natural, cultural, and recreational values of the Spit. Management objectives reflect that aim and are consistent with BLM policies and state and federal regulations. These objectives were described in detail in the Draft Shorelands Plan (USDI BLM 1989), incorporated in the Final Shorelands Plan (USDI BLM 1995), and included in North Spit ACEC planning documents (USDI BLM 1999). For the North Spit Plan, these objectives were reviewed and revised based on current conditions and needs, and will be implemented as funding allows. They are listed below, followed by the reasons for action, planned actions, and actions accomplished or ongoing since the 1995 Shorelands Plan. Due to the interrelationship of the various resources at the Spit, many actions apply to more than one objective.

## Management Objectives

**Objective 1 –** Preserve important cultural resources on the Spit.

**Objective 2 –** Promote awareness and appreciation for the Spit's many resource values and recreational opportunities, and support a minimum impact land use ethic through educational programs such as *Leave No Trace* and *Tread Lightly*.

**Objective 3 –** Prioritize land tenure adjustments based on natural resource values and recreational opportunities on non-BLM parcels, consolidation of BLM properties, and the safeguarding of public investments.

**Objective 4** – Manage the North Spit SRMA to provide for a range of recreational opportunities that contribute to meeting traditional as well as projected recreation demand within the region while protecting the area's natural, cultural, and scenic resources.

**Objective 5 –** Provide and maintain adequate visitor facilities, services, signing, and programs that are appropriate for the area's recreation opportunity setting and that serve to protect the Spit's sensitive resources.

**Objective 6 –** Conserve, enhance, or restore natural habitats, with an emphasis on habitats that support special status plant and wildlife species.

**Objective 7 –** Maintain wetland areas in a condition supportive of a healthy aquatic ecosystem.

**Objective 8 –** Facilitate improved management of the Spit through monitoring to learn more about the natural and cultural resources of the area and to assess the effects of management actions.

### Cultural Resources

**Objective 1.** Preserve important cultural resources on the Spit.

### Reasons for Action

- By law, BLM is required to protect cultural resources. These laws include the Archaeological Resources Protection Act, American Indian Religious Freedoms Act, National Historic Preservation Act, and the Native American Graves and Repatriations Act.

- The Coquille Indian Tribe (CIT) and Confederated Tribes of the Coos, Lower Umpqua and Siuslaw Indians (CTCLUSI), both federally-recognized tribes, have expressed concern about protection of cultural sites along the Southern Oregon Coast. The Spit is within the ancestral territory of the CTCLUSI.

### Actions Accomplished or Ongoing

- In 2000, a report was completed by noted historian Stephen Dow Beckham detailing the history of federal activities on the North Spit (Beckham 2000). The majority of this report concerns the construction and maintenance of the North Jetty, beginning in 1890. The history of the U.S. Lifesaving Service station is also described in detail.

- Continue to preserve remaining historic cultural resources.

### Proposed Actions

- Work with the Confederated Tribes of Coos, Lower Umpqua, and Siuslaw Indians as well as the Coquille Indian Tribe to assure continued protection and preservation of prehistoric resources.

- Remove damaged chain link fence from the perimeter of the World War II Quonset huts.

## Environmental Education and Interpretation

**Objective 2.** Promote awareness and appreciation for the Spit's many resource values and recreational opportunities, and support a minimum impact land use ethic through educational programs such as *Leave No Trace* and *Tread Lightly*.

### Reasons for Action

- Environmental education and interpretation can encourage responsible use of the Spit area, thereby reducing resource degradation, violations, and vandalism. Education and interpretation can enhance the visitors' experience.

- Education and interpretation may be used to communicate the BLM's management goals to visitors.

### Environmental Education and Interpretive Themes

The environmental education and interpretation conducted at the Spit should be planned and implemented according to the following themes:

**Theme #1:** The Spit landscape is an intricate web of related parts that is constantly changing due to natural and human actions.

> **Topics:** natural history · system dynamics · interrelationships · ecosystem concepts · plants and animals found at the Spit · dune systems · introduced species · hydrology · biodiversity · threatened and endangered species · habitats

**Theme #2:** Due to its close proximity to both the ocean and Coos Bay, people have used the Spit for a variety of purposes, including recreation, industry, military installations, commerce, transportation, etc.; all of these actions have shaped the land in some way.

> **Topics:** human history · human impacts · land use planning · introduced species · weeds · management goals · New Carissa · recreation opportunities

**Theme #3:** Good stewardship is essential in maintaining the health and integrity of the Spit.

> **Topics:** appropriate behavior · Watchable Wildlife methods · Leave No Trace / Tread Lightly outdoor ethic · management support and challenges · involving visitors

## Actions Accomplished

- A brochure was developed to provide visitors with a map of the Spit and inform them of regulations and opportunities.

- A variety of interpretive signs and a kiosk have been developed and installed at the boat launch ramp, the overlook to the New Carissa, and various access points. Seasonal interpreters have been hired in past summers to educate the public about seasonal closures and recreational opportunities.

## Ongoing Actions

- Continue to host field trips for schools at the Spit for students to learn about the area.

- BLM will continue to work cooperatively with the interagency snowy plover working team on issues pertaining to public education and outreach.

## Proposed Actions

- When a prospectus for environmental education and interpretation is developed for the District, include a section concerning the Spit. Use its recommendations when developing and conducting programs and interpretive materials.

- Utilize seasonal or volunteer interpreter(s) when feasible to contact visitors and disseminate information about the Spit on areas suited for recreation, seasonally closed areas, compliance issues, etc.

- Special educational opportunities may include: National Public Lands Day events, Elderhostel tours, beach clean ups, Christmas bird counts, or similar activities that involve the public.

- Ensure that any interpretation which deals with cultural or paleo-environmental history is coordinated with interested Indian tribes and the Coos Bay District Archaeologist.

- Rotate or replace interpretive displays as needed. Where applicable develop supplemental materials to support interpretation and environmental education, such as informational kiosks, trail guides, brochures, and educational kits.

- Use the draft Western Snowy Plover Outreach Plan (Western Snowy Plover Working Team 2004) when considering any outreach that deals with plovers on the Spit.

- Raise public awareness about the environmental and recreational values of riparian-wetland areas on the Spit.

## Land Tenure Adjustments

**Objective 3.** Prioritize land tenure adjustments based on natural resource values and recreational opportunities on non-BLM parcels, consolidation of BLM properties, and the safeguarding of public investments.

### Reasons for Action

- Adjacent landowner management objectives may not be consistent with BLM's objectives. For example, land ownership patterns on the Spit could limit or stop access to much of the public land.

### Actions Accomplished

- The 1995 Shorelands Plan identified four potential land acquisitions and one disposal. Three acquisitions were accomplished.

### Ongoing Actions

- In accordance with the RMP, BLM-administered lands on the Spit within zoning districts 3-EWD, 4CS, and 6WD as delineated by the Coos County Comprehensive Plan could be offered for exchange, sale, or lease to accommodate local economic expansion and industrial development. A land disposal is currently in progress for an 80 acre BLM parcel north of the Roseburg Chip Facility along the Trans Pacific Lane.

- All of the lands on the Spit administered by the BLM are public domain lands and therefore subject to public land laws. Under these laws, BLM manages for specific uses such as permits, rights-of-way, leases, special use permits, etc. Several utility and access rights-of-way were issued and are currently in use. Future applications for leases, permits, and right-of-ways will be reviewed and authorizations issued on a case-by-case basis.

### Proposed Actions

- Consider land tenure adjustments to ensure access to public lands as appropriate to meet objectives.

## Recreation

**Objective 4.** Manage the North Spit SRMA to provide for a range of recreation opportunities that contribute to meeting traditional as well as projected recreation demand within the region while protecting the area's natural, cultural, and scenic resources.

### Reasons for Action

- The BLM designated the North Spit as an SRMA to preserve opportunities for outdoor recreation and to manage this activity in a manner that is compatible with protecting the natural and cultural resource values of the ACEC.

- Visitors differ widely in their preferences for recreation activities, settings and facilities. Balancing these needs within the limited space available on the North Spit is necessary to provide for a quality resource-based experience, reduce conflicts between users and protect natural resource values.

- The Oregon Parks and Recreation Department Statewide Trail Plan identified trail connectivity between agency management jurisdictions as a key statewide trail management goal. Creating and maintaining connectivity between trail opportunities on BLM lands on the North Spit and the adjacent trail systems managed by the USFS, OPRD, and Weyerhaeuser would enhance overall trail opportunities in the region.

## Actions Accomplished

- Signs were placed at the ocean beach access points along the Foredune Road; other signs and maps were placed at various locations to inform visitors of regulations and recreational opportunities.
- Roads and trails that were not designated open were closed using logs, root wads, and signs. Many of these closed routes are disappearing through natural revegetation.
- A sign strategy was developed to assist BLM in providing information to the public on regulations, recreational opportunities, and natural resources on the Spit.

## Ongoing Actions

- Continue to provide and manage motorized access on the Spit to support the area's long-standing traditional recreation uses while protecting natrual, cultural and scenic resources.
- Manage the North Spit to retain a recreation setting compatible with the area's Rural and Semi-Primitive Motorized ROS classification.
- Provide timely press releases for public service announcements and newspaper notices prior to any seasonal access restrictions as needed.
- Clear sand and debris from the boat ramp each spring prior to reinstalling the docks for the summer season.
- Continue to allow primitive camping on BLM lands on the Spit, except in areas where signed to protect sensitive plants and wildlife.
- Continue to maintain the docks at the boat launch as funding allows.
- Continue to permit hunting and shooting on BLM lands on the Spit in conformance with applicable state and federal laws and regulations. These regulations prohibit shooting adjacent to and across public roadways and within developed recreation sites.

## Proposed Actions

- Increase information available about theNorth Spit,
- Place improved regulatory and information signs along the sand roads and at ocean beach access points. Advise visitors to inspect the three existing access points before they commit to driving onto the beach – the passability of these access points can change on a daily basis due to waves, high tides and winter storms.
- Remove dilapidated fences and fence posts from three locations on the Spit: the fence at the intersection of the Foredune Road and Trans Pacific Lane, the WWII bunker fence, and fencing material from the southern interior.
- Establish trails for pedestrian and equestrian use within the North Spit interior. Develop and support local partnerships to assist in maintaining and managing this trail system.
- Create and maintain connections between trail opportunities on BLM lands and the adjacent trail systems on Forest Service, OPRD and Weyerhaeuser lands.
- Determine feasibility of designating the Foredune Road open to motorized access from the South Dike Road north to the USFS boundary
- Construct a small equestrian and hiking staging area to provide parking and visitor information at the portal to the trail system.

- Implement the completed sign strategy developed to improve communication with Spit visitors.
- Explore the potential for placing picnic tables at the boat launch facility.
- Include information about wildlife viewing opportunities into the educational kiosk proposed for the boat ramp area.

## Site Protection and Administration

**Objective 5.** Provide and maintain adequate visitor facilities, services, signing, and programs that are appropriate for the area's recreation opportunity setting and that serve to protect the Spit's sensitive resources.

### Reasons for Action

- Visitation to the Spit is expected to grow as more people become aware of the area, and as tourism along the southern Oregon Coast increases.
- Facilities, designated roads and trails, signs, and other management tools (e.g., on-site hosts) reduce and prevent resource damage.
- Contracted services with Coos County agencies enhance fire response and law enforcement support for the area.

### Fire Management

### Accomplished and Ongoing Actions

- BLM contracts with the Coos Forest Protection Association for fire response, including the lands on the Spit. Contracted duties might include: specific action and preparedness plans; prevention, detection, initial attack, and suppression services; resource protection; fire notification services; fire investigation; debriefings and contract reviews; and reports.

### Proposed Actions

None at this time.

### Hazardous Materials Management

### Accomplished and Ongoing Actions

See below.

### Proposed Actions

- Finish the sampling and report for the Spit Life Guard Station Environmental Site Characterization.

The structures at the Spit Life Guard Station were serviced by a variety of fueled devices such as generators and power plants. In 1991, the Bureau of Land Management initiated a demolition and removal of the structures, and contracted for the location, assessment and removal of four known underground petroleum storage tanks (USTs) from the site. In late 2002, Oregon Department of Environmental Quality (DEQ) informed the Coos Bay District Hazardous Materials Coordinator that the removal of the USTs had not been finalized and documented under the UST program closure rules. A subsequent records search by BLM concurred. In consultation with DEQ, it was determined that a site assessment was necessary to comply with the state rules and to receive a No Further Action Required determination and closure of the case file. A draft plan for this site assessment and a report to DEQ was prepared, and implementation is planned pending funding. This project is known as the Spit Life Guard

Station Environmental Site Characterization, OR DEQ Log Number 06-91-0030; UST Facility ID # 10718. This is the only hazardous materials project on public lands on the Spit.

### Law Enforcement

#### Accomplished and Ongoing Actions

- BLM Law Enforcement Officers are trained and authorized to enforce federal regulations on BLM lands. The BLM also continues to contract with the Coos County Sheriff's Department, and contribute funds to OPRD for seasonal assistance with beach patrol.

- Continue to have law enforcement officers enforce Federal and Oregon State firearm regulations and encourage shooter safety while on patrol on the Spit.

#### Proposed Actions

None at this time.

### Facility Management

#### Accomplished Actions

None at this time.

#### Ongoing Actions

- Maintain existing facilities at the boat launch recreation area.

#### Proposed Actions

- Consider placing alternative toilet facilities at high use areas.

### Road Maintenance and Improvement

#### Accomplished and Ongoing Actions

None at this time.

#### Proposed Actions

- Consider raising and widening the Re-route Road to minimize the risk of vehicular collisions.

## Vegetation and Wildlife Resources

**Objective 6.** Conserve, enhance, or restore natural habitats, with an emphasis on habitats that support special status plant and wildlife species.

#### Reasons for Action

- The BLM is required to follow federal laws and regulations and has established a policy to prevent the need to list fish, wildlife, and plants under the Endangered Species Act. Furthermore, the BLM is directed to encourage management which will lead to the successful recovery and eventual delisting of federally recognized Endangered Species.

- Over the years, alterations to the habitat have interfered with natural community succession. For example, fires were suppressed, groundwater was pumped, and open sandy areas were vegetated by exotic plants.

- Exotic (non-native) vegetation species, such as European beach grass, and noxious weeds, such as Scotch broom, are replacing native vegetation and opportunistically becoming established on sites otherwise unoccupied by grass or shrub species. This spread of exotic and noxious vegetation is altering habitats and interfering with natural succession.

- Resource and vegetative management is necessary to maintain the natural communities, successional processes, and ecosystem health.

- Historic nesting areas of the Western snowy plover were altered by the introduction of European beach grass, increased predation, and accelerated human access and activity on beaches.

- Balanced management actions ensure protection and limit disturbance to plants and wildlife.

## Vegetation

### Actions Accomplished

- Plant communities were mapped and digitized for use with a Geographic Information System (GIS).

### Ongoing Actions

- Coordinate with other agencies and institutions to restore degraded and disturbed plant communities.

### Proposed Actions

- Complete the study of vegetation alliances to determine the plant associations of the Spit.

- Conduct a complete inventory of the vascular and non-vascular flora of the Spit to document all the present plant species.

## Special Status Plant Species and Communities

### Actions Accomplished

- Pink sandverbena was reintroduced under a cooperative agreement with the Institute of Applied Ecology.

- A permanent vehicle re-route was constructed along the bay side and barriers were installed to protect the Point Reyes bird's-beak population in the saltmarsh.

### Ongoing Actions

- Facilitate the recovery of the pink sandverbena by collecting seeds for dispersal to other sites along the coast. Coordinate conservation activities with management of Western snowy plover.

- In cooperation with the Port and the DSL, maintain protective barriers around the Point Reyes bird's-beak population on the bay side of the Spit.

- Continue inventory and management for SSS.

### Proposed Actions

The following actions only pertain to the North Spit Area of Critical Environmental Concern:

- Implement beach and dune ecosystem restoration for multiple species.
- Establish additional special status plant populations as warranted.
- Develop opportunities for collaborative habitat management to increase the amount of habitat suitable for rare species and to link isolated populations with one another.
- Collect special status plant seeds as necessary for storage at the Berry Botanic Garden's Cryogenic Seed Bank.
- Identify opportunities for restoration of globally ranked plant communities.

## Exotic Plants and Noxious Weeds

### Actions Accomplished

- Gorse was removed from the Coast Guard Lifesaving station.
- Scotch broom was cleared from HRAs.

### Ongoing Actions

- European beach grass is removed annually from HRAs.

### Proposed Actions

- Continue weed treatments on the Spit to remove exotic and noxious species. Use integrated pest management practices, such as fire, mechanical or manual removal, and herbicide application. Restore treated areas by spreading native seed and planting native plants.
- Use best management practices to prevent the further spread of exotic plants and noxious weeds.

## Wildlife

### Actions Accomplished or Ongoing

None at this time.

### Proposed Actions

- Survey suitable habitat for great blue herons and great egret rookeries.
- Conduct wildlife inventories at selected wetlands.
- Survey to locate the nests of protection buffer species raptors: osprey, red-tailed hawk, sharp-shinned hawk and Cooper's hawk.

## Special Status Wildlife Species

### Actions Accomplished or Ongoing

- Continue to implement Western snowy plover conservation actions as directed by the Biological Opinion (USDI FWS 2000). BLM will implement the Western snowy plover Pacific Coast Recovery Plan when finalized. Ongoing actions include the following:

  1. Closing the upper, dry sand portion of the ocean beach to all public access from the FAA Tower south to the BLM boundary during the Western snowy plover nesting season (March 15- September 15 annually; Map 3). The area is clearly marked with ropes and signs. Restrictions on motorized use of the adjacent lower, wet sand area are authorized by OPRD. Inland snowy plover nesting areas on BLM land are also signed closed to all use during the nesting season, and are open to nonmotorized use the remainder of the year.

  2. Removing beachgrass from the inland snowy plover Habitat Restoration Areas (HRAs) to maintain suitable open, sandy habitat suitable for nesting plovers (Map 3).

  3. Administering a contract with the Animal Plant and Health Inspection Service (APHIS) that implements an integrated predator damage management program to protect the plover population from further declines caused by predation. Targeted species include American crows, common ravens, and small mammalian predators. Most traps are located in areas closed to the public (e.g., the HRAs and the upper beach), clearly signed, and are designed to prevent injury to domestic animals and humans.

  4. Administering a contract with the Oregon Natural Heritage Information Center to intensively monitor plover nesting efforts and thereby gauge the success of management actions and determine progress toward plover recovery.

- Continue to coordinate with the FWS to implement recovery plans to protect other threatened and endangered species, as necessary.

- Nest boxes were installed for purple martins.

### Proposed Actions

- Develop and implement survey protocols to locate special status species.

- Actively manage habitats to promote the conservation of special status species and protection buffer species.

## Water Resources

**Management Objective 7**. Maintain wetland areas in a condition supportive of a healthy aquatic ecosystem.

### Reasons for Action

- The BLM has a responsibility to conserve native wildlife and plant species and the ecosystems upon which they depend. Many of these species are associated with wetlands.

### Actions Accomplished

- BLM participated in the creation of wetlands on BLM adjacent to Weyerhaeuser's Overlook wetlands site as part of the Henderson Marsh Mitigation Plan.

### Ongoing Actions

- Consider wetland project proposals consistent with the 1984 Henderson March Mitigation Plan. Proposal will require environmental review.

### Proposed Actions

None at this time.

## Monitoring and Research

**Objective 8.** Facilitate improved management of the Spit through monitoring to learn more about the natural and cultural resources of the area and to assess the effects of management actions.

### Reasons for Action

- Ensure compliance with federal and state laws and regulations.
- Fill existing information gaps to enable the BLM to better manage the area in the future.
- Evaluate existing management strategies to provide feedback on meeting established objectives.
- Broaden human understanding of the area.
- Identify recovery and conservation needs for special status species.
- Identify the nature and extent of human-caused impacts to sensitive resources early enough to take effective action to minimize adverse affects.
- Understand the dynamics of coastal ecosystems.

### Cultural Resources

### Actions Accomplished or Ongoing

None at this time.

### Proposed Actions

- Monitor stability of important cultural resources and propose actions to continue their preservation.

### Environmental Education and Interpretation

### Actions Accomplished or Ongoing

- Evaluate the effectiveness of educational brochures and signs.

### Proposed Actions

- Evaluate the effectiveness of environmental education programs and interpretive materials on a regular basis, and make modifications as necessary.

## Geology

### Actions Accomplished or Ongoing

None at this time.

### Proposed Actions

- Track elevation changes on the ocean foredune and monitor the effects of weather and beach grass removal on foredune erosion.

## Recreation

### Actions Accomplished or Ongoing

- Continue to use traffic and trail counters and field staff observations to monitor visitor use and to report findings in the Recreation Management Information System.

- Continue to monitor camping on BLM lands on the Spit.

### Proposed Actions

- Monitor the condition of beach access routes.

## Vegetation and Wildlife Resources

### Actions Accomplished or Ongoing

- Monitor noxious weed species to document existing population areas, effectiveness of management actions for removal, and the spread of these species to new sites.

- Evaluate and explore effective management strategies to meet recovery goals for the Western snowy plover. Monitor human and natural disturbance effects on breeding plovers.

- Continue to support the Oregon Natural Heritage Information Center in its efforts to monitor Western snowy plover reproductive success.

- Continue to monitor great blue heron and great egret rookeries.

- Continue to monitor selected special status species on the Spit.

- Continue to monitor the condition of riparian-wetland vegetation. If signs of excessive disturbance caused by unauthorized motorized recreation become evident, adjust patrols, signing and barriers to reduce or prevent impacts.

### Proposed Actions

- Monitor special status species' population status and trends. Pursue collaborative efforts to study SSS reproductive ecology, threats, habitats, and effects of management treatments and practices.

- Monitor the status and trends of globally ranked plant communities within the North Spit ACEC.

- Seek collaborative opportunities to survey migratory shorebirds and waterfowl to establish population status and trends.

# Appendix 1. North Spit Plant List.

Preliminary nonvascular and vascular plant species list for the North Spit. Information drawn from Coos Bay District herbarium, staff survey lists, Stansell (1989), Wagner (2000), and Zika et al. (1998). Common names in parentheses, taxonomy as per USDA, NRC (2004), E = exotic or non-native, * = special status species, and # = Bureau tracking species.

**NONVASCULAR PLANTS**
(lichens, sac fungi, club fungi, liverworts, hornworts, and mosses)

KINGDOM FUNGI

CLASS ASCOMYCETES & DISCOMYCETES (Lichens)
**Bryoria pseudocapillaris* Brodo & D.Hawksw. (brown beard lichen)
**Bryoria spiralifera* Brodo & D.Hawksw. (horsehair)
*Cavernularia hultenii* Degel. (Hulten's pitted lichen)
**Erioderma sorediatum* D.J. Galloway & P.M. Jorg. (ncn)
**Heterodermia leucomelos* (L.) Poelt (shield lichen)
*Hypogymnia enteromorpha* (Aceh.) Nyl. (beaded bone lichen)
*Hypogymnia physodes* (L.) Nyl. (hooded bone lichen)
*Hypotrachyna sinuosa* (Sm.) Hale (ncn)
**Leioderma soridiatum* D.J. Galloway & P.M. Jorg. (ncn)
*Nephroma laevigatum* Ach. (seaside kidney lichen)
*Nephroma resupinatum* (L.) Ach. (kidney lichen)
*Parmelia hygrophila* Goward & Ahti (shield lichen)
*Parmelia sulcata* Hale (waxpaper lichen)
*Parmeliopsis hyperopta* (Ach.) Arnold (ncn)
*Parmotrema arnoldii* (Du Rietz) Hale (eyelash lichen)
*Peltigera membranacea* (Ach.) Nyl. (membranous felt lichen)
*Plastismatia glauca* (L.) Culb. & C.Culb. (ragbag)
*Platismatia herrei* (Imshaug) Culb.& C.Culb. (Herre's ragged lichen)
*Pseudocyphellaria anomala* Brodo & Ahti (specklebelly)
*#*Pseudocyphellaria perpetua* McCune & Miadlikowska (ncn)
*Ramalina farinacea* (L.) Ach. (farinose cartilage lichen)
*Ramalina menziesii* Taylor (fishnet lichen)
*Ramalina roesleri* (Hochst. *ex* Schaerer) Hue (ncn)
*Ramalina thraustai* (Ach.) Nyl. (ncn)
*Sphaerophorus globosus* (Hudson) (globe ball lichen)
*Tuckermannopsis chlorophylla* (Willd.) Vainio (ncn) [=*Cetraria chlorophylla*]
*Tuckermannopsis orbata* (Nyl.) Fink (ncn) [=*Cetraria orbata*]

CLASS ASCOMYCOTINA (Sac Fungi)
None known at this time

CLASS HYMENOMYCETES & GASTEROMYCETES (Club Fungi)
*Boletus edulis* Bull. ex Fr. (king bolete, cep, steinpilz, porcini)
*Clavaria purpurea* (purple fairy club)
*Cortinarius allutus* (Secr.) Fr. (ncn)
*Cortinarius brunneus* (ncn)
*Cortinarius californicus* (ncn)

DIVISION BRYOPHYTA

CLASS HEPATICOPSIDE (Liverworts)
Calypogeia azurea Stotler & Crotz (blue pouchwort)
*Cephalozia bicuspidata* (L.) Dum. (two-horned pincerwort)

*Cephalozia lunulifolia* (Dum.) Dum. (ncn)
*Cephaloziella divaricata* (Sm.) Schiffn. (ncn)
**Diplophyllum plicatum* Lindb. (giant folded leaf liverwort)
*Frullania nisquallensis* Sull. (hanging millipede liverwort)
*Geocalyx graveolens* (Schrad.) Nees (ncn)
*Lepidozia reptans* (L.) Dum. (little hands liverwort)
*Lophocolea cuspidata* (Nees) Limpr. (ncn)
*Lophocolea heterophylla* (Schrad.)Dum. (ncn)
*Porella navicularis* (Lehm. & Lindenb.) Pfieff. (tree ruffle liverwort)
*Radula complanata* (L.) Dum. (flat-leaved liverwort)
*Riccardia latifrons* (Lindb.) Lindb. (ncn)
*Scapania bolanderi* Aust. (yellow-ladle liverwort)

CLASS ANTHOCEROTOPSIDA (Hornworts)
None known at this time.

CLASS MUSCOPSIDA (Mosses)
*Aulacomnium androgynum* (Hedw.) Schwaegr. (lover's moss)
*Aulacomnium palustre* (Hedw.) Schwaegr. (ribbed bog moss or glow moss)
*Brachythecium rivulare* Schimp. in B.S.G. (ncn)
*Bryum capillare* Hedw. (ncn)
*Campylium polygamum* (Schimp. in B.S.G.) C. Jens. (ncn)
*Campylopus introflexus* (Hedw.) Brid. (ncn)
*Ceratodon purpureus* (Hedw.) Brid. (red roof moss)
*Claopodium crispifolium* (Hook.) Ren. &Card. (rough moss)
*Dichelyma falcatum* (Hedw.) Myr. (ncn)
*Dicranoweisia cirrata* (Hedw.) Lindb. ex Milde (curly thatch moss)
*Dicranum fuscescens* Turn. (curly Heron's-bill moss)
*Dicranum scoparium* Hedw. (broom moss
*Dicranum tauricum* Sapeh. (broken-leaf moss)
*Drepanocladus aduncus* (Hedw.)Warnst. (ncn)
*Drepanocladus sendtner* (Schimp.)Warnst. (ncn)
*Eurhynchium oreganum* (Sull.) Jaeg. (Oregon beaked moss)
*Eurhynchium praelongum* (Hedw.) Schimp. in B.S.G. (slender beaked moss*)*
*Homalothecium fulgescens* (Mitt. ex C. Muell.) Lawt. (yellow moss)
*Homalothecium pinnatifidum* (Sull. & Lesq.) Lawt. (ncn)
*Hylocomium splendens* (Hedw.) Schimp. in B.S.G. (stair step moss)
*Hypnum circinale* Hook. (coiled-leaf moss)
*Isothecium stoloniferum* Brid. (cat-tail moss)
*Neckera douglasii* Hook. (Douglas' neckera)
*Orthotrichum consimile* Mitt. (ncn)
*Orthotrichum lyellii* Hook. & Tayl. (Lyell's bristle moss)
*Plagiothecium undulatum* (Hedw.) Schimp. in B.S.G. (wavy-leaved cotton moss)
*Pohlia wahlenbergii* (Web. &Mohr)Andrews (ncn)
*Polytrichum juniperinum* Hedw. (juniper haircap moss)
*Polytrichum piliferum* Hedw. (awned haircap moss)
*Pseudotaxiphyllum elegans* (Brid.) Iwats. (small flat moss)
*Racomitrium elongatum* Ehrh. ex Frisv. (roadside rock moss)
*Rhizomnium glabrescens* (Kindb.)T. Kop. (fan moss)
*Tortula princes* De Not. (ncn)
*Trachybryum megaptilum* (Sull.) Schof. (ncn)
*Ulota phyllantha* Brid. (ncn)

**VASCULAR PLANTS**

FERNS AND FERN ALLIES

DENNSTAEDTIACEAE — BRACKEN FERN FAMILY
*Pteridium aquilinum* (L.) Kuhn var. *pubescens* Underwood (northern bracken fern)

DRYOPTERIDACEAE — WOOD FERN FAMILY
*Polystichum munitum* (Kaulfuss) K. Presl (pineland sword fern)

POLYPODIACEAE — POLYPODY FAMILY
*Polypodium scouleri* Hook. & Grev. (leathery polypody)

GYMNOSPERMS

CUPRESSACEAE — CYPRESS FAMILY
*Chamaecyparis lawsoniana* (A. Murray) Parl (Port-Orford-cedar)

PINACEAE — PINE FAMILY
*Pinus contorta* Dougl. ex Loud. var. *contorta* (shore pine)
*Pinus attenuata* Lemmon (knob-cone pine)
*Picea sitchensis* (Bong.) Carr. (Sitka spruce)
*Pseudotsuga menziesii* (Mirbel.) Franco var. *menziesii* (Douglas-fir)

DICOTYLEDONS

APIACEAE — CARROT FAMILY
*Angelica lucida* L. (seacoast angelica)
*Glehnia littoralis* F. Schmidt ex Miq. (American silvertop)
*Lilaeopsis occidentalis* Coult. & Rose (western grasswort)

ARALIACEAE — GINSENG FAMILY
*Hedera helix* L. (English-ivy) E

ASTERACEAE — ASTER FAMILY
*Achillea millefolium* L. (common yarrow)
*Ambrosia chamissonis* (Less.) Greene (silver burr-ragweed) E
*Anaphalis margaritacea* (L.) Benth. (pearly-everlasting)
*Artemisia pycnocephala* (Less.) DC. (beach wormwood)
*Baccharis pilularis* DC. (coyotebrush)
*Cirsium arvense* (L.) Scop. (Canadian thistle) E
*Corethrogyne californica* var. *obovata* DC. var. *obovata* (Benth.) Kuntze (California sandaster)
*Erechtites glomerata* (Desf. ex Poir.) DC. (cut-leaf burnweed) [=*E. arguta*]
*Erechtites minima* (Poir.) DC. (coastal burnweed) E
*Gamochaeta purpurea* (L.) Cabrera (spoon-leaf purple everlasting) [=*Gnaphalium chilense*]
*Grindelia stricta* DC. (Oregon gumweed)
*Hieracium albiflorum* Hook. (white-flower hawkweed)
*Hypochaeris radicata* L. (hairy cat's-ear) E
*Jaumea carnosa* (Less.) Gray (marsh jaumea)
*Leontodon taraxacoides* (Vill.) Mérat ssp. *taraxacoides* (lesser hawkbit) [=*L. leysseri*] E
*Pseudognaphalium stramineum* (Kunth) A. Anderb. (cotton-batting-plant) [=*Gnaphalium purpureum*]
*Sonchus* L. (sow-thistle) E
*Symphyotrichum chilense* (Nees) Nesom (Pacific American-aster) [=*Aster chilense*]
*Tanacetum camphoratum* Less. (camphor tansy) E

BETULACEAE — BIRCH FAMILY
*Alnus rubra* Bong. (red alder)

BRASSICACEAE — MUSTARD FAMILY
*Brassica rapa* L. var. *rapa* (rape) E
*Cakile edentula* (Bigelow) Hook. (American searocket)
*Cakile maritima* Scop. (European searocket) E
*Cardamine nuttallii* Greene var. *nuttallii* (Nuttall’s toothwort)
*Draba verna* L. (spring whitlow-grass)
*Raphanus sativus* L. (radish) E

CAPRIFOLIACEAE — HONEYSUCKLE FAMILY
*Lonicera involucrata* (Richards.) Banks ex Spreng. (four-line honeysuckle)
*Sambucus nigra* L. ssp. *caerulea* (Raf.) R. Bolli (black elder)

CARYOPHYLLACEAE — PINK FAMILY
*Cardionema ramosissimum* (Weinm.) A. Nels. & J.F. Macbr. (sandcarpet)
*Cerastium arvense* L. (field mouse-ear chickweed) E
*Honckenya peploides* (L.) Ehrh. (seaside sandplant)
*Spergularia canadensis* (Pers.) G. Don (Canadian sandspurry)
*Spergularia macrotheca* (Hornem.) Heynh. (sticky sandspurry)
*Spergularia salina* J. & K. Presl (saltmarsh sandspurry) [=*S. marina*]

CHENOPODIACEAE — GOOSEFOOT FAMILY
*Atriplex patula* L. (halberd-leaf orache)
*Atriplex prostrata* Bouchér ex DC. (hastate orache) [=*A. hastata*]
*Salicornia depressa* Standl. (woody saltwort) [=*S. virginica*]

CONVOLVULACEAE — MORNING-GLORY FAMILY
*Calystegia soldanella* (L.) R. Br. (seashore false bindweed)

CUSCUTACEAE — DODDER FAMILY
*Cuscuta salina* Engelm. var. *major* (Yuncker goldenthread)

ERICACEAE — HEATH FAMILY
*Arbutus menziesii* Pursh (Pacific madrone)
*Arctostaphylos columbiana* Piper (bristly manzanita) [includes *A. tracyi*]
*Arctostaphylos uva-ursi* (L.) Spreng. (red bearberry)
*Gaultheria shallon* Pursh (salal)
*Vaccinium ovatum* Pursh (evergreen blueberry)
*Vaccinium oxycoccos* L. (small cranberry)
*Vaccinium uliginosum* L. (alpine blueberry)

FABACEAE — PEA FAMILY
*Cytisus scoparius* (L.) Link (Scotch broom) E
Genista monspessulana (L.) L. Johnson (French broom) E
*Lathyrus japonicus* Willd. (sea vetchling)
*Lotus corniculatus* L. (garden bird’s-foot-trefoil)
*Lotus unifoliolatus* (Hook.) Benth. (American bird’s-foot-trefoil)
*Lupinus littoralis* Dougl. (Chinook lupine)
*Medicago lupulina* L. (black medick)
*Melilotus officinalis* (L.) Lam. (yellow sweet-clover) [=*M. alba*]
*Trifolium arvense* L. (rabbit-foot clover)
*Trifolium pratense* L. (red clover)
*Trifolium repens* L. (white clover) E
*Trifolium wormskioldii* Lehm. (cow clover)
*Ulex europaeus* L. (common gorse) E

*Veronica scutellata* L. (grass-leaf speedwell)
*Vicia americana* Muhl. ex Willd. (American purple vetch)
*Vicia hirsuta* (L.) S.F. Gray (tiny vetch)

GENTIANACEAE — GENTIAN FAMILY
*Centaurium erythraea* Rafn (European centaury) E
*Gentiana sceptrum* Griseb. (king's-scepter gentian)

GERANIACEAE — GERANIUM FAMILY
*Geranium* sp. L. (crane's-bill) E

GROSSULARIACEAE — CURRANT FAMILY
*Ribes sanguineum* Pursh (blood currant)

MYRICACEAE — BAYBERRY FAMILY
*Morella californica* (Cham.) Wilbur (Pacific bayberry) [=*Myrica californica*]

NYCTAGINACEAE — FOUR-O'CLOCK FAMILY
**Abronia latifolia* Eschsch. (yellow sandverbena)
*#*Abronia umbellata* Lam. ssp. *breviflora* (Standl.) Munz (pink sandverbena)

ONAGRACEAE — EVENING-PRIMROSE FAMILY
*Camissonia cheiranthifolia* (Hornem. ex Spreng.) Raimann (beach suncup)
*Epilobium ciliatum* Raf. (fringed willowherb) [=*E. franciscanum*]
*Ludwigia peploides* (Kunth) Raven (floating primrose-willow)

PLANTAGINACEAE — PLANTAIN FAMILY
*Plantago maritima* L. var. *juncoides* (Lam.) Gray (goosetongue)

PLUMBAGINACEAE — LEADWORT FAMILY
**Limonium californicum* (Boiss.) Heller (western marsh-rosemary)

POLYGONACEAE — BUCKWHEAT FAMILY
*Polygonum paronychia* Cham. & Schlecht. (beach knotweed)
*Rumex acetosella* L. (common sheep sorrel) E
*Rumex* sp. L. (dock, sorrel)

PORTULACACEAE — PURSLANE FAMILY
*Claytonia perfoliata* Donn ex Willd. ssp. *perfoliata* (miner's-lettuce) [=*Montia perfoliata*]

PRIMULACEAE — PRIMROSE FAMILY
*Anagallis minima* (L.) Krause (chaffweed)
*Glaux maritima* L. (sea-milkwort)

RANUNCULACEAE — BUTTERCUP FAMILY
*Ranunculus flammula* L. var. *flammula* (greater creeping spearwort)

ROSACEAE — ROSE FAMILY
*Argentina egedii* (Wormsk.) Rydb. (Pacific silverweed) [=*Potentilla pacifica*]
*Fragaria chiloensis* (L.) P. Mill. (beach strawberry)
*Galium aparine* L. (sticky-willy)
*Malus fusca* (Raf.) Schneid. (Oregon crabapple)
*Rubus armeniacus* Focke (Himalayan blackberry) [=*R. procerus, R. discolor*] E
*Rubus spectabilis* Pursh (salmon raspberry)
*Rubus ursinus* Cham. & Schlecht. (California dewberry)

SALICACEAE — WILLOW FAMILY
*Salix hookeriana* Barratt ex Hook. (coastal willow)

VIOLACEAE — Violet Family
*Viola* spp. (ndentification pending)

SCROPHULARIACEAE — FIGWORT FAMILY
*Castilleja ambigua* Hook. & Arn. ssp. *ambigua* (johnnynip) [=*Orthocarpus castillejoides*]
**Cordylanthus maritimus* ssp. *palustris* (Behr) Chuang & Heckard (Point Reyes bird's-beak)
*Nuttallanthus texanus* (Scheele) D.A. Sutton (Texas toadflax)
*Parentucellia viscosa* (L.) Caruel (yellow glandweed) E

<u>MONOCOTYLEDONS</u>

CYPERACEAE — SEDGE FAMILY
*Carex lenticularis* Michx. var. *limnophila* (Holm) Cronq. (lakeshore sedge)
*Carex lyngbyei* Hornem. (Lyngbye's sedge)
*Carex obnupta* Bailey (slough sedge)
*Carex pansa* Bailey (sand-dune sedge)
*Carex unilateralis* Mackenzie (one-sided sedge)
*Carex viridula* Michx. ssp. *viridula* (little green sedge)
*Eleocharis macrostachya* Britt. (pale spike-rush)
*Eleocharis obtusa* (Willd.) J.A. Schultes (blunt spike-rush)
*Eleocharis palustris* (L.) Roemer & J.A. Schultes (common spike-rush)
*Schoenoplectus americanus* (Pers.) Volk. ex Schinz & R. Keller (chairmaker's club-rush)
[=*Scirpus americanus*]
*Schoenoplectus maritimus* (L.) Lye (saltmarsh club-rush)

IRIDACEAE — IRIS FAMILY
*Sisyrinchium californicum* (Ker-Gawl.) Ait. (golden blue-eyed-grass)

JUNCACEAE  RUSH FAMILY
*Juncus effusus* L. (lamp rush)
*Juncus falcatus* E. Mey. (sickle-leaf rush)
*Juncus gerardii* Loisel. (saltmarsh rush)
*Juncus lesueurii* Boland. (salt rush)

JUNCAGINACEAE — ARROW-GRASS FAMILY
*Triglochin concinna* Burtt-Davy (slender arrow-grass)
*Triglochin maritima* L. (seaside arrow-grass)
*Triglochin striata* Ruiz & Pavón (three-rib arrow-grass)

LILIACEAE -- LILY FAMILY
*Lilium columbianum* hort. ex Baker (Columbian lily)

ORCHIDACEAE — Orchid Family
*Goodyera oblongifolia* Raf. (green-leaf rattlesnake-plantain)
*Listera* sp. R. Br. ex Ait. f. (twayblade)
*Spiranthes romanzoffiana* Cham. (hooded ladies'-tresses)

POACEAE — GRASS FAMILY
*Agrostis stolonifera* L. (spreading bent) E
*Aira praecox* L. (early silver-hair grass)
*Ammophila arenaria* (L.) Link (European beach grass) E
*Bromus hordeaceus* L. (soft brome) E
*Bromus tectorum* L. (cheat grass) E
*Cynosurus echinatus* L. (bristly dog's-tail grass) E

*Dactylis glomerata* L. (orchard grass) E
*Distichlis spicata* (L.) Greene (coastal salt grass)
*Festuca idahoensis* Elmer (bluebunch fescue)
*Festuca rubra* L. (red fescue)
*Holcus lanatus* L. (common velvet grass) E
*Hordeum brachyantherum* Nevski (meadow barley)
*Hordeum jubatum* L. (fox-tail barley)
*Leymus mollis* (Trin.) Pilger (American lyme grass)
*Parapholis incurva* (L.) C.E. Hubbard (curved sickle grass)
*Poa confinis* Vasey (coastline blue crass)
*Puccinellia nuttalliana* (J.A. Schultes) A.S. Hitchc. (Nuttall's alkali grass)
**#Puccinellia pumila* (Vasey) A.S. Hitchc. (dwarf alkali grass)

# Appendix 2. North Spit Wildlife List.

Wildlife inventories are incomplete for the North Spit. Information on birds was drawn from staff observations and detailed data on the birds of Coos County (Contreras 1998). Information on other wildlife species is based on habitat associations, BLM files, and documented observations. Questions marks refer to information that is speculative.

**BIRDS**
**Legend**

Status:

**B**- breeding species
**M**- migrant (usually May/June and August-October)
**MS**- spring migrant only (usually May-June)
**MF**- fall migrant only (usually August-October)
**PB**- post breeding migrant (typically appearing in summer/fall)
**W-** wintering species (normally Oct/Nov- April/May)
**Y**- Year-round resident
**O**- offshore species occasionally seen from land
**S**- over-summering nonbreeder (typically, a few birds seen most years into summer)

Abundance:

**C-** common to abundant, easily observed in appropriate habitat.
**FC**- fairly common, usually observed in appropriate habitat.
**U**- uncommon, not always observed in appropriate habitat.
**R**- rare, not seen every year.
**V**- vagrant, very rare species with few records.
**I**- irregular, numbers fluctuate year-to-year.
**D**- dead specimen found on beach.

**Bolded** species are probable breeders.

SWANS/GEESE/DUCKS (Family Anatidae)

Tundra Swan (*Cygnus columbianus)* **W-U**
Greater White-fronted Goose (*Anser albifrons)* **MF-U, MS-R**
Snow Goose (*Chen caerulescens*) **M-R**
**Canada Goose** (*Branta Canadensis)* **Y-C**
Canada Goose (Aleutian subspecies, *Branta canadensis ssp. leucopareia)* **M-U**
Emperor Goose (*Chen canagica*) **V**
Brant *(Branta bernicula*) **MS-C, W-U, MF-U, OS-R**
**Wood Duck** *(Aix sponsa)* **Y-U**
American Wigeon *(Anas americana)* **W-C**
Eurasian Wigeon (*Anas penelope)* **W-U**
Green-winged Teal *(Anas crecca)* **W-C, OS-R**
**Mallard** *(Anas platyrhynchos*) **Y-C**
Gadwall *(Anas strepera*) **W-U, OS-R**
**Northern Shoveler** (*Anas clypeata)* **W-FC, B-R**
Northern Pintail *(Anas acuta*) **W-C, OS-R**
Cinnamon Teal *(Anas cyanoptera)* **M-U**
Blue-winged Teal (*Anas discors)* **MS-U, MF-R**
Canvasback (*Aythya valisineria )* **W-C, OS-R**
Redhead *(Aythya Americana)* **M-U, W-I**
**Ring-necked Duck** (*Aythya collaris)* **Y-C, B-R**

Greater Scaup *(Aythya marila)* **W-C, OS-U**
Lesser Scaup *(Aythya affinis*) **W-U, OS-R**
Steller's Eider (*Polysticta stelleri*) **V**
Harlequin Duck (*Histrionicus histrionicus*) **W-U**
Long-tailed Duck (*Clangula hyemalis)* **W-U**
Black Scoter *(Melanitta nigra)* **W-U**
Surf Scoter *(Melanitta perspicillata)* **W-C**
White-winged Scoter *(Melanitta fusca)* **W-U**
Common Goldeneye (*Bucephala clangula*) **W-C**
Barrow's Goldeneye (*Bucephala islandica*) **W-R**
Bufflehead *(Bucephala albeola)* **W-C, OS-R**
Red-breasted Merganser *(Mergus serrator)* **W-C**
Hooded Merganser (*Lophodytes cucullatus)* **W-U**
**Ruddy Duck** (*Oxyura jamaicensis)* **W-C, B-R**

PHEASANT (Family Phasianidae)

**Ring-necked Pheasant** *(Phasianus colchicus*) **Y-U**

QUAIL (Family Odontophoridae)

California Quail *(Callipepla californica*) **Y-R?**

LOONS (Family Gaviidae)

Common Loon *(Gavia immer*) **W-C, OS-U**
Pacific Loon *(Gavia pacifica*) **W-FC**
Red-throated Loon *(Gavia stellata*) **W-FC**
Yellow-billed Loon (*Gavia adamsii)* **V**

GREBES (Family Podicipedidae)

**Pied-billed Grebe** (*Podilymbus podiceps)* **Y-U**
Red-necked Grebe (*Podiceps grisegena)* **W-FC**
Horned Grebe (*Podiceps auritus )***W-C**
Eared Grebe (*Podiceps nigricollis)* **W-U**
Western Grebe (*Aechmophorus occidentalis)* **W-C, OS-R**
Clark's Grebe (*Aechmophorus clarkii)* **W-U**

SHEARWATERS (Family Procellariidae)

Northern Fulmar (*Fulmarus glacialis)* **O: MF-U, W-U**
Murphy's Petrel (*Pterodroma ultima*) **D**
Sooty Shearwater (*Puffinus griseus )* **O: MF-C, W-R**

STORM-PETRELS (Family Hydrobatidae)

Fork-tailed Storm-Petrel (*Oceanodroma furcata*) **O: M-R, W-R**
Leach's Storm-Petrel (*Oceanodroma leucorhoa*) **V**

PELICANS (Family Pelecanidae)

Brown Pelican (*Pelecanus occidentalis)* **PB-C**
American White Pelican (*Pelecanus erythrorhynchos)* **V**

CORMORANTS (Family Phalacrocoracidae)

**Double-crested Cormorant** (*Phalacrocorax auritus)* **Y-C**
Pelagic Cormorant (*Phalacrocorax pelagicus)* **Y-C**
Brandt's Cormorant (*Phalacrocorax penicillatus)* **Y-U**

HERONS (Family Ardeidae)

**American Bittern** (*Botaurus lentiginosus)* **B-U, W-R**
**Great Blue Heron** *(Ardea herodias)* **Y-C**
**Great Egret** *(Casmerodius albus)* **Y-C**
Snowy Egret (*Egretta thula*) **W-R**
Cattle Egret (*Bubulcus ibis*) **V**
**Green Heron** (*Butorides virescens*) **B-U**
Black-crowned Night-Heron (*Nycticorax nycticorax*) **M-R**

IBIS (Family Threskiornithidae)

White-faced Ibis (*Plegadis chihi*) **V**

VULTURES (Family Cathartidae)

**Turkey Vulture** *(Cathartes aura)* **B-C**

KITES/HAWKS/EAGLES (Family Accipitridae)

**Osprey** *(Pandion haliaetus*) **B-C, W-R**
**White-tailed Kite** *(Elanus caeruleus)* **W-C, B-R?**
Bald Eagle *(Haliaeetus leucocephalus*) **Y-U**
**Northern Harrier** *(Circus cyaneus*) **W-C, B-R**
**Sharp-shinned Hawk** *(Accipiter striatus*) **Y-U, B-R?**
**Cooper's Hawk** *(Accipiter cooperii*) **Y-U, B-R?**
**Red-tailed Hawk** *(Buteo jamaicensis*) **Y-FC**
Rough-legged Hawk (*Buteo lagopus*) **MF-R, W-I**
**Red-shouldered Hawk** (*Buteo lineatus*) **W-FC, B-R?**

FALCONS (Family Falconidae)

American Kestrel (*Falco sparverius*) **M-U**
Merlin *(Falco columbarius*) **W-U**
Peregrine Falcon *(Falco peregrinus*) **Y-U**
Prairie Falcon (*Falco mexicanus*) **V**
Gyrfalcon (*Falco rusticolus* ) **V**

RAILS/COOTS (Family Rallidae)

**Virginia Rail** *(Rallus limicola*) **Y-U**
**Sora** *(Porzana carolina*) **B-U, W-R**
American Coot *(Fulica americana*) **W-FC**

PLOVERS (Family Charadriidae)

Black-bellied Plover *(Pluvialis squatarola*) **W-U, M-FC**
Pacific Golden-plover (*Pluvialis fulva)* **MF-U, MS-R**
American Golden-plover (*Pluvialis dominica)* **MF-U, MS-R**
**Semipalmated Plover** *(Charadrius semipalmatus*) **Y-FC, B-R**
**Snowy Plover** (*Charadrius alexandrinus)* **Y-U**
**Killdeer** *(Charadrius vociferus*) **Y-C**

OYSTERCATCHER (Family Haematopodidae)

Black Oystercatcher (*Haematopus bachmani)* **W-U**

STILTS/AVOCETS (Family Recurvirostridae)

Black-necked Stilt (*Himantopus mexicanus)* **V**
American Avocet (*Recurvirostra americana)* **M-R**

SANDPIPERS (Family Scolopacidae)

Greater Yellowlegs *(Tringa melanoleuca*) **M-C, W-U**
Lesser Yellowlegs *(Tringa flavipes*) **M-U**
Wandering Tattler (*Heteroscelus incanus*) **M-U**
**Spotted Sandpiper** *(Actitus macularia*) **B-U, W-R**
Solitary Sandpiper (*Tringa solitaria*) **M-R**
Willet (*Catoptrophorus semipalmatus)* **M-U**
Whimbrel *(Numenius phaeopus*) **M-C**
Long-billed Curlew (*Numenius americanus)* **M-U**
Marbled Godwit (*Limosa fedoa)* **M-U, W-R**
Ruddy Turnstone (*Arenaria inter)* **M-U**
Black Turnstone *(Arenaria interpres*) **M-FC**, **W-FC**
Sanderling (*Calidris alba)* **W-C, OS-R**
Surfbird **(***Aphriza virgata***)** **W-U**
Red Knot (*Calidris canutus)* **M-U**
Semipalmated Sandpiper (*Calidris pusilla)* **MF-U, MS-R**
Red-necked Stint (*Calidris ruficollis*) **V**
Little Stint (*Calidris minuta*) **V**
Western Sandpiper *(Calidris mauri*) **M-C, W-U, OS-R**
Least Sandpiper *(Calidris minutilla*) **M-C, W-U, OS-R**
Baird's Sandpiper (*Calidris bairdii)* **MF-U, MS-R**
Pectoral Sandpiper (*Calidris melanotos)* **M-FC, MS-R**
Rock Sandpiper (*Calidris ptilocnemis*) **W-U**
Dunlin *(Calidris alpina*) **M-C, W-U**
Curlew Sandpiper (*Calidris ferruginea*) **V**
Stilt Sandpiper (*Calidris himantopus)* **MF-R**
Buff-breasted Sandpiper (*Tryngites subruficollis)* **MF-U**
Ruff (*Philomachus pugnax)* **MF-R**
Upland Sandpiper (*Bartramia longicauda)* **V**
Short-billed Dowitcher *(Limnodromus griseus*) **M-C, OS-R**
Long-billed Dowitcher *(Limnodromus scolopaceus*) **M-C, W-U, OS-R**
Wilson's Snipe *(Gallinago delicata*) **W-FC**
**Wilson's Phalarope** (*Phalaropus tricolor*) **M-R, B-R**
Red-necked Phalarope *(Phalaropus lobatus*) **M-U**
Red Phalarope (*Phalaropus fulicaria)* **O: M-U, W-I**

GULLS/TERNS (Family Laridae)

Pomarine Jaeger (*Stercorarius pomarinus*) **O: M-R**
Parasitic Jaeger (*Stercorarius parasiticus*) **O: M-R**
Franklin's Gull (*Larus pipixcan*) **M-R**
Bonaparte's Gull *(Larus philadelphia*) **M-U, W-I**
Little Gull (*Larus minutus*) **V**
Heermann's Gull (*Larus heermanni*) **PB-FC**
California Gull *(Larus californicus*) **W-C, PB-C, OS-U**
**Western Gull** *(Larus occidentalis*) **Y-C**
Glaucous-winged Gull *(Larus glaucescens*) **W-C**

Glaucous Gull (*Larus hyperboreus)* **W-R**
Herring Gull (*Larus argentatus*) **W-U**
Thayer's Gull (*Larus thayeri)* **W-U**
Mew Gull (*Larus canus)* **W-C**
Ring-billed Gull (*Larus delawarensis)* **W-C, OS-U**
Black-legged Kittiwake (*Rissa tridactyla)* **O: W-FC**
Red-legged Kittiwake (*Rissa brevirostris*) **V, D**
Sabine's Gull (*Xema sabini*) **O: M-R**
Elegant Tern (*Sterna elegans)* **PB-I**
Caspian Tern *(Sterna caspia)* **M-C, OS-U**
Common Tern (*Sterna hirundo*) **M-R**

AUKS (Family Alcidae)

Common Murre *(Uria aalge*) **Y-C**
**Pigeon Guillemot** (*Cepphus columba)* **B-C, W-R**
Marbled Murrelet *(Brachyramphus marmoratus*) **O: Y-U**
Rhinoceros Auklet (*Cerorhinca monocerata)* **Y-R**
Cassin's Auklet (*Ptychoramphus aleuticus*) **O: M-R**
Xantus' Murrelet (*Synthliboramphus hypoleucus*) **D**
Ancient Murrelet (*Synthliboramphus antiquus*) **O: W-R**
Tufted Puffin (*Fratercula cirrhata*) **O: M-R**
Horned Puffin (*Fratercula corniculata*) **D**

PIGEONS/DOVES (Family Columbidae)

**Rock Pigeon** (*Columba livia*) **Y-C**
**Band-tailed Pigeon** *(Columba fasciata*) **M-U, B-R?**
**Mourning Dove** *(Zenaida macroura*) **B-C, W-R**

OWLS (Family Strigidae)

**Great-horned Owl** *(Bubo virginianus*) **Y-U, B-U**
Snowy Owl (*Bubo scandiaca*) **V**
Short-eared Owl (*Asio flammeus*) **MF-R, W-R**
Western Screech-Owl (*Otus kennicottii)* **Y-R?**
Burrowing Owl (*Athene cunicularia*) **M-R**, **W-R**

NIGHTJARS (Family Caprimulgidae)

**Common Nighthawk** *(Chordeiles minor*) **M-U, B-R?**

SWIFTS (Family Apodidae)

Black Swift (*Cypseloides niger*) **MS-U**
**Vaux's Swift** (*Chaetura vauxi*) **M-FC, B-R?**

HUMMINGBIRDS (Family Trochilidae)

**Anna's Hummingbird** *(Calypte anna*) **Y-U**
**Rufous Hummingbird** *(Selasphorus rufus*) **B-C**

KINGFISHER (Family Alcedinidae)

**Belted Kingfisher** *(Ceryle alcyon)* **Y-C**

<u>WOODPECKERS</u> (Family Picidae)

**Northern Flicker** *(Colaptes auratus)* **Y-C**
**Downy Woodpecker** *(Picoides pubescens*) **Y-U**
**Hairy Woodpecker** *(Picoides villosus*) **Y-U**
**Pileated Woodpecker** *(Dryocopus pileatus)* **Y-U**
Red-breasted Sapsucker (Sphyrapicus ruber) **Y-R, B?**

<u>FLYCATCHERS</u> (Family Trannidae)

**Olive-sided Flycatcher** *(Contopus borealis*) **B-U**
**Western Wood-Pewee** *(Contopus sordidulus*) **M-FC**, **B-U**
Willow Flycatcher (*Empidonax traillii*) **M-U**
Hammond's Flycatcher (*Empidonax hammondii*) **M-R**
Dusky Flycatcher (*Empidonax oberholseri*) **M-R**
**Pacific Slope Flycatcher** *(Empidonax difficilis*) **B-C**
**Black Phoebe** *(Sayornis nigricans*) **W-C, B-U**
Say's Phoebe (*Sayornis saya*) **M-R**
Ash-throated Flycatcher (*Myiarchus cinerascens*) **M-R**
Tropical Kingbird (*Tyrannus melancholicus*) **PB-R**
Western Kingbird (*Tyrannus verti*) **M-R**
Scissor-tailed Flycatcher (*Tyrannus forficatus*) **V**

<u>SHRIKES</u> (Family Lannidae)

Northern Shrike (*Lanius excubitor)* **W-U**
Loggerhead Shrike (*Lanius ludovicianus*) **V**

<u>VIREOS</u> (Family Vireonidae)

**Hutton's Vireo** *(Vireo huttoni*) **Y-U**
**Warbling Vireo** *(Vireo gilvus*) **M, B-R**
Cassin's Vireo (*Vireo cassinii)* **M-R**

<u>JAYS/CROWS/RAVENS</u> (Family Corvidae)

**Steller's Jay** *(Cyanocitta stelleri*) **Y-C**
Western Scrub-Jay (*Aphelocoma californica*) **M-R**
**American Crow** *(Corvus brachyrhynchos*) **Y-C**
**Common Raven** *(Corvus corax)* **Y-C**

<u>HORNED LARKS</u> (Family Alaudidae)

Streaked Horned Lark (*Eremophila alpestris strigata)* **M-U, W-R**

<u>SWALLOWS</u> (Family Hirundinidae)

**Tree Swallow** *(Tachycineta bicolor*) **B-C, W-R**
**Violet-green Swallow** *(Tachycineta thalassina*) **B-U**
**Purple Martin** *(Progne subis*) **B-U**
**Northern Rough-winged Swallow** *(Stelgidopteryx serripennis*) **B-U**
**Barn Swallow** *(Hirundo rustica*) **B-FC**
**Cliff Swallow** *(Hirundo pyrrhonota)* **B-C**
Bank Swallow *(Riparia riparia)* **M-R**

<u>CHICKADEES</u> (Family Paridae)

**Black-capped Chickadee** *(Parus atricapillus*) **Y-C**
**Chestnut-backed Chickadee** *(Parus rufescens*) **Y-C**

BUSHTITS (Family Aegithalidae)

**Bushtit** *(Psaltriparus minimus*) **Y-U**

NUTHATCHES (Family Sittidae)

**Red-breasted Nuthatch** *(Sitta canadensis*) **B-U, W-I**
White-breasted Nuthatch (*Sitta carolinensis*) **V**

CREEPERS (Family Certhiidae)

**Brown Creeper** *(Certhia americana*) **W-U, B-R**

WRENS (Family Troglodytidae)

**Marsh Wren** *(Cistothorus palustris*) **Y-C**
**Bewick's Wren** *(Thryomanes bewickii)* **Y-FC**
**Winter Wren** (*Troglodytes troglodytes*) **W-C, B-U**
House Wren *(Troglodytes aedon*) **M-R**
Rock Wren (*Salpinctes obsoletus*) **V**
Sedge Wren (Cistothorus platensis) **V**

KINGLETS (Family Regulidae)

Ruby-crowned Kinglet *(Regulus calendula)* **W-C**
**Golden-crowned Kinglet** *(Regulus satrapa*) **Y-C**

GNATCATCHERS (Family Sylviidae)

Blue-gray Gnatcatcher (*Polioptila caerulea*) **V**

THRUSHES (Family Turdidae)

Western Bluebird (Sialia mexicana) **M-R, W-R**
Mountain Bluebird (*Sialia currucoides*) **V**
Varied Thrush *(Ixoreus naevius*) **W-C**
**Swainson's Thrush** (*Catharus ustulatus*) **B-C**
Hermit Thrush *(Catharus guttatus*) **W-FC**
**American Robin** *(Turdus migratorius*) **Y-C**

WRENTIT (Family Timaliidae)

**Wrentit** *(Chamaea fasciata*) **Y-C**

MIMIC THRUSHES (Family Mimidae)

Northern Mockingbird *(Mimus polyglottus*) **Y-R**
Sage Thrasher (*Oreoscoptes montanus*) **V**

STARLINGS (Family Sturnidae)

**European Starling** (*Sturnus vulgaris*) **Y-C**

PIPITS (Family Motacillidae)
American Pipit *(Anthus rubescens)* **M-C, W-U**

<u>WAXWINGS</u> (Family Bombycillidae)

**Cedar Waxwing** *(Bombycilla cedrorum)* **B-U**

<u>WARBLERS</u> (Family Parulidae)

**Orange-crowned Warbler** *(Vermivora celata)* **B-C, W-R**
Nashville Warbler *(Vermivora ruficapilla)* **M-R**
Virginia's Warbler (*Vermivora virginiae*) **V**
Yellow Warbler *(Dendroica petechia)* **M-C**
**Yellow-rumped Warbler** *(Dendroica coronata)* **Y-C**
**Black-throated Gray Warbler** *(Dendroica nigrescens)* **B-FC**
Black-and-white Warbler (*Mniotilta varia*) **V**
MacGillivray's Warbler *(Oporornis tolmiei)* **M-R**
**Common Yellowthroat** *(Geothlypis trichas)* **M-C, B-FC, W-R**
**Wilson's Warbler** *(Wilsonia pusilla)* **B-R**
Hermit Warbler (*Dendroica occidentalis)* **M-R**
Townsend's Warbler *(Dendroica occidentalis)* **W-U**
Palm Warbler (*Dendroica palmarum)* **M-FC, W-R**

<u>TANAGERS</u> (Family Thraupidae)

**Western Tanager** *(Piranga ludoviciana)* **B-U**

<u>SPARROWS</u> (Family Emberizidae)

**Song Sparrow** *(Melospiza melodia)* **Y-C**
Lincoln's Sparrow (*Melospiza lincolnii)* **W-U**
**White-crowned Sparrow** *(Zonotrichia leucophrys)* **Y-C**
Golden-crowned Sparrow *(Zonotrichia atricapilla)* **W-FC**
White-throated Sparrow (*Zonotrichia albicollis*) **W-U**
Harris's Sparrow (*Zonotrichia querula*) **V**
Fox Sparrow (*Passerella iliaca*) **W-C**
**Dark-eyed Junco** (*Junco hyemalis*) **Y-C**
**Savannah Sparrow** *(Passerculus sandwichensis)* **B-C, W-U**
Chipping Sparrow *(Spizella passerina)* **M-R**
Clay-colored Sparrow (*Spizella pallida*) **M-R, W-R**
American Tree Sparrow (*Spizella arborea*) **V**
**Spotted Towhee** *(Pipilo maculatus)* **B-C, W-U**
Oregon Vesper Sparrow *(Pooecetes gramineus affinis)* **M-R, W-R**
Lapland Longspur (*Calcarius lapponicus)* **MF-U, MS-R, W-R**
Chestnut-collared Longspur (*Calcarius ornatus*) **V**
Snow Bunting (*Plectrophenax nivalis*) **V**

<u>GROSBEAKS/BUNTINGS</u> (Family Cardinalidae)

**Black-headed Grosbeak** *(Pheucticus melanocephalus)* **B-U?**
Lazuli Bunting *(Passerina amoena)* **M-R**

<u>BLACKBIRDS</u> (Family Icteridae)

Bobolink (*Dolichonyx oryzivorus*) **V**
**Red-winged Blackbird** *(Agelaius phoeniceus)* **Y-C**
Yellow-headed Blackbird (*Xanthocephalus xanthocephalus*) **M-R**
**Brewer's Blackbird** (*Euphagus cyanocephalus*) **Y-R, B-R?**

**Brown-headed Cowbird** *(Molothrus ater*) **B-FC**
**Western Meadowlark** (Sturnella neglecta) **W-C, B-R?**

FINCHES (Family Fringillidae)

**Pine Siskin** *(Carduelis pinus*) **M-I, B-U?**
**American Goldfinch** *(Carduelis tristis*) **B-FC, W-R**
**Purple Finch** *(Carpodacus purpureus*) **B-C, W-R**
**House Finch** *(Carpodacus mexicanus*) **Y-C**
**Red Crossbill** (*Loxia curvirostra)* **Y-FC**
Evening Grosbeak *(Coccothraustes vespertinus)* **M-U?**

WEAVERS (Family Passeridae)

**House Sparrow** *(Passer domesticus*) **Y-R**

## Mammals[1]

OPOSSUMS (Family Didelphiidae)

Virginia Opossum (*Didelphis virginianus)*

SHREWS (Family Soricidae)

Vagrant Shrew (*Sorex vagrans)*
Trowbridge Shrew (*Sorex trowbridgii)*
Pacific Shrew (*Sorex pacificus*)
Pacific Water Shrew *(Sorex bendirii*)

MOLES (Talpidae)

Shrew Mole (*Neurotrichus gibbsii*)
Townsend's Mole (*Scapanus townsendii*)
Coast Mole (*Scapanus orarius*)

EVENING BATS (Family Vespertilionidae)

Little Brown Bat (*Myotis lucifugus*)
Long-eared Myotis (*Myotis evotis*)
Hoart Bay (*Lasiurus cinereus*)
Townsend's Big-eared Bat (*Corynorhinus townsendii*)
Long-legged Myotis (*Myotis volans*)
California Myotis (*Myotis californicus*)
Big Brown Bat (*Eptesicus fuscus*)
Yuma Myotis (*Myotis yumanensis*)
Silver-haired Bat (*Lasionycteris noctivagans*)

RABBITS (Family Leporidae)

Brush Rabbit (*Sylvilagus bachmani*)

SQUIRRELS (Family Sciuridae)

California Ground Squirrel (*Spermophilus beecheyi*)
Northern Flying Squirrel (*Glaucomys sabrinus*)

[1]Potential or documented occurences.

Townsend's Chipmunk (*Eutamias townsendi*)
Douglas' Squirrel (*Tamiasciurus douglasii*)

POCKET GOPHERS (Family Geomyidae)

Western Pocket Gopher (*Thomomys mazama*)

BEAVERS (Family Castoridae)

American Beaver (*Castor Canadensis*)

MICE/VOLES/MUSKRATS/RATS (Family Muridae)

Deer Mouse (*Peromyscus maniculatus*)
Long-tailed Vole (*Microtus longicaudus*)
Townsend's Vole (*Microtus townsendii*)
Creeping Vole (*Microtus oregoni*)
Western Red-backed Vole (*Clethrionomys californicus*)
Red Tree Vole (*Phenacomys longicaudus*)
Oregon or Creeping Vole (*Microtus oregoni*)
White-footed Vole (*Arborimus albipes*)
Bushy-tailed Woodrat (*Neotoma cinerea*)
Muskrat (*Ondatra zibethicus*)
Norway Rat (*Rattus norvegicus*)
Black Rat (*Rattus rattus*)
House Mouse (*Mus musculus*)

JUMPING MICE (Family Zapodidae)

Pacific Jumping Mouse (*Zapus trinotatus*)

PORCUPINES (Family Erethizontidae)

Porcupine (*Erethizon dorsatum*)

FOXES (Family Canidae)

Coyote (*Canis latrans*)
Gray Fox (*Vulpes velox*)

BEARS (Family Ursidae)

Black Bear (*Ursus americanus*)

RACCOONS (Family Procyonidae)

Raccoon (*Procyon lotor*)

WEASELS/SKUNKS/OTTER/MINK/MARTENS (Family Mustelidae)

Long-tailed Weasel (*Mustela frenata*)
Ermine (*Mustela erminea*)
Striped Skunk (*Mephitis mephitis*)
Spotted Skunk (*Spilogale gracilis*)
River Otter (*Lutra canadensis*)
Mink (*Mustela vison*)

American Marten (*Martes Americana*)
Fisher *(Martes pennanti)*

CATS (Family Felidae)

Mountain Lion (*Felis concolor*)
Bobcat (*Lynx rufus*)

DEER (Family Cervidae)

Black-tailed Deer (*Odocoileus hemionus columbians*)
Roosevelt Elk (*Cervise elaphus roosevelti*)

HAIR SEALS (Family Phocidae)

Harbor Seal (*Phoca vitulina*)

EARED SEALS (Family Otariidae)

Steller Sea Lion (*Eumetopias jubatus*)
California Sea lion (*Zalophus californianus*)

## Amphibians[1]

MOLE SALAMANDERS (Family Ambystomatidae)

Northwestern Salamander (*Ambystoma gracile*)
Pacific Giant Salamander (*Dicamptodon ensatus*)

LUNGLESS SALAMANDERS (Family Plethodontidae)

Clouded Salamander (*Aneides ferreus*)
Ensatina (*Ensatina eschscholtzi*)
Dunn's Salamander (*Plethodon dunni*)
Western Redback Salamander (*Plethodon vehiculum*)
California Slender Salamander (*Batrachoseps attenuatus*)

NEWTS (Family Salamandridae)

Roughskin Newt (*Taricha granulosa*)

TREE FROGS (Family Hylidae)

Pacific Treefrog (*Ascaphus regilla*)

TRUE FROGS (Family Ranidae)

Northern Red-legged Frog (*Rana aurora*)
Bullfrog (*Rana catesbeiana*)

## Reptiles[1]

SEA TURTLES (Family Dermochelyidae)

Leather-back Sea Turtle (*Dermochelys coriacea*)

[1]Potential or documented occurences.

WATER AND BOX TURTLES (Family Emydidae)

Northwestern Pond Turtle (*Clemmys marmorata*)

ALLIGATOR LIZARDS (Family Anguidae)

Northern Alligator Lizard (*Elgaria coerulea*)

IGUANIDS (Family Iguanidae)

Western Fence Lizard (*Sceloporus occidentalis*)
Northern Alligator Lizard (*Elgaria coerulea*)

BOAS (Family Bioidae)

Rubber Boa (*Charina bottae*)

COLUBRID SNAKES (Family Colubridae)

Northwestern Garter Snake (*Thamnophis ordinoides*)
Common Garter Snake (Thamnophis sirtalis)
Western Terrestrial Garter Snake (*Thamnophis elegans*)

# Appendix 3. Plan Conformance

## PLAN CONFORMANCE / NEPA COMPLIANCE RECORD
## North Spit Management Plan

Coos Bay District Office
Development of the North Spit Plan

The North Spit Management Plan is the ten year update to the 1995 Coos Bay Shorelands Management Plan (Shorelands Plan) and addresses the lands on the North Spit of Coos Bay under Buerau of Land Management jurisdiction. The North Spit of Coos Bay is a sandy, vegetated point of land separating the waters of Coos Bay from the Pacific Ocean. It is northwest of the communities of Coos Bay, North Bend, and Charleston in Coos County in southwestern Oregon. The BLM lands on the North Spit are all public domain lands, and provide habitat for several Special Status Species (SSS). BLM intends to conserve and improve when feasible, habitat for SSS on the North Spit, while preserving the recreational opportunities available.

**Plan Conformance Review**

The North Spit Plan incorporated the 1989 Draft Coos Bay Shorelands Management Plan, the 1994 Coos Bay Shorelands Draft Plan and Environmental Assessment, and the Final Coos Bay Shorelands Management Plan, signed September, 1995.

The North Spit is in compliance with the Coos Bay District Resource Management Plan (RMP) which was completed and signed in 1995.

Nancy Zepf 4-19-05
Nancy Zepf, ID Team Reviewer

**NEPA Review**

Existing Environmental Impact Statement (EIS) Review:
This plan is in conformance with the Coos Bay District Resource Management Plan and Environmental Impact Statement /Record of Decision, 1995.

The Draft Coos Bay Shorelands Plan Environmental Assessment No. EA120-93-07* is in conformance with the following existing decisions from the Coos Bay District Resource Management Plan (RMP)/ EIS Record of Decision (ROD).

1. The District RMP designated nearly half of the BLM lands on the Spit as an ACEC for outstanding values for wildlife, scenery, wetlands, SSS and recreation.
2. The District RMP designated motorized access on the Spit as "Motorized Access is Limited to designated roads and trails." The designated roads and trails have not changed.

3. The District RMP designated all the lands on the Spit as a Special Recreation Management Area due to the known popularity of the area and the challenges of managing for both recreation and SSS habitat.
4. The direct and indirect impacts of the North Spit Plan are less than those identified in the Shorelands Plan, due to land tenure adjustments (see * below).
5. There would be no additional cumulative impacts from the implementation of the North Spit Plan.
6. Public involvement that occurred during the development of the North Spit Plan occurred the same way as if a NEPA document was produced. No new issues were identified.

*The EA number was changed from EA No. OR126-93-07 (which is in the official draft plan booklet, to EA No. OR120-93-07. The change occurred due to the re-organization of the district in the early 1990's. OR126 referred to the Tioga Resource Area, which did not exist after the re-organization. OR 120 refers to the Coos Bay District. Many of the management actions proposed in the previous planning documents for the Spit included actions on lands the BLM identified as desirable to acquire through exchange. Three of the four proposed land exchanges have occurred, however, a key parcel used by the public for access, has not been acquired. Therefore, many of the management actions proposed for that parcel have been dropped in the updated North Spit Plan because they are not on BLM lands.

The North Spit Plan was written by an interdisciplinary team of BLM staff. Natural resource information was reviewed and updated. BLM management requirements for SSS and the designations in the RMP were further explained. There are no new public restrictions proposed, nor is there any surface-distrubing activity proposed. No new issues were identified. If BLM proposes surface disturbing projects, a new Environmental Analysis will be done. The basic goals and objectives from the District RMP, through the Shorelands drafts and final documents remain virtually the same: Allow recreational activities while conserving habitat for all species, with special attention on the SSS.

Steve Morris 4-19-05
Steve Morris, NEPA Reviewer

**Decision**

I have reviewed this Plan Conformance and NEPA Compliance Record and have determined that the North Spit Management Plan is in conformance with the approved land use plan and that no further environmental analysis is required. It is my decision to implement the plan as described.

M. Elaine Raper — 4/21/05

M. Elaine Raper
Umpqua Area Manager

Date

# Appendix 4. History of Land Tenure on the North Spit.

| | |
|---|---|
| 1857 | First survey of the North Spit. |
| 1878 | Beginning of numerous attempts to build a jetty on the east shore of the estuary. |
| 1882 | Cash entry patent to Sec. 24 Lot 4. |
| 1884 | Cash entry patent to Sec. 25 Lot 1. |
| 1887 | Sec. 25 Lot 2 Withdrawn to the Treasury Department for lifesaving purposes. The Life Saving Station was constructed and fully staffed by August 1891. The US later also acquired Sec. 24 Lot 4 and Sec. 25 Lot 1. |
| 1889 | The east shore was abandoned as a location of the jetty and planning began for construction on the North Spit. |
| 1889 | (June) Cash entry patent to Sec. 26 Lot 3. |
| 1889 | (November) All public domain land in T.25S., R13 & 14 W., withdrawn to the War Department for the Coos Bay Harbor. |
| 1890 | Congress appropriated money for the jetty construction. The Corps of Engineers began reclamation of the North Spit and jetty construction. |
| 1891 | The US acquired Section 26 Lot 3. |
| 1915 | Life Saving Station relocated to Coos Head because the location made it difficult to monitor the bar and quickly respond to accidents. US Navy assumed use of the old station on the North Spit. The Navy used the site as Radio Compass Station (on-shore facility for determining the direction of received radio signals) |
| 1947 | The Navy closed the Radio Compass Station on the North Spit and relocated to Coos Head. |
| 1950 | The Navy declared the old Radio Compass Station surplus. The withdrawn land (Sec. 25 Lot 2) was transferred to the Corps of Engineers. The parcels purchased in fee were disposed of by sale. |
| 1984 | The Corps of Engineers relinquished a portion of their withdrawal on the North Spit. BLM determined that it was suitable for return to the public domain and accepted jurisdiction. By accepting jurisdiction, BLM inherited numerous permits and leases issued by the COE. As these authorizations expired, they were replaced by FLPMA right of ways. |
| 1989 | A resurvey by BLM established that none of the buildings were on the land (sec. 24 Lot 4) purchased by Edward Altoffer in 1950. BLM demolished the buildings and removed the underground tanks. Attempts to purchase the land from Altoffer failed due to appraisal issues. Altoffer later sold the land to another party. |
| 1992 | BLM acquired a parcel in T.25S., R13 W., Sec. 8 for a boat ramp. |

1997 BLM acquired Sec. 25 Lot 1 and a 5-acre parcel located next to the BLM Boat Ramp in a land exchange with Weyerhaeuser. In the exchange, the Weyerhaeuser Company picked up the land encumbered by their effluent pond in T.25S., R13 W. The pond had been authorized under a lease by the COE.

2000 BLM acquired Sec. 24 Lot 4 by fee purchase.

2001 The Corps of Engineers relinquished the lands remaining under their withdrawal on the North Spit. BLM determined that it was suitable for return to the public domain and accepted jurisdiction.

# Appendix 5. Glossary

**Area of Critical Environmental Concern:** an area of BLM-administered lands where special management attention is needed to protect and prevent irreparable damage to important historic, cultural, or scenic values, fish and wildlife resources, or other natural systems or processes; or to protect life and provide safety from natural hazards (as defined in BLM Manual 8300).
**Biodiversity:** the full range of variety and variability within and among living organisms and the ecological complexes in which they occur.
**Breach**: term used in this plan to explain an opening in the foredune between Coos Bay and the Pacific Ocean, caused by floodwaters, ocean surf run-up, or by planned mechanical intervention.
**Cascadia seismic event:** a rupture of the interlocked North American Plate and the Juan de Fuca Plate along the subduction planes. The energy released is expected to generate an 8.8 magnitude earthquake.
**Cascadia subduction zone:** the generally north-south zone along the Northwest coast where the Juan de Fuca Plate is being over-ridden by the North American Plate.
**Community:** a group of plants and animals that occupy a given locale.
**Coniferous:** cone-bearing trees or shrubs; mostly evergreens such as pine, cedar, spruce, etc.
**Cubic foot per second (cfs):** a unit of measurement of the rate of water flow past a given point equal to one cubic foot in one second.
**Deflation plain:** area behind the foredune where wind has eroded the sand to the water table, forming a wet surface resistant to further erosion.
**Dune:** a hill of drifting sand formed by wind action.
**Ecosystem:** an assemblage of integrated organisms plus the local environment.
**Eolian:** (Aeolian) pertaining to the action or the effect of the wind, as in eolian sand dune deposits.
**Estuary:** the zone between the fresh water of a stream and the salt water of an ocean. An estuarine system extends upstream until ocean derived salt measures less than 0.5% during average annual flow. Estuaries are low energy systems and may include subtidal and intertidal areas with aquatic beds.
**Estuarine:** of, relating to, or found in an estuary.
**Exotic:** introduced species; not indigenous to a given area.
**Globally ranked plant community:** a prioritization system for determining global significance of plant communities. G1 communities are the most imperiled whereas G5 communities are widespread and secure.
**Good Friday Earthquake, 1964:** a tectonic event that originated in Alaska. The earthquake occurred on March 27, 1964, Good Friday and was a 9.2 magnitude, the second largest earthquake ever recorded. The earthquake triggered a tsunami that impacted Pacific coastlines including Oregon, California, Washington, and Alaska.
**Herbicide:** a chemical substance capable of killing or inhibiting plants.
**Interpretation:** a communication process that forges emotional and intellectual connections between the interests of the audience and the inherent meanings in the resource.
**Introduced species:** also referred to as exotic species, these are plants or animals occurring as a result of introduction or unnatural range expansion. These are species that did not occur before the arrival of European culture.
**Littoral cell:** segment of the shore or beach that is bound by headlands which extend sufficiently seaward to prevent along-shore transport of beach sediment, creating a relatively closed sediment system.
**Native:** a species indigenous to a given area; any species known to occur before the arrival of European culture or which has moved in through natural range extension.
**Non-vascular:** refers to the lichens, fungi, liverworts, hornworts, and mosses.
**Noxious weeds:** any plant designated by the Oregon State Weed Board that is injurious to public health, agriculture, recreation, wildlife, or any public or private property.
**Plant community:** a general term for an assemblage of plants growing together at a site which show a definite association or affinity to each other
**Precipitation ridge:** the leading landward edge of a dune field at the point of advancement of the dune.

**Riparian:** living on or adjacent to a water supply such as a riverbank, lake, or pond.
**Riverine:** relating to or resembling a river, in this case a coastal freshwater system.
**Special Recreation Management Area:** an area where a commitment has been made to provide specific recreation activity and experience opportunities. These areas usually require a high level of investment and/or management. They include recreation sites, but recreation sites alone do not constitute SRMAs (as defined in BLM Manual 8300).
**Special status species:** animals and plants considered being of conservation interest because of their rarity or vulnerability to extirpation or extinction, or they are under-represented in protected areas. BLM SSS are those designated by the BLM State Director, usually in cooperation with the Oregon Department of Agriculture and the Oregon Natural Heritage Information Center. The Oregon and Washington SSS policy identifies three tiers: Bureau Sensitive (BS), Bureau Assessment (BA), and Bureau Tracking (BT). BA species are those which are not presently eligible for official federal or state status but are of concern in Oregon or Washington and may at a minimum, need protection or mitigation in BLM activities. BT species are those which may become threatened or endangered in the future and are not considered SSS for management purposes. Surveys for SSS may be conducted prior to implementing proposed actions that may adversely affect special status species and their habitats.
**Succession:** the transition of plant species of a given area through a definite ecological stage (e.g., through succession of species composition, grasslands become tree-bearing forests).
**Threatened species:** plants and animals listed as threatened on the Endangered Species List that are in danger of becoming extinct.
**Vascular plants:** refers to vessels or ducts that conduct fluids in plants; includes the fern and fern allies, gymnosperms, dicotyledons, and monocotyledons.
**Wetland:** an area subjected to periodic inundation, usually with soil and vegetative characteristics that separates it from non-inundated area.

**[Docket No. 071227892–7894–01]**

**RIN 0648–AW39**

## Endangered and Threatened Species: Final Threatened Listing Determination, Final Protective Regulations, and Final Designation of Critical Habitat for the Oregon Coast Evolutionarily Significant Unit of Coho Salmon

**AGENCY:** National Marine Fisheries Service (NMFS), National Oceanic and Atmospheric Administration (NOAA), Commerce.

**ACTION:** Final rule.

**SUMMARY:** We are issuing a final determination to list the Oregon Coast coho salmon (*Oncorhynchus kisutch*) evolutionarily significant unit (ESU) as a threatened species under the Endangered Species Act (ESA). We are also issuing final protective regulations and a final critical habitat designation for the Oregon Coast coho ESU.

**DATES:** The listing determination, protective regulations, and designated critical habitat are effective on May 12, 2008. With respect to the protective regulations, the take prohibitions for the Oregon Coast coho ESU do not apply to research and enhancement activities specified in an application for a permit or approval under the protective regulations, provided that the application has been received by the Assistant Administrator for Fisheries (AA), NOAA, no later than June 10, 2008. This ''grace period'' for pending research and enhancement applications will remain in effect until the issuance or denial of authorization, or March 31, 2009, whichever occurs earliest.

**ADDRESSES:** NMFS, Protected Resources Division, 1201 NE Lloyd Boulevard, Suite 1100, Portland, Oregon 97232.

**FOR FURTHER INFORMATION CONTACT:** Scott Rumsey, NMFS, Northwest Region, Protected Resources Division, at (503) 872–2791, or Marta Nammack, NMFS, Office of Protected Resources, at (301) 713–1401. Reference materials regarding this determination are available upon request or on the Internet at *http://www.nwr.noaa.gov.*

**SUPPLEMENTARY INFORMATION:**

### Previous Federal ESA Actions Related to Oregon Coast Coho

In 1995, we completed a comprehensive status review of West Coast coho salmon (Weitkamp *et al.*, 1995) that resulted in proposed listing determinations for three coho ESUs, including a proposal to list the Oregon Coast coho ESU as a threatened species (60 FR 38011; July 25, 1995). On October 31, 1996, we announced a 6-month extension of the final listing determination for the ESU, pursuant to section 4(b)(6)(B)(I) of the ESA, noting substantial disagreement regarding the sufficiency and accuracy of the available data relevant to the assessment of extinction risk and the evaluation of protective efforts (61 FR 56211). On May 6, 1997, we withdrew the proposal to list the Oregon Coast coho ESU as threatened, based in part on conservation measures contained in the Oregon Coastal Salmon Restoration Initiative (later renamed the Oregon Plan for Salmon and Watersheds; hereafter referred to as the Oregon Plan) and an April 23, 1997, Memorandum of Agreement (MOA) between NMFS and the State of Oregon which further defined Oregon's commitment to salmon conservation (62 FR 24588). We concluded that implementation of harvest and hatchery reforms, and habitat protection and restoration efforts under the Oregon Plan and the MOA substantially reduced the risk of extinction faced by the Oregon Coast coho ESU. On June 1, 1998, the U.S. District Court for the District of Oregon issued an opinion finding that our May 6, 1997, determination to not list Oregon Coast coho was arbitrary and capricious (*Oregon Natural Resources Council* v. *Daley,* 6 F. Supp. 2d 1139 (D. Or. 1998)). The Court vacated our determination to withdraw the proposed rule to list the Oregon Coast coho ESU and remanded the determination to NMFS for further consideration. On August 10, 1998, we issued a final rule listing the Oregon Coast coho ESU as threatened (63 FR 42587), basing the determination solely on the information and data contained in the 1995 status review (Weitkamp *et al.*, 1995) and the 1997 proposed rule.

In 2001 the U.S. District Court in Eugene, Oregon, set aside the 1998 threatened listing of the Oregon Coast coho ESU (*Alsea Valley Alliance* v. *Evans,* 161 F. Supp. 2d 1154, (D. Or. 2001)) (Alsea). In response to the *Alsea* ruling and several listing and delisting petitions, we announced that we would conduct an updated status review of 27 West Coast salmonid ESUs, including the Oregon Coast coho ESU (67 FR 6215, February 11, 2002; 67 FR 48601, July 25, 2002).

In 2003 we convened the Pacific Salmonid Biological Review Team (BRT) (an expert panel of scientists from several Federal agencies including NMFS, the U.S. Fish and Wildlife Service (FWS), and the U.S. Geological Survey (USGS)) to review the extinction risks of naturally spawning populations in the 27 ESUs under review, including the Oregon Coast coho ESU (Good *et al.*, 2005; NMFS, 2003a). In making its recommendation, the BRT used a process where each member of the BRT was given 10 votes to divide among three conclusions. Members were allowed to assign votes to more than one conclusion, allowing them to express their relative degree of confidence in particular conclusions. The three options were ''In Danger of Extinction,'' ''Likely to Become Endangered,'' and ''Not Warranted.'' Fifty-six percent of the votes supported the conclusion that naturally spawning Oregon coast coho were likely to become endangered in the foreseeable future, and 44 percent supported the conclusion that naturally spawning Oregon coast coho was ''Not Warranted'' (that is, not likely to become in danger of extinction in the foreseeable future). The BRT noted considerable uncertainty regarding the future viability of the ESU given the uncertainty in predicting future ocean conditions for coho survival, as well as uncertainty in whether current freshwater habitats are of sufficient quality and quantity to support the recent high abundance levels and sustain populations during future downturns in ocean conditions. Although the BRT couched its conclusion in terms of the statutory definition of a threatened species (that is, not in danger of extinction, but likely to become endangered in the foreseeable future), the BRT's conclusion did not constitute a recommendation to list the species. Our listing determination also considered the risks and benefits from artificial propagation programs included in the ESU, efforts being made to protect the species, and the five factors listed under section 4(a)(1) of the ESA.

On June 14, 2004, based primarily on the BRT voting results, we proposed to list the Oregon Coast coho ESU as a threatened species (69 FR 33102). However, the proposed listing recognized that further information would likely become available and that this information could affect the outcome of the final determination. In the proposed rule, we noted that Oregon was initiating a comprehensive assessment of the viability of the Oregon Coast coho ESU and of the adequacy of actions under the Oregon Plan for conserving Oregon Coast coho. As part of that proposed rule we proposed amendments to existing protective regulations issued under ESA section

4(d) (''4(d) regulations'') for all threatened West Coast salmon and steelhead (50 CFR 223.203). These amendments were needed to: (1) Provide flexibility in fisheries and hatchery management; and (2) simplify and clarify the existing regulations so that they may be more efficiently and effectively accessed and interpreted by all affected parties.

On December 14, 2004, we proposed designations of critical habitat for 13 ESUs of Pacific salmon and steelhead in the Pacific Northwest, including the Oregon Coast coho ESU (69 FR 74572). We proposed critical habitat in 72 of 80 occupied watersheds, contained in 13 subbasins, totaling approximately 6,665 stream miles along the Oregon Coast, south of the Columbia River and north of Cape Blanco (Oregon). The estimated economic impact of the areas proposed for critical habitat was approximately $15.7 million. Eight occupied watersheds were proposed for exclusion because the high benefits of exclusion (due to economic impacts) outweighed the low benefits of inclusion (due to the low inherent conservation value for the listed species). These excluded watersheds included approximately 134 stream miles and represented a 15 percent reduction (approximately $2.75 million) in the economic impact of the proposed designation. To assess economic impacts we measured the co-extensive impacts because, based on the existing record, we could not distinguish between the costs associated with the species' listing from the costs of separately designating critical habitat.

In January 2005 the State of Oregon released a draft Oregon Coastal Coho Assessment (Oregon's Draft Viability Assessment), which (1) evaluated the current viability of the Oregon Coast coho ESU, and (2) evaluated the certainty of implementation and effectiveness of the Oregon Plan measures in addressing the factors for decline of the Oregon Coast coho ESU. The latter evaluation was intended to satisfy the joint NMFS—FWS Policy on Evaluating Conservation Efforts (''PECE''; 68 FR 15100; March 28, 2003). Oregon's Draft Viability Assessment concluded that the Oregon Coast coho ESU is currently viable and that measures under the Oregon Plan have stopped, if not reversed, the deterioration of Oregon Coast coho habitats. The Draft Viability Assessment also concluded that it is highly likely that existing monitoring efforts would detect any significant future deterioration in the ESU's viability, or degradation of environmental condition, allowing a timely and appropriate response to conserve the ESU. On February 9, 2005, we published a notice of availability of Oregon's Draft Viability Assessment for public review and comment in the **Federal Register** (70 FR 6840) and noted that information presented in the draft and final assessments would be considered in making the final listing determination for the Oregon Coast coho ESU.

We forwarded the public comments we received on Oregon's Draft Viability Assessment, as well as our technical reviews, for Oregon's consideration in developing its final assessment. The public comments and our review highlighted areas of uncertainty or disagreement regarding the sufficiency and accuracy of Oregon's Draft Viability Assessment, including: the assumption that Oregon Coast coho populations are inherently resilient at low abundance, and that this compensatory response will prevent extinction during periods of low marine survival; the apparent de-emphasis of abundance as a useful indicator of extinction risk; assumptions regarding the duration and severity of future periods of unfavorable marine and freshwater conditions; the ability of monitoring and adaptive management efforts to detect population declines or habitat degradation, and to identify and implement necessary protective measures; and the ability of Oregon Plan measures to halt or reverse habitat degradation once detected.

On May 13, 2005, Oregon issued its final Oregon Coastal Coho Assessment (Oregon's Final Viability Assessment). Oregon's Final Viability Assessment included several changes intended to address concerns raised regarding the sufficiency and accuracy of the draft assessment. Oregon's Final Viability Assessment concluded that: (1) The Oregon Coast coho ESU is viable under current conditions, and should be sustainable through a future period of adverse environmental conditions (including a prolonged period of poor ocean productivity); (2) given the assessed viability of the ESU, the quality and quantity of habitat is necessarily sufficient to support a viable ESU; and (3) the integration of laws, adaptive management programs, and monitoring efforts under the Oregon Plan will maintain and improve environmental conditions and the viability of the ESU into the foreseeable future.

On June 28, 2005 (70 FR 37217), we announced a 6-month extension of the final listing determination for the Oregon Coast coho ESU, finding that ''there is substantial disagreement regarding the sufficiency or accuracy of the available data relevant to the determination * * * for the purposes of soliciting additional data'' (section 4(b)(6)(B)(i) of the ESA). We announced a 30-day public comment period to solicit information regarding the validity of Oregon's Final Viability Assessment, particularly in light of the concerns raised with respect to Oregon's Draft Viability Assessment. In September 2005 we issued final critical habitat designations for 12 Pacific Northwest ESUs (70 FR 52685; September 2, 2005), but we did not issue a final critical habitat designation for Oregon Coast coho because it was only proposed for listing at that time.

On January 19, 2006, we issued a final determination that listing the Oregon Coast coho ESU under the ESA was not warranted (71 FR 3033). As part of this determination, we withdrew the proposed ESA section 4(d) regulations and critical habitat designation for the ESU. In reaching our determination not to list Oregon Coast coho, we found that the BRT's slight majority opinion that the ESU is ''likely to become endangered'' and the conclusion of the Oregon Final Viability Assessment that the ESU is viable represented competing reasonable inferences from the available scientific information and considerable associated uncertainty. The difference of opinion centered on whether the ESU was at risk because of the ''threatened destruction, modification, or curtailment of its habitat or range.'' We conducted an analysis of current habitat status and likely future habitat trends (NMFS, 2005a) and found that: (1) The sufficiency of current habitat conditions was unknown; and (2) likely future habitat trends were mixed (i.e., some habitat elements were likely to improve, some were likely to decline, others were likely to remain in their current condition). We concluded that there was insufficient evidence to support the conclusion that the ESU was more likely than not to become an endangered species in the foreseeable future throughout all or a significant portion of its range.

Our decision not to list the Oregon Coast coho ESU was challenged in *Trout Unlimited.* On October 9, 2007, the U.S. District Court for the District of Oregon invalidated our January 2006 decision not to list Oregon Coast coho (*Trout Unlimited* v. *Lohn, Civ. No. 06–01493 ST* (*D. Oreg., October 9, 2007*). The Court found that Oregon's Viability Assessment does not represent the best available science, and that we improperly considered it in reaching our final listing decision. The Court ordered us to issue a new final listing rule consistent with the ESA. This listing decision has been made in compliance with the Court's order.

**ESA Statutory Provisions**

*Listing Determinations*

The ESA defines an endangered species as one that is in danger of extinction throughout all or a significant portion of its range, and a threatened species as one that is likely to become endangered in the foreseeable future (sections 3(6) and 3(20), respectively). The statute requires us to determine whether any species is endangered or threatened because of any of five factors: the present or threatened destruction of its habitat, overexploitation, disease or predation, the inadequacy of existing regulatory mechanisms, or any other natural or manmade factors (section 4(a)(1)(A)–(E)). We are to make this determination based solely on the best available scientific information after conducting a review of the status of the species and taking into account any efforts being made by states or foreign governments to protect the species. The focus of our evaluation of these five factors is to evaluate whether and to what extent a given factor represents a threat to the future survival of the species. The focus of our consideration of protective efforts is to evaluate whether these efforts substantially have and will continue to address the identified threats and so ameliorate a species' risk of extinction. In making our listing determination, we must consider all factors that may affect the future viability of the species, including whether regulatory and conservation programs are inadequate and allow threats to the species to persist or worsen, or whether these programs are likely to mitigate threats to the species and reduce its extinction risk. The steps we follow in implementing this statutory scheme are to: review the status of the species, analyze the factors listed in section 4(a)(1) of the ESA to identify threats facing the species, assess whether certain protective efforts mitigate these threats, and make our best prediction about the species' future persistence.

As indicated above, the PECE provides direction for considering protective efforts identified in conservation agreements, conservation plans, management plans, or similar documents (developed by Federal agencies, state and local governments, tribal governments, businesses, organizations, and individuals) that have not yet been implemented, or have been implemented but have not yet demonstrated effectiveness. The policy articulates several criteria for evaluating the certainty of implementation and effectiveness of protective efforts to aid in determining whether a species warrants listing under the ESA. Evaluation of the certainty that an effort will be implemented includes whether: the necessary resources (e.g., funding and staffing) are available; the requisite agreements have been formalized such that the necessary authority and regulatory mechanisms are in place; there is a schedule for completion and evaluation of the stated objectives; and (for voluntary efforts) the necessary incentives are in place to ensure adequate participation. The evaluation of the certainty of an effort's effectiveness is made on the basis of whether the effort or plan: Establishes specific conservation objectives; identifies the necessary steps to reduce threats or factors for decline; includes quantifiable performance measures for the monitoring of compliance and effectiveness; incorporates the principles of adaptive management; and is likely to improve the species' viability at the time of the listing determination.

PECE also notes several important caveats. Satisfaction of the above mentioned criteria for implementation and effectiveness establishes a given protective effort as a candidate for consideration, but does not mean that an effort will ultimately change the risk assessment. The policy stresses that, just as listing determinations must be based on the viability of the species at the time of review, so they must be based on the state of protective efforts at the time of the listing determination. The PECE does not provide explicit guidance on how protective efforts affecting only a portion of a species' range may affect a listing determination, other than to say that such efforts will be evaluated in the context of other efforts being made and the species' overall viability.

*Protective Regulations*

ESA section 9(a) take and other prohibitions (16 U.S.C. 1538(a)(1)(B)) apply to all species listed as endangered. Hatchery stocks determined to be part of endangered ESUs are afforded all of the full section 9 protections. In the case of threatened species, ESA section 4(d) leaves it to the Secretary of Commerce's (Secretary) discretion to determine whether and to what extent regulatory requirements may be appropriate, by directing the Secretary to issue regulations determined to be necessary and advisable for the conservation of the species. We have flexibility under section 4(d) to tailor protective regulations based on the contributions of available conservation measures. The 4(d) regulations may prohibit, with respect to threatened species, some or all of the acts which section 9(a) of the ESA prohibits with respect to endangered species.

*Critical Habitat*

Section 3 of the ESA defines critical habitat as (1) specific areas within the geographical area occupied by the species at the time of listing, on which are found those physical or biological features that are essential to the conservation of the listed species and that may require special management considerations or protection, and (2) specific areas outside the geographical area occupied by the species at the time of listing that are essential for the conservation of a listed species. In designating critical habitat our regulations direct us to focus on ''primary constituent elements,'' or PCEs, in identifying these physical or biological features. Section 4 of the ESA requires us to consider the economic impacts, impacts on national security, and other relevant impacts of specifying any particular area as critical habitat. We may exclude any area from critical habitat if we determine that the benefits of such exclusion outweigh the benefits of specifying such area as part of the critical habitat, unless the failure to designate such an area will result in the extinction of the species.

At the time of a proposed listing determination, ESA section 4(a)(3) and our regulations require us to specify critical habitat to the maximum extent ''prudent and determinable.'' Critical habitat designation is not prudent if: (1) The species is threatened by taking or other human activity and the identification of critical habitat can be expected to increase such threat(s); or (2) critical habitat designation would not be beneficial to the species. Critical habitat is not determinable if: (1) Sufficient information is lacking to perform the required analyses of the impact of the designation; or (2) the biological needs of the species are not sufficiently well known to identify an area as critical habitat. In our proposed rule to designate specific areas as critical habitat (69 FR 74572; December 14, 2004), we determined that designating critical habitat for this species is prudent and determinable. The record continues to support this determination.

The ESA requires that a final regulation designating critical habitat be published concurrently with the final determination listing a species as threatened or endangered, unless: (1) It is essential to the conservation of such species that the species be listed promptly (e.g., in instances when a species is listed by emergency rule); or (2) critical habitat of such species is not then determinable. Section 7(a)(2) of the ESA requires that each Federal agency shall, in consultation with, and with the assistance of, NMFS, ensure that any action authorized, funded or carried out by such agency is not likely to jeopardize the continued existence of any listed species or result in the destruction or adverse modification of its designated critical habitat.

**Summary of Public and Independent Review**

Our regulations require that we allow a period of at least 60 days for the public to review and comment on a proposed rule to list, delist, or reclassify a species, or to designate or revise critical habitat. We may extend or reopen the comment period upon finding that there is good cause to do so by publishing notice in the **Federal Register**. We are required to hold at least one public hearing if any person so requests within 45 days of the publication of a proposed rule. Notice of the location and time of any hearings is published in the **Federal Register**.

A 1994 joint NMFS–FWS policy (Independent Review Policy) requires us to solicit independent expert review from at least three qualified specialists, concurrent with the public comment period following a proposed rule (59 FR 34270; July 1, 1994). In December 2004 the Office of Management and Budget (OMB) issued a Final Information Quality Bulletin for Peer Review (Peer Review Bulletin), establishing minimum peer review standards, a transparent process for public disclosure, and opportunities for public input. The OMB Peer Review Bulletin, implemented under the Information Quality Act (Pub. L. 106–554), is intended to ensure the quality of agency information, analyses, and regulatory activities and provide for a more transparent review process.

*Listing Determination and Protective Regulations*

We solicited public comment on the proposed listing determination and ESA section 4(d) regulations for the Oregon Coast coho ESU for a total of 208 days (69 FR 33102, June 14, 2004; 69 FR 53031, August 31, 2004; 69 FR 61348, October 18, 2004; 70 FR 6840, February 9, 2005; 70 FR 37217, June 28, 2005). In addition, we held eight public hearings in the Pacific Northwest concerning the June 2004 West Coast salmon and steelhead proposed 4(d) regulations and proposed listing determinations, including the proposed determination for the Oregon Coast coho ESU (69 FR 53031, August 31, 2004; 69 FR 61348, October 18, 2004). In compliance with the 1994 Independent Review Policy we solicited technical review of the June 2004 proposed 4(d) regulations and listing determinations, including the proposed determination for the Oregon Coast coho ESU, from over 50 independent experts selected from the academic and scientific community, Native American tribal groups, Federal and state agencies, and the private sector. The individuals from whom we solicited review of the proposals and the underlying science were selected because of their demonstrated expertise in a variety of disciplines including: Artificial propagation; salmonid biology, taxonomy, and ecology; genetic and molecular techniques and analyses; population demography; quantitative methods of assessing extinction risk; fisheries management; local and regional habitat conditions and processes; and conducting scientific analyses in support of ESA listing determinations. The individuals solicited represent a broad spectrum of perspectives and expertise. The individuals solicited include those who have been critical of past agency actions in implementing the ESA for West Coast salmon and steelhead, as well as those who have been supportive of these actions. These individuals were not involved in producing the scientific information for our determinations and were not employed by the agency. We received comments from four of these experts. In addition to these solicited reviews, several independent scientific panels and academic societies provided technical review of the proposals and the supporting documentation. With respect to the Peer Review Bulletin's requirements for ''adequate [prior] peer review,'' we believe the independent expert review under the 1994 Independent Review Policy, and the comments received from several academic societies and expert advisory panels, collectively satisfy the Peer Review Bulletin's requirements (NMFS, 2005b).

In response to our requests for information and comments on the June 2004 proposed listing determinations, we received over 28,250 comments by fax, standard mail, and e-mail. The majority of the comments received were from interested individuals who submitted form letters or form e-mails that addressed general issues not specific to the Oregon Coast coho ESU. Comments were also submitted by state and tribal natural resource agencies, fishing groups, environmental organizations, home builder associations, academic and professional societies, expert advisory panels, farming groups, irrigation groups, and individuals with expertise in Pacific salmonids. The majority of commenters focused on the consideration of hatchery-origin fish in ESA listing determinations, with only a few comments specifically addressing the Oregon Coast coho ESU. We also received comments from 4 of the 50 independent experts from whom we had requested technical review of the scientific information underlying the June 2004 proposed listing determinations. Their comments did not specifically address the proposed determination for the Oregon Coast coho ESU. The reader is referred to the final hatchery listing policy (70 FR 37204; June 28, 2005) and the final listing determinations and ESA section 4(d) regulations for 16 salmon ESUs (70 FR 37160; June 28, 2005) for a summary and discussion of issues raised by the comments that were not specific to the Oregon Coast coho ESU. The comments addressing the proposed listing determination for the Oregon Coast coho ESU are summarized below. We did not receive any comments that addressed the proposed 4(d) regulations in the specific context of the Oregon Coast coho ESU.

*Critical Habitat*

We solicited public comment on the proposed critical habitat designation for Oregon Coast coho for a total of 105 days (69 FR 74578, December 14, 2004; 70 FR 6394; February 7, 2005). We also contacted the appropriate Federal, state, and local agencies, scientific organizations, and other interested parties and invited them to comment on the proposed rule. To facilitate public participation, we made the proposed rule available via the Internet as soon as it was signed by the AA of NMFS (approximately 2 weeks prior to actual publication). In addition, we held four public hearings in the Pacific Northwest between January 11, 2005, and January 25, 2005. We received 5,230 written comments (5,111 of these were ''form e-mails'' with nearly identical verbiage) during the comment period on the proposed rule. Eight comments addressed specifically, or in part, the proposed critical habitat designation for the Oregon Coast coho ESU.

In compliance with the Peer Review Bulletin, prior to publishing the proposed rule we submitted the initial biological assessments of our Critical Habitat Analytical Review Teams (CHARTs) to state and tribal comanagers and asked them to review those findings. These comanager reviews resulted in several changes to the CHARTs' preliminary assessments (for example, revised fish distribution as well as conservation value ratings) and helped ensure that the CHARTs' revised findings incorporated the best available scientific data. Consistent with the 1994 Independent Review Policy, we later solicited technical review of the entire critical habitat proposal (including the underlying biological and economic reports) from 45 independent experts selected from the academic and scientific community, Native American tribal groups, Federal and state agencies, and the private sector. We also solicited opinions from three individuals with economics expertise to review the draft economics analysis supporting the proposed rule. All three of the economics reviewers and three of the biological reviewers submitted written opinions on our proposal. We have determined that the independent expert review and comments received regarding the science involved in this rulemaking constitute adequate prior review under section II.2 of the OMB Peer Review Bulletin (NMFS, 2005c) and satisfy the 1994 Independent Review Policy.

We reviewed all comments received from the peer reviewers and the public for substantive issues and new information regarding critical habitat for all 13 ESUs addressed in the proposed rule. The reader is referred to the final critical habitat designations for 12 Pacific Northwest ESUs (70 FR 52685; September 2, 2005) for a summary and discussion of general issues, or issues specific to other ESUs. The comments addressing the proposed critical habitat designation for the Oregon Coast coho ESU are summarized below.

**Comments Specific to Oregon Coast Coho**

Below we address the comments received that directly pertain to: (1) The listing determination for the Oregon Coast coho ESU, and (2) the designation of critical habitat for the Oregon Coast coho ESU. (Copies of the full text of comments received are available upon request, see **ADDRESSES** and **FOR FURTHER INFORMATION CONTACT,** above.)

*Comments Regarding the Listing Determination*

*Comment 1:* The Oregon Department of Fish and Wildlife (ODFW) expressed concern regarding the proposed inclusion of the North Fork Nehalem River coho hatchery program in the Oregon Coast coho ESU. ODFW explained that the hatchery program propagates two different stocks: The North Fork Nehalem River hatchery coho stock (ODFW stock #32) and the Fishhawk Lake hatchery coho stock (ODFW stock #99). ODFW noted that both stocks, although founded using local natural-origin fish, are presently managed as isolated broodstocks. Although the level of divergence between these hatchery stocks and the local wild populations is not known, ODFW noted that our hatchery reviews (NMFS, 2003b, 2004a, 2004b) acknowledged that the level of divergence may be substantial. ODFW recommended that both the North Fork Nehalem River and Fishhawk Lake hatchery stocks be excluded from the ESU.

ODFW also noted that the recently founded Calapooya Creek (Umpqua River basin, Oregon) hatchery coho stock was not included in our hatchery reviews. The Calapooya Creek program was a small, short-term (in operation from 2001–2003), research hatchery program conducted to evaluate the use of hatchery-reared fish in the supplementation of a wild coho population. The program is no longer releasing fish, and had adults returning through 2006. ODFW suggested that, had we included this stock in our initial evaluations, the progeny expected to return through 2006 would have been considered as part of the Oregon Coast coho ESU.

*Response:* We agree with ODFW's comments that the North Fork Nehalem River and Fishhawk Lake stocks propagated by the Nehalem hatchery coho program are substantially reproductively isolated from the local natural populations, and diverged substantially from the evolutionary legacy of the ESU. Moreover, since our 2006 final determination these two programs have been discontinued, with the last adults returning in 2007 (NMFS, 2007a). We conclude that the North Fork Nehalem River and Fishhawk Lake hatchery coho stocks are not part of the Oregon Coast coho ESU.

We did not include the Calapooya Creek coho hatchery stock in our hatchery reviews as the program is no longer collecting fish for broodstock or releasing smolts. We agree with ODFW that returns from Calapooya Creek hatchery stock, having been derived from local natural-origin fish, likely were no more than moderately diverged from the local natural populations. However, given that the program has been terminated, and 2006 was the last year of returns, the Calapooya Creek hatchery stock will not be considered part of the Oregon Coast coho ESU.

At the time of the 2004 proposed rule and our January 2006 final determination not to list the ESU, Cow Creek (ODFW stock #37), the North Umpqua River (ODFW stock #18), the Coos Basin (ODFW stock #37), and the Coquille River (ODFW stock #44) hatchery coho programs were considered part of the Oregon Coast coho ESU. The latter three of these programs have been discontinued since our 2006 final determination (NMFS, 2007a). The last year of returns for these programs is 2007. Given that the North Umpqua River, Coos Basin, and Coquille River hatchery programs have been terminated, and this winter (2007) is the last year of returns, these stocks will not be considered part of the Oregon Coast coho ESU.

*Comment 2:* A comment submitted by the Pacific Rivers Council (PRC) included a July 2003 report investigating the potential benefits of a modeled conservation hatchery program in supplementing Oregon Coast coho (Oosterhout and Huntington, 2003). PRC asserted that the report supports their position that hatchery fish should be considered as only a threat to wild salmonid populations, and that any potential short-term benefits of artificial propagation are outweighed by the long-term damaging genetic and ecological effects on wild populations. The Oosterhout and Huntington (2003) report modeled an ''idealized conservation hatchery'' program and evaluated the success of supplementation efforts under different scenarios of habitat quality and marine survival. The authors conclude from their modeling study that supplementation, even under optimized model assumptions, poses long-term ecological and genetic risks, and any short-term gains in salmon abundance are temporary.

*Response:* The use of artificial propagation represents a broad spectrum of hatchery practices and facilities, as well as a variety of ecological settings into which hatchery-origin fish are released. For this reason it is essential to assess hatchery programs on a case-by-case basis. Our assessment of the benefits, risks, and uncertainties of artificial propagation concluded that the specific hatchery programs considered to be part of the Oregon Coast coho ESU collectively do not substantially reduce the extinction risk of the ESU in-total (NMFS, 2004b). We noted that these hatchery programs likely contribute to an increased abundance of total natural spawners in the short term, although their contribution to the productivity of the supplemented populations is unknown. Our assessment is consistent with the findings of Oosterhout and Huntington (2003). The findings of scientific studies, such as the subject study on simulated conservation hatchery programs and their impacts on natural coho populations, inform our consideration of the benefits and risks to be expected from artificial propagation. However, it would be inappropriate to rely on theoretical conclusions about the effectiveness of hatchery programs while ignoring program-specific information regarding broodstock origin, hatchery practices, and performance of hatchery- and natural-origin fish.

*Comment 3:* Douglas County Board of Commissioners (Oregon) submitted a report (Cramer *et al.*, 2004) that concludes that NMFS' earlier viability analyses overstate the risks to Oregon Coast coho populations, and that the 2003 BRT's findings warrant reconsideration. The Cramer *et al.* (2004) report asserts that previous viability assessments failed to adequately consider connectivity among spawner aggregations, underestimated juvenile over-winter survival in smaller stream reaches, and underestimated coho population stability. The report asserts that sharp reductions in ocean harvest rates since 1994, declining influence of hatchery-origin fish, and improved monitoring and evaluation under the Oregon Plan confer a very low risk of extinction even if future marine survival rates are low and remain low.

*Response:* The Cramer *et al.* (2004) report does not present any substantial new information, other than including an additional year of abundance data that was not available to the BRT. The report emphasizes selective aspects of the available data including: reduction of threats by changes in fishery and harvest management; and improved biological status evidenced by increasing spawning escapements and successful juvenile rearing throughout the ESU. These observations and analyses were fully considered in the BRT's review (Good *et al.*, 2005; NMFS, 2003a). The Cramer *et al.* (2004) report does not, by itself, add to our consideration of the BRT's findings.

*Comment 4:* Several commenters felt that effective regulatory controls and monitoring programs are in place to ensure that harvest and hatchery practices no longer threaten the ESU.

*Response:* Many noteworthy and important regulatory changes have been made that adequately address historically harmful practices. Changes in ocean and freshwater fisheries management have resulted in sharp reductions in fishing mortality in Oregon Coast coho populations, and likely have contributed to recent population increases. It is unlikely that those harvest controls will weaken in the future, in light of Federal management of ocean fisheries. Reforms in hatchery management practices have limited the potential for adverse ecological interactions between hatchery-origin and natural fish, and have markedly reduced risks to the genetic diversity and reproductive fitness for the majority of naturally spawned populations in the ESU. It is also unlikely those reforms will be weakened in the future.

*Comment 5:* One commenter was critical of the Oregon Forest Practices Act, and argued that it is inadequate to prevent the future degradation of riparian habitats, particularly on private non-industrial forestlands. The commenter noted that the Forest Practices Act applies only to the commercial harvest of trees, and that non-commercial land owners may cut riparian trees without restriction if they do not sell the wood. The commenter noted that this unregulated practice is particularly evident in areas with increased rural residential development along streambanks.

Other commenters doubted whether regulations, restoration programs, and other protective efforts would improve habitat conditions in the foreseeable future. One commenter noted that there is an insufficient data record to evaluate the success of protective efforts aimed at restoring riparian habitats, particularly in increasing the recruitment of large woody debris. Several other commenters doubted whether forest management under the Oregon Plan has resulted, or will result, in an increased amount of large-diameter trees (important for the recruitment of large woody debris in coho rearing areas). The commenters argued that the shorter rotations being implemented on private industrial forest lands reduce the size of trees delivered to streams in landslides, and thus may result in diminished stream complexity in important coho rearing habitats.

*Response:* Our review suggests that there are likely to be improvements in some aspects of habitat condition, declines in others, and a continuation of current conditions in still others (NMFS, 2005a). For example, the Northwest Forest Plan instituted riparian habitat buffers and other measures on Federal lands that improved many of the historical forestry practices that led to the loss and degradation of riparian habitats. Development and implementation of Total Maximum Daily Loads under the Federal Clean Water Act are likely to result in improved water quality. Restoration efforts have treated approximately seven percent of the stream miles within the range of the ESU over the last 7 years with the intent of restoring stream complexity and riparian habitats and improving water quality, though it is unclear how much restoration is likely to occur in the future, given funding uncertainties.

Forest practices on state and private land include some improvements over historically harmful practices, such as the establishment of riparian management areas under revisions to Oregon forest practice rules in the 1990s. However, there are also offsetting practices that are expected to degrade habitat conditions and complexity, such as shorter harvest rotations, road construction, and logging on unstable slopes and along debris flow paths (NMFS, 2005a).

For agricultural lands, riparian management is governed by agricultural water quality management plans under Oregon Senate Bill 1010, as well as by subsequently developed riparian rules which synthesize elements of individual Senate Bill 1010 plans for a given basin. These agricultural plans and rules do not specify the vegetation composition or size of the riparian areas to be established. The lack of specificity of these agricultural plans makes the enforcement and effectiveness of these plans uncertain (NMFS, 2005a). Any modest improvements in riparian vegetation on agricultural lands under current rules that might be expected may be offset by habitat declines resulting from urban and rural development (NMFS, 2005a). On balance, habitat conditions on agricultural lands are not likely to show significant improvement or decline.

Future urbanization and development within the range of the ESU is projected at approximately 20 percent population growth, representing slightly more than 30,000 people over the next 40 years (NMFS, 2005a). Most of this development is expected to be concentrated in lowland areas with high intrinsic potential for rearing coho. Current urban or rural growth boundaries encompass approximately nine percent of high intrinsic potential riparian habitat areas, so future urbanization and development activities could have significant implications for some coho populations. The degree of potential impacts on coho habitat (both positive and negative) is highly uncertain and depends largely on the spatial distribution of future urbanization and development activities, their proximity to riparian areas, and the kinds of development activities undertaken and the land management practices used.

*Comment 6:* Several commenters expressed concern that inadequate funding has limited the ability of many

Oregon agencies to monitor non-permitted habitat-affecting activities, effectively enforce regulations, and ensure proper reporting of permitted activities. The commenters felt that these inadequacies should be considered evidence of uncertainty that some as yet, unproven elements under the Oregon Plan will be implemented.

*Response:* The commenters are correct that the availability of necessary funding and staffing resources is an important consideration in evaluating how likely it is that a given protective effort will be implemented. Our review has noted that funding declines have led to the loss of staff at the Oregon Department of Environmental Quality, Department of Forestry, and ODFW (NMFS, 2005a). The reduced funding has slowed the completion of Total Maximum Daily Load water quality standards, and reduced the ability to monitor water quality, habitat structure and complexity, and fish populations.

*Comments Regarding the Designation of Critical Habitat*

*Comment 7:* One Federal commenter provided information recommending changes to designated stream reaches in several watersheds due to errors in interpreting existing salmon distribution maps, recent field surveys, and the location of impassible barriers. This commenter also questioned the inclusion of Jackson and Josephine counties as within the range of areas designated as critical habitat for Oregon Coast coho salmon.

*Response:* In light of the specific comments received, we have reviewed all the data regarding habitat areas occupied by coho salmon and the location of impassible barriers. This review included discussions with local ODFW biologists familiar with the areas in question. The majority of suggested revisions were found to be warranted, and, as a result, we have updated the endpoints delineating areas occupied by coho salmon, including those designated as critical habitat, in ten watersheds (see ''*Summary of Changes from the Proposed Critical Habitat Designation*''). We have also removed Josephine and Jackson counties from the relevant critical habitat table in our regulations. These counties overlap slightly with upland areas in watersheds occupied by Oregon Coast coho salmon, but they do not contain stream reaches designated as critical habitat for this ESU.

*Comment 8:* Two commenters questioned the ''medium'' conservation-value rating assigned by the CHART to the habitat area for Devils Lake coho. These areas are within a larger Devils Lake/Moolack Frontal watershed. The commenters cited recent genetic data establishing that coho from Rock Creek/Devils Lake are genetically distinct from other populations in the ESU. The commenters believed that the coho in Devils Lake possess a unique and distinct genetic heritage warranting a ''high'' conservation value rating.

*Response:* The CHART considered these comments along with recent population identification work (Lawson *et al.*, 2007) and genetic analyses by Johnson and Banks (2007). The team maintained that the Devils Lake/Moolack Frontal watershed (which contains Devils Lake) was still of medium conservation value, noting that Devil's Lake coho are one of ten small and dependent populations in this watershed and appear to be most closely related to coho in the nearby Siletz River. The team acknowledged that Devils Lake was the most productive of these ten populations but that the overall watershed did not warrant a high conservation value relative to other adjacent watersheds with more extensive habitat areas and functionally independent populations (e.g., the Siletz River and Yaquina River watersheds). Regardless, Devils Lake and all other habitat areas in the Devils Lake/Moolack Frontal watershed are designated as critical habitat for Oregon Coast coho salmon.

*Comment 9:* One tribal government expressed support of the proposed exclusion of Indian lands from the area eligible for critical habitat designation. The tribe agreed with our proposal that designating Indian lands as critical habitat would adversely impact tribal partnerships with us and limit the benefits that result from collaboration. Additionally, the tribe felt that the proposal to not designate Indian lands as critical habitat appropriately acknowledges tribal sovereignty and authority in managing natural resources on their lands.

*Response:* This final rule maintains the exclusion of Indian lands for the reasons described in the *Exclusions Based on Impacts to Tribes* section below.

*Comment 10:* Several commenters argued that the conservation benefits provided by certain conservation measures on non-Federal lands provide sufficient protections so that there would be minimal benefit of designating the affected areas as critical habitat. One commenter felt that existing forest protections under the Oregon Forest Protection Act and associated best management practices adequately protect the PCEs found on private and state forest lands in the State of Oregon. Another commenter felt that protections under the Oregon Plan have demonstrated conservation benefits that warrant the exclusion of affected areas from designation as critical habitat. Another commenter felt that existing regulatory and other mechanisms under these conservation measures are inadequate to protect the ESU and its habitats. The commenter argued that it is essential to designate critical habitat in these areas where existing regulatory mechanisms do not prevent or alter certain activities that would adversely modify habitat.

*Response:* The comments imply that if an area is covered by a management plan, it either does not meet the ESA section 3(5)(a) definition of critical habitat or it must be excluded from critical habitat under ESA section 4(b)(2). Neither assertion is correct.

Section 3(5)(a) of the ESA defines critical habitat as occupied areas containing physical or biological features that are (1) essential to the conservation of the species and (2) which may require special management considerations or protections. Consistent with the statute, in identifying areas meeting the definition of critical habitat for this ESU, we identified the physical or biological features essential to the conservation of the ESU, identified the occupied areas where these features are present, and then determined whether these features in each area may require special management considerations and protections. The bases for these conclusions are described further below and in a separate report (NMFS, 2007b).

Section 4(b)(2) of the ESA gives the Secretary discretion to exclude areas from critical habitat if he determines that benefits of exclusion outweigh the benefits of designation. Exercising the discretion to exclude an area from critical habitat requires evidence of a benefit of exclusion. Section 4(b)(2) and the supporting legislative history make clear that the consideration and weight given to impacts are within the Secretary's (H.R. 95–1625) discretion and that exclusion is not required even when the benefits of exclusion outweigh the benefits of designation. In other critical habitat designations for Pacific salmon and steelhead, the Secretary excluded areas from critical habitat on private lands covered by habitat conservation plans because there was evidence in the record that exclusion would enhance the relationship between the landowner and the agency. That improved relationship was expected to result in improved implementation of the plan and incentives for the development of other plans, increasing conservation benefits for fish (70 FR 52630; September 2, 2005). Regarding private and state lands subject to Oregon's forest practice laws, there is no conservation agreement in place between landowners and NMFS, nor any evidence in the record supporting a conclusion that conservation actions of landowners subject to these laws would improve as a result of exclusion. The same is true for lands generally covered by the Oregon Plan. Based on our review of available information, we found there were insufficient data and analysis to conclude that there is a benefit of exclusion. Absent evidence of a benefit of exclusion, we could not conclude that the benefits of exclusion outweigh the benefits of inclusion.

*Comment 11:* Two Federal commenters felt that all Federal lands merited exclusion from designation as critical habitat. They contended that conservation benefits under PACFISH, the Northwest Forest Plan, and National Forest Land and Resource Management Plans (LRMPs) provide necessary protection and special management that eliminates the need to designate habitats on Federal lands as critical. These commenters contended that designating critical habitat on these Federal lands was unnecessarily duplicative of existing ESA section 7 consultation processes, inefficient (e.g., citing costs of re-initiating consultation), while offering no additional conservation benefit to the listed species. They believed that excluding Federal lands would be consistent with our exclusion of military lands that are subject to Integrated Natural Resource Management Plans, which they felt contain similar provisions for the protection and restoration of listed species.

*Response:* ESA section 4(b)(2) provides the Secretary with discretion to exclude areas from the designation of critical habitat if the Secretary determines that the benefits of exclusion outweigh the benefits of designation, and the Secretary finds that exclusion of the area will not result in extinction of the species. In the proposed rule, and the reports supporting it, we explained the policies that guided us and provided supporting analysis for a number of proposed exclusions. We also noted a number of additional potential exclusions, including those associated with the Oregon Coast coho salmon due to conservation measures within the Northwest Forest Plan on Federal lands, explaining that we were considering them because the Secretary of the Interior had recently made similar exclusions in designating critical habitat for the bull trout. In the final rule designating critical habitat for 12 Pacific Northwest ESUs (70 FR 52630; September 2, 2005), we considered extensive comments supporting and opposing the exclusion of Federal lands, as well as comments concerning alternative approaches for assessing the benefits of exclusion versus inclusion of lands as critical habitat. That final rule also stated the following with regard to the potential exclusion of Federal lands and alternative approaches to designation:

> We will continue to study this issue and alternative approaches in future rulemakings designating critical habitat. In particular, we intend to analyze the planning and management framework for each of the ownership categories proposed for consideration for exclusion. In each case, we envision that the planning and management framework would be evaluated against a set of criteria, which could include at least some or all of the following:
>
> 1. Whether the land manager has specific written policies that create a commitment to protection or appropriate management of the physical or biological features essential to long-term conservation of ESA-listed salmon and steelhead.
>
> 2. Whether the land manager has geographically specific goals for protection or appropriate management of the physical or biological features essential to long-term conservation of ESA-listed salmon and steelhead.
>
> 3. Whether the land manager has guidance for land management activities designed to achieve goals for protection or appropriate management of the physical or biological features essential to long-term conservation of ESA-listed salmon and steelhead.
>
> 4. Whether the land manager has an effective monitoring system to evaluate progress toward goals for protection or appropriate management of the physical or biological features essential to long-term conservation of ESA-listed salmon and steelhead.
>
> 5. Whether the land manager has a management framework that will adjust ongoing management to respond to monitoring results and/or external review and validation of progress toward goals for protection or appropriate management of the physical or biological features essential to long-term conservation of ESA-listed salmon and steelhead.
>
> 6. Whether the land manager has effective arrangements in place for periodic and timely communications with NOAA on the effectiveness of the planning and management framework in reaching mutually agreed goals for protection or appropriate management of the physical or biological features essential to long-term conservation of ESA-listed salmon and steelhead.

NMFS has continued dialogue with the Federal land management agencies since that time. Although we have not yet developed the type of information that would allow us to exclude Federal lands at this time, we will work with the land management agencies to develop the information and consider exclusion of Federal lands, as well as alternative approaches to designation, where the analysis provides appropriate support. We anticipate that further analyses using principles such as those above can result in additional data to inform the ESA Section 4(b)(2) analysis regarding possible exclusion of Federal lands from critical habitat designations.

*Comment 12:* One commenter and a peer reviewer expressed concern that the economic analysis failed to consider the full range of economic benefits of salmon habitat conservation and, therefore, provided a distorted picture of the economic consequences of designating versus excluding eligible habitat areas. The commenter expressed concern that the economic impact of not designating particular areas would impede recovery efforts, and this cost should be considered in the economic analysis. The commenter cited the lack of consideration in the economic analysis of the potential benefits of critical habitat designation to: (1) Other aquatic and riparian species; (2) water quality; (3) recreation; and (4) increased recreational, commercial, and tribal harvest opportunities that would be available with recovery.

*Response:* As described in the economic analysis (NMFS, 2007c) and ESA section 4(b)(2) report (NMFS, 2007d), we did not have information available at the scale of this designation that would allow us to quantify the benefits of designation in terms of increased fisheries. Such an estimate would have required us to estimate the additional number of fish likely to be produced as a result of the designation, and would have required us to determine how to allocate the economic benefit from those additional fish to a particular watershed. Instead, we considered the ''benefits of designation'' in terms of conservation value ratings for each particular area (see ''Methods and Criteria Used to Designate Critical Habitat'' section below). We also lacked information to quantify and include in the economic analysis the economic benefit that might result from such things as improved water quality or flood control, or improved condition of other species.

Moreover, we did not have information at the scale of this designation that would allow us to consider the relative ranking of these types of benefits on the ''benefits of designation'' side of the ESA section 4(b)(2) balancing process. Our primary focus was to determine, consider, and balance the benefits of designating these areas to the conservation of the listed species. Given the uncertainties involved in quantifying or even ranking these ancillary types of benefits, we did not include them in our analysis.

**Final Species Determination**

The Oregon Coast coho ESU includes all naturally spawned populations of coho salmon in Oregon coastal streams south of the Columbia River and north of Cape Blanco (63 FR 42587; August 10, 1998). One hatchery stock is considered part of the ESU: The Cow Creek (ODFW stock # 37) hatchery coho stock.

On June 14, 2004, we proposed that five artificial propagation programs should be considered part of the ESU (69 FR 33102), including the North Fork Nehalem River (ODFW stock # 32), the North Umpqua River (ODFW stock # 18), Coos Basin (ODFW stock # 37), and the Coquille River (ODFW stock # 44) coho hatchery programs. Informed by our analysis of the comments received from ODFW, and other recently available information (see Comment 1 and response, above), we conclude that these four hatchery programs are not part of the Oregon Coast coho ESU.

**Assessment of the Species' Status**

The steps we follow in making a listing determination are to: Review the status of the species, analyze the factors listed in section 4(a)(1) of the ESA to identify threats facing the species, assess whether certain protective efforts mitigate these threats, and predict the species' future persistence. Below we summarize the information we evaluated in reviewing the status of the Oregon Coast coho ESU. We considered the information included in the record for our January 2006 determination in a manner consistent with the Court's ruling in *Trout Unlimited*. We also considered additional status information that was readily available since our January 2006 decision, to determine if this new information is consistent with our conclusion based on the January 2006 (as the Court has ordered us to consider it).

We begin a typical listing determination for a salmon ESU by gathering the most recent available and relevant biological information and appointing a panel of Federal scientists (the BRT) familiar with the biology and population dynamics of salmon. This panel reviews the status information, considers and discusses various possible interpretations of the information, and prepares a written report containing its recommendations as well as the basis for them. In addition, the documents underlying the BRT's conclusions are made available to the decision maker for consideration. Typically, the BRT's review takes about 3–6 months to complete.

At the same time, regulatory staff gather updated information about the status and trends for other related factors, including the potential contributions (both positive and negative) from hatchery programs, the condition of the habitat, and the expected implementation and effectiveness of conservation efforts. This information is considered together with the BRT's recommendations in forming a final determination and preparing a written explanation of that determination.

While the above steps were conducted for Oregon Coast coho prior to the issuance of the 2004 proposed rule, the court order in *Trout Unlimited* requiring a final determination and the time allowed for making that final determination do not permit us to follow our typical practice anew for Oregon Coast coho. The available record contains a BRT recommendation and report made in 2003, based on status information through 2002. The information in the record about the condition of the habitat and the effectiveness of conservation efforts is also mostly data collected prior to 2003. We have also considered draft reports of the Technical Recovery Team for the Oregon Coast. These draft reports are directed primarily at the population structure of and recovery criteria for the Oregon Coast coho ESU, rather than the determination required for a listing decision.

Quantitative information available to us for this determination also includes numerical information on the abundance of Oregon Coast coho through 2006, preliminary spawner survey information for 2007, and estimates of the ocean survival for coho through 2006. Comparison of the abundance of the naturally-produced coho with the marine survival index suggests the possibility that much of the variability in coho numbers over the last decade or so may be due to fluctuations in the availability of food in the near-shore ocean (NMFS, 2007k). In addition, there is some indication that juvenile survival is limited by the supply of nutrients from the carcasses of spawning adult coho (Bilby *et al.*, 2001). It is possible that existing freshwater habitat is adequate to support a viable ESU, and that the fluctuations observed in Oregon Coast coho populations are partially driven by the supply of carcasses. The 2003 BRT did not explicitly consider the relationship between coho abundance and marine food availability, or the relationship between juvenile survival and the supply of carcasses. Our current record lacks the information and analyses necessary to assess the present status of freshwater habitat conditions and functional processes in the ESU. Oregon has aggressively implemented habitat conservation efforts, yet we lack the data necessary to resolve the benefits realized from these efforts by coho populations given the considerable variability in other environmental processes. In short, the recently available abundance information is not necessarily indicative of degraded freshwater habitat conditions, nor is it convincingly suggestive of a declining long-term trend for the ESU. Given the opportunity for further scientific review, it is possible that an improved understanding of the roles marine conditions and stream-nutrient supply play in determining coho population dynamics, might require revision of this determination. In summary, if we had been permitted to consider all the scientific information in the record, and if we had been allowed more time to do a complete scientific review of new information in a manner consistent with our typically thorough and comprehensive analytical processes, there is a reasonable possibility that we would have reached a different final listing determination.

*Consideration of Information in the January 2006 Record*

*Biological Review Team Findings*—The 2003 BRT considered data available through 2002. The abundance and productivity of Oregon Coast coho since the previous status review (NMFS, 1997a) represented some of the best and worst years on record. Yearly adult returns for the Oregon Coast coho ESU were in excess of 160,000 natural spawners in 2001 and 2002, far exceeding the abundance observed for the past several decades. These encouraging increases in spawner abundance in 2000–2002 were preceded, however, by three consecutive brood years (the 1994–1996 brood years returning in 1997–1999, respectively) exhibiting recruitment failure (recruitment failure is when a given year class of natural spawners fails to replace itself when its offspring return to the spawning grounds 3 years later). These 3 years of recruitment failure were the only such instances observed thus far in the entire 55-year abundance time series for Oregon Coast coho salmon (although comprehensive population-level survey data have only been available since 1980). The encouraging 2000–2002 increases in natural spawner abundance occurred in many populations in the northern portion of the ESU, populations that were the most depressed at the time of the last review (NMFS, 1997a). Although encouraged by the increase in spawner abundance in 2000–2002, the BRT noted that the long-term trends in ESU productivity were still negative due to the low abundances observed during the 1990s.

The majority of the BRT felt that the recent increases in coho returns were most likely attributable to favorable ocean conditions and reduced harvest rates. The BRT was uncertain as to whether such favorable marine conditions would continue into the future. Despite the likely benefits to spawner abundance levels gained by the dramatic reduction of harvest rates on Oregon Coast coho populations (PFMC, 1998), harvest cannot be significantly further reduced in the future to compensate for declining productivity due to other factors. The BRT was concerned that if the long-term decline in productivity reflected deteriorating conditions in freshwater habitat, this ESU could face very serious risks of local extirpations if ocean conditions reverted back to poor productivity conditions. Approximately 30 percent of the ESU has suffered habitat fragmentation by culverts and thermal barriers, generating concerns about ESU spatial structure. Additionally, the lack of response to favorable ocean conditions for some populations in smaller streams and the different patterns between north and south coast populations may indicate compromised connectivity among populations. The degradation of many lake habitats and the resultant impacts on several lake populations in the Oregon Coast coho ESU also pose risks to ESU diversity. The BRT noted that hatchery closures, reductions in the number of hatchery smolt releases, and improved marking rates of hatchery fish have significantly reduced risks to diversity associated with artificial propagation.

The BRT found high risk to the ESU's productivity, and comparatively lower risk to the ESU's abundance, spatial structure, and diversity. Informed by this risk assessment, a slight majority of the BRT concluded that the Oregon Coast coho ESU was ''likely to become endangered within the foreseeable future.'' However, a substantial minority of the BRT concluded that the ESU was ''not in danger of extinction or likely to become endangered within the foreseeable future.'' The minority believed that the large number of spawners in 2001–2002 and a high projected abundance for 2003 suggested that this ESU was not ''in danger of extinction'' or ''likely to become endangered within the foreseeable future.'' Furthermore, the minority believed that recent strong returns following 3 years of recruitment failure demonstrated that populations in this ESU are resilient.

*Consideration of Artificial Propagation*—Our review of the five hatchery programs that were proposed to be listed as part of the ESU concluded that they collectively do not substantially reduce the extinction risk of the ESU (NMFS, 2003a, 2004a, 2004b; see proposed rule for a more detailed explanation of this assessment, 69 FR 33102; June 14, 2004). Our final determination that the North Umpqua River, Coos Basin, Coquille River, North Fork Nehalem River, and Fishhawk Lake coho hatchery programs are not part of the ESU does not alter our previous conclusion that artificial propagation does not contribute appreciably to the viability of the ESU.

In *Trout Unlimited* v. *Lohn* (Civ. No. 06–0483–JCC (W. D. Wash., June 13, 2006), the U.S. District Court for the Western District of Washington set aside our 2005 Hatchery Listing Policy, finding that the Policy's consideration of both natural and hatchery fish in ESA listing determinations departs from the ESA's central purpose to promote and conserve naturally self-sustaining populations. Although the extinction risk assessment in the 2006 record evaluated the status of the ESU in-total (including both within-ESU natural and hatchery fish), we found that consideration of artificial propagation does not reduce the risk of extinction of the ESU. Therefore, the above described assessment of extinction risk does not require revision in light of the ruling in the above case.

*Preliminary Results of Oregon Coast Coho Recovery Planning*—NMFS' Technical Recovery Team (TRT) for the Oregon and Northern California Coast is charged with describing the historical population structure, developing biological recovery criteria with which to evaluate the status of an ESU relative to recovery, and identifying those factors limiting or impeding recovery. Prior to our 2006 determination not to list the Oregon Coast coho ESU, the TRT provided a preliminary report on its progress in developing these products for the Oregon Coast coho ESU (NMFS, 2005d). The TRT's preliminary report underscored the uncertainty associated with assessing the future status of the ESU. The TRT stated that ''at this time our evaluation indicates, with a moderate degree of uncertainty, that the ESU is persistent'' (the TRT defines a ''persistent'' ESU as one that is able to persist (i.e., not go extinct) over a 100-year period without artificial support, relating the term to ''the simple risk of extinction, which is the primary determination of endangered status under the ESA''). The TRT further stated that ''our evaluation of biological viability based on current and recent past conditions shows a high degree of uncertainty with respect to the statement that the ESU is sustainable'' (the TRT defines a ''sustainable'' ESU as ''one that, in addition to being persistent, is able to maintain its genetic legacy and long-term adaptive potential for the foreseeable future * * * so that risk of extinction will not increase in the future,'' relating the term to ''threatened status under the ESA'').

*Biological Implications of Ocean-Climate Conditions*—In an August 12, 2005, memorandum, NMFS' Northwest Fisheries Science Center (NWFSC) summarized the most recent information available on West Coast ocean conditions, described observations of impacts on marine communities, and offered predictions of the implications of recent ocean conditions on West Coast salmon stocks, including the Oregon Coast coho ESU (NMFS, 2005e). The memorandum described recent observations of anomalous ocean conditions that may portend lower returns of coho salmon for the fall of 2005 and the next several years. The memorandum noted that indices of ocean-climate variation are suggestive of a regime shift in ocean-climate conditions that in the past have been associated with warmer water temperature, poor primary productivity, and generally less favorable conditions for coho marine survival. The recent in-situ observations confirm delayed coastal upwelling, anomalously warm sea surface temperatures, altered zooplankton community structure, and low survey abundances of juvenile salmon, possibly indicating low marine survival. Strong upwelling occurred in mid-July 2005 resulting in cooler sea surface temperatures, increased primary productivity, and generally more favorable conditions for salmon survival. It was unclear whether this delayed onset of coastal upwelling would compensate for earlier unfavorable conditions which occurred during critical life-history stages for coho salmon. The memorandum noted that model projections indicate that fish populations that prey on juvenile coho salmon may be reduced, possibly compensating somewhat for unfavorable marine survival conditions for coho returns in 2006. The memorandum concluded that the NWFSC was relatively confident that the negative biological implications of recent ocean conditions for the Oregon Coast coho ESU would be dramatic over the next few years.

*Conclusions Regarding the Status of the Oregon Coast Coho ESU*

We conclude, after considering the above information contained in the record of our January 2006 determination (in a manner consistent with the Court's order), that the Oregon Coast coho ESU is likely to become an endangered species in the foreseeable future throughout all or a significant portion of its range. This finding is based, in part, on the BRT's slight majority conclusion that the ESU is ''likely to become endangered in the foreseeable future.'' The TRT's subsequent preliminary assessment of ESU viability (NMFS, 2005d) was consistent with the BRT's assessment, finding a high degree of uncertainty whether the ESU is sustainable for the foreseeable future. Although returns in 2001 and 2002 were extremely encouraging, there remained concern whether future ocean conditions would favor such high levels of recruitment. The NWFSC's August 2005 memorandum describing the implications of recent ocean-climate conditions (NMFS, 2005e) did not assuage this concern, concluding that recent ocean conditions portended unfavorable marine survival conditions for Oregon Coast coho in the near term.

*Consideration of New Information Since the January 2006 Determination*

The ESA requires that listing determinations be made solely on the basis of the best scientific and commercial data available. To that end, we also considered new status and trend information made available since the 2003 BRT report, and since our January 2006 ''not warranted'' determination to ensure that our present listing determination for the Oregon Coast coho ESU has considered the best information available. We evaluated these new data to determine whether they supported our risk assessment based on the information contained in the January 2006 record alone.

Since the BRT convened in January 2003, the total abundance of natural spawners in the Oregon Coast coho ESU has declined each year (i.e., 2003–2006). The abundance of total natural spawners in 2006 (111,025 spawners) was approximately 43 percent of the recent peak abundance in 2002 (255,372 spawners). In 2003, ESU-level productivity (evaluated in terms of the number of spawning recruits resulting from spawners 3 years earlier) was above replacement (approximately 3.2 recruits per spawner). ESU-level productivity was essentially at replacement in 2004 (approximately 0.99 recruits per spawner), but below replacement in 2005 and 2006. The productivity observed in 2006 (approximately 0.49 recruits per spawner) is the lowest observed since 1991. From 2003–2006 harvest rates remained low, averaging approximately 12 percent of the total run. Marine survival from 2003–2006 (estimated in terms of the number of returning hatchery adults resulting from the number of hatchery smolts released 2 years earlier) was generally at or above the average during 1990–2006. The decline in ESU productivity from 2003–2006, while marine survival conditions were generally favorable, suggests that factors other than ocean conditions are responsible for the decline.

In August 2007, the Oregon and Northern California Coast TRT released a draft report entitled ''Biological Recovery Criteria for the Oregon Coast coho Salmon Evolutionarily Significant Unit'' (Wainwright *et al.*, 2007). This draft report presents biological criteria for assessing the ESU's progress toward recovery, and also applies these criteria in assessing the current biological status of the ESU. The TRT considered the population data available through 2004. This draft report thus represents a more recent assessment of the ESU's status relative to the 2003 BRT's review. The results of the recent draft report are consistent with the TRT's preliminary progress report described above (NMFS, 2005d), finding that there is low to moderate certainty that the ESU is sustainable for the foreseeable future. The recent draft report considered the population data available through 2004, and thus does not reflect the declining abundance and productivity observed in 2005 and 2006.

Preliminary spawner survey data for 2007 (the average peak number of spawners per mile observed during random coho spawning surveys in 41 streams) suggest that the 2007–2008 return of Oregon Coast coho is either (1) much reduced from abundance levels in 2006, or (2) exhibiting delayed run timing from previous years. As of December 13, 2007, the average peak number of spawners per mile was below 2006 levels in 38 of 41 surveyed streams (ODFW, 2007). It is possible that the timing of peak spawner abundance is delayed relative to previous years, and that increased spawner abundance in late December 2007 and January 2008 will compensate for the low levels observed thus far in the 2007–2008 spawning season.

Our review of the above new abundance and productivity information and the TRT's 2007 draft report does not indicate that the status of the Oregon Coast coho ESU has improved since the 2003 BRT report. The recent 5-year geometric mean abundance (2002–2006) of approximately 152,960 total natural spawners remains well above that of a decade ago (approximately 52,845 from 1992–1996). However, the decline in productivity from 2003 to 2006, despite generally favorable marine survival conditions and low harvest rates, is of concern.

After reviewing the scientific and commercial information available in the record concerning the status of the Oregon Coast Coho (in a manner consistent with the Court's order) and adding to the record the Draft 2007 TRT report, 2003–2006 abundance and marine survival information, and preliminary spawner survey information for 2007, we conclude that this information requires a conclusion that the ESU is likely to become an endangered species in the foreseeable future throughout all or a significant portion of its range. The recent declines in the ESU's abundance and productivity are not necessarily indicative of a substantial degradation of the ESU's status. Similar interannual variability in abundance and productivity has been observed previously for the Oregon Coast coho ESU, and similar variability is expected to occur in the future. The principal inquiry in determining if the ESU warrants listing is whether present habitat conditions are sufficient to support a viable ESU, and whether future freshwater habitat conditions are expected to degrade. The present and future status of freshwater habitat for the Oregon Coast coho ESU remains uncertain. As noted above, we believe that if we had been permitted to consider all the scientific information in the record, and if we had been allowed more time for a complete scientific review of new information in a manner consistent with our typically thorough and comprehensive analytical processes, there is a reasonable possibility that we would have reached a different final listing determination.

**Final Listing Determination**

*Consideration of ESA Section 4(a)(1) Factors*

Section 4(a)(1) of the ESA and NMFS' implementing regulations (50 CFR part 424) requires us to add a species to the

List of Endangered and Threatened Species if it is endangered or threatened because of any one or a combination of the following factors: (1) The present or threatened destruction, modification, or curtailment of its habitat or range; (2) overutilization for commercial, recreational, scientific, or educational purposes; (3) disease or predation; (4) inadequacy of existing regulatory mechanisms; or (5) other natural or human-made factors affecting its continued existence. We have previously detailed the impacts of various factors contributing to the decline of Pacific salmonids as part of our prior listing determinations for 27 ESUs, as well as in supporting technical reports (e.g., NMFS, 1997b, ''Coastal coho habitat factors for decline and protective efforts in Oregon;'' NMFS, 1997c, ''Factors Contributing to the Decline of Chinook Salmon—An Addendum to the 1996 West Coast Steelhead Factors for Decline Report;'' NMFS, 1996a, ''Factors for Decline—A Supplement to the Notice of Determination for West Coast Steelhead Under the Endangered Species Act''). Our prior listing determinations and technical reports concluded that all of the factors identified in section 4(a)(1) of the ESA have played a role in the decline of West Coast salmon and steelhead. In our 1998 threatened listing determination for the Oregon Coast coho ESU (63 FR 42588; August 10, 1998), we concluded that the decline of Oregon Coast coho populations is the result of several longstanding, human-induced factors (e.g., habitat degradation, water diversions, harvest, and artificial propagation) that exacerbate the adverse effects of natural environmental variability (e.g., floods, drought, and poor ocean conditions). The following discussion briefly summarizes our findings regarding the threats currently facing the Oregon Coast coho ESU. While these threats are treated in general terms, it is important to underscore that impacts from certain threats are more acute for some populations in the ESU.

A. The Present or Threatened Destruction, Modification, or Curtailment of Its Habitat or Range

In many Oregon coastal streams, past human activities (e.g., logging, agriculture, gravel mining, urbanization) have resulted in impediments to fish passage, degradation of stream complexity, increased sedimentation, reduced water quality and quantity, loss and degradation of riparian habitats, and loss and degradation of lowland, estuarine, and wetland coho rearing habitats. The relevant issues are whether current habitat conditions are adequate to support the ESU's persistence (that is, whether the species is endangered or threatened because of present destruction, modification, or curtailment of its habitat or range) and whether habitat conditions are likely to worsen in the future (that is, whether the species is endangered or threatened because of threatened destruction, modification, or curtailment of its habitat or range). Regarding the first issue, the 2003 BRT noted uncertainty about the adequacy of current habitat conditions, and this uncertainty contributed to the slight majority finding that the ESU was likely to become an endangered species within the foreseeable future.

Regarding the second issue, the threat of future habitat declines, the 2003 BRT noted that ''if the long-term decline in productivity [of the Oregon Coast coho ESU] reflects deteriorating conditions in freshwater habitat, this ESU could face very serious risks of local extinction during the next cycle of poor ocean conditions.'' The BRT thus identified potential future habitat declines as a potential concern. As part of our January 2006 determination we evaluated the likely future trend of various habitat elements and the likely impact of future population growth (NMFS, 2005a). With respect to population growth and urbanization, we found that approximately 3.4 percent of ''high intrinsic potential'' habitat areas for coho (e.g., lowland stream reaches particularly important to juvenile coho rearing and overwintering survival) are within currently designated urban growth areas, suggesting that future human population growth may not represent a significant threat to the ESU (NMFS, 2005a). With respect to lowland and upland habitat areas under various types of land use and ownership, we found that some areas are likely to improve, some are likely to decline, and others are likely to remain in their current condition. Overall, there is a high level of uncertainty associated with projections of future habitat conditions due to underlying economic and sociopolitical factors influencing forest harvest and restoration rates, urban conversion of agricultural and forest lands, and the enforcement and implementation of land-use plans and regulations. Based on our analysis, we found that there is insufficient evidence to conclude that the Oregon Coast coho ESU was more likely than not to become an endangered species because of the ''threatened destruction, modification, or curtailment of its habitat or range.'' It remains uncertain whether future freshwater habitat conditions will be adequate to support a viable coho ESU, particularly during periods of unfavorable ocean conditions and poor marine survival.

B. Overutilization for Commercial, Recreational, Scientific or Educational Purposes

Harvest rates on Oregon Coast coho populations ranged between 60 and 90 percent between the 1960s and 1980s (Good *et al.*, 2005). Modest harvest restrictions were imposed in the late 1980s, but harvest rates remained high until most directed coho salmon harvest was prohibited in 1994. These restrictive harvest regulations, developed concurrently with the Oregon Plan and subsequently revised, have imposed conservative restrictions on directed and incidental fishery mortality, and appropriately consider marine survival conditions and the biological status of naturally produced coho populations. Under these revised regulations, harvest rates are stipulated to be between 0 and 8 percent during critically low spawner abundance, and may increase to a maximum exploitation rate of 45 percent under high survival and abundance conditions (Oregon, 2005). Empirical data over the last 10 years show that harvest mortality for Oregon Coast coho has been maintained below 15 percent since the adoption of the revised regulations (Oregon, 2005). We agree with the 2003 BRT's finding that overutilization has been effectively addressed for Oregon Coast coho populations.

C. Disease or Predation

Past species introductions and habitat modifications have resulted in increased non-native predator populations, notably in coastal lake habitats. Predation by increased populations of marine mammals (principally sea lions) may influence salmon abundance in some local populations when other prey species are absent and where physical conditions lead to the concentration of adults and juveniles (e.g., Cooper and Johnson, 1992). However, the extent to which marine mammal predation threatens the persistence of Oregon coast coho populations is unknown.

Infectious disease is one of many factors that can influence adult and juvenile salmon survival. Salmonids are exposed to numerous bacterial, protozoan, viral, and parasitic organisms in spawning and rearing areas, hatcheries, migratory routes, and the marine environment. Specific diseases such as bacterial kidney disease, ceratomyxosis, columnaris, furunculosis, infectious hematopoietic necrosis virus, redmouth and black spot disease, erythrocytic inclusion body syndrome, and whirling disease, among others, are present and known to affect West Coast salmonids (Rucker *et al.*, 1953; Wood, 1979; Leek, 1987; Foott *et al.*, 1994; Gould and Wedemeyer, undated). In general, very little current or historical information exists to quantify trends over time in infection levels and disease mortality rates. However, studies have shown that naturally spawned fish tend to be less susceptible to pathogens than hatchery-reared fish (Buchanon *et al.*, 1983; Sanders *et al.*, 1992). Native salmon populations have co-evolved with specific communities of these organisms, but the widespread use of artificial propagation has introduced exotic organisms not historically present in a particular watershed. Habitat conditions such as low water flows and high temperatures can exacerbate susceptibility to infectious diseases.

Aggressive hatchery reform efforts implemented by the State of Oregon have reduced the magnitude and distribution of hatchery fish releases in the ESU, and, consequently, the interactions between hatchery- and natural-origin fish and the potential transmission of infectious diseases. Additionally, regulations controlling hatchery effluent discharges into streams have reduced the potential of pathogens being released into coho habitats.

D. The Inadequacy of Existing Regulatory Mechanisms

Existing regulations governing coho harvest have dramatically improved the ESU's likelihood of persistence. These regulations are unlikely to be weakened in the future. Of the wide range of land uses and other activities affecting salmon habitat, however, some are more amenable to regulation than others. In the range of Oregon Coast coho, the regulation of some activities and land uses will alter past harmful practices, resulting in habitat improvements; the regulation of other activities is inadequate to alter past harmful practices, resulting in habitat conditions continuing in their present state; and the regulation of still other activities and land uses will lead to further degradation (NMFS, 2005a).

E. Other Natural or Manmade Factors Affecting Its Continued Existence

Natural variability in ocean and freshwater conditions has at different times exacerbated or mitigated the effects on Oregon Coast coho populations of habitat limiting factors. There is considerable uncertainty in predicting ocean-climate conditions into the foreseeable future and their biological impacts on the Oregon Coast coho ESU. Variability in ocean-climate conditions is expected, and coho productivity and abundance are similarly expected to fluctuate in response to this natural environmental variability. It is unknown whether unfavorable ocean conditions will predominate in the foreseeable future.

Prior to the 1990s, coho hatchery programs along the Oregon coast posed substantial risks to the survival, reproductive fitness, and diversity of natural populations. High numbers of hatchery coho were released in most of the basins in the ESU, most programs propagated non-native broodstocks, and naturally spawning hatchery-origin strays were common in most natural production areas. Oregon's aggressive hatchery reform efforts have resulted in substantial reductions of this threat. Hatchery coho are released in less than half of the populations in the ESU, and the magnitude of releases has declined from a peak of 35 million smolts in 1981, to approximately 800,000 in 2005. Hatchery programs are currently constrained to releasing no more than 200,000 smolts in any basin. The reduction in the number of hatchery fish released has reduced the potential for competition with, and predation on, natural coho. The proportion of hatchery-origin fish in natural spawning areas has been reduced to below 10 percent in all but two populations in the ESU. All hatchery coho releases in the ESU are now marked, affording improved monitoring and assessment of the co-existing naturally produced coho populations. Broodstock management practices have been modified to minimize the potential for hatchery-origin fish to pose risks to the genetic diversity of local natural populations. We conclude the ESU is not in danger of extinction or likely to become endangered in the foreseeable future because of hatchery practices.

**Efforts Being Made To Protect the Species**

Section 4(b)(1)(A) of the ESA requires the Secretary to make listing determinations solely on the basis of the best scientific and commercial data available after taking into account efforts being made to protect a species. In making listing determinations we first assess the species' level of extinction risk, identify factors that threaten its continued existence, and assess existing efforts being made to protect the species to determine if those measures ameliorate the risks it faces. The reader is referred to the June 14, 2004, proposed rule for a summary of efforts, including those under the Oregon Plan, being made to protect Oregon Coast coho populations (69 FR 33102, at 33142). Harvest reductions and improvements in hatchery management are noteworthy in that they have been fully implemented and their effectiveness is manifested in the improved status of Oregon Coast coho populations. The benefits of these accomplishments in hatchery and harvest management under the Oregon Plan, however, were fully considered in the 2003 BRT's assessment of ESU extinction risk. In our June, 14, 2004, proposed listing for the Oregon Coast coho ESU (69 FR 33102), we evaluated all other relevant protective efforts and determined that they did not substantially alter our finding that the ESU is likely to become an endangered species within the foreseeable future throughout all or a significant portion of its range.

Since our January 2006 determination, the State of Oregon released a draft Coho Conservation Plan for Oregon Coast coho. The draft Conservation Plan culminated a 2-year development process including significant input and involvement from local stakeholders. The draft conservation plan establishes ambitious conservation goals and is an important step in describing limiting factors and threats, identifying specific conservation actions to address these factors and threats, and designing a robust research and monitoring program to evaluate the effectiveness of conservation actions that contribute to rebuilding the Oregon Coast coho ESU. As reflected in the comments that we provided on the draft Conservation Plan (NMFS, 2007e), the plan lacks the necessary detail, specificity, and commitment of resources to provide sufficient certainty of implementation and effectiveness to alter our assessment that the ESU is likely to become an endangered species within the foreseeable future throughout all or a significant portion of its range.

**Final Listing Determination**

The ESA defines an endangered species as any species in danger of extinction throughout all or a significant portion of its range, and a threatened species as any species likely to become an endangered species within the foreseeable future throughout all or a significant portion of its range. Section 4(b)(1) of the ESA requires that the listing determination be based solely on the best scientific and commercial data available, after conducting a review of the status of the species and taking into account those efforts, if any, being made to protect such species.

The information included in the record of our January 2006 determination (as the Court has ordered us to consider it) indicates that the Oregon Coast coho ESU is likely to become an endangered species within the foreseeable future throughout all or a significant portion of its range. New abundance and productivity data do not suggest that the ESU's biological status has improved since our January 2006 determination. Efforts being made to protect the species, at present, do not provide sufficient certainty of implementation or effectiveness to mitigate the assessed level of extinction risk. Therefore, we conclude that the Oregon Coast coho ESU warrants listing under the ESA as a threatened species.

**Prohibitions and Protective Regulations**

On June 28, 2005, as part of the final listing determinations for 16 ESUs of West Coast salmon, we amended and streamlined the previously promulgated ESA section 4(d) regulations for threatened salmon and steelhead (70 FR 37160). We finalized an amendment to provide the necessary flexibility to ensure that fisheries and artificial propagation programs are managed consistently with the conservation needs of threatened salmon and steelhead. Under this change the section 4(d) protections apply to natural and hatchery fish with an intact adipose fin, but not to listed hatchery fish that have had their adipose fin removed prior to release into the wild. Additionally, we made several simplifying and clarifying changes to the 4(d) regulations, including updating an expired limit (section 223.203(b)(2)), providing a temporary exemption for ongoing research and enhancement activities, and applying the same set of 14 limits to all threatened salmon and steelhead.

*Description of Protective Regulations Being Afforded Oregon Coast Coho*

Consistent with the June 2005 amended ESA section 4(d) regulations, this final rule applies the ESA section 9(a)(1) take and other prohibitions (subject to the ''limits'' discussed below) to unmarked members of the Oregon Coast coho ESU with an intact adipose fin. (The clipping of adipose fins in juvenile hatchery fish just prior to release into the natural environment is a commonly employed method for the marking of hatchery production). We believe this approach provides needed flexibility to appropriately manage the artificial propagation and directed take of threatened salmon and steelhead for the conservation and recovery of the listed species.

The June 2005 amended ESA section 4(d) regulations simplified the previously promulgated 4(d) rules by applying the same set of 14 ''limits'' to all threatened salmon and steelhead. These limits allow us to exempt certain activities from the take prohibitions, provided that the applicable programs and regulations meet specific conditions to adequately protect the listed species. In this final rule we are applying this same set of 14 limits to the Oregon Coast coho ESU. Comprehensive descriptions of each 4(d) limit are contained in ''A Citizen's Guide to the 4(d) Rule'' (available on the Internet at *http://www.nwr.noaa.gov*), and in previously published **Federal Register** notices (65 FR 42422, July 10, 2000; 65 FR 42485, July 10, 2000; 69 FR 33102; June 14, 2004; 70 FR 37160, June 28, 2005). These ''limits'' include: activities conducted in accordance with ESA section 10 incidental take authorization (50 CFR 223.203(b)(1)); scientific or artificial propagation activities with pending permit applications at the time of rulemaking (§ 223.203(b)(2)); emergency actions related to injured, stranded, or dead salmonids (§ 223.203(b)(3)); fishery management activities (§ 223.203(b)(4)); hatchery and genetic management programs (§ 223.203(b)(5)); activities in compliance with joint tribal/state plans developed within *United States (U.S.)* v. *Washington* or *U.S.* v. *Oregon* (§ 223.203(b)(6)); scientific research activities permitted or conducted by the states (§ 223.203(b)(7)); state, local, and private habitat restoration activities (§ 223.203(b)(8)); properly screened water diversion devices (§ 223.203(b)(9)); routine road maintenance activities (§ 223.203(b)(10)); certain park pest management activities (§ 223.203(b)(11)); certain municipal, residential, commercial, and industrial development and redevelopment activities (§ 223.203(b)(12)); management activities on state and private lands within the State of Washington (§ 223.203(b)(13)); and activities undertaken consistent with an approved tribal resource management plan (§ 223.204).

Limit § 223.203(b)(2) exempts scientific or artificial propagation activities with pending applications for ESA section 4(d) approval. The limit was amended as part of the June 28, 2005, final rule to temporarily exempt such activities from the take prohibitions during a ''grace period,'' provided that a complete application for 4(d) approval was received within a specified period from the notice's publication (70 FR 37160). The limit was again modified in February 2006 when the 4(d) regulations were extended to the Upper Columbia River steelhead DPS (71 FR 5178; February 1, 2006). The deadlines associated with this exemption have expired. Consistent with the 2004 proposed rule to list Oregon Coast coho and extend 4(d) regulations to the ESU (69 FR 33102; June 14, 2004), we believe it is necessary and advisable for the conservation and recovery of Oregon Coast coho to allow research and enhancement activities to continue uninterrupted while we process the necessary permits and approvals. Provided we receive a complete application by June 10, 2008, the take prohibitions will not apply to research and enhancement activities which affect Oregon Coast coho until the application is rejected as insufficient, a permit or 4(d) approval is issued, or until March 31, 2009, whichever occurs earliest. The length of this ''grace period'' is necessary because we process applications for 4(d) approval annually.

*Other Protective ESA Provisions*

Section 7(a)(4) of the ESA requires that Federal agencies confer with NMFS on any actions likely to jeopardize the continued existence of a species proposed for listing and on actions likely to result in the destruction or adverse modification of proposed critical habitat. For listed species, section 7(a)(2) requires Federal agencies to ensure that activities they authorize, fund, or conduct are not likely to jeopardize the continued existence of a listed species or to destroy or adversely modify its critical habitat. If a proposed Federal action may affect a listed species or its critical habitat, the responsible Federal agency must enter into consultation with NMFS or the FWS, as appropriate. Examples of Federal actions likely to affect salmon include authorized land management activities of the USFS and the BLM, as well as operation of hydroelectric and storage projects of the Bureau of Reclamation (BOR) and the U.S. Army Corps of Engineers (USACE). Such activities include timber sales and harvest, permitting livestock grazing, hydroelectric power generation, and flood control. Federal actions, including the USACE section 404 permitting activities under the Clean Water Act, USACE permitting activities under the River and Harbors Act, Federal Energy Regulatory Commission (FERC) licenses for non-Federal development and operation of hydropower, and Federal salmon hatcheries, may also require consultation.

Sections 10(a)(1)(A) and 10(a)(1)(B) of the ESA provide NMFS with authority to grant exceptions to the ESA's ''take'' prohibitions. Section 10(a)(1)(A) scientific research and enhancement permits may be issued to entities (Federal and non-Federal) conducting research that involves a directed take of listed species. A directed take refers to the intentional take of listed species. We have issued section 10(a)(1)(A) research/enhancement permits for currently listed ESUs for a number of activities, including trapping and tagging, electroshocking to determine population presence and abundance, removal of fish from irrigation ditches, and collection of adult fish for artificial propagation programs. Section 10(a)(1)(B) incidental take permits may be issued to non-Federal entities performing activities which may incidentally take listed species. The types of activities potentially requiring a section 10(a)(1)(B) incidental take permit include the operation and release of artificially propagated fish by state or privately operated and funded hatcheries, state or academic research that may incidentally take listed species, the implementation of state fishing regulations, logging, road building, grazing, and diverting water into private lands.

## Identification of Those Activities That Would Constitute a Violation of Section 9 of the ESA

NMFS and the FWS published in the **Federal Register** on July 1, 1994 (59 FR 34272), a policy that NMFS shall identify, to the maximum extent practicable at the time a species is listed, those activities that would or would not constitute a violation of section 9 of the ESA. The intent of this policy is to increase public awareness of the effect of this listing on proposed and ongoing activities within the species' range. At the time of the final rule, we must identify to the extent known specific activities that will not be considered likely to result in violation of section 9, as well as activities that will be considered likely to result in violation. We believe that, based on the best available information, the following actions will not result in a violation of section 9:

1. Possession of fish from the Oregon Coast coho ESU that are acquired lawfully by permit issued by NMFS pursuant to section 10 of the ESA, or by the terms of an incidental take statement issued pursuant to section 7 of the ESA; or

2. Federally funded or approved projects that involve activities such as silviculture, grazing, mining, road construction, dam construction and operation, discharge of fill material, stream channelization or diversion for which section 7 consultation has been completed, and when activities are conducted in accordance with any terms and conditions provided by NMFS in an incidental take statement accompanying a biological opinion.

There are many activities that we believe could potentially take salmon by harming them. ''Harm'' is defined by our regulations as ''an act which actually kills or injures fish or wildlife. Such an act may include significant habitat modification or degradation which actually kills or injures fish or wildlife by significantly impairing essential behavioral patterns, including, breeding, spawning, rearing, migrating, feeding or sheltering'' (50 CFR 222.102 (harm)). Activities that may harm the Oregon Coast coho ESU resulting in a violation of the section 9 take and other prohibitions, include, but are not limited to:

1. Land-use activities that degrade habitats for the Oregon Coast coho ESU (e.g., logging, grazing, farming, urban development, road construction in riparian areas and areas susceptible to mass wasting and surface erosion);

2. Destruction/alteration of the habitats for the Oregon Coast coho ESU, such as removal of large woody debris and ''sinker logs'' or riparian shade canopy, dredging, discharge of fill material, draining, ditching, diverting, blocking, gravel mining, or altering stream channels or surface or ground water flow;

3. Discharges or dumping of toxic chemicals or other pollutants (e.g., sewage, oil, gasoline) into waters or riparian areas supporting the Oregon Coast coho ESU;

4. Violation of discharge permits;

5. Application of pesticides affecting water quality or riparian areas for the Oregon Coast coho ESU;

6. Interstate and foreign commerce of fish from the Oregon Coast coho ESU and import/export of fish from the Oregon Coast coho ESU without a threatened or endangered species permit;

7. Collecting or handling of fish from the Oregon Coast coho ESU. Permits to conduct these activities are available for purposes of scientific research or to enhance the conservation or survival of the species; and

8. Introduction of non-native species likely to prey on fish from the Oregon Coast coho ESU or displace them from their habitat.

These lists are not exhaustive. They are intended to provide some examples of the types of activities that might or might not be considered by NMFS as constituting a take of fish in the Oregon Coast coho ESU under the ESA and its regulations. Questions regarding whether specific activities would constitute a violation of the section 9 take and other prohibitions, and general inquiries regarding prohibitions and permits, should be directed to NMFS (see **ADDRESSES**).

## Designating Critical Habitat

## Methods and Criteria Used to Designate Critical Habitat

The following paragraphs and sections describe the relevant definitions and guidance found in the ESA and our implementing regulations, and the key methods and criteria we used to designate critical habitat after incorporating, as appropriate, comments and information received on the proposed rule.

Section 4 of the ESA (16 U.S.C. 1533(b)(2) and our regulations at 50 CFR 424.12(a) require that we designate critical habitat, and make revisions thereto, ''on the basis of the best scientific data available.'' Section 3 of the ESA (16 U.S.C. 1532(5)) defines critical habitat as ''(i) the specific areas within the geographical area occupied by the species, at the time it is listed * * * on which are found those physical or biological features (I) essential to the conservation of the species and (II) which may require special management considerations or protection; and (ii) specific areas outside the geographical area occupied by the species at the time it is listed upon a determination by the Secretary that such areas are essential for the conservation of the species.'' Section 3 of the ESA (16 U.S.C. 1532(3)) also defines the terms ''conserve,'' ''conserving,'' and ''conservation'' to mean ''to use, and the use of, all methods and procedures which are necessary to bring any endangered species or threatened species to the point at which the measures provided pursuant to this chapter are no longer necessary.''

Pursuant to our regulations, when identifying physical or biological features essential to conservation, we consider the following requirements of the species: (1) Space for individual and population growth, and for normal behavior; (2) food, water, air, light, minerals, or other nutritional or physiological requirements; (3) cover or shelter; (4) sites for breeding, reproduction, or rearing of offspring;

and, generally, (5) habitats that are protected from disturbance or are representative of the historical geographical and ecological distributions of the species (see 50 CFR 424.12(b)). In addition to these factors, we also focus on the more specific primary constituent elements (PCEs) within the occupied areas that are essential to the conservation of the species. The regulations identify PCEs as including, but not limited to: ''roost sites, nesting grounds, spawning sites, feeding sites, seasonal wetland or dryland, water quality or quantity, host species or plant pollinator, geological formation, vegetation type, tide, and specific soil types.'' For an area containing PCEs to meet the definition of critical habitat, we must conclude that the PCEs in that area ''may require special management considerations or protection.'' Our regulations define special management considerations or protection as ''any methods or procedures useful in protecting physical and biological features of the environment for the conservation of listed species.'' Both the ESA and our regulations, in recognition of the divergent biological needs of species, establish criteria that are species specific rather than a ''one size fits all'' approach.

Our regulations state that, ''[t]he Secretary shall designate as critical habitat areas outside the geographic area presently occupied by the species only when a designation limited to its present range would be inadequate to ensure the conservation of the species' (50 CFR 424.12(e)). Accordingly, when the best available scientific data do not demonstrate that the conservation needs of the species so require, we will not designate critical habitat in areas outside the geographic area occupied by the species.

Section 4 of the ESA (16 U.S.C. 1533(b)(2)) requires that, before designating critical habitat, we consider the economic impacts, impacts on national security, and other relevant impacts of specifying any particular area as critical habitat, and the Secretary may exclude any area from critical habitat if the benefits of exclusion outweigh the benefits of designation, unless excluding an area from critical habitat will result in the extinction of the species. This exercise of discretion must be based upon the best scientific and commercial data. Once critical habitat for a salmon or steelhead ESU is designated, section 7(a)(2) of the ESA requires that each Federal agency, in consultation with and with the assistance of NMFS, ensure that any action they authorize, fund, or carry out is not likely to result in the destruction or adverse modification of critical habitat.

**Identifying the Geographical Area Occupied by the Species and Specific Areas Within the Geographical Area**

In past critical habitat designations, we had concluded that the limited availability of species distribution data prevented mapping salmonid critical habitat at a scale finer than occupied river basins (65 FR 7764; February 16, 2000). Therefore, the 2000 designations defined the ''geographical area occupied by the species, at the time of listing'' as all accessible river reaches within the current range of the listed species.

In the 2004 proposed rule to designate critical habitat for 13 ESUs of Pacific salmon and steelhead (69 FR 74572; December 14, 2004) we described in greater detail that, since the previous designations in 2000, we can now be more precise about the ''geographical area occupied by the species'' because Federal, state, and tribal fishery biologists have made progress documenting and mapping actual species distribution at the level of stream reaches. Moreover, much of the available data can now be accessed and analyzed using Geographic Information System (GIS) software to produce consistent and fine-scale maps (NMFS, 2007b; StreamNet, 2005). The current maps document fish presence by identifying occupied stream reaches where the species has been observed. It also identifies stream reaches where the species is presumed to occur based on the professional judgment of biologists familiar with the watershed (although in some cases there are streams classified as occupied based on professional judgment when in fact the species has been observed but the GIS data have not been updated). We made use of these finer-scale data for the final critical habitat designations for 12 Pacific Northwest ESUs (70 FR 52630; September 2, 2005), as well as for the current critical habitat designation. We believe that this approach enables a more accurate delineation of the ''geographical area occupied by the species'' referred to in the ESA definition of critical habitat. We received some comments on this approach, some in support and some against it (see comments in final critical habitat designations for 12 Pacific Northwest ESUs, 70 FR 52630, September 2, 2005). However, none of the latter comments described a specific methodology that would yield a better approach than what we used.

We are now also able to identify ''specific areas'' (ESA section 3(5)(a)) and ''particular areas'' (ESA section 4(b)(2)) at a finer scale than in 2000. Since 2000, various Federal agencies have mapped fifth field hydrologic units (referred to as ''HUC5s'' or ''watersheds'') throughout the Pacific Northwest using USGS mapping conventions (Seaber *et al.*, 1986). This information is now generally available via the internet (NMFS, 2007b), and we have expanded our GIS resources to use these data. As in the 2000 designations (in which we used larger fourth field hydrologic units), we used the HUC5s to organize critical habitat information systematically and at a scale that is applicable to the spatial distribution of salmon. Organizing information at this scale is especially relevant to salmonids, since their innate homing ability allows them to return to the watersheds where they were born. Such site fidelity results in spatial aggregations of salmonid populations that generally correspond to the area encompassed by subbasins or HUC5 watersheds (Washington Department of Fisheries *et al.*, 1992; Kostow, 1995; McElhany *et al.*, 2000). As noted above regarding our use of finer scale data, none of the comments received provided us with a specific alternative methodology that would yield a better approach than the watershed-scale approach we adopted.

The USGS maps watershed units as polygons, bounding a drainage area from ridge-top to ridge-top, encompassing streams, riparian areas and uplands. Within the boundaries of any watershed, there are stream reaches not occupied by the species. Land areas within the HUC5 boundaries are also generally not ''occupied'' by the species (though certain areas such as flood plains or side channels may be occupied at some times of some years). We used the watershed boundaries as a basis for aggregating occupied stream reaches, for purposes of delineating ''specific'' areas at a scale that often corresponds well to salmonid population structure and ecological processes. Although we are designating only the streams and not the entire watershed, our documents frequently refer to the ''specific areas'' as ''watersheds'' because that is the term often used as a convenient shorthand. We also refer to the stream reaches as ''habitat areas.'' Each watershed was reviewed by the CHART to verify occupation, PCEs, and special management considerations (see ''Critical Habitat Analytical Review Team'' section below).

The watershed-scale aggregation of stream reaches also allowed us to analyze the impacts of designating a ''particular area,'' as required by ESA section 4(b)(2). As a result of watershed processes, many activities occurring in riparian or upland areas and in non-fish-bearing streams may affect the physical or biological features essential to conservation in the occupied stream reaches. The watershed boundary thus describes an area in which Federal activities have the potential to affect critical habitat (Spence *et al.*, 1996). Using watershed boundaries for the economic analysis ensured that all potential economic impacts were considered. Section 3(5) defines critical habitat in terms of ''specific areas,'' and section 4(b)(2) requires the agency to consider certain factors before designating ''particular areas.'' In the case of West Coast salmon and steelhead, the biology of the species, the characteristics of their habitat, the nature of the impacts, and the limited information currently available at finer geographic scales made it appropriate to consider ''specific areas'' and ''particular areas'' as the same unit for purposes of economic exclusions.

Occupied estuarine and marine areas were also considered in the context of defining ''specific areas.'' In our proposed rule (69 FR 74572; December 14, 2004) we noted that estuarine areas are crucial for juvenile salmonids, given their multiple functions as areas for rearing/feeding, freshwater-saltwater acclimation, and migration (Simenstad *et al.*, 1982; Marriott *et al.*, 2002). Within the geographic range of the Oregon Coast coho ESU all estuaries fall within the boundaries of a HUC5 and so were assessed along with upstream freshwater habitats within the watershed. In all occupied estuarine areas we were able to identify physical or biological features essential to the conservation of the species, and that may require special management considerations or protection. For those estuarine areas designated as critical habitat we are again delineating them in similar terms to our past designations, as being defined by a line connecting the furthest land points at the estuary mouth.

In previous designations of salmonid critical habitat we did not designate offshore marine areas (with the exception of deep waters in Puget Sound (65 FR 7764, February 16, 2000; 70 FR 52630, September 2, 2005). In the Pacific Ocean, we concluded that there may be essential habitat features, but we could not identify any special management considerations or protection associated with them as required under section 3(5)(A)(I) of the ESA (65 FR 7776; February 16, 2000). Since that time we have carefully considered the best available scientific information, and related agency actions, such as the designation of Essential Fish Habitat under the Magnuson-Stevens Fishery Conservation and Management Act. We believe that forage species are a feature in the Pacific Ocean that are essential for salmon conservation and that may require special management considerations or protection, at least for those forage species that are a target of human harvest. However, because salmonids are opportunistic feeders we could not identify ''specific areas'' beyond the nearshore marine zone where these or other essential features are found within this vast geographic area occupied by salmon and steelhead. In contrast to estuarine and nearshore areas, we conclude that it is not possible to identify ''specific areas'' in the Pacific Ocean that contain essential features for salmonids, and, therefore, we are not designating critical habitat in offshore marine areas. We requested comment on this issue in our proposed rule but did not receive comments or information that would change our conclusion (70 FR 52630, September 2, 2005).

*Primary Constituent Elements*

In determining what areas are critical habitat, agency regulations at 50 CFR 424.12(b) require that we ''consider those physical or biological features that are essential to the conservation of a given species * * *, including space for individual and population growth and for normal behavior; food, water, air, light, minerals, or other nutritional or physiological requirements; cover or shelter; sites for breeding, reproduction, and rearing of offspring; and habitats that are protected from disturbance or are representative of the historical geographical and ecological distribution of a species.'' The regulations further direct us to ''focus on the principal biological or physical constituent elements * * * that are essential to the conservation of the species,'' and specify that the ''known primary constituent elements shall be listed with the critical habitat description.'' The regulations identify PCEs as including, but not limited to: ''roost sites, nesting grounds, spawning sites, feeding sites, seasonal wetland or dryland, water quality or quantity, host species or plant pollinator, geological formation, vegetation type, tide, and specific soil types.''

NMFS biologists developed a list of PCEs that are essential to the species' conservation and based on the unique life history of salmon and steelhead and their biological needs (Hart, 1973; Beauchamp *et al.*, 1983; Laufle *et al.*, 1986; Pauley *et al.*, 1986, 1988, and 1989; Groot and Margolis, 1991; Spence *et al.*, 1996). Guiding the identification of PCEs was a decision matrix we developed for use in ESA section 7 consultations (NMFS, 1996b) which describes general parameters and characteristics of most of the essential features under consideration in this critical habitat designation. We identified these PCEs and requested comment on them in the advance notice of proposed rulemaking (ANPR)(68 FR 55931; September 29, 2003) and proposed rule (69 FR 74636; December 14, 2005) but did not receive information to support changing them. These PCEs include sites essential to support one or more life stages of the ESU (sites for spawning, rearing, migration and foraging). These sites in turn contain physical or biological features essential to the conservation of the ESU (for example, spawning gravels, water quality and quantity, side channels, forage species). The specific PCEs include:

1. Freshwater spawning sites with water quantity and quality conditions and substrate supporting spawning, incubation, and larval development. These features are essential to conservation because without them the species cannot successfully spawn and produce offspring.

2. Freshwater rearing sites with water quantity and floodplain connectivity to form and maintain physical habitat conditions and support juvenile growth and mobility; water quality and forage supporting juvenile development; and natural cover such as shade, submerged and overhanging large wood, log jams and beaver dams, aquatic vegetation, large rocks and boulders, side channels, and undercut banks. These features are essential to conservation because without them juveniles cannot access and use the areas needed to forage, grow, and develop behaviors (e.g., predator avoidance, competition) that help ensure their survival.

3. Freshwater migration corridors free of obstruction with water quantity and quality conditions and natural cover such as submerged and overhanging large wood, aquatic vegetation, large rocks and boulders, side channels, and undercut banks supporting juvenile and adult mobility and survival. These features are essential to conservation because without them juveniles cannot use the variety of habitats that allow them to avoid high flows, avoid predators, successfully compete, begin the behavioral and physiological changes needed for life in the ocean, and reach the ocean in a timely manner. Similarly, these features are essential for adults because they allow fish in a non-feeding condition to successfully swim

upstream, avoid predators, and reach spawning areas on limited energy stores.

4. Estuarine areas free of obstruction with water quality, water quantity, and salinity conditions supporting juvenile and adult physiological transitions between fresh- and saltwater; natural cover such as submerged and overhanging large wood, aquatic vegetation, large rocks and boulders, and side channels; and juvenile and adult forage, including aquatic invertebrates and fishes, supporting growth and maturation. These features are essential to conservation because without them juveniles cannot reach the ocean in a timely manner and use the variety of habitats that allow them to avoid predators, compete successfully, and complete the behavioral and physiological changes needed for life in the ocean. Similarly, these features are essential to the conservation of adults because they provide a final source of abundant forage that will provide the energy stores needed to make the physiological transition to fresh water, migrate upstream, avoid predators, and develop to maturity upon reaching spawning areas.

5. Nearshore marine areas free of obstruction with water quality and quantity conditions and forage, including aquatic invertebrates and fishes, supporting growth and maturation; and natural cover such as submerged and overhanging large wood, aquatic vegetation, large rocks and boulders, and side channels. As in the case with freshwater migration corridors and estuarine areas, nearshore marine features are essential to conservation because without them juveniles cannot successfully transition from natal streams to offshore marine areas. We have focused our designation on nearshore areas in Puget Sound because of its unique and relatively sheltered fjord-like setting (as opposed to the more open coastlines of Washington and Oregon).

6. Offshore marine areas with water quality conditions and forage, including aquatic invertebrates and fishes, supporting growth and maturation. These features are essential for conservation because without them juveniles cannot forage and grow to adulthood. However, for the reasons stated previously in this document, it is difficult to identify specific areas containing this PCE as well as human activities that may affect the PCE condition in those areas. Therefore, we have not designated any specific areas based on this PCE but instead have identified it because it is essential to the species' conservation, and specific offshore areas may be identified in the future (in which case any revision to this designation would be subject to separate rulemaking).

The occupied habitat areas designated in this final rule contain PCEs required to support the biological processes for Oregon Coast coho using the habitat. The CHART verified this for each watershed/nearshore zone by relying on the best available scientific data (including species distribution maps, watershed analyses, and habitat surveys) during its review of occupied areas and resultant assessment of area conservation values (NMFS, 2007b). The contribution of the PCEs varies by site and biological function such that the quality of the elements may vary within a range of acceptable conditions. The CHART took this variation into account when it assessed the conservation value of an area.

Special Management Considerations or Protections

An occupied area meets the definition of critical habitat only if it contains physical and biological features that ''may require special management considerations or protection.'' Agency regulations at 50 CFR 424.02(j) define ''special management considerations or protection'' to mean ''any methods or procedures useful in protecting physical and biological features of the environment for the conservation of listed species.''

As part of the biological assessment described below under ''Critical Habitat Analytical Review Team,'' a team of biologists examined each habitat area to determine whether the physical or biological features may require special management consideration. These determinations are identified for each area in the final CHART report for the Oregon Coast coho ESU (NMFS, 2007b). Consistent with the final critical habitat designations for 12 Pacific Northwest ESUs (70 FR 52630; September 2, 2005), the CHART identified a variety of activities that threaten the physical and biological features essential to listed salmon and steelhead (see review by Spence *et al.*, 1996), including: (1) Forestry; (2) grazing; (3) agriculture; (4) road building/maintenance; (5) channel modifications/diking; (6) urbanization; (7) sand and gravel mining; (8) mineral mining; (9) dams; (10) irrigation impoundments and withdrawals; (11) river, estuary, and ocean traffic; (12) wetland loss/removal; (13) beaver removal; and (14) exotic/invasive species introductions. In addition to these, the harvest of salmonid prey species (e.g., forage fishes such as herring, anchovy, and sardines) may present another potential habitat-related management activity (Pacific Fishery Management Council, 1999).

*Unoccupied Areas*

ESA section 3(5)(A)(ii) defines critical habitat to include ''specific areas outside the geographical area occupied'' if the areas are determined by the Secretary to be ''essential for the conservation of the species.'' NMFS regulations at 50 CFR 424.12(e) emphasize that we ''shall designate as critical habitat areas outside the geographical area presently occupied by a species only when a designation limited to its present range would be inadequate to ensure the conservation of the species.'' For the Oregon Coast coho ESU we are not designating unoccupied areas at this time. The CHART did not identify any unoccupied areas that may be essential for the conservation of the Oregon Coast coho ESU. Thus, we are not designating any unoccupied areas at this time. Any future designation of unoccupied areas would be based on the required determination that such area is essential for the conservation of the ESU and would be subject to separate rulemaking with the opportunity for notice and comment.

*Lateral Extent of Critical Habitat*

In past designations we have described the lateral extent of critical habitat in various ways, ranging from fixed distances to ''functional'' zones defined by important riparian functions (65 FR 7764; February 16, 2000). Both approaches presented difficulties, and this was highlighted in several comments (most of which requested that we focus on aquatic areas only) received in response to the ANPR (68 FR 55926; September 29, 2003). Designating a set riparian zone width will (in some places) accurately reflect the distance from the stream on which PCEs might be found, but in other cases may over- or understate the distance. Designating a functional buffer avoids that problem, but makes it difficult for Federal agencies to know in advance what areas are critical habitat. To address these issues we have defined the lateral extent of designated critical habitat as the width of the stream channel defined by the ordinary high-water line as defined by the USACE in 33 CFR 329.11. This approach is consistent with the specific mapping requirements described in agency regulations at 50 CFR 424.12(c)). In areas for which ordinary high-water has not been defined pursuant to 33 CFR 329.11, the width of the stream channel shall be defined by its bankfull elevation. Bankfull elevation is the level at which water begins to leave the channel and move into the floodplain

(Rosgen, 1996) and is reached at a discharge which generally has a recurrence interval of 1 to 2 years on the annual flood series (Leopold *et al.*, 1992). Such an interval is commensurate with the juvenile freshwater life phases of coho salmon. Therefore, it is reasonable to conclude that for an occupied stream reach this lateral extent is regularly ''occupied.'' Moreover, the bankfull elevation can be readily discerned for a variety of stream reaches and stream types using recognizable water lines (e.g., marks on rocks) or vegetation boundaries (Rosgen, 1996).

As underscored in previous critical habitat designations, the quality of aquatic habitat within stream channels is intrinsically related to the adjacent riparian zones and floodplain, to surrounding wetlands and uplands, and to non-fish-bearing streams above occupied stream reaches. Human activities that occur outside the stream can modify or destroy physical and biological features of the stream. In addition, human activities that occur within and adjacent to reaches upstream (e.g., road failures) or downstream (e.g., culverts and dams) of designated stream reaches can also have demonstrable effects on physical and biological features of designated reaches.

In the relatively few cases where we are designating lake habitats (e.g., Devils, Siltcoos, Tahkenitch, Sand, and Tenmile lakes), we believe that the lateral extent may best be defined as the perimeter of the water body as displayed on standard 1:24,000 scale topographic maps or the elevation of ordinary high water, whichever is greater. In estuarine areas we believe that extreme high water is the best descriptor of lateral extent. As noted above for stream habitat areas, human activities that occur outside the area inundated by extreme or ordinary high water can modify or destroy physical and biological features of the estuarine habitat areas, and Federal agencies must be aware of these important habitat linkages as well.

*Critical Habitat Analytical Review Team*

To assist in the designation of critical habitat, we convened a CHART for the Oregon Coast domain. The CHART consisted of eight Federal biologists and habitat specialists from NMFS, USFS, and BLM, with demonstrated expertise regarding salmonid habitat and related protective efforts within the domain. The CHART was tasked with assessing biological information pertaining to areas under consideration for designation as critical habitat. The CHART also reconvened to review the public comments and any new information regarding the ESU and its habitat. Its work and determinations are documented in a final CHART report (NMFS, 2007b).

The CHART examined each habitat area within a watershed to determine whether the stream reaches or lakes occupied by the Oregon Coast coho contain the physical or biological features essential to conservation. As noted previously, the CHART also relied on its experience conducting ESA section 7 consultations and existing management plans and protective measures to determine whether these features may require special management considerations or protection. In addition to occupied areas, the definition of critical habitat also includes unoccupied areas if we determine the area is essential for conservation. Accordingly, the CHART was next asked whether there were any unoccupied areas within the historical range of the ESU that may be essential for conservation. The CHART did not identify any such unoccupied areas.

The CHART was next asked to determine the relative conservation value of each area for each ESU. The CHART scored each habitat area based on several factors related to the quantity and quality of the physical and biological features. It next considered each area in relation to other areas and with respect to the population occupying that area. Based on a consideration of the raw scores for each area, and a consideration of that area's contribution in relation to other areas and in relation to the overall population structure of the ESU, the CHART rated each habitat area as having a ''high,'' ''medium,'' or ''low'' conservation value. The preliminary CHART ratings were reviewed by several state and tribal comanagers in advance of the proposed rule, and the CHART made needed changes prior to that rule. State and tribal comanagers also evaluated our proposed rule (69 FR 74572; December 14, 2004) and provided comments and new information which were also reviewed and incorporated as needed by the CHART in the preparation of this final designation.

The rating of habitat areas as having a high, medium, or low conservation value provided information useful to inform the Secretary's exercise of discretion in determining whether the benefits of exclusion outweigh the benefits of designation (i.e., ESA section 4(b)(2)). The higher the conservation value for an area, the greater the likely benefit of the ESA section 7 protections. We recognized that the ''benefit of designation'' would also depend on the likelihood of a consultation occurring and the improvements in species' conservation that may result from changes to proposed Federal actions. To address this concern, we asked the CHART to develop a profile for a ''low leverage'' watershed—that is, a watershed where it was unlikely there would be a section 7 consultation, or where a section 7 consultation, if it did occur, would yield few conservation benefits. For watersheds not meeting the ''low leverage'' profile, we considered their conservation rating to be a fair assessment of the benefit of designation. For watersheds meeting the ''low leverage'' profile, we considered the benefit of designation to be an increment lower than the conservation rating. For example, a watershed with a ''high'' conservation value but ''low leverage'' was considered to have a ''medium'' benefit of designation, and so forth (NMFS, 2007b).

As discussed earlier, the scale chosen for the ''specific area'' referred to in section 3(5)(a) was a watershed, as delineated by USGS methodology. There were some complications with this delineation that required us to adapt the CHARTs' approach for some areas. In particular, a large stream or river might serve as a rearing and migration corridor to and from many watersheds, yet be embedded itself in a watershed. In any given watershed through which it passes, the stream may have a few or several tributaries. For rearing/migration corridors embedded in a watershed, the CHART was asked to rate the conservation value of the watershed based on the tributary habitat. We assigned the rearing/migration corridor the rating of the highest-rated watershed for which it served as a rearing/migration corridor. The reason for this treatment of migration corridors is the role they play in the salmon's life cycle. Salmon are anadromous—born in fresh water, migrating to salt water to feed and grow, and returning to fresh water to spawn. Without a rearing/migration corridor to and from the sea, salmon cannot complete their life cycle. It would be illogical to consider a spawning and rearing area as having a particular conservation value and not consider the associated rearing/migration corridor as having a similar conservation value.

**Application of ESA Section 4(b)(2) (16 U.S.C. 1533(b)(2))**

The foregoing discussion describes those areas that are eligible for designation as critical habitat—the specific areas that fall within the ESA section 3(5)(A) definition of critical habitat. However, specific areas eligible for designation are not automatically designated as critical habitat. Section 4(b)(2) of the ESA requires the Secretary to first consider the economic impact, impact on national security, and any other relevant impact of designation. The Secretary has the discretion to exclude an area from designation if he determines the benefits of exclusion (that is, avoiding the impact that would result from designation) outweigh the benefits of designation based upon best scientific and commercial data. The Secretary may not exclude an area from designation if exclusion will result in the extinction of the species. Because the authority to exclude is discretionary, exclusion is not required for any areas. In this rulemaking, the Secretary has applied his statutory discretion to exclude areas from critical habitat for several different reasons (NMFS, 2007d).

In this exercise of discretion, the first issue we must address is the scope of impacts relevant to the ESA section 4(b)(2) evaluation. We proposed new critical habitat designations for 13 Pacific Northwest ESUs, including the Oregon Coast coho ESU (69 FR 74572; December 14, 2004), because the previous designations were vacated following a Court ruling that we had inadequately considered the economic impacts of designating critical habitat. (*National Association of Homebuilders* v. *Evans*, 2002 WL 1205743 No. 00–CV–2799 (D.D.C.) (NAHB)). The *NAHB* court had agreed with the reasoning of the Court of Appeals for the Tenth Circuit in *New Mexico Cattle Growers Association* v. *U.S. Fish and Wildlife Service*, 248 F.3d 1277 (10th Cir. 2001). In that decision, the Tenth Circuit stated ''[t]he statutory language is plain in requiring some kind of consideration of economic impact in the critical habitat designation phase.'' The court concluded that, given the FWS' failure to distinguish between ''adverse modification'' and ''jeopardy'' in its 4(b)(2) analysis, the FWS must analyze the full impacts of critical habitat designation, regardless of whether those impacts are coextensive with other impacts (such as the impact of the jeopardy requirement).

In redesignating critical habitat for the 13 Pacific Northwest ESUs, we followed the Tenth Circuit Court's directive regarding the statutory requirement to consider the economic impact of designation. Areas designated as critical habitat are subject to ESA section 7 requirements, which provide that Federal agencies ensure that their actions are not likely to destroy or adversely modify critical habitat. To evaluate the economic impact of critical habitat we first examined our voluminous section 7 consultation record for Oregon Coast coho as well as other ESUs of salmon and steelhead. (For thoroughness, we examined the consultation record for other ESUs to see if it provided information relevant to Oregon Coast coho.) That record includes consultations on habitat-modifying Federal actions both where critical habitat has been designated and where it has not. We could not discern a distinction between the impacts of applying the jeopardy provision versus the adverse modification provision in occupied critical habitat. Given our inability to detect a measurable difference between the impacts of applying these two provisions, the only reasonable alternative seemed to be to follow the recommendation of the Tenth Circuit, approved by the *NAHB* court—to measure the coextensive impacts; that is, measure the entire impact of applying the adverse modification provision of section 7, regardless of whether the jeopardy provision alone would result in the identical impact.

The Tenth Circuit's opinion only addressed ESA section 4(b)(2)'s requirement that economic impacts be considered. The court did not address how ''other relevant impacts'' were to be considered, nor did it address the benefits of designation. Because section 4(b)(2) requires a consideration of other relevant impacts of designation, and the benefits of designation, and because our record did not support a distinction between impacts resulting from application of the adverse modification provision versus the jeopardy provision, we are uniformly considering coextensive impacts and coextensive benefits, without attempting to distinguish the benefit of a critical habitat consultation from the benefit that would otherwise result from a jeopardy consultation that would occur even if critical habitat were not designated. To do otherwise would distort the balancing test contemplated by section 4(b)(2).

The principal benefit of designating critical habitat is that Federal activities that may affect such habitat are subject to consultation pursuant to section 7 of the ESA. Such consultation requires every Federal agency to ensure that any action it authorizes, funds or carries out is not likely to result in the destruction or adverse modification of critical habitat. This complements the section 7 provision that Federal agencies ensure that their actions are not likely to jeopardize the continued existence of a listed species. Another benefit is that the designation of critical habitat can serve to educate the public regarding the potential conservation value of an area and thereby focus and contribute to conservation efforts by clearly delineating areas of high conservation value for certain species. It is unknown to what extent this process actually occurs for Oregon Coast coho, and what the actual benefit is to Oregon Coast coho, as there are also concerns, noted above, that a critical habitat designation may discourage such conservation efforts.

The balancing test in ESA section 4(b)(2) contemplates weighing benefits that are not directly comparable—the benefit associated with species conservation balanced against the economic benefit, benefit to national security, or other relevant benefit that results if an area is excluded from designation. Section 4(b)(2) does not specify a method for the weighing process. Agencies are frequently required to balance benefits of regulations against impacts; Executive Order (E.O.) 12866 established this requirement for Federal agency regulations. Ideally such a balancing would involve first translating the benefits and impacts into a common metric. Executive branch guidance from the OMB suggests that benefits should first be monetized (i.e., converted into dollars). Benefits that cannot be monetized should be quantified (for example, numbers of fish saved). Where benefits can neither be monetized nor quantified, agencies are to describe the expected benefits (OMB, 2003).

It may be possible to monetize benefits of critical habitat designation for a threatened or endangered species in terms of willingness-to-pay (OMB, 2003). However, we are not aware of any available data that would support such an analysis for salmon. In addition, ESA section 4(b)(2) requires analysis of impacts other than economic impacts that are equally difficult to monetize, such as benefits to national security of excluding areas from critical habitat. In the case of salmon designations, impacts to Northwest tribes are an ''other relevant impact'' that also may be difficult to monetize.

An alternative approach, approved by OMB (OMB, 2003), is to conduct a cost-effectiveness analysis. A cost-effectiveness analysis ideally first involves quantifying benefits, for example, percent reduction in extinction risk, percent increase in productivity, or increase in numbers of fish. Given the state of the science, it would be difficult to quantify reliably the benefits of including particular areas in the critical habitat designation. Although it is difficult to monetize or quantify benefits of critical habitat designation, it is possible to differentiate among habitat areas based on their relative contribution to conservation. For example, habitat areas can be rated as having a high, medium, or low conservation value. The qualitative ordinal evaluations can then be combined with estimates of the economic costs of critical habitat designation in a framework that arguably moves the designation to a more efficient outcome. Individual habitat areas are assessed using both their biological evaluation and economic cost, so that areas with high conservation value and lower economic cost might be considered to have a higher priority for designation, while areas with a low conservation value and higher economic cost might have a higher priority for exclusion. While this approach can provide useful information to the decision-maker, there is no rigid formula through which this information translates into exclusion decisions. Every geographical area containing habitat eligible for designation is different, with a unique set of ''relevant impacts'' that may be considered in the exclusion process. Regardless of the analytical approach, ESA section 4(b)(2) makes clear that what weight the agency gives various impacts and benefits, and whether the agency excludes areas from the designation, is discretionary.

*Exclusions Based on Impacts to Tribes*

A broad array of activities on Indian lands may trigger section 7 consultation under the ESA. For this analysis, we considered what those activities may be and what the likely effect would be on conservation of the Oregon Coast coho ESU if the activities were not subject to section 7 consultation. (We realize that the activities in question would still be subject to section 7 consultation and to the requirement that Federal agencies not jeopardize species' continued existence. However, as described above, because we cannot discern a difference in the application of the jeopardy and adverse modification requirements in our consultations for Oregon coast coho, we are considering coextensive impacts and coextensive benefits.) To determine the benefit of designation, we considered the number of stream miles within Indian lands, whether those stream miles were located in high, medium, or low conservation value areas, and the number of expected section 7 consultations in those areas (NMFS, 2007f).

There are several benefits to excluding Indian lands. The longstanding and distinctive relationship between the Federal and tribal governments is defined by treaties, statutes, executive orders, judicial decisions, and agreements, which differentiate tribal governments from the other entities that deal with, or are affected by, the Federal Government. This relationship has given rise to a special Federal trust responsibility involving the legal responsibilities and obligations of the United States toward Indian Tribes and the application of fiduciary standards of due care with respect to Indian lands, tribal trust resources, and the exercise of tribal rights. Pursuant to these authorities, Indian lands are recognized as unique and have been retained by Indian Tribes or have been set aside for tribal use. These lands are managed by Indian Tribes in accordance with tribal goals and objectives within the framework of applicable treaties and laws.

In addition to the distinctive trust relationship, for salmon and steelhead in the Northwest, there is a unique partnership between the Federal Government and Indian tribes regarding salmon management. Two of the four tribes with land in Oregon coast coho critical habitat are active participants in local watershed restoration and management aimed at coho conservation (NMFS, 2007f).

The benefits of excluding Indian lands from designation include: (1) The furtherance of established national policies, our Federal trust obligations, and our deference to the tribes in management of natural resources on their lands; (2) the maintenance of effective long-term working relationships to promote the conservation of Oregon coast coho; and (3) continued respect for tribal sovereignty over management of natural resources on Indian lands through established tribal natural resource programs. Regarding benefits of designation, many actions on Indian lands involve the Bureau of Indian Affairs (BIA), triggering a section 7 consultation. This means the benefit of designating Indian land is potentially high. However, coho habitat on Indian lands represents a tiny proportion of overall habitat—2.7 stream miles (4.35 km) out of a total of 6,652. Accordingly, we find the benefits of promoting tribal sovereignty and the trust responsibility outweigh the benefits of applying ESA section 7 to Federal activities on these 2.7 miles (4.35 km) of coho habitat (NMFS, 2007f).

The Indian lands specifically excluded from critical habitat are those defined in the Secretarial Order, including: (1) Lands held in trust by the United States for the benefit of any Indian tribe; (2) land held in trust by the United States for any Indian Tribe or individual subject to restrictions by the United States against alienation; (3) fee lands, either within or outside the reservation boundaries, owned by the tribal government; and (4) fee lands within the reservation boundaries owned by individual Indians. We have determined that these exclusions, together with the other exclusions described in this rule, will not result in extinction of the species (NMFS, 2007d).

*Exclusions Based on Economic Impacts*

Our assessment of economic impact generated considerable interest from commenters on the ANPR (68 FR 55926; September 29, 2003) and the proposed rule (69 FR 74572; December 14, 2004). Based on new information and comments received on the proposed rule we have updated our estimates of economic impacts of designating each of the particular areas found to meet the definition of critical habitat (NMFS, 2007d). This report is available from NMFS (see **ADDRESSES**).

The first step in the overall economic analysis was to identify existing legal and regulatory constraints on economic activity that are independent of critical habitat designation, such as Clean Water Act (CWA) requirements. Coextensive impacts of the ESA section 7 requirement to avoid jeopardy were not considered part of the baseline.

Next, from the consultation record, we identified Federal activities that might affect habitat and that might result in an ESA section 7 consultation. (We did not consider Federal actions, such as the approval of a fishery, that might affect the species directly but not affect its habitat.) We identified ten types of activities including: Hydropower dams; non-hydropower dams and other water supply structures; Federal lands management, including grazing (considered separately); transportation projects; utility line projects; instream activities, including dredging (considered separately); activities permitted under the Environmental Protection Agency's (EPA's) National Pollution Discharge Elimination System; sand and gravel mining; residential and commercial development; and agricultural pesticide applications. Based on our consultation record and other available information, we determined the modifications each type of activity was likely to undergo as a result of section 7 consultation (regardless of whether the modification might be required by the jeopardy or the adverse modification provision). We developed an expected direct cost for each type of action and projected the likely occurrence of each type of project in each watershed, using existing spatial databases (e.g., the USACE 404(d) permit database). Finally, we aggregated the costs from the various types of actions and estimated an annual impact, taking into account the probability of consultation occurring and the likely rate of occurrence of that project type.

This analysis allowed us to estimate the coextensive economic impact of designating each ''particular area'' (that is, each habitat area, or aggregated occupied stream reaches in a watershed). Expected annual economic impacts in the Oregon Coast coho ESU ranged from zero to $869,861 per habitat area, with a median of $222,419. Where a watershed included both tributaries and a migration corridor that served other watersheds, we estimated the separate impacts of designating the tributaries and the migration corridor. We did this by identifying those categories of activities most likely to affect tributaries and those most likely to affect larger migration corridors.

Because of the methods we selected and the data limitations, portions of our analysis both under- and over-estimate the coextensive economic impact of ESA section 7 requirements. For example, we lacked complete data on the likely impact on flows at non-Federal hydropower projects, which would increase economic impacts. Also, we did not have information about potential changes in irrigation flows associated with section 7 consultation. These impacts would increase the estimate of coextensive costs. On the other hand, we estimated an impact on all activities occurring within the geographic boundaries of a watershed, even though in some cases activities would be far removed from occupied stream reaches and so might not require modification (or even consultation). In addition, we were unable to document significant costs of critical habitat designation that occur outside the section 7 consultation process, including costs resulting from state or local regulatory burdens imposed on developers and landowners as a result of a Federal critical habitat designation.

In determining whether the economic benefit of excluding a habitat area might outweigh the benefit of designation to the species, we took into account many data limitations, including those described above. The ESA requires that we make critical habitat designations within a short time frame ''with such data as may be available'' at the time. Moreover, the approach we adopted accommodated many of these data limitations by considering the relative benefits of designation and exclusion, giving priority to excluding habitat areas with a relatively lower benefit of designation and a relatively higher economic impact (NMFS, 2007d).

The circumstances of the Oregon Coast coho ESU are well suited to this approach. Coho salmon is a wide-ranging species that occupies numerous habitat areas with thousands of stream miles. Not all occupied areas, however, are of equal importance to conserving the ESU. Within the currently occupied range there are areas that support highly productive populations, areas that support less productive populations, and areas that support production in only some years. Some populations within the ESU may be more important to long-term conservation of the ESU than other populations. Therefore, in many cases it may be possible to construct different scenarios for achieving conservation. Different scenarios might have more or less certainty of achieving conservation, and more or less economic impact.

Our first step in constructing an exclusion scenario was to identify all areas we would consider for an economic exclusion, based on dollar thresholds. The next step was to examine whether any of the areas eligible for exclusion make an important contribution to conservation, in the context of the areas that remained (that is, those areas not identified as eligible for exclusion). We did not consider habitat areas for exclusion if they had a high conservation value rating. Based on the rating process used by the CHART we judged that all of the high value areas make an important contribution to conservation.

In developing criteria for the first step, we chose dollar thresholds that we anticipated would lead most directly to a more cost-effective scenario. We considered for exclusion low value habitat areas with an economic impact greater than $91,556 and medium value habitat areas with an economic impact greater than $323,138. These criteria we selected for identifying habitat areas as eligible for exclusion do not represent an objective determination that, for example, a given low value area is worth a certain dollar amount and no more. The statute directs us to balance dissimilar values under a statutorily-limited time frame. The statute emphasizes the discretionary nature of the section 4(b)(2) balancing task. Moreover, while our approach follows the Tenth Circuit's direction to consider coextensive economic impacts, we nevertheless must acknowledge that not all of the costs will be avoided by exclusion from designation. Finally, the cost estimates developed by our economic analysis do not have obvious break points that would lead to a logical division between ''high,'' ''medium,'' and ''low'' costs. Given these factors, a judgment that any particular dollar threshold is objectively ''right,'' would be neither necessary nor possible. Rather, what economic impact is ''high,'' and therefore might outweigh the benefit of designating a medium or low conservation value habitat area, is a matter of agency discretion and policy.

In the second step of the process, we asked the CHART whether any of the habitat areas eligible for exclusion make an important contribution to conservation. The CHART considered this question in the context of all of the areas eligible for exclusion as well as the information they had developed in providing the initial conservation ratings. The following section describes the results of applying the two-step process to the Oregon Coast coho ESU. The results are discussed in greater detail in a separate report that is available for public review and comment (NMFS, 2007d). We have determined that the exclusions, together with the other exclusions described in this rule (i.e., Indian lands), will not result in extinction of the species (NMFS, 2007d).

*Summary of Changes From the Proposed Critical Habitat Designation*

We evaluated the comments and new information received on the proposed rule to ensure that they represented the best scientific data available and made a number of general types of changes to the critical habitat designations, including:

(1) We revised habitat maps and related biological assessments based on a final CHART assessment (NMFS, 2007b) of information provided by commenters, peer reviewers, and agency biologists (including CHART members). We also evaluated watersheds to determine how well the conservation value rating corresponded to the benefit of designation, in particular the likelihood of an ESA section 7 consultation occurring in that area and whether the consultation would yield conservation benefits if it was likely to occur.

(2) We revised our economic analysis based on information provided by commenters and peer reviewers as well as our own efforts as referenced in the proposed rule and described in the final economic analysis (NMFS, 2007c). Major changes included assessing new impacts associated with pesticide consultations, revising Federal land management costs to take into account wilderness areas, and modifying the

analysis of Federal grazing land impacts to more accurately reflect the likely geographic extent of ESA section 7 implementation. We also documented the economic costs of changes in flow regimes for some hydropower projects. To account for inflationary changes in the economic impacts, we adjusted the cost estimates based on changes in a producer price index over the period 2005 to 2007 (NMFS 2007c).

(3) We conducted a new ESA section 4(b)(2) analysis based on economic impacts to take into account the above revisions. This resulted in the final exclusion of many of the same watersheds proposed for exclusion. It also resulted in some areas originally proposed for exclusion not being excluded. The analysis is described further in the 4(b)(2) report (NMFS, 2007d).

(4) In the regulations, we've removed reference to ''units'' to avoid possible confusion with the concept of ''recovery units'' as described in our section 7 handbook.

The following section summarizes the changes to the proposed critical habitat rule. These changes are also reflected in final agency reports pertaining to the biological, economic, and policy assessments supporting these designations (NMFS, 2007b; NMFS, 2007c; and NMFS, 2007d). We conclude that these changes are warranted based on new information and analyses that constitute the best scientific data available.

**Description of Specific Changes**

The CHART elevated the conservation value rating for five watersheds within the Umpqua River basin. The changes were made as a result of recent population identification work (Lawson *et al.*, 2007) that further subdivides this basin into four (versus two) independent populations. We made several changes to the delineation of occupied habitat areas based on comments and field surveys indicating that our original coho distribution maps/data were in error. As a result of revised economic data for this ESU and our final 4(b)(2) assessment, we are no longer excluding habitat areas in three watersheds that were previously proposed for designation. We have also removed Josephine and Jackson counties from the relevant critical habitat table in our regulations. These counties overlap slightly with upland areas in watersheds occupied by Oregon Coast coho salmon, but they do not contain stream reaches designated as critical habitat for this ESU. Table 1 summarizes the changes made for specific watersheds in the range of this ESU.

TABLE 1.—CHANGES TO CRITICAL HABITAT DESIGNATION FOR OREGON COAST COHO

| Subbasin | Watershed code | Watershed name | Changes from proposed rule |
|---|---|---|---|
| NEHALEM | 1710020206 | Lower Nehalem River/Cook Creek. | Added 1.3 miles (2.1 km) of occupied habitat areas. |
| WILSON/TRASK/NESTUCCA | 1710020302 | Nestucca River | Added 4.2 miles (6.8 km) of occupied habitat areas and removed 3 miles (4.8 km) of unoccupied stream reaches. |
| NORTH UMPQUA | 1710030106 | Boulder Creek | No longer excluded from designation. |
| NORTH UMPQUA | 1710030110 | Rock Creek/North Umpqua River. | Added 1.8 miles (2.9 km) of occupied habitat areas. |
| SOUTH UMPQUA | 1710030202 | Jackson Creek | Elevated HUC5 conservation value from Low to Medium. No longer excluded from designation. |
| SOUTH UMPQUA | 1710030204 | Elk Creek/South Umpqua | Elevated HUC5 conservation value from Low to Medium. No longer excluded from designation. |
| SOUTH UMPQUA | 1710030205 | South Umpqua River | Removed 2 miles (3.2 km) of unoccupied stream reaches. |
| SOUTH UMPQUA | 1710030207 | Middle Cow Creek | Elevated HUC5 conservation value from Medium to High. |
| SOUTH UMPQUA | 1710030209 | Lower Cow Creek | Removed 3 miles (4.8 km) of unoccupied stream reaches. |
| SOUTH UMPQUA | 1710030211 | Myrtle Creek | Elevated HUC5 conservation value from Medium to High. |
| UMPQUA | 1710030301 | Upper Umpqua River | Removed 2 miles (3.2 km) of unoccupied stream reaches. |
| UMPQUA | 1710030303 | Elk Creek | Removed 1 mile (1.6 km) of unoccupied stream reaches and elevated HUC5 conservation value from Medium to High. |
| UMPQUA | 1710030304 | Middle Umpqua River | Removed 1.5 mile (2.4 km) of unoccupied stream reaches. |
| UMPQUA | 1710030305 | Lake Creek | Removed 5.3 mile (8.5 km) of unoccupied stream reaches. |
| COQUILLE | 1710030504 | East Fork Coquille | Removed 1.5 mile (2.4 km) of unoccupied stream reaches. |

**Final Critical Habitat Designation**

We are designating approximately 6,568 stream miles (10,570 km) and 15 square miles (38.8 sq km) of lake habitat within the geographical area presently occupied by the Oregon Coast coho ESU (see Table 2). The Oregon Coast coho ESU is the only listed species in this domain, so the areas designated as critical habitat do not overlap with critical habitat areas designated for other listed ESUs.

TABLE 2.—APPROXIMATE QUANTITY OF HABITAT AND OWNERSHIP WITHIN WATERSHEDS CONTAINING HABITAT AREAS DESIGNATED AS CRITICAL HABITAT FOR THE EVOLUTIONARILY SIGNIFICANT UNIT OF OREGON COAST COHO SALMON (ONCORHYNCHUS KISUTCH)

| Streams mi (km) | Lakes sq mi (sq km) | Nearshore marine mi (km) | Land ownership type (percent) | | | |
|---|---|---|---|---|---|---|
| | | | Federal | Tribal | State | Private |
| 6,568 (10,570) | 15 (38.8) | n/a | 32.9 | <0.1 | 9.1 | 58.0 |

The areas designated, summarized below, are all occupied and contain physical and biological features essential to the conservation of the species and that may require special management considerations or protection. No unoccupied areas were identified that are considered essential for the conservation of the species. There are 80 watersheds within the range of this ESU. Eight watersheds received a low conservation value rating, 27 received a medium rating, and 45 received a high rating to the ESU (NMFS, 2007b). As a result of the balancing process for economic impacts described above, the Secretary is excluding from the designation the five watersheds listed in Table 3. Of the habitat areas eligible for designation, approximately 84 stream miles (135 km) or 1.3 percent are being excluded because the economic benefits of exclusion outweigh the benefits of designation. Total potential estimated economic impact, with no exclusions, would be $22.2 million. The exclusions identified in Table 3 would reduce the total estimated economic impact to $20.1 million (NMFS, 2007d).

TABLE 3.—HABITAT AREAS WITHIN THE GEOGRAPHICAL RANGE OF THE EVOLUTIONARILY SIGNIFICANT UNIT OF OREGON COAST COHO SALMON (ONCORHYNCHUS KISUTCH) AND EXCLUDED FROM CRITICAL HABITAT

| Subbasin | Watershed code | Watershed name | Area proposed for exclusion |
|---|---|---|---|
| North Fork Umpqua River subbasin | 1710030108 | Steamboat Creek | Entire watershed. |
| North Fork Umpqua River subbasin | 1710030109 | Canton Creek | Entire watershed. |
| South Fork Umpqua River subbasin | 1710030201 | Upper South Umpqua River | Entire watershed. |
| Umpqua River subbasin | 1710030305 | Lake Creek | Entire watershed. |
| Coquille River subbasin | 1710030501 | Coquille South Fork, Lower | Entire watershed. |

## Effects of Critical Habitat Designation

### *ESA Section 7 Consultation*

Section 7(a) of the ESA requires Federal agencies, including NMFS, to evaluate their actions with respect to any species that is proposed or listed as endangered or threatened and with respect to its critical habitat, if any is proposed or designated. Regulations implementing this provision of the ESA are codified at 50 CFR 402.

If a species is listed or critical habitat is designated, ESA section 7(a)(2) requires Federal agencies to ensure that activities they authorize, fund, or carry out are not likely to jeopardize the continued existence of such a species or to destroy or adversely modify its critical habitat. If a Federal action may affect a listed species or its critical habitat, the responsible Federal agency (action agency) must enter into consultation with us. Through this consultation, we would review actions to determine if they would destroy or adversely modify critical habitat.

If we issue a biological opinion concluding that a project is likely to result in the destruction or adverse modification of critical habitat, we will also provide reasonable and prudent alternatives to the project, if any are identifiable. Reasonable and prudent alternatives are defined at 50 CFR 402.02 as alternative actions identified during consultation that can be implemented in a manner consistent with the intended purpose of the action, that are consistent with the scope of the Federal agency's legal authority and jurisdiction, that are economically and technologically feasible, and that we believe would avoid destruction or adverse modification of critical habitat. Reasonable and prudent alternatives can vary from slight project modifications to extensive redesign or relocation of the project. Costs associated with implementing a reasonable and prudent alternative are similarly variable.

Regulations at 50 CFR 402.16 require Federal agencies to reinitiate consultation on previously reviewed actions in instances where critical habitat is subsequently designated and the Federal agency has retained discretionary involvement or control over the action or such discretionary involvement or control is authorized by law. Consequently, some Federal agencies may request reinitiation of consultation or conference with us on actions for which formal consultation has been completed, if those actions may affect designated critical habitat or adversely modify or destroy proposed critical habitat.

Activities on Federal lands that may affect these ESUs or their critical habitat will require ESA section 7 consultation. Activities on private or state lands requiring a permit from a Federal agency, such as a permit from the USACE under section 404 of the CWA, a section 10(a)(1)(B) permit from NMFS, or some other Federal action, including funding (e.g., Federal Highway Administration (FHA) or Federal Emergency Management Agency (FEMA) funding), will also be subject to the section 7 consultation process. Federal actions not affecting listed species or critical habitat and actions on non-Federal and private lands that are not Federally funded, authorized, or permitted do not require section 7 consultation.

### *Activities Affected by Critical Habitat Designation*

Section 4(b)(8) of the ESA requires that we evaluate briefly and describe, in any proposed or final regulation that designates critical habitat, those activities involving a Federal action that may adversely modify such habitat or that may be affected by such designation. A wide variety of activities may affect critical habitat and, when carried out, funded, or authorized by a Federal agency, require that an ESA section 7 consultation be conducted. Generally these include water and land management actions of Federal agencies (e.g., USFS, BLM, USACE, BOR, the FHA, the National Resource Conservation Service (NRCS), National Park Service (NPS), BIA, and FERC) and related or similar actions of other Federally regulated projects and lands, including livestock grazing allotments by the USFS and BLM; hydropower sites licensed by the FERC; dams built or operated by the USACE or BOR; timber sales and other vegetation management activities conducted by the USFS, BLM, and BIA; irrigation diversions authorized by the USFS and BLM; road building and maintenance activities authorized by the FHA, USFS, BLM, NPS, and BIA; and mining and road building/maintenance activities authorized by the states of Washington, Oregon, and Idaho. Other actions of concern include dredge and fill, mining, diking, and bank stabilization activities authorized or conducted by the USACE, habitat modifications authorized by the FEMA, and approval of water quality standards and pesticide labeling and use restrictions administered by the EPA.

The Federal agencies that will most likely be affected by this critical habitat designation include the USFS, BLM, BOR, USACE, FHA, NRCS, NPS, BIA, FEMA, EPA, and the FERC. This designation will provide these agencies, private entities, and the public with clear notification of critical habitat designated for listed salmonids and the boundaries of the habitat. This designation will also assist these agencies and others in evaluating the potential effects of their activities on listed salmon and their critical habitat and in determining if ESA section 7 consultation with NMFS is needed.

As noted above, numerous private entities also may be affected by this critical habitat designation because of the direct and indirect linkages to an array of Federal actions, including Federal projects, permits, and funding. For example, private entities may harvest timber or graze livestock on Federal land or have special use permits to convey water or build access roads across Federal land; they may require Federal permits to armor stream banks, construct irrigation withdrawal facilities, or build or repair docks; they may obtain water from Federally funded and operated irrigation projects; or they may apply pesticides that are only available with Federal agency approval. These activities will need to be analyzed with respect to their potential to destroy or adversely modify critical habitat. In some cases, proposed activities may require modifications that may result in decreases in activities such as timber harvest and livestock and crop production. The transportation and utilities sectors may need to modify the placement of culverts, bridges, and utility conveyances (e.g., water, sewer and power lines) to avoid barriers to fish migration. Developments occurring in or near salmon streams (e.g., marinas, residential, or industrial facilities) that require Federal authorization or funding may need to be altered or built in a manner that ensures that critical habitat is not destroyed or adversely modified as a result of the construction, or subsequent operation, of the facility. These are just a few examples of potential impacts, but it is clear that the effects will encompass numerous sectors of private and public activities. If you have questions regarding whether specific activities will constitute destruction or adverse modification of critical habitat, contact NMFS (see **ADDRESSES** and **FOR FURTHER INFORMATION CONTACT**).

## Classification

### *Administrative Procedure Act*

The proposed listing determination, proposed protective regulations, and proposed critical habitat designation addressing 27 ESUs generated substantial public interest. In addition to comments received during 12 public hearings, we received 33,480 written comments. Many of the comments addressing the critical habitat designation expressed concerns about how the rule would be implemented. Our experience in implementing previous listing determinations, protective regulations, and critical habitat designations suggests that neither the Administrative Procedure Act (APA) and ESA implementing regulations' minimum of a 30-day delay in effective date, nor the 60-day delay in effective date required by the Congressional Review Act for a ''major rule,'' are sufficient for this final rule. In order to provide for efficient administration of the rule once effective, we are providing a 90-day delay in effective date. As a result this rule will be effective on May 12, 2008. This will allow us the necessary time to provide for outreach to and interaction with the public, to minimize confusion and educate the public about activities that may be affected by the rule, and to work with Federal agencies and applicants to provide for an orderly implementation of the rule.

### *National Environmental Policy Act (NEPA)*

ESA listing decisions are exempt from the requirement to prepare an environmental assessment or environmental impact statement under the NEPA. See NOAA Administrative Order 216–6.03(e)(1) and *Pacific Legal Foundation* v. *Andrus,* 657 F.2d 825 (6th Cir. 1981). Thus, we have determined that the final listing determination for Oregon Coast coho described in this notice is exempt from the requirements of the NEPA. Similarly, we have determined that we need not prepare environmental analyses for critical habitat designations made pursuant to the ESA. See *Douglas County* v. *Babbitt,* 48 F.3d 1495 (9th Cir. 1995), cert. denied, 516 U.S. 1042 (1996).

We conducted Environmental Assessments (EAs) under the NEPA analyzing the ESA section 4(d) regulations promulgated in 2000 for Pacific salmonids (65 FR at 42422 and 42481; July 10, 2000) and the amendments to the 4(d) regulations promulgated in 2005 (70 FR 37160; June 28, 2005). Both EAs analyzed the protective regulations for the Oregon Coast coho ESU which are being finalized in this notice. We solicited comment on the EAs as part of the proposed rules, as well as during a subsequent comment period following formal notice in the **Federal Register** of the availability of the draft EAs for review. We have reviewed new information available since the 2000 and 2005 analyses and determined that none of the new information would change the earlier analyses, nor would it change our conclusion that adoption of the 4(d) rule will have no significant impacts on the human environment (NMFS, 2007g).

### *Regulatory Flexibility Act*

Under the Regulatory Flexibility Act (5 U.S.C. 601 *et seq.*, as amended by the Small Business Regulatory Enforcement Fairness Act (SBREFA) of 1996), whenever an agency is required to publish a notice of rulemaking for any proposed or final rule, it must prepare and make available for public comment a regulatory flexibility analysis that describes the effects of the rule on small entities (i.e., small businesses, small organizations, and small government jurisdictions). For the proposed designation of critical habitat for 13 ESUs, including Oregon coast coho, we published an Initial Regulatory Flexibility Act Analysis for public comment. We received comments specific to some of the ESUs, but not to Oregon Coast coho. We received one general comment, stating that our analysis should include more references. We have prepared a final regulatory flexibility analysis for the designation of critical habitat, which is available upon request (see **ADDRESSES**) and which includes additional references. This analysis estimates that the number of regulated small entities potentially affected by the final critical habitat designation for the Oregon Coast coho salmon ESU is 920, and the estimated coextensive costs of section 7 consultation incurred by small entities is $5,072,840. As described in the analysis, we considered various alternatives for designating critical habitat for this ESU. We considered and rejected the alternative of not designating critical habitat for the ESU because such an approach did not meet the legal requirements of the ESA. We also examined and rejected an alternative in which all the eligible habitat areas in the ESU are designated (i.e., no areas are excluded) because many of the areas considered to have a low conservation value also had relatively high economic impacts that might be mitigated by excluding those areas from designation. A third alternative we examined and rejected would exclude all habitat areas with a low or medium conservation value. While this alternative furthers the goal of reducing economic impacts, we could not make a determination that the benefits of excluding all habitat areas with low and medium conservation value outweighed the benefits of designation. Moreover, for some habitat areas the incremental economic benefit from excluding that area is relatively small. Therefore, after considering these alternatives in the context of the section 4(b)(2) process of weighing benefits of exclusion against benefits of designation, we determined that the current approach to designation (i.e., designating some but not all areas with low or medium conservation value) provides an appropriate balance of conservation and economic mitigation and that excluding the areas identified in this rulemaking would not result in extinction of the ESU. It is estimated that small entities will save $281,687 in compliance costs due to the exclusions made in the final designation.

ESA section 4(d) regulations for Oregon Coast coho were originally proposed on December 30, 1999 (64 FR 73479). The rule adopted here is substantially the same as that proposed in 1999. At that time we published an Initial Regulatory Flexibility Act analysis, which considered four alternative approaches to protective regulations. We concluded that there were no legally viable alternative to the one we proposed in 1999 that would have less impact on small entities and still fulfill agency obligations to protect listed salmonids. We received five public comments on the Initial Regulatory Flexibility Act analysis and the economic impacts of the proposed 4(d) rule. When the rule was adopted in 2000, we completed a Final Regulatory Flexibility Act analysis, which responded to public comments, and reached the same conclusion as the initial analysis. The 2000 4(d) regulations for Oregon Coast coho were invalidated when the underlying listing was vacated in 2001. In 2004 when we proposed to again list Oregon Coast coho, we also proposed to reinstate the 4(d) regulations. We did not conduct a new Regulatory Flexibility Act analysis at that time because there were no new issues to consider.

In preparing the final ESA section 4(d) regulations adopted here, we determined it was advisable to update our Regulatory Flexibility Act analysis, to ensure that we were considering current information. Our updated analysis led us to again conclude that among the available alternative approaches, the one adopted here minimizes economic costs, disruptions, and burdens, for the reasons expressed in the 2000 analysis (attached to NMFS, 2007i) and summarized at 65 FR 42422, 42473 (July 10, 2000). The economic assessment and analysis (NMFS, 2007i) are available upon request (see **ADDRESSES**).

*Paperwork Reduction Act (PRA)*

Notwithstanding any other provision of the law, no person is required to respond to, nor shall any person be subject to a penalty for failure to comply with, a collection of information subject to the requirements of the PRA, unless that collection of information displays a currently valid OMB Control Number.

This final rule does not contain a collection-of-information requirement for purposes of the PRA.

*Regulatory Planning and Review—E.O. 12866*

We prepared a Regulatory Impact Review in 2000 when the ESA section 4(d) regulations were initially adopted and concluded that among the alternative regulatory approaches, the proposed 4(d) rule would maximize net benefits and minimize costs, within the constraints of the ESA. We have reviewed that analysis and new information available since the analysis was initially prepared, including OMB Circular A–4 (2003). We have determined that none of the new information would change the earlier analysis or conclusion (NMFS, 2007i).

The critical habitat component of this notice is a significant rule and has been reviewed by the OMB. As noted above, we have prepared several reports to support the exclusion process under section 4(b)(2) of the ESA. The economic costs of the critical habitat designations are described in our economic report (NMFS, 2007c). The benefits of the designations are described in the CHART report (NMFS, 2007b) and the 4(b)(2) report (NMFS, 2007d). The CHART report uses a biologically-based ranking system for gauging the benefits of applying section 7 of the ESA to particular watersheds. Because data are not available to monetize these benefits, we have adopted a framework that implicitly evaluates the benefits and costs based on a biological metric as outlined in the section 4(b)(2) report (NMFS, 2007b). This approach is consistent with the spirit of OMB's Circular A–4 in that it attempts to assess the benefits and costs even when limitations in data may not allow quantification or monetization. By taking this approach, we seek to designate sufficient critical habitat to meet the biological goal of the ESA while imposing the least burden on society, as called for by E.O. 12866.

The annual total coextensive economic impact of the critical habitat designations is approximately $15.7 million (in contrast to a $18.4 million annual economic impact from designating *all* eligible areas considered in the 4(b)(2) process for this ESU). This amount includes impacts that are coextensive with the implementation of the jeopardy requirement of section 7 (NMFS, 2007c).

We did not estimate the economic impacts associated solely with the listing of Oregon Coast coho ESU under the ESA.

*E.O. 13084—Consultation and Coordination With Indian Tribal Governments*

E.O. 13084 requires that, if we issue a regulation that significantly or uniquely affects the communities of Indian tribal governments and imposes substantial direct compliance costs on those communities, we must consult with those governments or the Federal Government must provide the funds necessary to pay the direct compliance costs incurred by the tribal governments. The final listing determination and protective regulations included in this rule do not impose substantial direct compliance costs on the communities of Indian tribal governments. Accordingly, the requirements of section 3(b) of E.O. 13084 do not apply to the listing and protective regulations components of this final rule. Nonetheless, we intend to inform potentially affected tribal governments and to solicit their input and coordinate on future management actions.

The Departments of Commerce and Interior Secretarial Order ''American Indian Tribal Rights, Federal-Tribal Trust Responsibilities, and the Endangered Species Act'' (June 5, 1997) provides that the Services * * * ''shall consult with the affected Indian tribe(s) when considering the designation of critical habitat in an area that may impact tribal trust resources, tribally owned fee lands, or the exercise of tribal rights. Critical habitat shall not be designated in such areas unless it is determined essential to conserve a listed species.'' Pursuant to the Secretarial Order and in response to written and oral comments provided by various tribes in Washington, Oregon, and Idaho, we met and corresponded with many of the affected tribes concerning the inclusion of Indian lands in final critical habitat designations. These discussions resulted in significant clarifications regarding the tribes' general position to exclude their lands, as well as specific issues regarding our interpretation of Indian lands under the Secretarial Order.

As described above (see Exclusions Based on Impacts to Tribes) and in our assessment of Indian lands associated with this final rulemaking (NMFS, 2007f), we have determined that Indian lands should be excluded from the final critical habitat designations for the Oregon Coast coho ESU. The Indian lands specifically excluded from critical habitat are those defined in the Secretarial Order, including: (1) Lands held in trust by the United States for the benefit of any Indian tribe; (2) land held in trust by the United States for any Indian Tribe or individual subject to restrictions by the United States against alienation; (3) fee lands, either within or outside the reservation boundaries, owned by the tribal government; and (4) fee lands within the reservation boundaries owned by individual Indians. We have determined that these exclusions, together with the other exclusions described in this final rule, will not result in extinction of the species (NMFS, 2007d).

*E.O. 13211*

On May 18, 2001, the President issued an Executive Order on regulations that significantly affect energy supply, distribution, and use. E.O. 13211 requires agencies to prepare Statements of Energy Effects when undertaking certain actions. This rule may be a significant regulatory action under E.O. 12866. We have determined, however, that the energy effects of the regulatory action are unlikely to exceed the energy impact thresholds identified in E.O. 13211.

The available data do not allow us to separate precisely these incremental impacts from the impacts of all conservation measures on energy production and costs. There is historical evidence, however, that the ESA section 7 jeopardy standard alone is capable of imposing all of these costs (NMFS, 2007j). While this evidence is indirect, it is sufficient to draw the conclusion that the designation of critical habitat for this one ESU does not significantly affect energy supply, distribution, or use.

*Unfunded Mandates Reform Act (2 U.S.C. 1501 et seq.)*

In accordance with the Unfunded Mandates Reform Act, we make the following findings:

(a) This final rule listing Oregon Coast coho and designating critical habitat will not produce a Federal mandate. In general, a Federal mandate is a provision in legislation, statute, or regulation that would impose an enforceable duty upon state, local, tribal governments, or the private sector and includes both ''Federal intergovernmental mandates'' and ''Federal private sector mandates.'' These terms are defined in 2 U.S.C. 658(5)–(7). ''Federal intergovernmental mandate'' includes a regulation that ''would impose an enforceable duty upon State, local, or tribal governments'' with two exceptions. It excludes ''a condition of Federal assistance.'' It also excludes ''a duty arising from participation in a voluntary Federal program,'' unless the regulation ''relates to a then-existing Federal program under which $500,000,000 or more is provided annually to State, local, and tribal governments under entitlement authority,'' if the provision would ''increase the stringency of conditions of assistance'' or ''place caps upon, or otherwise decrease, the Federal Government's responsibility to provide funding'' and the state, local, or tribal governments ''lack authority'' to adjust accordingly. (At the time of enactment, these entitlement programs were: Medicaid; Aid to Families with Dependent Children work programs; Child Nutrition; Food Stamps; Social Services Block Grants; Vocational Rehabilitation State Grants; Foster Care, Adoption Assistance, and Independent Living; Family Support Welfare Services; and Child Support Enforcement). ''Federal private sector mandate'' includes a regulation that ''would impose an enforceable duty upon the private sector, except (i) a condition of Federal assistance; or (ii) a duty arising from participation in a voluntary Federal program.''

ESA listing and the designation of critical habitat do not impose a legally binding duty on non-Federal government entities or private parties. Under the ESA, the only regulatory effect is that Federal agencies must ensure that their actions do not jeopardize the continued existence of the species or destroy or adversely modify critical habitat under section 7. While non-Federal entities who receive Federal funding, assistance, permits or otherwise require approval or authorization from a Federal agency for an action may be indirectly impacted by the listing or designation of critical habitat, the legally binding duty to avoid jeopardy and the destruction or adverse modification of critical habitat rests squarely on the Federal agency. Furthermore, to the extent that non-Federal entities are indirectly impacted because they receive Federal assistance or participate in a voluntary Federal aid program, the Unfunded Mandates Reform Act would not apply; nor would the listing or critical habitat shift the costs of the large entitlement programs listed above to state governments.

(b) The ESA section 4(d) regulations prohibit any person from taking a listed member of the Oregon Coast coho ESU, except under certain circumstances. This prohibition applies to state and local government actions as well as private individuals. The 4(d) regulations prohibit certain activities, but do not impose an ''enforceable duty'' with associated costs to implement. As such, the 4(d) regulations are not considered an unfunded mandate for the purposes of the Unfunded Mandates Reform Act.

*Takings*

The final threatened listing determination is a non-discretionary action and therefore is not subject to the requirements of E.O. 12630. In accordance with E.O. 12630, this final rule does not have significant takings implications. Under E.O. 12630, ''Actions undertaken by governmental officials that result in a physical invasion or occupancy of private property, and regulations imposed on private property that *substantially affect its value or use,* may constitute a taking of property'' [emphasis added]. Neither the critical habitat designation nor 4(d) regulations can be expected to substantially affect the value or use of property. A takings implication assessment is not required.

The designation of critical habitat confers the ESA section 7 protection against ''the destruction or adverse modification of [critical] habitat.'' The designation of critical habitat in this rule affects only Federal agency actions, and will not increase or decrease the current restrictions on private property concerning take of salmon. While it is possible that real estate market values may temporarily decline following designation, due to the perception that critical habitat designation may impose additional regulatory burdens on land use, our experience is that such impacts do not occur or are short lived (NMFS, 2007d). Owners of areas that are included in the designated critical habitat will continue to have the opportunity to use their property in ways consistent with the survival of listed salmon. Therefore, the designation of critical habitat does not substantially affect the value or use of private property, and does not constitute a taking.

The adoption of ESA section 4(d) regulations includes a prohibition against ''take'' of a listed species (the definition of ''take'' is to ''harass, harm, pursue, hunt, shoot, wound, kill, trap, capture, or collect, or to attempt to engage in any such conduct.''). The take prohibition applies to any person subject to the jurisdiction of the United States, and may be perceived as affecting the value or use of property. However, the 4(d) regulations do not substantially affect the value or use of property for the following reasons. First, private property is already subject to state and local land-use regulations. Second, any action on private property authorized, funded, or carried out by a Federal agency that may take listed species is already subject to the section 7 ''no jeopardy'' protection by virtue of the listing determination. Third, our experience with Pacific salmonid 4(d) regulation since 1997 is that any declines in property value are either in perception only or short lived. Land owners quickly realize that the 4(d) regulations do not impose restrictions in addition to pre-existing land-use laws and the listing itself, or they conduct actions on their property in ways consistent with the survival of listed salmon by availing themselves to the exceptions provided under the 4(d) limits.

*E.O. 13132—Federalism*

E.O. 13132 requires agencies to take into account any Federalism impacts of regulations under development. It includes specific consultation directives for situations where a regulation will preempt state law, or impose substantial direct compliance costs on state and local governments (unless required by statute). Neither of those circumstances is applicable to this final rule. In fact, the adopted ESA section 4(d) regulations provide mechanisms by which NMFS, in the form of limits to take prohibitions, may defer to state and local governments where they provide adequate protections for threatened salmonids.

With respect to the designation of critical habitat, this final rule does not have significant federalism effects. In keeping with Department of Commerce policies, we requested information from, and coordinated development of, this critical habitat designation with appropriate state resource agencies in the State of Oregon. The designation may have some benefit to the State and local resource agencies in that the areas essential to the conservation of the species are more clearly defined, and the PCEs of the habitat essential to the conservation of the species are specifically identified. While making these clarifications does not alter where and what federally sponsored activities may occur, it may assist local governments in long-range planning (rather than waiting for case-by-case section 7 consultations to occur).

*Civil Justice Reform*

One commenter asserted that we failed to properly conduct and provide a Civil Justice Reform analysis pursuant to E.O. 12988. The Department of Commerce has determined that this final rule does not unduly burden the judicial system and meets the requirements of sections 3(a) and 3(b)(2) of the E.O. We are designating critical habitat in accordance with the provisions of the ESA. This final rule uses standard property descriptions and identifies the PCEs within the designated areas to assist the public in understanding the habitat needs of the Oregon Coast coho ESU.

## PART 226—DESIGNATED CRITICAL HABITAT

■ 4. The authority citation of part 226 continues to read as follows:

**Authority:** 16 U.S.C. 1533.

■ 5. In § 226.212, the section's heading and introductory text are revised and paragraphs (a)(13) and (u) are added to read as follows:

### § 226.212 Critical habitat for 13 Evolutionarily Significant Units (ESUs) of salmon and steelhead (Oncorhynchus spp.) in Washington, Oregon and Idaho.

Critical habitat is designated in the following states and counties for the following ESUs as described in paragraph (a) of this section, and as further described in paragraphs (b) through (g) of this section. The textual descriptions of critical habitat for each ESU are included in paragraphs (i) through (u) of this section, and these descriptions are the definitive source for determining the critical habitat boundaries. General location maps are provided at the end of each ESU description (paragraphs (i) through (u) of this section) and are provided for general guidance purposes only, and not as a definitive source for determining critical habitat boundaries.

(a) * * *

| ESU | State—Counties |
|---|---|
| * * * | * * * * |
| (13) Oregon Coast coho salmon | *OR*—Benton, Clatsop, Columbia, Coos, Curry, Douglas, Lane, Lincoln, Polk, Tillamook, Washington, and Yamhill. |

* * * * *

(u) Oregon Coast Coho Salmon (*Oncorhynchus kisutch*). Critical habitat is designated to include the areas defined in the following subbasins:

(1) Necanicum Subbasin 17100201—*Necanicum River Watershed 1710020101.* Outlet(s) = Arch Cape Creek (Lat 45.8035, Long −123.9656); Asbury Creek (45.815, −123.9624); Ecola Creek (45.8959, −123.9649); Necanicum River (46.0113, −123.9264); Short Sand Creek (45.7595, −123.9641) upstream to endpoint(s) in: Arch Cape Creek (45.8044, −123.9404); Asbury Creek (45.8150, −123.9584); Beerman Creek (45.9557, −123.8749); Bergsvik Creek (45.8704, −123.7650); Brandis Creek (45.8894, −123.8529); Charlie Creek (45.9164, −123.7606); Circle Creek (45.9248, −123.9436); Circle Creek Trib A (45.9335, −123.9457); North Fork Ecola Creek (45.8705, −123.9070); West Fork Ecola Creek (45.8565, −123.9424); Grindy Creek (45.9179, −123.7390); Hawley Creek (45.9259, −123.8864); Joe Creek (45.8747, −123.7503); Johnson Creek (45.8885, −123.8816); Klootchie Creek (45.9450, −123.8413); Klootchie Creek Trib A (45.9250, −123.8447); Lindsley Creek (45.9198, −123.8339); Little Humbug Creek (45.9235, −123.7653); Little Joe Creek (45.8781, −123.7852); Little Muddy Creek (45.9551, −123.9559); Mail Creek (45.8887, −123.8655); Meyer Creek (45.9279, −123.9135); Mill Creek (46.0245, −123.8905); Mill Creek Trib 1 (46.0142, −123.8967); Neacoxie Creek (46.0245, −123.9157); Neawanna Creek (45.9810, −123.8809); Necanicum River (45.9197, −123.7106); North Fork Necanicum River (45.9308, −123.7986); North Fork Necanicum River Trib A (45.9398, −123.8109); South Fork Necanicum River (45.8760, −123.8122); Shangrila Creek (45.9706, −123.8778); Short Sand Creek (45.7763, −123.9406); Thompson Creek (46.0108, −123.8951); Tolovana Creek (45.8581, −123.9370); Unnamed (45.8648, −123.9371); Unnamed (45.8821, −123.9318); Unnamed (45.8881, −123.7436); Unnamed (45.8883, −123.9366); Unnamed (45.8906, −123.7460); Unnamed (45.8912, −123.9433); Unnamed (45.8950, −123.8715); Unnamed (45.9026, −123.9540); Unnamed (45.9046, −123.9578); Unnamed (45.9050, −123.9585); Unnamed (45.9143, −123.8656); Unnamed (45.9161, −123.9000); Unnamed (45.9210, −123.8668); Unnamed (45.9273, −123.8499); Unnamed (45.9292, −123.8900); Unnamed (45.9443, −123.9038); Unnamed (45.9850, −123.8999); Unnamed (46.0018, −123.8998); Volmer Creek (45.9049, −123.9139); Warner Creek (45.8887, −123.7801); Williamson Creek (45.9522, −123.9060).

(2) Nehalem Subbasin 17100202—(i) *Upper Nehalem River Watershed 1710020201.* Outlet(s) = Nehalem River (Lat 45.9019, Long −123.1442) upstream to endpoint(s) in: Bear Creek (45.7781, −123.4252); Bear Creek (45.8556, −123.2205); Beaver Creek (45.7624, −123.2073); Beaver Creek Trib A (45.8071, −123.2143); Beaver Creek Trib B (45.7711, −123.2318); Carlson Creek (45.7173, −123.3425); Castor Creek (45.7103, −123.2698); Cedar Creek (45.8528, −123.2928); Clear Creek, Lower North Fork (45.8229, −123.3111); Clear Creek (45.8239, −123.3531); Coal Creek Trib B (45.8149, −123.1174); Coal Creek (45.7978, −123.1293); Coon Creek (45.8211, −123.1446); Dell Creek (45.7919, −123.1559); Derby Creek (45.7225, −123.3857); Dog Creek (45.8957, −123.0741); Elk Creek (45.8256, −123.1290); Fall Creek (45.8626, −123.3247); Ginger Creek (45.8520, −123.3511); Ivy Creek (45.8938, −123.3160); Jim George Creek (45.8009, −123.1041); Kenusky Creek (45.8859, −123.0422); Kist Creek (45.7826, −123.2507); Lousignont Creek (45.7424, −123.3722); Lousignont Creek, North Fork (45.7463, −123.3576); Martin Creek (45.8474, −123.4025); Maynard Creek (45.8556, −123.3038); Military Creek (45.8233, −123.4812); Nehalem River (45.7269, −123.4159); Nehalem River, East Fork (45.8324, −123.0502); Olson Creek (45.8129, −123.3853); Pebble Creek (45.7661, −123.1357); Pebble Creek, West Fork (45.7664, −123.1899); Robinson Creek (45.7363, −123.2512); Rock Creek (45.8135, −123.5201); Rock Creek, North Fork (45.8616, −123.4560); Rock Creek, South Fork (45.7598, −123.4249); Rock Creek Trib C (45.7957, −123.4882); South Fork Rock Creek Trib A (45.7753, −123.4586); South Fork Nehalem River (45.7073, −123.4017); Selder Creek (45.8975, −123.3806); South Fork Clear Creek (45.8141, −123.3484); South Prong Clear Creek (45.7832, −123.2975); Step Creek (45.6824, −123.3348); Swamp Creek (45.8217, −123.2004); Unnamed (45.7270, −123.3419); Unnamed (45.8095, −123.0908); Unnamed (45.7558, −123.2630); Unnamed (45.7938, −123.3847); Unnamed (45.7943, −123.4059); Unnamed (45.8197, −123.0679); Unnamed (45.8477, −123.0734); Unnamed (45.8817, −123.1266); Unnamed (45.8890, −123.3817); Unnamed (45.9019, −123.1346); Weed Creek (45.8707, −123.4049); Wolf Creek,

South Fork (45.7989, −123.4028); Wolf Creek (45.7768, −123.3556).

(ii) *Middle Nehalem River Watershed 1710020202.* Outlet(s) = Nehalem River (Lat 45.9838, Long −123.4214) upstream to endpoint(s) in: Adams Creek (46.0263, −123.2869); Archibald Creek (45.9218, −123.0829); Beaver Creek (46.0554, −123.2985); Boxler Creek (46.0486, −123.3521); Calvin Creek (45.9514, −123.2976); Cedar Creek (45.9752, −123.1143); Cook Creek (45.9212, −123.1087); Cow Creek (46.0500, −123.4326); Crooked Creek (45.9043, −123.2689); Deep Creek (45.9461, −123.3719); Deep Creek Trib A (45.9127, −123.3794); Deep Creek Trib B (45.9314, −123.3809); Deer Creek (45.9033, −123.3142); Eastman Creek (46.0100, −123.2262); Fall Creek (45.9438, −123.2012); Fishhawk Creek (46.0596, −123.3857); Fishhawk Creek, North Fork (46.0907, −123.3675); Fishhawk Creek, Trib C (46.0808, −123.3692); Ford Creek (46.0570, −123.2872); Gus Creek (45.9828, −123.1453); Johnson Creek (46.0021, −123.2133); Lane Creek (45.9448, −123.3253); Little Deer Creek (45.9378, −123.2780); Lousignont Creek (46.0342, −123.4186); Lundgren Creek (46.0240, −123.2092); McCoon Creek (46.0665, −123.3043); Messing Creek (46.0339, −123.2260); Nehalem River (45.9019, −123.1442); Northrup Creek (46.0672, −123.4377); Oak Ranch Creek (45.9085, −123.0834); Sager Creek (45.9388, −123.4020); Unnamed (45.9039, −123.2044); Unnamed (45.9067, −123.0595); Unnamed (45.9488, −123.2220); Unnamed (45.9629, −123.3845); Unnamed (45.9999, −123.1732); Unnamed (46.0088, −123.4508); Unnamed (46.0208, −123.4588); Unnamed (46.0236, −123.2381); Unnamed (46.0308, −123.3135); Unnamed (46.0325, −123.4650); Unnamed (46.0390, −123.3648); Unnamed (46.0776, −123.3274); Unnamed (46.0792, −123.3409); Unnamed (46.0345, −123.2956); Warner Creek (46.0312, −123.3817); Wrong Way Creek (46.0789, −123.3142).

(iii) *Lower Nehalem River Watershed 1710020203.* Outlet(s) = Nehalem River (Lat 45.7507, Long −123.6530) upstream to endpoint(s) in: Alder Creek (45.9069, −123.5907); Beaver Creek (45.8949, −123.6764); Big Creek (45.8655, −123.6476); Bull Heifer Creek (45.9908, −123.5322); Buster Creek (45.9306, −123.4165); Cedar Creek (45.8931, −123.6029); Cow Creek (45.8587, −123.5206); Crawford Creek (45.9699, −123.4725); Cronin Creek, Middle Fork (45.7719, −123.5747); Cronin Creek, North Fork (45.7795, −123.6064); Cronin Creek, South Fork (45.7456, −123.5596); Destruction Creek (45.8750, −123.6571); East Humbug Creek (45.9454, −123.6358); Fishhawk Creek (45.9666, −123.5895); Fishhawk Creek (46.0224, −123.5374); George Creek (45.8461, −123.6226); George Creek (45.9118, −123.5766); Gilmore Creek (45.9609, −123.5372); Hamilton Creek (46.0034, −123.5881); Klines Creek (45.8703, −123.4908); Larsen Creek (45.8757, −123.5847); Little Fishhawk Creek (45.9256, −123.5501); Little Rock Creek (45.8886, −123.4558); McClure Creek (45.8560, −123.6227); Moores Creek (45.8801, −123.5178); Nehalem River (45.9838, −123.4214); Quartz Creek (45.8414, −123.5184); Spruce Run Creek (45.8103, −123.6028); Squaw Creek (45.9814, −123.4529); Stanley Creek (45.8861, −123.4352); Strum Creek (45.9321, −123.4275); Trailover Creek (46.0129, −123.4976); Unnamed (45.8083, −123.6280); Unnamed (45.8682, −123.6168); Unnamed (45.9078, −123.6630); Unnamed (45.9207, −123.4534); Unnamed (45.9405, −123.6338); Unnamed (45.9725, −123.5544); West Humbug Creek (45.9402, −123.6726); Walker Creek (45.9266, −123.4423); Walker Creek (46.0391, −123.5142); West Brook (45.9757, −123.4638).

(iv) *Salmonberry River Watershed 1710020204.* Outlet(s) = Salmonberry River (Lat 45.7507, Long −123.6530) upstream to endpoint(s) in: Pennoyer Creek (45.7190, −123.4366); Salmonberry River (45.7248, −123.4436); Salmonberry River, North Fork (45.7181, −123.5204); Wolf Creek (45.6956, −123.4485).

(v) *North Fork of Nehalem River Watershed 1710020205.* Outlet(s) = Nehalem River, North Fork (Lat 45.7317, Long −123.8765) upstream to endpoint(s) in: Acey Creek (45.7823, −123.8292); Anderson Creek (45.7643, −123.9073); Big Rackheap Creek (45.7546, −123.8145); Boykin Creek (45.8030, −123.8595); Buchanan Creek (45.8270, −123.7901); Coal Creek (45.7897, −123.8676); Coal Creek, West Fork (45.7753, −123.8871); Cougar Creek (45.8064, −123.8090); Fall Creek (45.7842, −123.8547); Fall Creek (45.8226, −123.7054); Gods Valley Creek (45.7689, −123.7793); Grassy Lake Creek (45.7988, −123.8193); Gravel Creek (45.7361, −123.8126); Henderson Creek (45.7932, −123.8548); Jack Horner Creek (45.8531, −123.7837); Lost Creek (45.7909, −123.7195); Nehalem River, Little North Fork (45.9101, −123.6972); Nehalem River, North Fork (45.8623, −123.7463); Nehalem River, North Fork, Trib R (45.8287, −123.6625); Nehalem River, North Fork, Trib T (45.8492, −123.6796); Rackheap Creek (45.7677, −123.8008); Sally Creek (45.8294, −123.7468); Soapstone Creek (45.8498, −123.7469); Soapstone Creek, Trib A (45.8591, −123.7616); Sweethome Creek (45.7699, −123.6616); Unnamed (45.7457, −123.8490); Unnamed (45.7716, −123.7691); Unnamed (45.7730, −123.7789); Unnamed (45.7736, −123.7607); Unnamed (45.7738, −123.7534); Unnamed (45.7780, −123.7434); Unnamed (45.7784, −123.7742); Unnamed (45.7794, −123.7315); Unnamed (45.7824, −123.7396); Unnamed (45.7833, −123.7680); Unnamed (45.7841, −123.7299); Unnamed (45.7858, −123.7660); Unnamed (45.7898, −123.7424); Unnamed (45.7946, −123.7365); Unnamed (45.7966, −123.7953); Unnamed (45.8008, −123.7349); Unnamed (45.8193, −123.7436); Unnamed (45.8322, −123.7789); Unnamed (45.8359, −123.7766); Unnamed (45.8569, −123.7235); Unnamed (45.8629, −123.7347); Unnamed (45.8662, −123.7444); Unnamed (45.8962, −123.7189).

(vi) *Lower Nehalem River/Cook Creek Watershed 1710020206.* Outlet(s) = Nehalem River (Lat 45.6577, Long −123.9355) upstream to endpoint(s) in: Alder Creek (45.7286, −123.9091); Anderson Creek (45.6711, −123.7470); Bastard Creek (45.7667, −123.6943); Bob's Creek (45.7444, −123.9038); Cook Creek (45.6939, −123.6146); Cook Creek, East Fork (45.6705, −123.6440); Daniels Creek (45.6716, −123.8606); Dry Creek (45.6449, −123.8507); Dry Creek (45.6985, −123.7422); East Foley Creek (45.6621, −123.8068); Fall Creek (45.7489, −123.7778); Foley Creek (45.6436, −123.8933); Gallagher Slough (45.7140, −123.8657); Hanson Creek (45.6611, −123.7179); Harliss Creek (45.6851, −123.7249); Helloff Creek (45.7545, −123.7603); Hoevett Creek (45.6894, −123.6276); Jetty Creek (45.6615, −123.9103); Lost Creek (45.7216, −123.7164); Neahkahnie Creek (45.7197, −123.9247); Nehalem River (45.7507, −123.6530); Peterson Creek (45.6975, −123.8098); Piatt Canyon (45.6844, −123.6983); Roy Creek (45.7174, −123.8038); Snark Creek (45.7559, −123.6713); Unnamed (45.6336, −123.8549); Unnamed (45.6454, −123.8663); Unnamed (45.6483, −123.8605); Unnamed (45.6814, −123.8786); Unnamed (45.7231, −123.9016).

(3) Wilson/Trask/Nestucca Subbasin 17100203—(i) *Little Nestucca River Watershed 1710020301.* Outlet(s) = Little Nestucca River (Lat 45.1827, Long −123.9543) upstream to endpoint(s) in: Austin Creek (45.1080, −123.8748);

Austin Creek, West Fork (45.1074, −123.8894); Baxter Creek (45.1149, −123.7705); Bear Creek (45.1310, −123.8500); Bowers Creek (45.1393, −123.9198); Cedar Creek (45.0971, −123.8094); Fall Creek (45.1474, −123.8767); Hiack Creek (45.0759, −123.8042); Kautz Creek (45.0776, −123.8317); Kellow Creek (45.1271, −123.9072); Little Nestucca River (45.0730, −123.7825); Little Nestucca River, South Fork (45.0754, −123.8393); Louie Creek (45.1277, −123.7869); McKnight Creek (45.1124, −123.8363); Small Creek (45.1151, −123.8227); Sourgrass Creek (45.0917, −123.7623); Sourgrass Creek, Trib A (45.1109, −123.7664); Squaw Creek (45.1169, −123.8938); Stillwell Creek (45.0919, −123.8141); Unnamed (45.1169, −123.7974).

(ii) *Nestucca River Watershed 1710020302.* Outlet(s) = Nestucca Bay (Lat 45.1607, Long −123.9678) upstream to endpoint(s) in: Alder Creek (45.1436, −123.7998); Alder Creek (45.2436, −123.7364); Bays Creek (45.3197, −123.7240); Bear Creek (45.3188, −123.6022); Bear Creek (45.3345, −123.7898); Beulah Creek (45.2074, −123.6747); Bible Creek (45.2331, −123.5868); Boulder Creek (45.2530, −123.7525); Buck Creek (45.1455, −123.7734); Cedar Creek (45.3288, −123.4531); Clarence Creek (45.2649, −123.6395); Clear Creek (45.1725, −123.8660); Crazy Creek (45.1636, −123.7595); Dahl Fork (45.2306, −123.7076); East Beaver Creek (45.3579, −123.6877); East Creek (45.3134, −123.6348); Elk Creek (45.3134, −123.5645); Elk Creek, Trib A (45.2926, −123.5381); Elk Creek, Trib B (45.2981, −123.5471); Fan Creek (45.2975, −123.4994); Farmer Creek (45.2593, −123.9074); Foland Creek (45.2508, −123.7890); Foland Creek, West Fork (45.2519, −123.8025); George Creek (45.2329, −123.8291); Ginger Creek (45.3283, −123.4680); Hartney Creek (45.2192, −123.8632); Horn Creek (45.2556, −123.9212); Lawrence Creek (45.1861, −123.7852); Limestone Creek (45.2472, −123.7169); Mina Creek (45.2444, −123.6197); Moon Creek (45.3293, −123.6762); North Beaver Creek (45.3497, −123.8961); Nestucca River (45.3093, −123.4077); Niagara Creek (45.1898, −123.6637); Pheasant Creek (45.2121, −123.6366); Pollard Creek (45.1951, −123.7958); Powder Creek (45.2305, −123.6974); Saling Creek (45.2691, −123.8474); Sanders Creek (45.2254, −123.8959); Slick Rock Creek (45.2683, −123.6106); Swab Creek (45.2889, −123.7656); Testament Creek (45.2513, −123.5488); Three Rivers (45.1785, −123.7557); Tiger Creek (45.3405, −123.8029); Tiger Creek, Trib A (45.3346, −123.8547); Tony Creek (45.2575, −123.7735); Turpy Creek (45.2537, −123.7620); Unnamed (45.1924, −123.8202); Unnamed (45.2290, −123.9398); Unnamed (45.3018, −123.4636); Unnamed (45.3102, −123.6628); Unnamed (45.3148, −123.6616); Unnamed (45.3158, −123.8679); Unnamed (45.3292, −123.8872); Walker Creek (45.2914, −123.4207); West Beaver Creek (45.3109, −123.8840); West Creek (45.2899, −123.8514); Wildcat Creek (45.3164, −123.8187); Wolfe Creek (45.3113, −123.7658); Woods Creek (45.1691, −123.8070).

**50 CFR Part 17**

**Endangered and Threatened Wildlife and Plants; 12-month Finding for a Petition To List the West Coast Distinct Population Segment of the Fisher (*Martes pennanti*); Proposed Rule**

**DEPARTMENT OF THE INTERIOR**

**Fish and Wildlife Service**

**50 CFR Part 17**

## Endangered and Threatened Wildlife and Plants; 12-month Finding for a Petition to List the West Coast Distinct Population Segment of the Fisher (*Martes pennanti*)

**AGENCY:** Fish and Wildlife Service, Interior.

**ACTION:** Notice of 12-month petition finding.

**SUMMARY:** We, the U.S. Fish and Wildlife Service (Service), announce a 12-month finding for a petition to list the West Coast distinct population segment of the fisher (*Martes pennanti*) under the Endangered Species Act of 1973, as amended. After review of all available scientific and commercial information, we find that the petitioned action is warranted, but precluded by higher priority actions to amend the Lists of Endangered and Threatened Wildlife and Plants. Upon publication of this 12-month petition finding, this species will be added to our candidate species list. We will develop a proposed rule to list this population pursuant to our Listing Priority System.

**DATES:** The finding announced in this document was made on April 2, 2004. Comments and information may be submitted until further notice.

**ADDRESSES:** You may send data, information, comments, or questions concerning this finding to the Field Supervisor (Attn: FISHER), Sacramento Fish and Wildlife Office, U.S. Fish and Wildlife Service, 2800 Cottage Way, Room W–2605, Sacramento, CA 95825 or via fax at 916/414–6710. You may inspect the petition, administrative finding, supporting information, and comments received during normal business hours by appointment at the above address.

**FOR FURTHER INFORMATION CONTACT:** Jesse Wild or Arnold Roessler at the above address (telephone: 916/414–6600; fax: 916/414–6710; electronic mail: *fisher@fws.gov*). In the event that our Internet connection is not functional, please submit your comments by the alternate methods mentioned above.

**SUPPLEMENTARY INFORMATION:**

### Background

Section 4(b)(3)(B) of the Endangered Species Act of 1973, as amended (Act) (16 U.S.C. 1531 *et seq.*), requires that, for any petition to revise the List of Threatened and Endangered Species that contains substantial scientific and commercial information that listing may be warranted, we make a finding within 12 months of the date of the receipt of the petition on whether the petitioned action is: (a) Not warranted, or (b) warranted, or (c) warranted but that the immediate proposal of a regulation implementing the petitioned action is precluded by other pending proposals to determine whether any species is threatened or endangered, and expeditious progress is being made to add or remove qualified species from the List of Threatened and Endangered Species. Section 4(b)(3)(C) of the Act requires that a petition for which the requested action is found to be warranted but precluded shall be treated as though resubmitted on the date of such finding, *i.e.*, requiring a subsequent finding to be made within 12 months. Such 12-month findings are to be published promptly in the **Federal Register**.

On December 5, 2000, we received a petition dated November 28, 2000, to list a distinct population segment (DPS) of the fisher, including portions of California, Oregon, and Washington, as endangered pursuant to the Act, and to concurrently designate critical habitat for this distinct population segment. A court order was issued on April 4, 2003, by the U.S. District Court, Northern District of California, that required us to submit for publication in the **Federal Register** a 90-day finding on the November 2000 petition (*Center for Biological Diversity, et al.* v. *Norton, et al.*, No. C 01–2950 SC). On July 10, 2003, we published a 90-day petition finding (68 FR 41169) that the petition provided substantial information that listing may be warranted and initiated a 12-month status review. Through a stipulated order, the court set a deadline of April 3, 2004, for the Service to make a 12-month finding under 16 U.S.C. 1533 (b)(3)(B).

### Taxonomy

The fisher is classified in the order Carnivora, family Mustelidae, subfamily Mustelinae, and is the largest member of the genus *Martes* (Anderson 1994). The only other North American member of the genus *Martes* is the American marten (*M. americana*). The fisher (*Martes pennanti* Erxleben 1777) is the only extant species in its subgenus *Pekania.*

Goldman (1935) recognized three subspecies of fisher, although he stated they were difficult to distinguish. Both Grinnell *et al.* (1937) and Hagmeier (1959) examined specimens from across the range of the fisher and concluded that differences in skull morphology or pelage were not sufficient to support recognition of separate subspecies. Hall (1981) retained all three subspecies in his compilation of North American mammals, as did Anderson (1994), but neither addressed Hagmeier's conclusion that the subspecies should not be recognized (Powell 1993). Several authors address genetic variation in fisher populations in their northern and eastern ranges (Williams *et al.* 1999, 2000; Kyle *et al.* 2001) and in the west (Drew *et al.* 2003; Aubry and Lewis 2003; Wisely *et al.* in litt. 2003). These analyses found patterns of population subdivision similar to the earlier described subspecies (Drew *et al.* 2003). Drew *et al.* (2003) stated that, although it is not clear whether Goldman's (1935) subspecific designations are taxonomically valid, ''* * * it is clear (based on genetic results) that population subdivision is occurring within the species, especially among populations in the western USA and Canada.''

### Description

The fisher is light brown to dark blackish brown with the face, neck, and shoulders sometimes being slightly gray. The chest and underside often has irregular white patches. The fisher has a long body with short legs and a long bushy tail. At 6.6 to 13.2 pounds (lbs) (3 to 6 kilograms (kg)), male fishers weigh about twice as much as females (3.3 to 5.5 lbs; 1.5 to 2.5 kg). Males range in length from 35 to 47 inches (in) (90 to 120 centimeters (cm)) while females range from 29 to 37 in (75 to 95 cm) in length. The fishers from the Pacific States may weigh less than fishers in the eastern United States (Seglund 1995; Dark 1997; Golightly 1997; Aubry and Lewis 2003). Fishers are estimated to live up to 10 years (Powell 1993).

### Distribution and Status

Fishers occur in the northern coniferous and mixed forests of Canada and the northern United States, from the mountainous areas in the southern Yukon and Labrador Provinces in Canada southward to central California and Wyoming, the Great Lakes and Appalachian regions, and New England (Graham and Graham 1994; Powell 1994). The fisher's range was reduced dramatically in the 1800s and early 1900s through overtrapping, predator and pest control, and alterations of forested habitats by logging, fire, and farming (Douglas and Strickland 1987; Powell 1993; Powell and Zielinski 1994; Lewis and Stinson 1998). Since the 1950s, fishers have recovered in some of the central and eastern portions of their historic range in the United States as a result of trapping closures, changes in forested habitats (*e.g.*, forest regrowth in abandoned farmland), and reintroductions (Brander and Books 1973; Powell and Zielinski 1994). However, fishers are still absent from their former range southeast of the Great Lakes (Gibilisco 1994). Grinnell *et al.* (1937) estimated extremely low population numbers for the fisher in California at a time when trapping for the fur trade had greatly reduced populations of furbearing animals. Although it is possible that fisher populations recovered somewhat immediately following the trapping prohibitions in the 1930s and 40s, Powell and Zielinski (1994) more recently note population declines for fisher populations in the west. Fishers are believed to be extirpated from the lower mainland of British Columbia; however, they may still occupy the higher elevations of these areas in low densities (BC Species and Ecosystems Explorer 2003). In the Pacific States, fishers were historically more likely to be found in low to mid-elevation forests up to 8,200 feet (ft) (2,500 meters (m)) (Grinnell *et al.* 1937; Schempf and White 1977; Aubry and Houston 1992). In recent decades, the scarcity of detections in Washington, Oregon, and the northern Sierra Nevada indicates that the fisher may be extirpated or reduced to very low numbers in much of this area (Aubry and Houston 1992; Zielinski *et al.* 1995; Aubry and Lewis 2003).

**Washington**

The fisher historically occurred both east and west of the Cascade Crest in Washington (Scheffer 1938; Aubry and Houston 1992). Lewis and Stinson (1998) conclude that, "Based on habitat, the historical range of fishers in Washington probably included all the wet and mesic forest habitats at low to mid-elevations. The distribution of trapping reports and fisher specimens collected in Washington confirms that fishers occurred throughout the Cascades, Olympic Peninsula, and probably southwestern and northeastern Washington.'' Aubry and Houston (1992) compared current and historical records of fishers in Washington to determine their distribution in relation to major vegetation and elevation zones. In total, they found 88 reliable records, dating from 1955 to 1991. West of the Cascades, fishers occurred from 328 to 5,900 ft (100 to 1800 m), with most records from below 3,280 ft (1,000 m). On the east slope of the Cascades where precipitation is lower, fishers were recorded from 1,970 to 7,200 ft (600 to 2,200 m) (Aubry and Houston 1992). Similar to elsewhere in the range, the upper elevational limit may be determined by snow depth (Krohn *et al.* 1997). Based on a lack of recent sightings or trapping reports, the fisher is considered to be extirpated or reduced to scattered individuals in Washington (Aubry and Houston 1992; Lewis and Stinson 1998).

**Oregon**

Aubry and Houston (1992) noted that most fisher records for Washington occurred in the western hemlock and sitka spruce forest zones. Given that these forest zones occupy large portions of northwestern Oregon (Franklin and Dyrness 1988), it is likely that the fisher historically occurred in this part of the State. Based on extensive camera and track plate surveys, Lewis and Stinson (1998) concluded that the fisher is greatly reduced in Oregon. Based on extensive inquiry and review of records, Aubry and Lewis (2003) found that extant fisher populations in Oregon are restricted to two disjunct and genetically isolated populations in the southwestern portion of the State: one in the northern Siskiyou Mountains of southwestern Oregon and one in the southern Cascade Range. The fishers in the Siskiyou Mountains near the California border are probably an extension of the northern California population (Aubry and Lewis 2003). The population in the southern Cascade Range is reintroduced and is descended from fishers that were translocated to Oregon from British Columbia and Minnesota (Aubry and Lewis 2003). The Oregon Cascade Range population is separated from known populations in British Columbia by more than 404 miles (mi) (650 kilometers (km)) (Aubry and Lewis 2003).

**California**

In eastern California, the fisher historically ranged throughout the Sierra Nevada, from Greenhorn Mountain in northern Kern County northward to the southern Cascades at Mount Shasta (Grinnell *et al.* 1937). In western California, it ranged from the Klamath Mountains and north Coast Range near the Oregon border southward to Lake and Marin Counties (Grinnell *et al.* 1937). Krohn *et al.* (1997) note that the map of fisher distributions by Grinnell *et al.* (1937) suggests that fishers may have been less common in the central Sierra Nevada than elsewhere in California during the early 1900s, but it is unknown whether this distribution was the historical condition or reflects human effects on forests and fishers prior to their assessment. The map was based on the trapping records of one 5-year period prior to which there was already concern that trapping had dangerously decreased the population of fisher in California (Grinnell *et al.* 1937).

Substantial efforts have been made in recent years to assess the status of fishers and other forest carnivores in California using systematic grids of baited track and camera stations (Zielinski *et al.* 1995, 1997a, 1997b, 2000; Zielinski and Stauffer 1996; Zielinski 1997). Recent surveys indicate that fishers appear to occupy less than half of the range they did in the early 1900s in California, and this population has divided into two remnant populations that are separated by approximately 260 mi (420 km) (Zielinski *et al.* 1995), almost four times the species' maximum dispersal distance as reported by York (1996) for fishers in Massachusetts. One population is located in northwestern California and the other is in the southern Sierra Nevada Mountains. Since 1990, there have generally been no detections outside these areas except for one in 1995 in Mendocino County and one in 1995 in Plumas County (CDFG 2002, updated November 13, 2003).

Failure to detect fishers in the central and northern Sierra Nevada, despite reports of their presence there by Grinnell *et al.* (1937) and reports from the 1960s collected by Schempf and White (1977), suggests that the fisher population in this region has declined, effectively isolating fishers in the southern Sierra Nevada from fishers in northern California (Truex *et al.* 1998; Lamberson *et al.* 2000). However, prior to the recent development of a rigorous fisher survey protocol, differences in the type and quality of data available over the previous 60-year period make interpretation of distributional changes difficult (Zielinski *et al.* 1995).

**Population Size**

Although reductions in the fisher's distribution in the Pacific States are well documented (Aubry and Lewis 2003; Gibilisco 1994; Powell and Zielinski 1994), accurate information on fisher densities and abundance outside the northeastern United States is very limited. There have been no good population estimates for fisher populations in California, Oregon, and Washington, so it is unknown precisely how many fishers exist. Estimates of fisher abundance and vital rates (*e.g.*, survival, reproduction) are very difficult to obtain (Douglas and Strickland 1987) and may vary widely based on habitat composition and prey availability (York 1996). In addition, the assumptions of many methods for estimating populations (*e.g.*, equal trapability, no learned trap response, sufficient trapability to yield adequate sample sizes) may not be valid for fishers (Powell and Zielinski 1994). Consequently, only a few estimates of local fisher population density are available for the Pacific States and British Columbia, and are summarized here.

In British Columbia, densities of fishers are estimated to be between 1 and 1.54 fishers per 38.6 mi $^2$ (100 km $^2$) in the highest quality habitats in the province (Weir 2003). Using the area of each habitat capability rank within the extent of occurrence of fishers in British Columbia, the late-winter population for the province is estimated to be between 1,113 and 2,759 fishers (Weir 2003). In a preliminary progress report of fisher studies on the Hoopa Valley Indian Reservation in the Klamath mountain range (Humboldt County, California), Higley *et al.* (1998) report high capture numbers and small home ranges, some of which overlap each other, indicating that densities in this 25 mi $^2$ (65 km $^2$) study area may be very high relative to those in the rest of the occupied West Coast range. In their analysis of two fisher studies in California, Zielinski *et al.* (in press 2003a) provided a rough estimate of approximately 5 female fishers per 38.6 mi $^2$ (100 km $^2$) for their 154 mi $^2$ (400 km) north coast study area (in the Six Rivers and Shasta-Trinity National Forests of southeastern Humboldt and southwestern Trinity Counties), whereas they estimated approximately 8 females per 100 km $^2$ in their 108 mi $^2$ (280 km $^2$) southern Sierra Nevada study area (in the Sequoia National Forest in Tulare County). For the purpose of modeling population viability, Lamberson *et al.* (2000) estimated that there were between 100 and 500 individuals in the southern Sierra Nevada fisher population. Based on trapping records from the 1920s, Grinnell and colleagues (1937) provided a dire estimate of 1 fisher per 100 mi $^2$, or 300 in California. However, although Grinnell *et al.* employed accepted methodologies at the time they conducted their research, we believe that their population estimate for California is incorrect by modern standards due to the lack of a significant sample size, survey bias, and inadequate knowledge of the historical baseline.

Despite the lack of precise empirical data on fisher numbers in the western states, the relative reduction in the range of the fisher on the West Coast, the lack of detections or sightings over much of its historical distribution, and the high degree of genetic relatedness within some populations (esp., native fishers in California) (Drew *et al.* 2003), indicate that it is likely extant fisher populations are small.

**Diet**

The fisher is an opportunistic predator with a diverse diet that includes birds, squirrels, mice, shrews, voles, reptiles, insects, carrion, vegetation, and fruit (Powell 1993; Martin 1994; Zielinski *et al.* 1999; Zielinski and Duncan, in press 2003). Fishers hunt exclusively in forested habitats and generally avoid openings (Earle 1978; Rosenberg and Raphael 1986; Powell 1993; Buskirk and Powell 1994; Jones and Garton 1994; Seglund 1995; Dark 1997). Being dietary generalists, fishers tend to forage in areas where prey is both abundant and vulnerable to capture (Powell 1993).

**Reproduction**

Except during the breeding season, fishers are solitary animals. The breeding season for the fisher is generally from late February to the end of April (Leonard 1986; Douglas and Strickland 1987; Powell 1993; Frost and Krohn 1997). Birth occurs nearly 1 year after copulation, due to delayed implantation in which the embryos remain in a state of arrested development for approximately 10 months. Arthur and Krohn (1991) and Powell (1993) speculate that this system allows adults to breed in a time when it is energetically efficient, while still giving kits adequate time to develop before winter. Raised entirely by the female, kits are completely dependent at birth and weaned by 10 weeks (Powell 1993). The mother becomes increasingly active as kits grow in order to provide enough food (Arthur and Krohn 1991; Powell 1993), and females may move their kits periodically to new dens (Arthur and Krohn 1991). At 1 year, kits will have developed their own home ranges (Powell 1993). Fishers have a low annual reproductive capacity, and reproductive rates may fluctuate widely from year to year (Truex *et al.* 1998).

**Home Range Size**

A home range is an area repeatedly traveled by an individual in its normal activities of feeding, drinking, resting, and traveling. Fishers have large home ranges and male home ranges are considerably larger than those of females (Buck *et al.* 1983; Truex *et al.* 1998). Fisher home range sizes across North America vary from 3,954 to 30,147 acres (ac) (16 to 122 km $^2$ for males and from 988 to 13,096 ac (4 to 53 km $^2$ for females (Powell and Zielinski 1994; Lewis and Stinson 1998). However, Beyer and Golightly (1996) reported that male home ranges in northern California may be as large as 31,629 ac (128 km$^2$).

Truex *et al.* (1998) compared fisher home range sizes in three study areas: the Klamath Mountains (Shasta-Trinity National Forest, the North Coast Ranges), Six Rivers National Forest, and the southern Sierra Nevada (Sequoia National Forest). They found the largest home range sizes in the eastern Klamath study area in northern California where habitat quality was generally considered poor. A preliminary summary of an unpublished study conducted in coastal redwood forests in the Coast Ranges of northwestern California indicates female home range sizes of 790 to 2050 ac (3.2 km $^2$ to 8.3 km $^2$) (Joel Thompson unpublished data; Neal Ewald, pers. comm. 2003), which is somewhat larger than range sizes reported by other researchers for the species in North America. Zielinski *et al.* (in press 2003a) found that females had home ranges that were almost three times larger in their northern California study area in the Coast Ranges than in their southern Sierra Nevada study area. They too suggest that this difference in home range size is a result of better quality habitats in the southern Sierra Nevada, which are occupied by a higher density of animals within a smaller area of suitable habitat (Zielinski *et al.*, in press 2003a). Based on northeastern fisher home range sizes, Allen (1983) assumed that a minimum of 62 mi $^2$ (161 km $^2$ of potentially suitable and connected habitat must be present before an area can sustain a population of fishers. However, Allen's estimates of amount of habitat required to support a fisher population may be an underestimate when applied to western forests, where male home ranges have been found to be somewhat larger (Beyer and Golightly 1996).

**Dispersal**

Dispersal (movement away from the natal home range) is the primary mechanism for the spread of a population. Arthur *et al.* (1993) reported an average maximum dispersal distance of 9.3 and 10.7 mi (14.9 and 17.3 km) for females and males, respectively (range = 4.7 to 14.0 mi (7.5 to 22.6 km) for females and 6.8 to 14.3 mi (10.9 to 23.0 km) for males) in a population in Maine with high trapping mortality and low density. In areas with high mortality and low density, young fishers may not have to disperse as far in order to find unoccupied home ranges (Arthur *et al.* 1993). York (1996) reported dispersal distances for juvenile male and female fishers averaging 20 mi (33 km) (range = 6 to 66 mi; 10 to 107 km) for a high-density population in Massachusetts. Based on field observation and microsatellite genotype analyses of the southern Cascades fisher population, Aubry *et al.* (USDA Forest Service, Pacific Northwest Research Station, in press 2003) found empirical evidence of male-biased juvenile dispersal and female philopatry (the drive or tendency of an individual to return to, or stay in, its home area) in fishers, which may have a direct bearing on the rate at which the fisher may be able to colonize formerly occupied areas within its historical range.

**Habitat**

Assessment of habitat relationships of fisher in current western U.S. forests is complicated by broad-scale changes in forest structure and composition over the past century. Grazing, wildfire suppression, and timber harvest have resulted in dramatic changes in forest ecosystems, including reduction of large tree component, increased dominance of shade-tolerant conifer species, increased stand density, and reduced structural diversity (McKelvey and Johnson 1992; Agee 1993; Skinner 1995; Chang 1996; Norman 2003). These effects vary among forest ecosystems, but generally are more pronounced in drier interior forests of the eastern Cascades, Sierra Nevada, and eastern Klamath Mountain ranges. The degree to which currently-described habitat relationships, particularly at broader scales, existed under historical conditions is unknown.

According to Buskirk and Powell (1994), the physical structure of the forest and prey associated with forest structures are thought to be the critical features that explain fisher habitat use, rather than specific forest types. Powell (1993) stated that forest type is probably not as important to fishers as the vegetative and structural aspects that lead to abundant prey populations and reduced fisher vulnerability to predation, and that they may select forests that have low and closed canopies. In the Klamath and north coast regions of California, Carroll *et al.* (1999) also found a strong association with high levels of tree canopy cover, tree size class, and percent conifer. Within a given region, the distribution of fishers is likely limited by elevation and snow depth (Krohn *et al.* 1997), and fisher are unlikely to occupy forest habitats in areas where elevation and snow depth act to limit their movements. However, in mid-elevation areas with intermediate snow depth, fishers may use dense forest patches with large trees because the overstory closure increases snow interception (Weir 1995a).

In a track-plate study conducted on private timberlands in the redwood-Douglas-fir transition zone of the Coast Ranges of northwestern California, Klug (1997) detected fishers on 238 occasions at 26 of 40 (65 percent) survey segments located in second-growth Douglas-fir and redwood. Fishers were detected more frequently than expected (based on availability) in areas at higher elevations, in stands where Douglas-fir was the dominant or co-dominant vegetation type, and with greater amounts of hardwoods. Klug (1997) found no relation between fisher occurrence and stand age or old-growth habitats; however there was less than 2 percent old-growth on his study area. The mean canopy cover for all stations Klug sampled was 94.7 percent, and mean stand age was 42.6 years, an age which, in productive lowland redwood and Douglas-fir habitats, often correlates with large-tree conditions. During subsequent studies in this area (Ewald, pers. comm. 2003), 24 individual fisher were captured (10 males, 14 females). Nine of 11 adult females showed signs of reproduction, and 9 natal and maternal dens were located. In their adjacent study area in Redwood National and State Parks with coastal forests dominated by redwood, Slauson *et al.* (2003) found that redwood was the dominant overstory and understory species where fishers were detected; Douglas-fir was dominant at sites where they were not. This study area had 38 percent old-growth habitat; however, fisher were detected more often in second-growth redwood stands. In contrast to forests further north and further inland, the milder temperature and higher humidity in these coastal areas may create suitable habitat conditions, at least for foraging, in younger forests.

**Fragmentation**

A number of studies have shown that the fisher avoids areas with little forest cover or significant human disturbance and conversely prefers large areas of contiguous interior forest (Coulter 1966; Kelly 1977; Buck 1982; Mullis 1985; Rosenberg and Raphael 1986; Arthur *et al.* 1989a; Powell 1993; Jones and Garton 1994; Seglund 1995; Dark 1997).

Rosenberg and Raphael (1986) assessed forest fragmentation in northwestern California and its effect on fishers. Their study shows a significant positive association with a plot's distance to a clearcut, and significant negative associations with a stand's length of edge, degree of insulation (defined as "the percentage of its perimeter that was clearcut edge''), percent clearcut, and total edge. Rosenberg and Raphael (1986) state, "Among the species suspected of being most sensitive to forest fragmentation in our study, only the fisher and spotted owl were also associated with old-growth forests.'' They show a significant positive association between fisher presence and forest stand area, detecting fishers more frequently in stands over 247 ac (100 ha) (70 percent frequency of occurrence) and stands of 126 to 247 ac (51 to 100 ha) (90 percent frequency of occurrence) than in smaller stands; fishers were detected in 55 percent of stands that were 52 to 124 ac (21 to 50 ha), in 30 percent of stands that were 27 to 49 ac (11 to 20 ha), and in 17 percent of stands under 25 ac (10 ha).

The fisher's need for overhead cover is very well-documented. Many researchers report that fishers select stands with continuous canopy cover to provide security cover from predators (de Vos 1952; Coulter 1966; Kelly 1977; Arthur *et al.* 1989; Weir and Harestad 1997, 2003). Fishers may use forest patches with large trees because the overstory closure increases snow interception (Weir 1995a). Forested areas with higher density overhead cover provide the fisher increased protection from predation and lower the energetic costs of traveling between foraging sites. Fishers probably avoid open areas because in winter open areas have deeper, less supportive snow which inhibits travel (Leonard 1980; Raine 1983; Krohn *et al.* 1997), and because they are more vulnerable to potential predators without forest cover (Powell 1993). Furthermore, preferred prey species may be more abundant or vulnerable in areas with higher canopy closure (Buskirk and Powell 1994).

Several studies have shown that fishers are associated with riparian areas (Buck 1982; Jones 1991; Aubry and Houston 1992; Seglund 1995; Dark 1997; Zielinski *et al.* 1997c; Zielinski *et al.* in press 2003b, in press 2003a). Riparian forests are in some cases protected from logging and are generally more productive, thus having the dense canopy closure, large trees and general structural complexity associated with fisher habitat (Dark 1997). According to Seglund (1995), riparian areas are important to fishers because they provide important rest site elements, such as broken tops, snags, and coarse woody debris.

**Composition of Home Ranges**

Mazzoni (2002) measured habitat composition within the home ranges of 11 fisher in the southern Sierra Nevada. Home range areas averaged 24.8 percent coverage by "late-successional'' (greater than 50 percent canopy cover, greater than 24 in (61 cm) diameter) conifer forest habitat (range 15.0 to 32.1 percent). The mean percent of home range area with dense (greater than 50 percent canopy cover) conifers of all sizes was 53.6 percent (range 34.9 to 76 percent). Also in the southern Sierra Nevada, Zielinski *et al.* (in press 2003a) found that home ranges of 12 fishers consisted of 12.8 percent (SD=10.9) large tree (greater than 24 in (61 cm) ) conditions. Intermediate tree size classes (12–24 in dbh), dense (greater than 60 percent) canopy closure, and Sierran Mixed Conifer forest type composed the greatest proportion of the home ranges studies (60.7, 66.3, and 40.1 percent, respectively).

In the North Coast Range of northern California, Zielinski *et al.* (in press 2003a) found that home ranges of nine fishers were dominated by mid-seral Douglas-fir and white fir (42.8 percent); home ranges included 14 percent (SD=13.36) late-successional Douglas-fir on average and 13.97 percent true fir (SD=10.23), on average.

**Resting and Denning Habitat**

Powell and Zielinski (1994) and Zielinski *et al.* (2003b) suggest that habitat suitable for resting and denning sites may be more limiting for fishers than foraging habitat. Numerous studies have documented that fishers in the western United States utilize stands with certain forest characteristics for resting and denning such as large trees and snags, coarse woody-debris, dense canopy closure and multiple-canopy layers, large diameter hardwoods, and steep slopes near water (Powell and Zielinski 1994; Seglund 1995; Dark 1997; Truex *et al.* 1998; Self and Kerns 2001; Aubry *et al.* 2002; Carroll *et al.* 1999; Mazzoni 2002; Zielinski *et al.* in press 2003b).

Rest sites have structures that provide protection from unfavorable weather and predators. Fishers also use rest sites as protected locations to consume prey following a successful foraging bout (Zielinski, pers. comm.). Re-use of rest sites is relatively low (14 percent: Zielinski *et al.* in press 2003b), indicating that habitats providing suitable resting structures need to be widely distributed throughout home ranges of fishers (Powell and Zielinski 1994; Truex *et al.* 1998), and spatially interconnected with foraging habitats.

**Rest Site—Stand Characteristics**

The most influential variables affecting rest site selection in California fisher populations include maximum tree sizes and dense canopy closure, but other features are important to rest site choice as well, such as large diameter hardwoods, large conifer snags, and steep slopes near water (Zielinski *et al.* in press 2003b). Fishers select areas as rest sites where structural features are most variable but where canopy cover is least variable, suggesting that resting fishers place a premium on continuous overhead cover but prefer resting locations that also have a diversity of sizes and types of structural elements (Zielinski *et al.* in press 2003b). Seglund (1995) found that a majority of fisher rest sites (83 percent) were further than 328 ft (100 m) from human disturbance and Dark (1997) found that fishers used and rested in areas with less habitat fragmentation and less human activity. Characteristics of forest stands containing rest sites on industrial timberlands were similar to those reported elsewhere in northern California. Fishers in Shasta County used rest sites in stands of the largest tree size classes available, with mean canopy closure of 71 percent (Self and Kerns 2001).

**Rest Site Structure Type and Size**

Rest site structures used by fishers include: cavities in live trees, snags, hollow logs, fallen trees, canopies of live trees, platforms formed by mistletoe ("witches brooms'') or large or deformed branches, and to a lesser extent stick nests, rocks, ground cavities, and slash and brush piles (Heinemeyer and Jones 1994; Higley *et al.* 1998; Mazzoni 2002; Zielinski *et al.* 2003b). Tree size, age, and structural features are important characteristics of a rest structure. Zielinski *et al.* (in press 2003b) stated that rest structures in their study areas in the North Coast and the southern Sierra Nevada were among the largest diameter trees available, averaging 46.2, 47.2, and 27.2 in (117.3, 119.8, and 69.0 cm) for live conifers, conifer snags, and hardwoods, respectively. Most rest locations in the study areas of Zielinski *et al.* (2003b) were in cavities or broken tops of standing trees. Trees must be large and old enough to bear the type of stresses that initiate cavities, and the type of ecological processes (*e.g.*, decay, woodpecker activity) that form cavities of sufficient size to be useful to fishers; tree species that typically decay to form cavities in the bole are more important than those that do not (Zielinski *et al.* 2003b). Cavities in hardwoods were the most frequently used rest structure in the southern Sierra Nevada study area where Douglas-fir is absent (37.5 percent of rest structures were in black oaks); and in the North Coast study area, Douglas-firs were the most frequently used species (65.6 percent) and black oaks were used less frequently (11.4 percent) (Zielinski *et al.* 2003b). Higley *et al.* (1998) found that fishers in their Klamath study area use live hardwood trees most frequently for resting (57.14 percent) followed by live conifer trees (26.29 percent), snags and logs (14.86 percent—hardwoods and conifers combined) and the ground (1.71 percent). On managed industrial timberlands in northwestern California, fisher resting sites (N=35) were predominantly located on dwarf mistletoe in western hemlocks, large lateral branches and mammal nests in Douglas-firs, and cavities in cedars (Simpson Resource Company 2003). The majority of 34 rest sites described by Self and Kerns (2001) were located in mistletoe brooms in live Douglas-firs, whereas only 20 percent were in snags or hardwoods.

**Natal and Maternal Dens**

Most dens are found in live trees, and there is little evidence that den sites are reused over time (Campbell *et al.* 2000). The trees must be large enough for cavities that can be used for natal and maternal dens. Of 19 tree dens documented by Truex *et al.* (1998) across three study areas in California, the average diameter was 45 in (115 cm) for conifers and 25 in (63 cm) for hardwoods. Of 16 maternal and natal dens located on managed timberlands in northwestern California, nine were in cavities in hardwoods and seven were in conifer snags: diameters of den trees ranged from 24.6 in (62.5 cm) to 116 in (295 cm) (Simpson Resource Company 2003). According to Lewis and Stinson (1998), natal dens are most commonly found in tree cavities at heights of greater than 20 ft (6 m), while maternal dens may be in cavities closer to the ground so active kits can avoid injury in the event of a fall from the den. The mean height of natal and maternal dens found in British Columbia was 99 ft (26 m) above ground (Weir and Harestad 2003). The height of these dens may help prevent predation by the larger male fishers or by other species.

**Foraging Habitats**

Fishers in the Pacific States appear to be dietary generalists, and therefore, they may be flexible in their requirements for foraging habitat. Selection of foraging habitat may be driven by habitat relationships of primary prey species.

Several studies have characterized foraging habitat which, similar to resting habitat, is often typified by characteristics associated with mature and late-successional forests (Jones and Garton 1994; Zielinski *et al.* 1997c).

However, fishers have been found to use a broader range of successional stages for hunting than for resting (Jones 1991; Heinemeyer 1993; Jones and Garton 1994). Jones (1991) found that younger-aged forests appeared suitable for hunting but were rarely used for summer resting; more structurally complex forests seemed to have been preferred for both activities, but simpler stand structures were used for hunting. In their use of younger forests, fishers in Idaho still appeared to select localities with higher availability of large-diameter trees, snags, and logs (trees over 18 in (47 cm) diameter, snags over 20 in (52 cm) diameter, and logs over 18 in (47 cm)) relative to randomly-located plots in the home range (Jones 1991).

Complex down woody material including large down logs, and multi-layered vegetative cover are important habitat elements for fishers. Fishers are often detected at sites with higher amounts of downed logs than at random sites (Klug 1997; Slauson *et al.* 2003), and high volumes of coarse woody debris and structural complexity near the forest floor (Weir and Harestad 2003), at least in part because high structural diversity is associated with prey species richness and abundance (Slauson *et al.* 2003) and greater prey vulnerability to capture (Buskirk and Powell 1994). Shrubs also provide food for prey and for fishers in the form of fruits and berries. Slauson *et al.* (2003) found that sites in their study area where fishers were detected had higher shrub cover (40–60 percent) than sites where they were not detected. Fishers may also avoid areas with too much low shrub cover because it may adversely affect the hunting success of fishers (Weir and Harestad 2003).

**Conclusion**

The key aspects of fisher habitat are best expressed in forest stands with late-successional characteristics. Fishers use habitat with high canopy closure, large trees and snags, large woody debris, large hardwoods, multiple canopy layers, and avoidance of areas lacking overhead canopy cover (Aubry and Houston 1992; Buskirk and Powell 1994; Buck *et al.* 1994; Seglund 1995; Klug 1996; Dark 1997; Truex *et al.* 1998; Mazzoni 2002; Weir and Harestad 2003; Zielinski *et al.* in press 2003b, in press 2003a). Fisher also occupy and reproduce in some managed forest landscapes and forest stands not classified as late-successional that provide some of the habitat elements important to fisher, such as relatively large trees, high canopy closure, large legacy trees, and large woody debris, in second-growth forest stands (Klug 1997; Simpson Resource Company 2003). However, intensive management for fiber production on industrial timberlands does not typically provide for retention of these elements. It is unlikely that early and mid-successional forests, especially those that have resulted from timber harvest, will provide the same prey resources, rest sites and den sites as more mature forests (Zielinski and Powell 1994).

Late-successional coniferous or mixed forests provide the most suitable fisher habitat because they provide abundant potential den sites and preferred prey species (Allen 1987). Forest structure of good quality fisher habitat should provide high diversity of dense prey populations, high vulnerability of prey to fishers, and natal and maternal dens and resting sites (Powell and Zielinski 1994). Younger forests in which complex forest structural components such as large logs, snags, and tree cavities are maintained in significant numbers, and which provide a diverse prey base, may be suitable for fisher (Lewis and Stinson 1998).

**Distinct Population Segment**

In a 12-month finding, we must determine if (1) the petitioned action is warranted, in which case we would promptly publish a proposed rule to list the species; (2) the petitioned action is not warranted; or (3) the petitioned action is warranted but precluded by other higher priority listing activities. Under the Act, a species is defined as including any subspecies and any distinct population segment of a vertebrate species. To implement the measures prescribed by the Act and its Congressional guidance, we and the National Marine Fisheries Service (National Oceanic and Atmospheric Administration—Fisheries), developed a joint policy that addresses the recognition of DPSs of vertebrate species for potential listing actions (61 FR 4722). The policy allows for a more refined application of the Act that better reflects the biological needs of the taxon being considered, and avoids the inclusion of entities that do not require its protective measures. The DPS policy specifies that we are to use three elements to assess whether a population segment under consideration for listing may be recognized as a DPS: (1) the population segment's discreteness from the remainder of the species to which it belongs and (2) the significance of the population segment to the species to which it belongs. Our evaluation of significance is made in light of Congressional guidance that the authority to list DPSs be used "sparingly'' while encouraging the conservation of genetic diversity. If we determine that a population segment meets the discreteness and significance standards, then the level of threat to that population segment is evaluated based on the five listing factors established by the Act to determine whether listing the DPS as either threatened or endangered is warranted.

Below, we address under our DPS policy the population segment of the fisher that occurs in the western United States in Washington, Oregon and California. The area for this DPS includes the Cascade Mountains and all areas west, to the coast in Oregon and Washington; and in California, the North Coast from Mendocino County north to Oregon, east across the Klamath (Siskiyou, Trinity, and Marble) Mountains, across the southern Cascade Mountains and south through the Sierra Nevada Mountains. The mountainous areas east of the Okanogan River in Washington and the Blue Mountains west to the Ochoco National Forest in eastern Oregon are not included in this DPS due to their geographical isolation from the remainder of the DPS.

**Discreteness**

Under our DPS policy, a population segment of a vertebrate species may be considered discrete if it satisfies either one of the following two conditions: (1) it is markedly separated from other populations of the same taxon as a consequence of physical, physiological, ecological, or behavioral factors (quantitative measures of genetic or morphological discontinuity may provide evidence of this separation); or (2) it is delimited by international governmental boundaries within which differences in control of exploitation, management of habitat, conservation status, or regulatory mechanisms exist that are significant with regard to conservation of the taxon in light of section 4(a)(1)(D) of the Act.

The proposed DPS is markedly separated from other fisher populations as a result of several factors. Native populations of the fisher in California and the reintroduced population in the southern Cascade Mountains of Oregon are physically isolated from the Canadian populations by over 200 miles (Weir 2003), given the northward contraction of the British Columbia population (Weir 2003) in Canada. Substantial information is available indicating the West Coast population is also physically separated from known populations of the fisher to the east.

The range of the fisher in Washington, Oregon, and California is separated from the Rocky Mountains and the rest of the taxon in the central and eastern United

States by natural physical barriers including the non-forested high desert areas of the Great Basin in Nevada and eastern Oregon, and the Okanogan Valley in eastern Washington. At its extreme northern (unoccupied) extent in northern Washington, the DPS is separated from the western extension of the Rocky Mountains and associated ranges by the Okanogan Valley, a distance of approximately 93 to 124 mi (150 to 200 km), which is well beyond the dispersal range for the species. Other physical barriers that separate the West Coast population from Rocky Mountain and eastern U.S. fisher populations include major highways, urban and rural open-canopied areas, agricultural development, and other nonforested areas. Fishers have a strong aversion to areas lacking in forest cover or to crossing large rivers that do not freeze in the winter (Powell 1993; Powell and Zielinski 1994; Aubry and Lewis 2003); these behavioral factors, along with the other numerous barriers identified above, represent a significant impediment to eastward or westward movement for the fisher.

We currently have limited information on dispersal distances of fishers in the western United States. However, studies conducted on fisher dispersal in the northeastern United States indicate that dispersal distances are relatively short (Arthur *et al.* 1993; York 1996). There is no evidence that fishers are successfully dispersing outside of known population areas in California and Oregon. This is possibly due to the extent of habitat fragmentation, developed or disturbed landscapes, and highways and interstate corridors (see dispersal section above).

Genetic information (Drew *et al.* 2003) indicates that the West Coast population of fisher originally colonized the Pacific states from British Columbia. The current range of fisher in British Columbia has been reduced and connection to fisher populations in the continental United States no longer exists (Weir 2003, BC Species and Ecosystems Explorer 2003). The fisher's present range in British Columbia has contracted northward from the international boundary by about 200 kilometers. (Weir 2003). Movement of fisher from British Columbia southward to areas occupied by the West Coast population is not possible based on lack of available habitat, habitat preferences, and dispersal behavior of the fisher.

The West Coast population also appears to be separated from other populations as a result of ecological factors, as they use forest types that differ in species composition, tree size, and habitat structure as compared to those used by fishers in other populations. The fisher is regarded as a habitat specialist in the western United States (Buskirk and Powell 1994), occurring only at mid to lower elevation in mature conifer and mixed conifer/hardwood forests characterized by dense canopies and abundant large trees, snags, and logs (Powell and Zielinski 1994). In contrast, fishers in the northeastern United States and the Great Lakes region inhabit areas with a large component of deciduous hardwood forest containing American beech (*Fagus grandifolia*), sugar maple (*Acer saccharum*), and other broadleaf species (Powell and Zielinski 1994). The majority of conifer forest habitat in Canada is characterized as boreal forest, which is different from the relatively dryer environmental conditions associated with Washington, Oregon, and California. In the Rocky Mountains of north central Idaho, certain all-conifer habitat types which include grand fir and Engelmann spruce appear to be important to, and preferentially selected by fishers (Jones 1991).

With regard to physiological differences, the fishers in the native northern California population are significantly smaller in size (based on condylobasal length) than fishers from western and central Canada (Hagmeier 1959; Zielinski *et al.* 1995; Aubry and Lewis 2003.

The West Coast population of the fisher is also delimited to the north by the international governmental boundary between the United States and Canada because of differences in control of exploitation, management of habitat, conservation status, and regulatory mechanisms that may be significant with respect to section 4(a)(1)(D) of the Act. Canada has no overarching forest practices laws governing management of its national lands. In contrast, lands within the National Forest System in the United States are considered under the National Forest Management Act of 1976, as amended (16 U.S.C. 1600), and associated planning regulations. The fisher is covered by British Columbia's Wildlife Act which protects virtually all vertebrate animals from direct harm, except as allowed by regulation (*e.g.*, hunting or trapping). The fisher is designated as a Class 2 furbearer in British Columbia and, as such, can be legally harvested by licensed trappers under regional regulations. However, the fisher was reclassified to the Red List in British Columbia in 2003 with a provincial conservation ranking of "S2,'' as assigned by the British Columbia Conservation Data Centre to "score'' the risk of extinction or extirpation (BC Species and Ecosystems Explorer 2003). The Red List designation means that the species is considered imperiled at the provincial level. The change in the fisher designation was the result of an estimated provincial population of fewer than 3,000 individuals and habitat loss due to logging, hydro-electric development and other land use changes (BC Species and Ecosystems Explorer 2003). Although the change in Red List designation for the fisher in British Columbia carries no legal implications, trapping seasons for it have been closed until new information is collected that indicates the population is secure (BC Ministry of Land, Water, and Air Protection 2003). Beyond this voluntary closure of the trapping season, the fisher carries no protected status in British Columbia. Trapping the species has been prohibited for decades in Washington, Oregon, and California (Lewis and Stinson 1998). For the reasons stated above, we believe that these factors collectively play a role in delimiting the northern DPS boundary along the international border with Canada from the Cascade Mountains west to the Pacific Ocean.

Based on the available information on fisher range and distribution, we conclude that the West Coast population of fisher is distinct and separate from other fisher populations in the United States and meets the requirements of our DPS policy for discreteness. The West Coast population of fisher is separated from fisher populations to the east by geographical barriers and to the north by habitat availability; it is further delineated by the international boundary with Canada, within which there are differences in control of exploitation, conservation status, and regulatory mechanisms that are significant to its conservation.

**Significance to the Species**

Under our DPS policy, once we have determined that a population segment is discrete, we consider its biological and ecological significance to the larger taxon to which it belongs. This consideration may include, but is not limited to, the following factors: (1) Persistence of the discrete population segment in an ecological setting unusual or unique for the taxon; (2) evidence that loss of the discrete population segment would result in a significant gap in the range of the taxon; (3) evidence that the population segment represents the only surviving natural occurrence of a taxon that may be more abundant elsewhere as an introduced population outside its historical range; and (4) evidence that the discrete population segment differs markedly from other populations of the species in its genetic characteristics. Significance is not determined by a quantitative analysis, but instead by a qualitative finding. We have found substantial evidence that the West Coast DPS of the fisher meets two of the significance factors and is supported by a third significance factor, and we have described them below.

Fishers in the West Coast population persist in an ecological setting that is unusual in comparison to the rest of the taxon, with a different climate, topography, and habitat than that found in the majority of its range. The forests inhabited by fishers on the west coast lack the extensive broadleaf hardwood component that is common in the eastern portions of the species' range. The Pacific coast's wet winter followed by a dry summer is unique in comparison to climate types in the east and Canada, and produces distinctive sclerophyll forests of hardleaved evergreen trees and shrubs (Smith *et al.* 2001). This climate is characterized by mild, wet winters and warm, dry summers (Bailey 1995), while the climate in the animal's range in the Rocky Mountains consists of cold winters and cool, dry summers, and in the Great Lake States, eastern Canada, and the northeast United States it is characterized by cold winters, and warm, wet summers. Fishers on the west coast primarily occur in habitat in steep, mountainous terrain, while those in the Great Lakes region, eastern Canada, and the northeastern United States inhabit level terrain or low lying glaciated mountains. Releases of eastern fishers into western forests have generally been unsuccessful; Powell and Zielinski (1994) state that, "Roy's (1991) results [unsuccessful attempts to reintroduce Minnesota fishers to Montana] indicate that many fishers from eastern North America may lack behaviors, and perhaps genetic background, to survive in western ecological settings.'' The repeated introductions of fishers from British Columbia and Minnesota to the southern Cascade Mountains of Oregon (from 1960s to 1980s) have resulted in an apparently stable, but small population there; however, the species is not expanding and dispersing from the areas into which it was introduced.

The loss of the West Coast DPS of the fisher would eliminate the entire southwest portion of the fisher's North American range. Additionally, the West Coast DPS of the fisher represents the southernmost range of the *Martes* genus. The West Coast populations represent three of the known remaining four populations in the western United States (fourth being the Rocky Mountain population), and a significant portion of the western range of fishers in North America. Based on figures from Weir (2003), the total range of the fisher in North America has been reduced approximately 33 percent in geographical area since the 1600s. This reduction is most apparent in the fishers southern and western range—largely in the United States. Based on our review of Lewis and Stinson's (1998) maps (modified from Gibilisco 1994), these are three of only six or seven remaining areas occupied by fishers in the United States. Although these maps consider a large area of Canada to be within the 1994 range of the fisher, distribution has diminished in some areas of southeastern Ontario and Quebec, in the prairie provinces (Alberta, Saskatchewan, and Manitoba), and in the western United States (Gibilisco 1994); and because of the lack of inventories for the species in Canada, it is not known to what extent the range in Canada is occupied. Additionally, the populations in the southern Sierra Nevada and northern California/southern Oregon appear to be the only native populations of the fisher remaining in the west (Truex *et al.* 1998; Aubry *et al.* in press 2003; Drew *et al.* 2003), and are "the only populations that have not been augmented with individuals (and genes) from other regions'' (Zielinski *et al.* 2003b).

As stated earlier (see distribution section), the extent of area known to be currently occupied by fishers in Washington, Oregon, and California is roughly 20 percent of their historical extent in these States. The loss of the species from the United States west of the Rocky Mountains and south of British Columbia would result in a significant gap in the range of the species as a whole and represent the loss of a major geographical area of the range of the taxon. It would represent a loss of the species from about 20 percent of its historical range in the United States, a significant portion of its North American range, recognizing that the historical range was not continuously occupied spatially or temporally, and that the present range we identify is also not occupied continuously nor is all of the historical habitat still available, especially in the midwest and east.

The extinction of fishers in their west coast range would also result in the loss of a significant genetic entity, since they have been described as being genetically distinct from fishers in the remainder of North America. More specifically, native fishers in California have reduced genetic diversity compared to other populations (Drew *et al.* 2003). Additionally, the extant native populations in California share one haplotype that is not found in any other populations (Drew *et al.* 2003).

Quantitative measures of genetic discontinuity indicate that there is no naturally occurring genetic interchange with the California fisher populations. Based on genetic evidence, and supported by paleontological and archeological evidence, Wisely *et al.* (in litt. 2003) theorize that fishers probably colonized the Pacific peninsula from the north, not the east. The fisher was once distributed throughout much of the dense coniferous forests in British Columbia, Washington, Oregon, and California (Drew *et al.* 2003). This historical connectivity among populations along the Pacific Coast is evidenced by the presence of British Columbia haplotypes in museum specimens from California and Washington (Drew *et al.* 2003). The historical continuity in fisher distribution no longer exists, as discussed above. Genetic variation shows the Oregon southern Cascade population is a reintroduced population descended from fishers translocated to Oregon from British Columbia and Minnesota (Drew *et al.* 2003). There is evidence that there has been no genetic interchange between the native northern California/southwestern Oregon Siskiyou population and the reintroduced southern Cascade Oregon population (Aubry *et al.* in press 2003).

**Conclusion**

We have evaluated as a DPS the population of fishers in the West Coast range and have addressed the elements our policy requires us to consider in deciding whether a vertebrate population may be recognized as a DPS and considered for listing under the Act. In assessing the population segment's discreteness from the remainder of the taxon, we have described the factors separating it from other populations. We considered distributional, ecological, behavioral, morphological, and genetic information, information from status surveys, and geographical and biogeographical patterns, and have concluded that this population segment is discrete under our DPS policy. In assessing the population segment's significance to the taxon to which it belongs, we have considered the geographical area represented by the western DPS, its genetic distinctness from fisher populations in the central and eastern United States, its unique ecological setting, and other considerations and factors as they relate to the species as a whole. We conclude that loss of the species from the west coast range in the United States would represent (1) a significant gap in the species' range, (2) the loss of genetic differences from fisher in the central and eastern United States, and (3) the loss of the species from a unique ecological setting. Therefore, as the population segment meets both the discreteness and significance criteria of our DPS policy, it qualifies as an entity that may be considered for listing. We now evaluate its status as endangered or threatened. In making this determination, we evaluate the factors enumerated in section 4(a)(1) of the Act (16 U.S.C. 1533 (a)(1)).

**Summary of Factors Affecting the Species**

Section 4 of the Act (16 U.S.C. 1533), and implementing regulations at 50 CFR 424, set forth procedures for adding species to the Federal endangered and threatened species list. In making this finding, information regarding the status and threats to this species in relation to the five factors in section 4 of the Act is summarized below.

*Factor A. The Present or Threatened Destruction, Modification, or Curtailment of the Species' Habitat or Range.* Vegetation management activities such as timber harvest and fuels reduction treatments, stand-replacing fire, large-scale forest disease outbreaks or insect infestations (*e.g.*, pine beetle), and development can destroy, alter, or fragment forest habitat suitable for fishers.

*Timber Harvest*

The extent of past timber harvest is one of the primary causes of fisher decline across the United States (Powell 1993), and may be one of the main reasons fishers have not recovered in Washington, Oregon, and portions of California as compared to the northeastern United States (Aubry and Houston 1992; Powell and Zielinski 1994; Lewis and Stinson 1998; Truex *et al.* 1998). Timber harvest can fragment fisher habitat, reduce it in size, or change the forest structure to be unsuitable for fishers.

Habitat fragmentation has contributed to the decline of fisher populations because they have limited dispersal distances and are reluctant to cross open areas to recolonize historical habitat. Based on northeastern fisher home range sizes, Allen (1983) estimated that a minimum of 161 $km^2$ (39,780 ac) of potentially suitable and contiguous habitat must be present before an area can sustain a population of fishers. However, fisher populations in western forests may need even larger areas because male home ranges in northern California have been reported to be as large as 128 $km^2$ (Beyer and Golightly 1996). A habitat suitability model developed in British Columbia figures that a minimum of 259 $km^5$ of contiguous habitat is required for fisher transplant attempts (Apps 1996 as cited in Craighead *et al.* 1999).

Fishers use large areas of primarily coniferous forests with fairly dense canopies and large trees, snags, and down logs; vegetated understory and large woody debris appear important for their prey species. Fishers in the Pacific Northwest use late-successional forest more frequently than the early to mid-successional forests that result from timber harvest (Aubry and Houston 1992; Buck *et al.* 1994; Rosenberg and Raphael 1986). Elimination of late-successional forest from large portions of the Sierra Nevada and Pacific Northwest (Morrison *et al.* 1991; Aubry and Houston 1992; McKelvey and Johnston 1992; Franklin and Fites-Kauffman 1996) has probably significantly diminished the fisher's historical range on the west coast (Lewis and Stinson 1998).

Several studies have found sharp declines in late-successional/old-growth forests (Beardsley *et al.* 1999, Bolsinger and Waddell 1993, the Report of the Forest Ecosystem Management Assessment Team (FEMAT) 1993, Franklin and Fites-Kaufmann 1996, Morrison *et al.* 1991, Service 1990). Old growth comprised about 50 percent of the forests of Washington, Oregon, and California in the 1930s and 1940s, but made up less than 20 percent of those forests in 1992 (about 10.3 million ac; 41,683 $km^2$) (Bolsinger and Waddell 1993).

Franklin and Fites-Kaufman (1996) find that forests with high late successional/old-growth structural rankings are now uncommon in the Sierra Nevada of California (8 percent of mapped area). Mixed conifer forests are a particularly poorly represented forest type as a result of past timber harvesting, and key structural features of late successional/old-growth forests, such as large-diameter trees, snags, and logs, are generally at low levels (Franklin and Fites-Kaufman 1996). The loss of structurally complex forest and the loss and fragmentation of suitable habitat by roads and residential development have likely played significant roles in both the loss of fishers from the central and northern Sierra Nevada and the fisher's failure to recolonize these areas (USDA Forest Service 2000).

Within the Northwest Forest Plan area, 60 to 70 percent of the forested area of the region was historically dominated by late-successional and old-growth forest conditions. Most of the forest (perhaps 80 percent) probably occurred in relatively large contiguous areas (greater than 1000 ac; 4 $km^2$) (Bolsinger and Waddell 1993, USDA Forest Service and U.S. Department of Interior Bureau of Land Management (USDI BLM) 1994a). Franklin and Spies (1986) estimated that 15 million ac (60,703 $km^2$) of old-growth forest existed west of the Cascade Mountains in Oregon and Washington in the 1800s, and only about 5 million ac (20,234 $km^2$; 33 percent) remain. FEMAT (1993) reports the status of forests in several regions: private and State lands within western Washington and western Oregon Cascades have mostly been harvested, whereas Forest Service and Bureau of Land Management lands (BLM) still include significant areas (albeit highly fragmented) of late successional/old-growth forest; the Klamath Provinces of southwestern Oregon and northwestern California have forests that are highly fragmented by timber harvest and natural factors (poor soils, dry climate, wildfires); the southern end of the Cascades Range in Oregon extending into California has forests that are highly fragmented due to harvest activities and natural factors.

The NWFP states that fisher populations are believed to have declined on Federal lands in old-growth habitat for two primary reasons: (1) Loss of habitat due to forest fragmentation resulting from clearcutting, and (2) the removal of large down coarse woody debris and snags from the cutting units (USDA Forest Service and USDI BLM 1994). Fishers in the eastern Klamath area of northern California have lower population densities, larger home ranges, lower capture rates, and a higher proportion of juveniles than other populations studied, possibly due in part to timber harvest having decreased habitat quality for the fisher in this area (Truex *et al.* 1998).

The conversion of low-elevation forests in western Washington to plantations and non-forest uses may have eliminated a large portion of the fisher habitat in the state (Powell and Zielinski 1994). There were historically many mature and old-growth stands (Aubry and Houston 1992). Over 60 percent of the 24.7 million ac (100,000 $km^2$) of forest believed to be present in Washington when white settlers first arrived were potential fisher habitat (Lewis and Stinson 1998). By 1992, the area of old-growth forest was reduced to 2.7 million ac (10,927 $km^2$) (Bolsinger and Waddell 1993). During the last 50 years, the structure, composition, and landscape context of much of

Washington's 16,803,100 ac (68,000 $km^2$) of commercial timberland has significantly changed because of intensive timber harvesting activities (Morrison 1988). Most of the remaining younger low and mid-elevation forest is fragmented and has reduced amounts of large snags and coarse woody debris, and may not be able to sustain fisher populations (Rosenberg and Raphael 1986; Lyon *et al.* 1994; Powell and Zielinski 1994). The higher elevation forests are less suitable for fishers because of deep snowpacks (Aubry and Houston 1992; FEMAT 1993).

Some forest management practices change the dominance of certain forest subtypes in western states (Lewis and Stinson 1998, Bouldin 1999). This change in forest structure is important because certain habitat types or tree species are suitable for fishers. In addition, logging and fire suppression have created higher densities of small trees which have led to higher insect and pathogen-induced mortality and the loss of structural diversity, and increased chances for stand-destroying fires (Bouldin 1999), the effects of which are discussed below.

Mazzoni (2002) found that timber harvest, fire, and succession resulted in fisher habitat fragmentation in the southern Sierra Nevada from 1958 to 1997. Rosenberg and Raphael (1986) emphasize that the fragmentation of northwestern California Douglas-fir forests is relatively recent in comparison with forests of other regions, and that the true long-term responses of species to the break-up of their habitat cannot yet be discerned.

The effects of timber harvest on fisher habitat depend on the silvicultural prescriptions used and the condition of the habitat prior to harvest. Habitat fragmentation is a concern. Clearcutting, selective logging, and thinning change the suitability of fisher habitat by removing overhead cover and insulating canopy, exposing the site to the drying effects of sun and wind (Buck *et al.* 1994) or to increased snow deposition, removing prime resting and denning trees, and increasing exposure of the fisher to predators.

*Fuels Reduction and Loss of Habitat From Fire*

Mechanical thinning or prescribed fire negatively affect fishers if it impacts habitat quality by reducing canopy cover and coarse woody debris over large areas or fragment habitat. Fuels reduction treatments, including thinning and the removal of down woody debris, dense understory, snags, and low overstory tree crowns may significantly affect fishers in the immediate area. Prescribed burning generally promotes forest health, and can enhance suitability for wildlife, but may vary in its effect on fishers. Small fires should not be detrimental to fishers because of the fishers' large home ranges (unless they impact natal dens during breeding season); however, hotter or more widespread fires may displace fishers or destroy habitat. Prescribed fire can also consume habitat structural elements such as snags and downed logs that are important to fishers.

The potential for stand-replacing wildfire has increased in areas where fire suppression has played a role in raising fuel load to levels that place late successional forest-dependent species at a higher risk of habitat loss (USDA Forest Service and USDI BLM 1994b). Stand replacing fires can impact large areas and render them unsuitable for fisher for several decades (Lewis and Stinson 1998). The combination of increased tree density and standing tree mortality (with associated increased surface/ground fuel loads) over the past century presents the greatest single threat to the integrity of Sierra Nevada forest ecosystems (McKelvey *et al.* 1996, USDA Forest Service 2000). On the other hand, while increased density of trees and woody debris (“fuel loading'') increases the risk of stand-replacing fire, they may also enhance habitat for the fisher in the short term.

*Forest Disease and Insect Outbreaks*

Although large area epidemics may displace fishers if canopy cover is lost, the usual pattern of localized outbreaks and low density of insect and disease damage is probably not a great threat to fisher habitat. In some cases, the diseased trees are beneficial, providing structures conducive to resting and denning. However, timber removal and thinning prescriptions in response to outbreaks may fragment or degrade habitat in the short term in order to prevent catastrophic fire that will eliminate habitat altogether for decades (see previous discussion). In addressing outbreaks of the mountain pine beetle (*Dendroctonus ponderosae*) and other insects in British Columbia, Weir (2003) states that reduction in overhead cover may be detrimental to fishers and that wide-scale salvage operations may substantially reduce the availability and suitability of fisher habitat.

Sudden Oak Death Phytophthora affects oaks and redwoods and may affect tanoak, evergreen huckleberry, and Pacific rhododendron (*Rhododendron macrophyllum*). Four sites on Federal, private industrial, and private nonindustrial forestlands in Oregon (near Brookings) have been confirmed as having Sudden Oak Death. The outbreaks at these sites affect from less than 1 ac (0.4 ha) to approximately 8 ac (3 ha) in size. Chances of continued introductions and establishment of the disease appear high in southwestern Oregon and northwestern California because these areas have the hosts, the climatic conditions preferred by the pathogen, and many potential pathways for its movement. It is a potentially significant threat if it spreads into areas in which oaks are the primary trees used for fisher denning.

*Development, Recreation, and Roads*

Urban Development and Recreation

Forested area in the Pacific coast region decreased by about 8.5 million ac (34,400 $km^2$) between 1953 and 1997 (Smith *et al.* 2001). Alig *et al.* (2003) state that “Forest cover area [in the Pacific coast states] is projected to continue to decrease through 2050, with timberland area projected to be about 6 percent smaller in 2050 than in 1997. Forest area is projected to decline in all three subregions [Washington, Oregon, and California]. Population and income are expected to further fuel development in the region, as population is projected to increase at rates above the national average, leading to more conversion of forest to nonforest uses.''

Rural and recreational development, such as campgrounds, recreation areas, and hiking, biking, off-road vehicle and snowmobile trails, may adversely affect fishers. Recreational activities can alter wildlife behavior, cause displacement from preferred habitat, and decrease reproductive success and individual vigor (USDA Forest Service 2000). A study of fisher habitat use on the Shasta-Trinity National Forest indicates that fishers use landscapes with more contiguous, unfragmented Douglas-fir forest and less human activity (Dark 1997).

Roads

Highways and associated developments can substantially influence movement patterns of wildlife (Bier 1995). The adverse effects of roads include direct loss of habitat, displacement from noise and human activity, direct mortality, secondary loss of habitat due to the spread of human development, increased exotic species invasion, and creation of barriers to fisher dispersal. The impacts of these effects on low density carnivores like fishers are more severe than most other wildlife species due to their large home ranges, relatively low fecundity, and low natural population density

(Ruediger *et al.* 1999), and their general avoidance of non-forested habitats. Disruption of movement can contribute to a loss of available habitat (Mansergh and Scotts 1989), isolate populations, and increase the probability of local extinctions (Mader 1984). The loss of structurally complex forest (Beesley 1996) and the loss and fragmentation of suitable habitat by roads and residential development (Duane 1996) has likely played a significant role in both the loss of fishers from the central and northern Sierra Nevada and its failure to recolonize these areas.

Areas with more roads may have increased fisher mortality due to road kill (Heinemeyer and Jones 1994). Given patterns of human population growth in areas near and within fisher habitat, road development and traffic, and associated mortality, can be expected to increase. Campbell *et al.* (2000) stated that many records of fisher locations come from roadkills; for example, Yosemite National Park reported four fishers killed by automobiles between 1992 and 1998. Proulx *et al.* (1994), York (1996), and Zielinski *et al.* (1995, 1997a) all cite the risk of fishers being struck and killed by vehicles as a potential threat to populations. The potential for vehicle collisions increases with the density of open roads in suitable habitat. Vehicles caused the death of two of the 50 radio-collared fishers in a 5-year Maine study (Krohn *et al.* 1994), and three of 97 fishers in a 3-year study in Massachusetts (York 1996). Vehicle collisions could be a significant mortality factor, especially for small fisher populations. Off-highway and over-snow vehicles are used throughout the range of the fisher, and can also directly kill fishers or cause behavioral changes due to disturbance.

Vehicle traffic during the breeding season in suitable habitat may impact foraging and breeding activity. Dark (1997) found that fishers more often used areas with a greater than average density of low use roads, and may not have used areas that were dissected by moderate to high use roads. Campbell (2004) found that sample units within the central and southern Sierra Nevada region occupied by fishers were negatively associated with road density. This relationship was significant at multiple spatial scales (from 494 to 7,413 ac (2 to 30 $km^2$). In a stand-scale level study, Robitaille and Aubry (2000) found that martens, close relatives of fishers, were less active near roads. Paved roads are expected to cause more mortality than unpaved roads because of the higher use and speeds associated.

The access to forest areas provided by roads leads to increased human disturbances from resource use and extractive activities. These disturbances result in an overall degradation of habitat. Because fishers occur at relatively low elevations, they are likely to be directly affected by human activities (Campbell *et al.* 2000). Roads also provide access for trappers who target other species, but might incidentally trap fishers (Lewis and Zielinski 1996).

In conclusion, habitat loss and fragmentation appear to be significant threats to the fisher. Forested habitat in the Pacific coast region decreased by about 8.5 million ac (34,400 $km^2$) between 1953 and 1997 (Smith *et al.* 2001). Forest cover in the Pacific coast is projected to continue to decrease through 2050, with timberland area projected to be about 6 percent smaller in 2050 than in 1997 (Alig *et al.* 2003). Thus fisher habitat is projected to decline in Washington, Oregon, and California in the foreseeable future.

*Factor B. Overutilization for commercial, recreational, scientific, or educational purposes.* The fisher has been commercially trapped since the early-1800s. Although exact numbers are unknown, trapping caused a severe decline in fisher populations. Aubry and Lewis (2003) state that overtrapping appears to have been the primary initial cause of fisher population losses in southwestern Oregon. The high value of the skins, the ease of trapping fishers (Powell 1993), year-round accessibility in the low to mid-elevation coniferous forests, and the lack of trapping regulations resulted in heavy trapping pressure on fishers in the late 1800s and early 1900s (Aubry and Lewis 2003).

In 1936, the Chief of the U.S. Biological Survey urged closing the hunting/trapping season for 5 years to save fisher and other furbearers from joining the list of extinct wild animals, noting that these species had disappeared from much of their former range in Oregon, Washington, and other states (USDA 1936). Commercial trapping of fishers has been prohibited in Oregon since 1937, in California since 1946 (Aubry and Lewis 2003), and in Washington since 1933 (Lewis and Stinson 1998). Where trapping is legal in other states and in Canada, it is a significant source of mortality. Krohn *et al.* (1994), for example, found that over a 5-year period, trapping was responsible for 94 percent of all mortality for a population of the fisher in Maine. In British Columbia, the fisher is classified as a furbearing mammal that may be legally harvested; however, due to a recent change in conservation status, the trapping season has been closed until it can be determined that the populations can withstand trapping pressure.

Although it is currently not legal to trap fishers intentionally in California, Oregon and Washington, they are often incidentally captured in traps set for other species (Earle 1978; Luque 1983; Lewis and Zielinski 1996). It is legal to harvest many mammals that are found in fisher habitat, including bobcat (*Lynx rufus*), gray fox (*Urocyon cinereoargenteus*), coyote (*Canis latrans*), mink (*Mustela vison*) and other furbearers. Red fox (*Vulpes vulpes*) and marten (*Martes americana*) may also be trapped in Oregon and Washington. Incidental captures often result in crippling injury or mortality (Luque 1983; Strickland and Douglas 1984; Cole and Proulx 1994). Lewis and Zielinski (1996) estimated an incidental capture of 1 per 407 trap set-nights (number of set locations—where usually 1 or 2 leg-hold traps were set—multiplied by the number of nights when traps were set) and an average mortality-injury rate of 24 percent, based on reports from five practicing trappers in California (72 incidental fisher captures over 50,908 set-nights).

Even low rates of additive mortality from trapping have been predicted to affect fisher population stability (Powell 1979, Lewis and Stinson 1998), and may slow or negate population responses to habitat improvement (Powell and Zielinski 1994). Powell (1979) reported that as few as one to four additional mortalities per year due to trapping over a 100 $km^2$ (39 $mi^2$) area could cause a significant decline in a reduced fisher population. The potential effects on fishers of legal trapping of other species may be significant when considered in conjunction with habitat loss and other sources of mortality.

In summary, information available suggests that historical trapping caused a severe population decline, and current mortalities and injuries from incidental captures of fishers could be frequent and widespread enough to prevent local recovery of populations, or prevent the re-occupation of suitable habitat.

*Factor C. Disease or Predation.* Fishers are susceptible to many viral-borne diseases, including rabies (Family *Rhabdoviridae*), canine and feline distemper (*Mobillivirus* sp.), and plague (*Yersinia pestis*). Contact between fishers and domesticated dogs and cats and other wild animals susceptible to such diseases (raccoons, coyotes, martens, bobcats, chipmunks, squirrels, *etc.*) may lead to infection in fishers. Although specific information on fisher diseases is limited, populations of three other mustelids, the black-footed ferret (*Mustela nigripes*), the marten, and the sea otter (*Enhydra lutris*), have experienced outbreaks of various parasitic, fungal, or bacterial diseases. An epidemic of canine distemper in black-footed ferret in 1985 led to the extirpation of the species from the wild (Thorne and Williams 1988). Evidence of plague was found in martens in California through detection of plague antibodies and host fleas (Zielinski 1984). In a study on sea otter, it was determined that infectious disease caused the deaths of 38.5 percent of the sea otters examined at the National Wildlife Health Center collected in California from 1992–1995 (Thomas and Cole 1996).

Studies in the urban-wildland interface suggest a correlation between the prevalence of disease in wild populations and contact with domestic animals, however fisher populations do not currently appear to be at risk.

Mortality from predation could be a significant threat to fishers. Potential predators include mountain lions (*Puma concolor*), bobcats, coyotes, and large raptors (Powell 1993; Powell and Zielinski 1994; Truex *et al.* 1998). Although generalist predators such as bobcats and mountain lions are not common in dense forest environments, they can invade disturbed habitat. Healthy adult fishers are apparently not usually subject to predation, except for those that have been translocated (Powell and Zielinski 1994) to an unfamiliar area, or those in areas with less canopy cover and forest structure (Buck *et al.* 1994). However, Powell and Zielinski (1994) and Truex *et al.* (1998), report that predation as well as human-caused death are significant sources of mortality. Of mortalities recorded by Truex *et al.* (1998), nine were suspected to be from predation and five were suspected to be human-caused, including two vehicle collisions, two cases where the collar was cut (indicating poaching), and one fisher that died after being trapped in a water tank. Four fishers out of seven that died during a study by Buck *et al.* (1994) were killed by other carnivores; the death of one juvenile was suspected to have been caused by another fisher.

In conclusion, mortality from disease and predation does not appear to be a significant threat unless populations are extremely small as is the case of the West Coast population of the fisher. Diseases in other mustelids affect this species and there is the potential for such disease outbreaks to occur in fisher populations.

*Factor D. The Inadequacy of Existing Regulatory Mechanisms.* Existing regulatory mechanisms that could provide some protection for the fisher include: (1) Federal laws and regulations; (2) State laws and regulations; and (3) local land use processes and ordinances. However, these regulatory mechanisms have not prevented continued habitat fragmentation and modification, incidental trapping, and predator control programs all of which result in population declines of fisher in the west. Although many States, Tribes, and Federal agencies recognize the fisher as a species which has declined substantially, their use of available regulatory mechanisms to conserve the species is limited. There are no regulatory mechanisms that specifically address the management or conservation of functional fisher habitat. However, the states in the petitioned area provide the fisher with protections from hunting and trapping, and regulatory mechanisms governing timber harvests incidentally provide conservation benefits for the fisher. The fisher is regulated under the Convention on International Trade in Endangered Species of Wild Fauna and Flora (CITES), a treaty established to prevent international trade that may be detrimental to the survival of wild plants and animals.

*Federal Regulations*

National Forests

Federal activities on National Forest lands are subject to compliance with Federal environmental laws including the Multiple-Use Sustained-Yield Act of 1960 (16 U.S.C. 528 *et seq.*), National Environmental Policy Act of 1969 (42 U.S.C. 4321 *et seq.*), and Clean Water Act of 1972 as amended (33 U.S.C. 1251 *et seq.* 1323 *et seq.*), as well as the National Forest Management Act of 1976 (90 Stat. 2949 *et seq.*; 16 U.S.C. 1601–1614) (NFMA).

The 1982 NFMA planning rules currently in effect require the Forest Service to “maintain viable populations of existing native and desired non-native vertebrates in the planning area [National Forests System lands]’’ (30 CFR 219.19). The 2000 planning rule shifted the emphasis from maintaining viable populations of individual vertebrate species to providing ecological conditions that provide a high likelihood of supporting the viability of native and desired non-native species well distributed throughout their ranges within the plan area (§ 219.20). The viable population mandate, with associated monitoring requirements, could serve as the basis for forest management consistent with maintaining fishers. The viability requirement was integral in guiding the protection and management of late successional forest through the NWFP process, and through the SNFPA amendment process; the regulatory contributions of both plans to fisher conservation is discussed below.

The Forest Service’s Sensitive Species Policy (Forest Service Manual 2670.32) calls National Forests to assist and coordinate with states, the Service, and NOAA Fisheries in conserving species with viability concerns. The fisher has been identified as a sensitive species by the Region 5 (Pacific Southwest Region) Regional Forester. The Forest Service defines Sensitive Species as “those plant and animal species identified by a Regional Forester for which population viability is a concern as evidenced by significant current or predicted downward trend in numbers or density.’’

On December 6, 2002, the Forest Service published a proposed rule to revise the 2000 NFMA planning rule. It is uncertain how the proposed rule, if and when implemented, will affect the interpretation of viability and the implementation of management for species viability.

National Environmental Policy Act

The National Environmental Policy Act of 1969, as amended (NEPA), requires all Federal agencies to formally document, consider, and publicly disclose the environmental impacts of major federal actions and management decisions significantly affecting the human environment. The resulting documents are primarily disclosure documents, and NEPA does not require or guide mitigation for impacts.

Projects that are covered by certain “categorical exclusions’’ are exempt from NEPA biological evaluation. The Forest Service and the Department of Interior have recently revised their internal implementing procedures describing categorical exclusions under NEPA 68 FR 33813 (June 5, 2003). The joint notice of NEPA implementing procedures adds two categories of actions to the agency lists of categorical exclusions: (1) Hazardous fuels reduction activities; and (2) rehabilitation activities for lands and infrastructure impacted by fires or fire suppression. These exclusions apply only to activities meeting certain criteria: mechanical hazardous fuels reduction projects up to 1,000 ac (4 $km^2$) in size can be exempt, and hazardous fuels reduction projects using fire can be exempt if less than 4,500 ac (18.2 $km^2$). See 68 FR 33814 for other applicable criteria. Exempt post-fire rehabilitation activities may affect up to 4,200 ac (17 km²). As stated above under Factor A, fuels reduction activities can reduce key fisher habitat elements such as large down logs and woody debris, large snags, but have counter-balancing benefits of reducing fire probability and brushy undergrowth which is not favored by fishers.

On July 29, 2003, the Forest Service published a notice of final interim directive (68 FR 44597) that adds three categories of small timber harvesting actions to the Forest Service's list of NEPA categorical exclusions: (1) The harvest of up to 70 ac (28 ha) of live trees with no more than 0.5 mi (.8 km) of temporary road construction; (2) the salvage of dead and/or dying trees not to exceed 250 ac (101 ha) with no more than 0.5 mi (.8 km) of temporary road construction; and (3) felling and removal of any trees necessary to control the spread of insects and disease on not more than 250 ac (101 ha) with no more than 0.5 mi (.8 km) of temporary road construction. Again, as stated above under Factor A, timber harvest and road construction can reduce key habitat elements for the fisher such as dense canopy cover and large trees, and results in at least temporary habitat fragmentation, but have corresponding long-term benefits.

Northwest Forest Plan

The NWFP was adopted in 1994 to guide the management of 24 million ac (97,125 km²) of Federal lands in portions of western Washington, Oregon, and northwestern California. The NWFP represents a 100-year strategy intended to provide the basis for conservation of the northern spotted owl (spotted owl) and other late-successional and old-growth forest-associated species on Federal lands (USDA *et al.* 1993).

Implementation of the NWFP (November 2003) would over time provide a network of connected reserves of late successional forest habitat surrounded by younger forest. Implementation of the plan will lead to a substantial improvement in current habitat conditions for the fisher on Federal lands. However, the assessment of NWFP implementation on the fisher projected a 63 percent likelihood of achieving an outcome in which habitat is of sufficient quality, distribution, and abundance to allow the fisher population to stabilize and be well distributed across Federal lands. We will need to reassess this prediction as the NWFP is implemented and other fisher conservation efforts (*e.g.*, reintroductions) are initiated.

Sierra Nevada Forest Plan Amendment (SNFPA)

The SNFPA was adopted in January 2001 as a guidance and policy document for managing 11 national forests and about 11 million ac (44,516 km²) of California's National Forest lands in the Sierra Nevada and Modoc Plateau. The SNFPA includes measures expected to lead to an increase over time of late-successional forest; these measures include requirements to retain conifers greater than 30 in (76.2 cm) DBH and hardwoods greater than 12 in (30.5 cm) DBH in westside forests, retention of important wildlife structures such as large diameter snags and coarse downed wood, and management of about 40 percent of the plan area as old forest emphasis areas (USDA Forest Service 2001). The SNFPA also established a Southern Sierra Fisher Conservation Area with additional requirements intended to maintain and expand the fisher population of the southern Sierra Nevada. Conservation measures for the fisher conservation area include maintaining at least 60 percent of each watershed in mid-to-late successional forest (11 to 24 in (28 to 61 cm) dbh and greater) with forest canopy closure of 50 percent or more. The plan also includes protections for den sites; as discussed elsewhere in this document, this tends to provide limited conservation value. Implementation of the 2001 plan was expected to maintain and restore fisher habitat in Southern Sierra Fisher Conservation Area, and encourage recovery to its historic range (USDA Forest Service 2001).

In response to appeals to the adoption of the SNFPA, the Regional Forester assembled a review team to evaluate specific plan elements, including the fuels treatment strategy, consistency with the National Fire Plan, and agreement with the Herger-Feinstein Quincy Library Group Recovery Act. The review was completed in March 2003 (USDA Forest Service 2003b), and in June 2003, the Forest Service issued a Draft Supplemental Environmental Impact Statement (DSEIS) for proposed changes to the SNFPA (USDA Forest Service 2003a). The Final Supplemental Environmental Impact Statement (FSEIS) was issued in January 2004, and the new Record of Decision was issued on January 21, 2004 (USDA Forest Service 2004).

The preferred alternative in the FSEIS, Alternative S2, was chosen in the final Record of Decision. This alternative includes an objective to retain 30 in (76.2 cm) and larger trees (with exceptions allowed to meet needs for equipment operability) and a desired condition for the Southern Sierra Conservation Area which states that outside of any Wildland Urban Interface areas, a minimum of 50 percent of the forested area has at least 60 percent canopy cover for known or estimated female fisher home ranges (USDA Forest Service 2004, Record of Decision p. 41). Furthermore, it directs that where home range information is lacking, the watershed mapped at the Hydrologic Unit Code 6 level be used as the analysis area for this desired condition. The Record of Decision also states that if fishers are detected outside of the Southern Fisher Conservation Area, habitat conditions should be evaluated and appropriate mitigation measures implemented to retain suitable habitat within the estimated home range.

The FSEIS preferred alternative includes standards and guidelines which apply to fishers and provide protections for verified fisher den sites, including a 700 ac (2.8 km²) buffer around confirmed fisher birthing and rearing dens during March 1 through June 30. However, the guidelines would provide little protection to fishers or their habitat, because: (1) Den sites are difficult to detect even in studies using radio-collared fishers (fewer than 10 den sites have been found to date) and project-level surveys are unlikely to locate dens (USDA Forest Service 2000); (2) there is little evidence that den sites are reused over time (Campbell *et al.* 2000), limiting the value of protecting past den sites; (3) some restrictions can be waived, including the limited operating period for vegetation treatments; and (4) it is unclear how and to what extent the impacts of roads, off highway vehicles, and recreation would be minimized.

National Forest Land and Resource Management Plans

Each National Forest is operated under a Land and Resource Management Plan (LRMP). The NWFP standards and guidelines apply for National Forests within the range of the northern spotted owl except when the standards and guidelines of LRMPs are more restrictive or provide greater benefits to late-successional forest species. Most National Forests within the range of the fisher in its west coast range have LRMPs that incorporate the provisions of the NWFP or are amended by the SNFPA, and therefore implement the standards and guidelines of the applicable plan. Most individual Forest LRMPs do not provide any additional protections to fisher or fisher habitat; therefore, the above discussion regarding the NWFP and SNFPA summarizes the primary regulatory mechanisms in place on National Forest lands within the DPS area.

In California, the Humboldt-Toiyabe, Modoc, Lassen, Plumas, Tahoe, Eldorado, Stanislaus, Sierra, Inyo, and Sequoia National Forests and the Lake Tahoe Basin Management Unit are within the area covered by the SNFPA.

In Oregon, National Forests located on the west side of the Cascade Mountains (Mt. Hood, Willamette, Umpqua, Rogue, Siuslaw, Siskiyou National Forests) are within the boundaries of the NWFP.

Forests on the east side of the Cascade Mountains (Winema, Deschutes, Fremont National Forests) only partially overlap the NWFP area. Outside of the NWFP boundaries, the Inland Native Fish Strategy (INFISH) and Interim Management Direction Establishing Riparian, Ecosystem, and Wildlife Standards for Timber Sales (Eastside Screens) amend the LRMPs for the eastern portion of the Winema National Forest and all of the Fremont National Forest. The guidelines, developed to protect fish habitat, may also provide benefits to fisher by protecting riparian corridors; establishing large woody debris requirements (greater than 20 pieces per mi (12.4 pieces per km); greater than 12 in (30.5 cm) diameter; greater than 35 ft (10.7 m) long); and delineating Riparian Habitat Conservation Areas (RHCAs), which would prohibit timber harvests within them in most situations. Minimum widths for RHCAs range from a minimum of 300 ft (91 m) slope distance on either side of fish-bearing streams to 150 ft (46 m) on either side of perennial non-fish-bearing streams and around most lakes, ponds, reservoirs and wetlands. Seasonally flowing or intermittent streams, wetlands less than an acre, landslides, and landslide-prone areas would have protections ranging from about 50 to 100 ft (15 m to 30 m) or one site-potential tree height, depending on watershed priority.

The Eastside Screens provide interim direction for timber harvest associated with forest health and prohibit the harvest of large diameter trees (21 in (53 cm) DBH or larger) and protect snags and large woody debris for wildlife. Both INFISH and the Eastside Screens were expected to be short-term strategies to be replaced once LRMPs are amended by other guidance, such as the Interior Columbia Basin Ecosystem Management Project (ICBEMP).

At this time, a decision notice for ICBEMP has not been issued, although a Memorandum of Understanding (MOU) has been signed which implements the associated Interior Columbia Basin Strategy (Strategy). The purpose of the MOU is to cooperatively implement the Interior Columbia Basin Strategy guiding the amendment and revision of Forest Service National Forest and BLM LRMPs and project implementation on public lands. The plans and MOU currently being implemented could maintain or enhance fisher habitat by preventing the loss of old-growth forests and promoting long-term sustainability of old forest habitat, although short-term adverse impacts may occur as a result of activities including thinning and silvicultural treatments. Maintaining wildlife movement corridors primarily associated with deer and elk are usually included as part of project designs and may also benefit fishers.

Potential fisher habitat in Washington State is located on the Olympic, Mount Baker-Snoqualmie, Gifford Pinchot, Wenatchee, and Okanogan National Forests. There are approximately 1,479,749 ac (5,987 $km^2$) of fisher habitat on Federal lands in Washington State, of which 1,108,994 ac (4,489 $km^2$; 75 percent) are in National Forests and the remainder is in National Parks.

Most of the potential fisher habitat in Washington State is within the range of the northern spotted owl and thus also within the NWFP Area. Over 80 percent of the habitat is in areas that are designated as reserves (Congressionally withdrawn, LSRs, or natural areas). Logging within these areas is restricted and limited to thinning or individual tree removal. The WDFW recently conducted a feasibility analysis to determine areas for potential reintroduction of the fisher. Based on this analysis, the largest blocks of suitable habitat are located in the Olympic NF, areas around the Goat Rocks and Indian Heaven Wilderness on the Gifford Pinchot NF, portions of the Wenatchee NF east of Mount Rainier National Park, and the foothills to the west of the Alpine Lakes and Glacier Peak Wilderness Areas on the Mount Baker-Snoqualmie NF. Approximately 81 percent of the Olympic, 75 percent of the Gifford Pinchot, 63 percent of the Mount Baker-Snoqualmie, 40 percent of the Wenatchee, and 22 percent of the Okanogan National Forests are below 4000 ft (1,220 m) in elevation. Although most of the remaining fisher habitat will be protected as long as the NWFP remains in effect, the landscape remains fragmented.

Bureau of Land Management (BLM) Lands

The NWFP standards and guidelines apply to BLM lands within the range of the northern spotted owl except when the standards and guidelines of Resource Management Plans (RMPs) are more restrictive or provide greater benefits to late-successional forest species. The BLM's Alturas District in northern California is currently in the process of rewriting its RMP. However, the District has very little land with potential fisher habitat. Neither fishers nor their potential habitat are mentioned in the RMP, and the RMP is not affected by the SNFPA or NWFP. The RMPs for the Arcata, Redding, and Ukiah Field Offices also do not contain any protective measures for fisher or require pre-project surveys. In Oregon, BLM Resource Management Plans were amended by the NWFP in the west Cascades, and by INFISH and Eastside Screen interim guidance in the east Cascades. Therefore, management would be similar to that described above for the National Forests. The BLM and U.S. Timberlands (private landowner) are working together, where their land ownerships are checkerboarded, to reduce wildlife impacts by restricting access and closing roads. BLM lands are limited in Washington state and do not contribute to fisher habitat.

National Park Lands

The land management plan for Redwood National Park does not contain any protective measures for fishers and does not require pre-project surveys. Undeveloped areas of Crater Lake National Park are managed toward natural processes and are expected to maintain fisher habitat. Hunting and trapping are not allowed in the park, and park facilities are currently confined to certain areas, primarily in the higher elevations above fisher habitat. Studies are planned to evaluate snowmobile use in the park.

The Columbia River Gorge National Scenic Area in Oregon (and Washington) encompasses about 292,500 ac (1,184 $km^2$) and is operated under a land use management plan that provides protection to all lands in the gorge. About half of the land in the Gorge is state or federally owned and has special management area guidelines dedicated to scenic and natural values. The remainder of the Gorge is private lands managed under general guidelines that are currently being revised. The fisher is a protected species within the area covered by the Columbia River Gorge management plan. On Federal lands, the restriction against removal of old-growth forests and clearcut logging would protect fisher habitat. After the Gorge forest practices guidelines are revised it is expected that habitat conditions will be retained for fisher because of the priority concept of retaining old growth, scenic, and natural values in the Gorge.

Fisher habitat occurs in the Olympic, North Cascades and Mount Rainier National Parks. However, the interiors of all three parks are classified as alpine and are too steep and rugged to be suitable for fishers. Approximately 33 percent of the 1 million ac (4,047 $km^2$) Olympic National Park, 30 percent of the North Cascades NP and Ross Lake National Recreation Area (just over 500,000 ac (2,023 $km^2$), combined), and less than 15 percent of Mount Rainier National Park (235,500 ac; 953 $km^2$) is typed as fisher habitat. The largest blocks of habitat occur in a ring around the mountainous interior of the Olympic Peninsula, in areas to the south and east of Mount Rainier National Park, in the Ross Lake National Recreation Area, and in river valleys on the west side of the North Cascades National Park.

Because the interior of the Cascades and Olympic Peninsula are alpine, fisher habitat is limited to a relatively narrow band along the foothills. In addition, most of the low elevation passes are bisected by major transportation corridors. Efforts are currently under way to provide wildlife corridors (under or overpasses) along Interstate 90 to facilitate north-south movement of wildlife through the Washington Cascades.

National Resource Conservation Service (NRCS)

The NRCS does not manage lands, and has not been involved with forest related work, but plans to develop forest-related projects in the near future. Initial projects will likely be east of the NWFP boundary, along the Sprague River in Oregon and elsewhere. Focus would be on thinning projects to enhance wildlife habitat and could enhance potential fisher habitat where it exists. The NRCS would be subject to NEPA and other existing regulatory mechanisms discussed elsewhere.

Tribal

In California, the Hoopa Valley Indian Reservation forest management plan (Tribal Forestry 1994) addresses the 88,958 ac (360 $km^2$) where fishers are known to be present, and which contains about 75,000 ac (303.5 $km^2$) of commercial timberland. The forest management plan also recognizes the fisher as a traditional and culturally important species and designates the fisher as a species of special concern, and forest management activities are not allowed to knowingly result in "take'' of species of concern unless approved by the Tribal Council. The plan contains some protective measures for fisher such as setting aside three to seven habitat reserves (each 50 ac (20 ha) or less in size) for pileated woodpeckers, mink, and fishers. Intensive timber harvest will not occur within the reserves. The plan establishes 32 no-harvest reserves (minimum of 60 ac (24 ha) each) for late-seral, cultural, sensitive, and listed species.

The Yurok Tribe manages roughly 4,000 ac (16 $km^2$) of collective Tribal land holdings, held in trust by the Department of the Interior. Tribal lands include about 1,000 ac (4 $km^2$) of late-seral redwood forest. The land management plan for the Yurok Tribe does not contain specific protective measures for fishers and does not require pre-project surveys. It is unclear to what extent this plan will help to maintain appropriate habitat elements for the fisher.

The Tule River Reservation in the southern Sierra Nevada includes about 56,000 ac (227 $km^2$) of lands, which includes forest lands managed for timber and firewood. Information is not available regarding regulatory mechanisms for these Tribal lands.

The Warm Springs Reservation of Oregon encompasses almost 1,000 $mi^2$ (2,590 $km^2$) on the western slope of the Cascade Range. The Integrated Resource Management Plan (IRMP) for forested areas of the Warm Springs Reservation of the Confederated Tribes includes guidelines that ensure buffers of 30 to 100 ft (9 to 30 m) (depending on the size of the feature) for riparian features such streams, wetlands, seeps, springs, or bogs. Standards to protect wildlife habitats and species include protection of at least four overstory trees per acre, retaining a minimum of ten class 1–3 logs per ac (12 in (30 cm)) diameter and 20 ft (6 m) long), and a 60:40 forage to cover ratio in wildlife management zones. The IRMP identifies conditional use areas that are not part of the commercial forest base although these areas could be harvested at some point in the future. These areas typically have cultural value and comprise about five percent of the Reservation. There are 14 spotted owl activity centers on the reservation.

For the Klamath Tribes in Oregon, the only activity identified that may impact the fisher is bobcat trapping. According to Rick Ward (Klamath Tribe biologist), trapping activity is currently very low due to presently low pelt prices. However, as reported in the Klamath News, an official publication of the Klamath Tribe (2003), there is a current effort to return approximately 690,000 ac (2,792 $km^2$) of the former reservation from the Fremont-Winema National Forest to the Klamath Tribes. This includes areas where fisher have been documented. If the land ownership changes, that would likely alter management of fisher habitat.

The Coquille Tribe of Oregon manages their land according to the guidelines of the NWFP. The Coquille lands were formerly managed by the BLM. When the lands were transferred from the BLM to the Tribe, the Tribe agreed to manage their lands according to the guidelines in the NWFP and the Coos Bay BLM Resource Management Plan. Their land holdings in southwest Oregon are all in NWFP "matrix'' designation (*i.e.*, areas contemplated for timber harvest) which does not provide any benefits to fisher conservation.

There are 19 Tribes with forest lands within the range of the fisher in Washington State. The majority of those Tribes do not have any suitable fisher habitat or do not have sufficient acreage. The Tribal lands of the Makah, Quinault, and Yakama Indian Nations may have suitable fisher habitat, but only the Quinault and Yakama Tribes have management plans that protect enough habitat for the northern spotted owl (a late-successional associate) that the plans likely incidentally also provide habitat for fishers.

The Confederated Tribes and Bands of the Yakama Nation reservation is located in south central Washington State, east of the Cascade crest, and contains about 526,000 ac (2,129 $km^2$) of forests. In 1998, 144,559 ac (585 $km^2$) of reservation forest were typed as suitable habitat for spotted owls (Yakama Nation 2003). Of these, about 43 percent (62,266 ac; 252 $km^2$) are currently not managed for commercial timber production, while the remaining 57 percent will receive some level of stand management. Timber harvest is generally conducted using uneven-aged management prescriptions (King *et al.* 1997), in which up to 30 percent of the volume may be removed during an entry. Based on the Tribe's forest management practices and the distribution of spotted owl habitat, Yakama lands may widely provide suitable foraging habitat for fishers, and sufficient habitat elements including snags and downed logs to provide some denning/resting habitat, particularly in the areas reserved from harvest. Owl habitat may be a rough surrogate for fisher habitat, since both require late successional forests.

The North Boundary Area of the Quinault Tribe Reservation is contiguous with Forest Service Late Successional Reserves to the north and southeast, and National Park Service lands to the east, and is the only area on the reservation that has potential habitat for the fisher. Negotiations are currently under way with the Tribe to protect habitat around occupied owl and murrelet sites, which may incidentally protect potential fisher habitat.

*State*

Washington

The Washington Department of Natural Resources (WDNR) manages the State lands in Washington. State lands occupy a substantial portion of the fisher's historic range in the State, consisting of roughly 1.6 million ac (6,475 km$^2$) of forest within the range of the northern spotted owl (primarily lands west of the crest of the Cascade Mountains). Because these lands generally occur at lower elevations than National Forest lands, a higher proportion is within the elevation range preferred by the fisher (Aubry and Houston 1992; WDNR 1997). Thus, State lands are important to the conservation of the fisher. However, over half of all WDNR forests are less than 60 years in age and less than 150,000 ac (607 km$^2$, about 9 percent) are over 150 years, indicating that most old growth on Washington State lands has been liquidated (WDNR 1997).

Several State Parks in Washington contain remnant stands of mature and late-successional forest and may have suitable habitat for the fisher. Like elsewhere, these parks are widely scattered and isolated by large areas that are unsuitable for fishers. There are approximately 18,858 ac (76 km$^2$) of mature or old-growth forests within State Parks in Washington. Unfortunately, many of the larger parks are on islands and would not contribute to the recovery of the fisher. A few state parks and forests, such as Mount Pilchuck State Forest, and Rockport, Ollalie, Hamilton Mountain/Beacon Rock, Twin Falls, and Wallace Falls State Parks have limited habitat which may provide some foraging opportunities for dispersing fishers and extend the habitat on Federal lands in the Cascades. Trapping of fishers has been prohibited in Washington since 1933, but fishers have been caught incidentally in traps set for other species, and the impact of incidental captures in Washington is unknown (Lewis and Stinson 1998).

In October 1998, the State of Washington listed the fisher as Endangered (WAC 232–12–297), which provides additional protections in the form of more stringent fines for poaching and a process for environmental analysis of projects affecting the species. There are no special regulations to protect habitat for the fisher or to conduct surveys for this species prior to obtaining forest activity permits. Although a few individuals may still reside in remote areas, the species is believed to be extirpated from Washington and the State is currently in the process of completing a feasibility report to determine suitable areas for reintroduction.

About 7 million ac (28,330 km$^2$) of non-Federal forest lands exist within the possible range of the fisher in the Olympic Peninsula and Cascades in Washington. A geographic information system (GIS) analysis of general habitat suitability typed about 2 percent (approximately 152,300 ac (616 km$^2$)) as suitable habitat for fisher. This analysis included mature/old-growth, northern spotted owl habitat, and habitat meeting other criteria as suitable fisher habitat. Because the remnant patches of mature forest are widely scattered and isolated, it is unlikely that there is sufficient habitat on non-Federal lands to support resident fishers. However, if proposed fisher reintroduction efforts occur and are successful, private lands may be important to maintain habitat in key linkage areas across the Puget Trough lowlands to provide connectivity between the Olympic Peninsula and the Cascades.

The primary regulatory mechanism on non-Federal forest lands in western Washington is the Washington State Forest Practice Rules, Title 222 of the Washington Administrative Code. These rules apply to all commercial timber growing, harvesting, or processing activities on non-Federal lands, and give direction on how to implement the Forest Practice Act (Title 76.09 Revised Code of Washington), and Stewardship of Non-Industrial Forests and Woodlands (Title 76.13 RCW). The rules are administered by the WDNR, and related habitat assessments and surveys are coordinated with the Washington Department of Fish and Wildlife (WDFW).

Washington's forest practice rules are more protective of riparian and aquatic habitats, and require more trees to be left than Oregon's forest practice rules. Clearcuts are limited to 120 ac (49 ha) in size with exceptions given up to 240 ac (97 ha). In all cutting units, three wildlife reserve trees (over 12 in (30)) in diameter), two green recruitment trees (over 10 in (25 cm) diameter, 30 ft (9 m) in height, and ⅓ of height in live crown) and two logs (small end diameter over 12 in (30 cm), over 20 ft (6 m) in length) must be retained per acre of harvest. These trees may be counted from those left in the "riparian management zones,'' which range in size from 80 to 200 ft (25 to 62 m) for fish-bearing streams, depending on the size of the stream, the class of site characteristics, and whether the harvest activity is east or west of the Cascade crest (Washington Administrative Code 222–30). Riparian management zones for non fish-bearing streams are 50 ft (15 m), applied to specified areas along the streams. Seventy acres (28 ha) of habitat must be protected around all known spotted owl activity centers during the nesting season, outside of which logging can occur. Washington's forest practices rules do not specifically preserve key components of fisher habitat.

Riparian buffers may provide some habitat for fishers, primarily along perennial fish-bearing streams where the riparian buffer requirements are widest. In western Washington—the majority of the State area addressed by the petition, the Forest Practice Rules require 90 to 200 ft (27 to 61 m) buffers on fish-bearing streams, depending on site class (site potential for tree growth). The riparian buffer of fish-bearing streams is divided into three zones, including a 50-ft (15-m) "core zone'' where no timber cutting is permitted. The remainder of the buffer is divided into an "inner zone'' where partial harvest is permitted consistent with achieving stand basal area requirements, and an outer zone where logging must generally leave at least 20 conifers per acre, of 12 inches DBH or greater. For parcels of 20 contiguous acres or less, landowners with total parcel ownership of less than 80 forested acres are exempt from the riparian buffer requirements described above; less stringent rules apply to those parcels.

While it has been noted that the Washington State Forest Practice Rules do not specifically address the fisher and its habitat requirements, some habitat components important to the fisher, like snags, canopy cover, *etc.*, are likely to be retained as a result of the rules.

Oregon

In Oregon, two final forest management plans for state forests in northwest and southwest Oregon were approved by the Oregon Board of Forestry in January 2001: the Northwest Oregon State Forests Plan and the Southwest Oregon State Forests Plan. The Elliott State Forest Management Plan was approved in 1994 and the Elliott State Forest Habitat Conservation Plan for northern spotted owls and marbled murrelets was approved in 1995, however, both the management plan and HCP are now being revised. Additionally, Oregon has proposed to develop the Western Oregon State

Forests Habitat Conservation Plan for threatened and endangered species and other species of concern on western Oregon state forests in 2004–2005.

The management plans for Oregon's State Forests generally appear to be of little benefit to the fisher. The 18,074 ac (73 $km^2$) of State forest lands in the Southwest Oregon State Forests Plan area consists of generally small parcels that range in size from 40 ac to 3,500 ac (0.16 $km^2$ to 14 $km^2$) and are widely scattered. There are no specific measures for or mention of the fisher in the plan. The Northwest Oregon State Forests Management Plan provides management direction for 615,680 ac (2,491 $km^2$) of state forest land, located in twelve northwest Oregon counties, but has no specific provisions for fishers. Both plans include provisions to protect some forest reserves, but these are not likely to benefit the fisher because of the fragmented nature of the lands. In Oregon, the fisher is designated a protected non-game species, and is listed as a "Sensitive Species—Critical Category.'' The Oregon Department of Fish and Wildlife (ODFW) does not allow take of fisher in Oregon, but some fishers may be injured and killed by traps set for other species. Training and testing is required of applicants for trapping licenses in order to minimize the potential take of non-target species such as fisher.

The Oregon Department of Forestry (ODF) implements the Forest Practice Administrative Rules and Forest Practices Act (ODF 2000). Interim procedures (section 629–605–0180, Oregon Forest Practice Rules) exist for protecting sensitive resource sites on all State, county, and private lands in Oregon. These procedures apply only to threatened and endangered species, and to bird species listed as "sensitive'' in the rules, and currently do not apply to the fisher. Prior approval from the State Forester is also required before operating near or within critical wildlife habitat sites (629–605–0190), including habitat of species classified by ODFW as threatened or endangered, or any federally listed species, but fisher does not currently benefit from this status.

Although Oregon's rules governing forest management on State, county and private lands do not directly protect the fisher or its habitat, the rules may provide some fisher habitat elements. In clearcut harvest units that exceed 25 ac (10 ha), operations must retain two snags or two green trees, and two downed logs per acre. Green trees must be over 11 in (28 cm) DBH and 30 ft (9m) in height, and down logs must be over 6 feet long and 10 cubic feet in volume. Riparian management areas (RMAs) provide for vegetation retention along fish-bearing (Type F) and domestic-use streams without fish (Type D), in a band of 20 to 100 ft (6 to 30 m) width, depending on stream size and type. In general, RMAs for fish-bearing and domestic-use streams require no tree harvesting within 20 ft (6 m) of the stream, and, within the entire RMA, retention of a minimum basal area of conifer trees (40 trees per 1000 ft of stream for thinning operations). Along fish-bearing streams, the RMAs are intended to become similar to mature streamside stands, dominated by conifers; streams lacking fish will have sufficient streamside vegetation to support the functions and processes important to downstream fisheries, domestic water use, and wildlife habitat. Similar guidelines retain vegetation around wetlands, lakes, seeps and springs. No RMA is required for streams that do not provide for domestic water use or bear fish, for small wetlands, or for lakes 0.5 ac (.2 ha) or less.

California

The State of California manages relatively little forested lands. California has eight Demonstration State Forests totaling 71,000 ac (287 $km^2$), of which less than 20,000 ac (81 $km^2$) are within the current range of the fisher. These forests are managed primarily to achieve maximum sustained production of forest products, not for late-successional characteristics, and appear to provide little habitat for the fisher. California has about 270 State Park units and 1.3 million ac (5260 $km^2$), which are mostly outside the historic range of the fisher and appear to provide little habitat for fishers. The largest state park in the fisher's historic range, Humboldt Redwoods State Park, includes about 53,000 ac (214 $km^2$) in southern Humboldt County and has a Preliminary General Plan (June 2001) with a stated goal of protecting California species of concern. Although it does not include specific measures for fisher management, the general emphasis on retention of some habitat components (snags, canopy cover, *etc.*) will provide incidental benefits to the fisher.

The State of California classifies the fisher as a furbearing mammal that is protected from commercial harvest, which provides protection to the fisher in the form of minor fines for illegal trapping; trapping is discussed further under Factor B. The fisher is not listed under the California Endangered Species Act or as a State "fully protected'' species and thus does not receive protections available under those statutory provisions. The California Department of Fish and Game (CDFG) has identified the fisher as a Species of Special Concern (CDFG 1986). This status is applied to animals not listed under the Federal or the State endangered species acts, but judged vulnerable to extinction.

The California Environmental Quality Act (CEQA) requires disclosure of potential environmental impacts of public or private projects carried out or authorized by all non-Federal agencies in California. CEQA guidelines require a finding of significance if the project has the potential to "reduce the number or restrict the range of an endangered, rare or threatened species'' (CEQA Guidelines 15065). The lead agency can either require mitigation for unavoidable significant effects, or decide that overriding considerations make mitigation infeasible (CEQA 21002), although such overrides are rare. CEQA can provide protections for a species that, although not listed as threatened or endangered, meet one of several criteria for rarity (CEQA 15380).

Regulatory Mechanisms for Private and State Timberlands

In California, logging activities on commercial (private and State) forestlands are regulated through a process that is separate from but parallel to CEQA. Under CEQA provisions, the State has established an independent regulatory program to oversee timber management activities on commercial forestlands, under the Z'berg-Nejedly Forest Practice Act of 1973 and the California Forest Practice Rules (FPRs) (CDF 2003). The California FPRs are administered by the California Department of Forestry and Fire Protection (CDF), and apply to commercial harvesting operation for non-Federal, non-Tribal landowners of all sizes.

While the FPRs may incidentally protect some habitat or habitat elements used by the fisher, the rules do not require fisher surveys, protection of fisher or fisher den sites, or a mechanism for identifying individual or cumulative impacts to the fisher or its habitat.

The California FPRs provide specific, enforceable protections for species listed as threatened or endangered under CESA or the ESA, and for species identified by the California Board of Forestry as "sensitive species'' (CDF 2003); however, the fisher is not currently on any of these lists. The FPRs also include intent language about reducing significant impacts to non-listed species (FPR § 919.4, 939.4, 959.4) and maintaining functional wildlife habitat (FPR § 897(b)(1)), however, implementation of these measures to provide protection to the fisher is not documented or tracked.

Some California FPR provisions could incidentally contribute to protection of important elements of fisher habitat, such as late seral forests and snags, downed wood, and large live trees containing the structural attributes that are used by fishers for resting and denning sites and contribute to the diversity and abundance of prey species. These are discussed below.

While the California FPRs generally require that snags within a logged area be retained to provide wildlife habitat, they also allow exceptions to this requirement. The FPRs do not require the retention of downed woody material, decadent or other large trees with structural features such as platforms, cavities, and basal hollows, which appear to be important components of fisher habitat. Some timber operations, such as salvage, fuelwood harvest, powerline right-of-way clearing, and fire hazard reduction are exempt from timber harvest plan preparation and submission requirements. In 2002, new rules were passed that prohibit the harvest of large old trees under exemptions, although harvest is still allowed in cases of safety, building construction, or when the tree is dead or will be dead within the year. Overall retention of habitat features important to fishers does occur to some degree but is specific to fishers.

California's FPRs provide for disclosure of impacts to late successional forest stands, in some cases. The rules require that information about late successional stands be included in a timber harvest plan when late successional stands over 20 ac (8 ha) in size are proposed for harvesting and such harvest will "significantly reduce the amount and distribution of late succession forest stands'' (FPR § 919.16, 939.16, 959.16). If the harvest is found to be "significant,'' FPR § 919.16 requires mitigation of impacts where it is feasible. In practice, such a finding during plan review can be challenged by the landowner.

The California FPRs require retention of trees within riparian buffers to maintain a minimum canopy cover, dependent on stream classification and slope. The rules currently mandate retention of large trees in watersheds identified as having "threatened or impaired'' values (watersheds with listed anadromous fish). For Class I (fish-bearing) streams, the 10 largest conifer trees per 330 ft (133 m) of stream channel must be retained along qualifying watercourses. These trees are retained within the first 50 ft (15 m) of permanent woody vegetation measured out from the stream channel; this provides about 26 trees per acre within that zone. The threatened and impaired provision applies to many streams within the fisher's range in northern California, but not to most of the Sierra Nevada nor to most of the upper Trinity River basin (where fishers still occur), and is set to expire in 3 years. Where applied, the threatened and impaired rules should result in the retention of some large trees of value to fishers, but the value may be limited, as it applies to only a small part of any affected watershed and in a fragmentary pattern. Averaged over the landscape, the measure provides on average less than one retained tree per forested acre in qualifying watersheds, based on an evaluation of a sample of timber harvest plans (Scott Osborn, CDFG, pers. comm. 2003). Over time, the retained trees may develop late seral and decadent characteristics, but this is likely to take place over time scales of decades and centuries.

Outside of "threatened and impaired'' watersheds, watercourse protection measures are limited. Class I streams must retain at least 50 percent of the overstory and 50 percent of the understory. No minimum canopy closure requirements are specified for Class II and Class III streams. Harvest plans are required to leave 50 percent of the existing total canopy including understory, and provide no protection for large trees or other late-seral habitat elements.

Regulations Providing Protections for Other Listed Species

Regulatory protections for habitat of the federally-listed northern spotted owl, marbled murrelet, and anadromous salmonids may provide some elements that benefit the fisher, but because these protections are not implemented consistent with specific life history requirements of the fisher (wide ranging, avoids open areas, *etc.*), these measures may be of limited conservation value for fishers. For example, fishers are likely to require larger habitat blocks in contiguous spacing (Lewis and Stinson 1998). Finally, a large part of the current and historic west coast range of the fisher is outside the range of the listed owl, murrelet and salmonids.

Regulatory Mechanisms for Private and State Timberlands

In California, logging activities on commercial (private and State) forestlands are regulated through a process that is separate from but parallel to CEQA. Under CEQA provisions, the State has established an independent regulatory program to oversee timber management activities on commercial forestlands, under the Z'berg-Nejedly Forest Practice Act of 1973 and the California Forest Practice Rules (FPRs) (CDF 2003). The California FPRs are administered by the California Department of Forestry and Fire Protection (CDF), and apply to commercial harvesting operation for non-Federal, non-Tribal landowners of all sizes.

Based on the best available information on fisher habitat, fishers can use areas of younger (non-old-growth) forest, but the presence of late seral elements within those forests is important in providing resting/denning sites and adding to increased foraging opportunities and prey base.

The California FPRs provide specific, enforceable protections for species listed as threatened or endangered under CESA or the ESA, and for species identified by the California Board of Forestry as "sensitive species'' (CDF 2003); however, the fisher is not currently on any of these lists. The FPRs also include intent language about reducing significant impacts to non-listed species (FPR § 919.4, 939.4, 959.4) and maintaining functional wildlife habitat (FPR § 897(b)(1)). However, this language has not been effective in securing protections for the species, due to the lack of specific enforceable measures in the rules. Moreover, FPR language (§ 1037.5(f)) makes it difficult for CDF to adopt mitigation measures above those specified in the California FPRs, unless the landowner agrees to them. In comments to CDF on timber harvest plans in northwestern California, CDFG has raised concerns regarding adverse effects on fishers and other species associated with the loss of late seral habitat elements and has recommended retention of such elements. These efforts have generally not been successful in effecting mitigation measures for the fisher and other late-seral species (Ken Moore, CDFG, Yreka, pers. comm., 2003; Scott Osborn, CDFG, pers. comm., 2003).

Some California FPR provisions could incidentally contribute to protection of important elements of fisher habitat, such as late seral forests and snags, downed wood, and large live trees containing the structural attributes that are used by fishers for resting and denning sites and contribute to the diversity and abundance of prey species. These are discussed below.

While the California FPRs generally require that all snags within a logged area be retained to provide wildlife habitat, they also allow broad discretionary exceptions to this requirement, which greatly reduce the effectiveness of the snag retention requirement. The FPRs do not require the retention of downed woody material, making retention of these structural elements voluntary. Similarly, the California FPRs do not contain enforceable and/or effective measures for protection of decadent or other large trees with structural features such as platforms, cavities, and basal hollows, which appear to be important components of fisher habitat. Some timber operations, such as salvage, fuelwood harvest, powerline right-of-way clearing, and fire hazard reduction are exempt from timber harvest plan preparation and submission requirements. CDF considers applications for exemptions as ministerial in nature, and therefore exemptions receive minimal review by CDF. In 2002, new rules were passed that prohibit the harvest of large old trees under exemptions, although harvest is still allowed in cases of safety, building construction, or when the tree is dead or will be dead within the year.

California's FPRs provide for disclosure of impacts to late successional forest stands, in some cases. The rules require that information about late successional stands be included in a timber harvest plan when late successional stands over 20 ac (8 ha) in size are proposed for harvesting and such harvest will "significantly reduce the amount and distribution of late succession forest stands'' (FPR § 919.16, 939.16, 959.16). If the harvest is found to be "significant,'' FPR § 919.16 requires mitigation of impacts where it is feasible. In practice, such a finding during plan review is very rare and likely to be challenged by the landowner. Also, few proposed harvests trigger the late successional analysis because very little forest on commercial timberlands meets the definition of late successional forest, due to past logging history (Curt Babcock, CDFG, pers. comm. 2003).

The California FPRs require retention of trees within riparian buffers to maintain a minimum canopy cover, dependent on stream classification and slope. The FPR prescriptions are not designed or intended to protect late seral habitat, but this may occur at times. The rules currently mandate retention of large trees in watersheds identified as having "threatened or impaired'' values (watersheds with listed anadromous fish). For Class I (fish-bearing) streams, the 10 largest conifer trees per 330 ft (133 m) of stream channel must be retained along qualifying watercourses. These trees are retained within the first 50 ft (15 m) of permanent woody vegetation measured out from the stream channel; this provides about 26 trees per acre within that zone. There are no additional protection measures required for non-fish-bearing streams (classes II and III) within "threatened or impaired'' watersheds. The threatened and impaired provision applies to many streams within the fisher's range in northern California, but not to most of the Sierra Nevada nor to most of the upper Trinity River basin (where fishers still occur), and is set to expire in 3 years. Where applied, the threatened and impaired rules should result in the retention of some large trees of value to fishers, although the protective value is limited, as it applies to only a small part of any affected watershed and in a fragmentary pattern. Averaged over the landscape, the measure provides on average less than one retained tree per forested acre in qualifying watersheds, based on an evaluation of a sample of timber harvest plans (Scott Osborn, CDFG, pers. comm. 2003), and on Arcata FWO calculations on watercourse density on commercial timberland ownerships in northwestern California. Also, in many watersheds, few large trees remain along watercourses, thus most of the trees retained under this measure are likely to be of a size and age that provide little current value as late seral elements commonly used by fishers. Over time, the retained trees may develop late seral and decadent characteristics, but this is likely to take place over time scales of decades and centuries.

Outside of "threatened and impaired'' watersheds, watercourse protection measures are limited. Class I streams must retain at least 50 percent of the overstory and 50 percent of the understory. No minimum canopy closure requirements are specified for Class II and Class III streams. Harvest plans are required to leave 50 percent of the existing total canopy including understory, and provide no protection for large trees or other late-seral habitat elements.

*Habitat Conservation Plans (HCPs)*

Some non-Federal lands are managed under HCPs with strategies that conserve habitat. These HCPs may provide some incidental benefit to fishers and some have fisher-specific protection measures. Habitat conservation plans cover large areas within the historic range of the fisher, particularly in western Washington and northwestern California. Although the fisher is a covered species in seven HCPs within Washington and California, the species is currently known to be present only on lands under two California HCPs. In most HCPs, the areas where late successional habitat will be protected or allowed to develop are mostly in riparian buffers and smaller blocks of remnant old forest. The HCP conservation strategies generally do not provide the large blocks of forest with late seral structure that appear to be important for sustaining resident fisher populations, particularly for providing denning and resting sites.

In conclusion, the primary threats are the loss and fragmentation of habitat and further decline and isolation of the remaining small populations. Any of the key elements of fisher habitat (*see* Habitat section) may be affected by Federal and State management activities. Reduction of any of these elements could pose a risk to the fishers. Activities under Federal regulatory control that result in fisher habitat fragmentation or population isolation pose a risk to the persistence of fishers. A large proportion of forests within the range of the West Coast DPS for the fisher are managed under the NWFP or SNFPA. These regional planning efforts provide for retention and recruitment of older forests, and provide for spatial distribution of this type of habitat that will benefit late successional forest dependent species such as the fisher. The adequacy of these plans, however is uncertain, as evidenced in the FEMAT's own assessment of fisher viability under the NWFP.

Proposed changes to both the NWFP and SNFPA are in progress, which could weaken habitat measures that benefit the fisher. Even with these plans in place, timber harvest, fuels reduction treatments, and road construction may continue to result in the loss of habitat and habitat connectivity in areas, resulting in a negative impact on fisher distribution, abundance and recovery/recolonization potential.

The same potential risks apply to non-Federal forested lands as discussed for lands under Federal regulatory control. Protections provided under state regulation of forest practices are less than provided on Federal lands, where the NWFP and SNFPA provide greater consideration of late-successional forest and dependent species, and of forest management at larger geographic scales. Existing regulatory processes for non-Federal, non-Tribal timberlands in California and Washington do not include specific measures for management and conservation of fishers or fisher habitat. Regulations regarding late successional forest rarely provide protection of these forests on commercial timberlands. This is largely because the regulations lack specific and enforceable conservation measures for these forests, and for most unlisted wildlife species, including the fisher. While the State regulatory process for these lands in all three States incidentally protects some fisher habitat via the Forest Practice Rules, the benefits are limited and do not include strategies which target either the fisher or key fisher habitat requirements. Existing habitat conservation plans for non-Federal timberlands provide some additional benefits to the fisher. These plans are focused on providing some level of protection for the habitat of spotted owls, marbled murrelets, and listed salmonids, which can protect important habitat elements for the fisher where habitat overlaps. However, many of these plans only protect occupied habitat, and harvest deferrals may be lifted if the mature stands no longer support listed species. Thus, benefits to the fisher from these HCPs may be ephemeral, especially in the case of listed species decline, like that of the spotted owl population occurring in Washington. HCPs only apply to a small part of the fisher's currently occupied range on non-Federal lands in California and Oregon, and the adequacy of the measures in these plans is uncertain. Because of the loss and fragmentation of low-elevation habitat, large geographic areas that were once occupied have become unsuitable, which poses a significant challenge for fisher genetic exchange across isolated patches of habitat.

In addition to the inadequacy of regulations to address fisher habitat requirements, current trapping regulations in Washington, Oregon, and California, while prohibiting intentional trapping of fishers, do not provide accurate reporting of the numbers of incidental captures of fishers, and appear inadequate to control such incidental trapping where fishers are present. Any source of additional mortality in small fisher populations could prevent recovery or reoccupation of suitable habitat (Lewis and Stinson 1998; Lewis and Zielinksi 1996).

It is uncertain whether current regulations will be effective in reducing the level of threat to the fisher. We therefore believe that existing regulatory mechanisms are not sufficient to protect the DPS as a whole from the acknowledged habitat pressures discussed under Factors A and E.

*Factor E. Other natural or manmade factors affecting the continued existence of the species.* Fisher populations in the West Coast DPS are small and isolated and may be threatened by numerous factors including inbreeding depression and unpredictable variation (stochasticity) in demographic or environmental characteristics. Other natural or anthropogenically-influenced factors, including urban development, barriers to dispersal, contaminants, pest control programs, non-target poisoning, stand-replacing fire, timber harvest, accidental trapping in manmade structures, decrease in prey base, and climate change may cause additional fisher declines. Because of small population size, accidental death is a threat.

*Other Causes of Mortality*

There have been several incidents of fishers being found dead in open water tanks. The remains of eight fishers were discovered in an abandoned water tank near a logging road in the northwestern California Coast Ranges (Folliard 1997). The tank had been used to store water for transferring into tank trucks to spread on roads for dust abatement during summer months. The fishers had entered the cylindrical 13-foot-long, 7.5-foot-deep tank from a lidless, 1.5-foot opening in the top. Fisher remains were the only species found inside. It was apparent from the carcasses' different stages of decay that the fishers had been trapped over a period of several years. In another instance of a manmade structure trapping fishers, Truex *et al.* (1998) reported that a 5-year-old female fisher died in the southern Sierra Nevada study area due to a combination of starvation and exposure after becoming entrapped in an uncovered, empty water storage tank. This source of mortality is cause for concern.

*Population Size and Isolation*

Preliminary analyses indicate West Coast fisher populations, particularly in the southern Sierra, may be at significant risk of extinction because of small population size and factors consequent to small population size such as isolation, low reproductive capacity, demographic and environmental stochasticity. A scarcity of sightings in Washington, Oregon, and the northern and central Sierra Nevada of California suggests that fisher is extirpated from most of its historical range in Washington, Oregon, and California (Zielinski *et al.* 1997b; Carroll *et al.* 1999; Aubry *et al.* 2000). The southern Sierra Nevada and northern California/Oregon Siskiyou populations are the only naturally-occurring, known breeding populations of fishers in the Pacific region from southern British Columbia to California that we have been able to identify (Zielinski *et al.* 1997b).

The current rarity of fishers in Washington brings their continued existence there into question. Eleven years ago, Thomas *et al.* (1993) stated that existing fisher populations in northern Oregon and Washington were at a medium to high risk of extirpation on National Forest lands within the next 50 years. According to FEMAT (1993), it was unknown whether the individual fishers that may exist in Washington could repopulate the State in the future. Recovery of the fisher in Washington will probably not occur without reintroductions (Lewis and Stinson 1998). Immigration of fishers into Washington from British Columbia, Idaho, or Montana is unlikely to provide significant demographic support to Washington's fisher population; fisher populations in adjacent parts of Idaho and British Columbia are small, the number of dispersing individuals is probably very low (Heinemeyer 1993), and the geographical separation is large. Reintroductions have apparently been successful in some, but not all other parts of the fisher's national range.

The introduced population in the southern Cascades of Oregon is small and isolated. It stems from the release of 28 fishers from British Columbia between 1961 and 1980, and an additional release of 13 fishers from Minnesota in 1981 (Aubry *et al.* 2002; Drew *et al.* 2003). Aubry *et al.* (in press 2003) concluded, "The high degree of relatedness among fishers in the southern Cascade Range (R = .56) is consistent with the hypothesis that this population is small and isolated.'' This reintroduced population is separated from the northwestern California/southwestern Oregon population by large expanses of non-forested areas, an interstate highway (Interstate 5), recreational developments, and densely populated areas. The isolation of these populations from each other in Oregon is further demonstrated by evidence indicating that there has been no genetic exchange between fishers in the northern Siskiyou Mountains and those in the southern Cascade Range (Aubry *et al.* in press 2003). Small size and isolation make the Oregon populations vulnerable to extirpation.

Because of the apparent loss of viable fisher populations from most of Oregon and Washington, and the northern contraction in the British Columbia populations, fishers in California are reproductively isolated from fishers in the rest of North America. This isolation precludes both immigration and associated genetic interchange, increasing the vulnerability of the California/southern Oregon populations to the adverse effects of deterministic and stochastic factors. Wisely *et al.* (in litt. 2003) documented that fishers in northern California already have lower genetic diversity than other populations in North America. Drew *et al.* (2003) cite evidence of genetic divergence between the California and British Columbia fisher populations; since becoming isolated, the California populations have lost a genetic haplotype still found in British Columbia fishers. The genetic divergence of California populations from each other and from British Columbia fishers could be associated with adaptation to local conditions, but is more likely the result of reduction of population numbers with habitat loss (Drew *et al.* 2003). Isolation makes it unlikely that in the event of population decline, immigration from other populations could temporarily augment the population, rescuing it from extinction.

Genetic studies using mitochondrial and nuclear DNA sequencing indicate that California populations, in particular, differ strongly in haplotype frequencies from each other and from all other populations (Drew *et al.* 2003). These results are consistent with the conclusions of Aubry and Lewis (2003) that native populations in California and the reintroduced population in southwestern Oregon have become isolated from the main body of the species' range due to the apparent extirpation of fishers in Washington and northern Oregon. According to Drew *et al.* (2003), their findings suggest that gene flow once occurred between fisher populations in British Columbia and those in the Pacific states, but extant populations in these regions are now genetically isolated. The southern Sierra Nevada population is geographically isolated from others by approximately 420 km (260 mi) (Zielinski *et al.* 1995, 1997b). There is a low probability that it could be rescued through migration of individuals from other populations were it to decline, since the distance to the nearest population is almost four times the species' maximum dispersal distance of 66 mi (107 km) as reported by York (1996). The unexpected magnitude of Pacific states fishers' genetic structure and lack of gene flow indicates that intermediate distances may represent evolutionarily important barriers to movement that can facilitate rapid genetic divergence (Wisely *et al.* in litt. 2003). Truex *et al.* (1998) concluded that, "Recolonization of the central and northern Sierra Nevada may be the only way to prevent fisher extinction in the isolated southern Sierra Nevada population.''

Indications that extant fisher populations are small in size include the apparent reduction in the range of the fisher on the west coast, the lack of detections or sightings over much of its historical distribution, and the apparently high degree of genetic relatedness within some populations. Small fisher population sizes are cause for concern, particularly considering that the West Coast populations are isolated from the larger continental populations and may have high female mortality (Truex *et al.* 1998). Small populations are at risk of extinction solely from demographic and environmental stochasticity, independent of deterministic factors such as anthropogenic habitat loss (Lande and Barrowclough 1987; Lande 1993). Random fluctuations in gender ratio, fecundity, mortality, droughts, cold weather, heavy snow years and other temporal environmental changes can lead to declines that, in small populations, result in rapid extinction. These factors present threats to the long-term survival of isolated populations such as the southern Sierra Nevada population (Lamberson *et al.* 2000). Catastrophes, such as stand-replacing fire or severe storms, magnify risk of extinction further (Shaffer 1987; Lande 1993).

According to Heinemeyer and Jones (1994), the greatest long-term risk to the fisher in the western United States is probably population extinction due to isolation of small populations. Fishers are known to be solitary and territorial with large home ranges. This results in low population densities as the population requires a large amount of quality habitat for survival and proliferation. Additionally, fishers are long-lived, have low reproductive rates, and small dispersal distances. Given the apparent reluctance of fishers to cross open areas (Coulter 1966; Kelly 1977; Powell 1977; Buck *et al.* 1994; Jones and Garton 1994), it is more difficult for fishers to locate and occupy distant, but suitable, habitat. These factors together imply that fishers are highly prone to localized extirpation, their colonizing ability is somewhat limited, and their populations are slow to recover from deleterious impacts. Isolated populations are therefore unlikely to persist.

Some fisher populations in northeastern North America have shown patterns of rapid density fluctuation consistent with those following cycles in prey numbers (deVos 1952; Rand 1944), or with changes expected for animals whose density-dependent feedback comes through changes in mortality rather than in reproduction, allowing them to recover into areas from which they had been extirpated. Western populations, however, do not appear to be recovering from early overtrapping and habitat degradation. Powell and Zielinski (1994) state:

> This pattern of rapid population increase has not been observed in western populations, many of which have failed to recover despite decades of protection from trapping (*e.g.*, northern Sierra Nevada, Olympic Peninsula), reintroductions (*e.g.*, Oregon), or both. Therefore, one or more major life requisites must be missing. Suitable habitat may be limited, colonization of suitable habitat may be limited due to habitat fragmentation, or some other factor or combination of factors may be involved.

Low fecundity retards the recovery of populations from declines, further increasing their vulnerability. As stated above, fishers have very low reproductive capacity. After 2 years of age, they generally produce only one to four kits per year, and only a portion of all females breed (Powell 1993; Truex *et al.* 1998; Lamberson *et al.* 2000). Truex *et al.* (1998) documented that of the females in the southern Sierra Nevada study area (one of three study areas that they analyzed in California), about 50 to 60 percent successfully gave birth to young. In the study area they analyzed on the North Coast, however, 73 percent of females gave birth to young in 1995, but only 14 percent (one of seven) did so in 1996, indicating fisher reproductive rates may fluctuate widely. Low survival rates for kits, coupled with low reproductive rates, would result in very low reproductive success rates. In their study on the west slope of the Cascade Range in southern Oregon, Aubry *et al.* (2002) radio-collared 13 females and monitored two to four adult females each year from 1995 to 2001. Although their data are preliminary at this point, they found that the average annual reproductive success was only 44 percent.

Female survival has been shown to be the most important single demographic parameter determining fisher population stability (Truex *et al.* 1998; Lamberson *et al.* 2000). Truex *et al.* (1998) documented a low annual survival rate, pooled across years, of 61.2 percent of adult female fishers in the southern Sierra Nevada from 1994 to 1996, 72.9 percent for females and 85.5 percent for males in their eastern Klamath study area, and 83.8 percent for both females and males in their North Coast study area. Addressing the southern Sierra Nevada population, Truex *et al.* (1998) conclude that, "High annual mortality rates raise concerns about the long-term viability of this population.'' Lamberson *et al.* (2000) used a model (deterministic, Leslie stage-based matrix) to gauge risk of extinction for the southern Sierra Nevada population of the fisher and found that the population has a very high likelihood of extinction given reasonable assumptions with respect to demographic parameters. They concluded, "In our model population, growth only occurs when parameter combinations are extremely optimistic and likely unrealistic: if female survival and fecundity are high, other parameters can be relaxed to medium or low values. If female survival and fecundity are medium and all other parameters high, a steady decline toward extinction occurs.''

As with any small, isolated population, risks of extinction are enhanced by stochastic factors (Lamberson *et al.* 2000). Demographic stochasticity, the chance events associated with annual survival and reproduction, and environmental stochasticity, temporal fluctuations in environmental conditions, tend to reduce population persistence (Shaffer 1981; Boyce 1992). Habitat specificity coupled with human-induced habitat fragmentation may also contribute to the exceptionally low levels of gene flow (migrants per generation) estimated among populations of fishers (Wisely *et al.* in litt. 2003). Wisely *et al.* (in litt. 2003) found that populations of the fisher exhibit high genetic structure (FST = 0.45, SE = 0.07) and limited gene flow (Nm < 1) within their 994 mi (1,600 km) long peninsular distribution down through Washington, Oregon, and California. They state concerns about the future viability of the western fisher: * * * we found that * * * genetic diversity decreases from the base [British Columbia] to the tip [southern Sierra Nevada] of the peninsula, and that populations do not show an equilibrium pattern of isolation-by-distance. Genetic structure was greater at the periphery than at the core of the distribution and our data fit a one-dimensional model of stepping-stone range expansion. Multiple lines of paleontological and genetic evidence suggest that the fisher recently (<5000 ybp) expanded into the mountain forests of the Pacific coast. The reduced dimensionality of the distribution of the fisher in the West appears to have contributed to the high levels of structure and decreasing diversity from north to south. These effects were likely exacerbated by human-caused changes to the environment. The low genetic diversity and high genetic structure of populations in the southern Sierra Nevada suggest that populations in this part of the geographic range are vulnerable to extinction.

It is difficult for subpopulations to rescue each other when distributed in such a narrow, linear fashion north-south peninsular distribution. Even isolated from other threats, the north-south peninsular distribution of fishers in the Sierra Nevada is a risk factor for the southern Sierra Nevada population. Being at the southernmost extent of the genus' distribution, the population already exists at the edge of environmental tolerances. The loss of remaining genetic diversity may lead to inbreeding and inbreeding depression. Given the recent evidence for elevated extinction rates of inbred populations, inbreeding may be a greater general threat to population persistence than is generally recognized (Vucetich and Waite 1999).

Combinations of factors can interact to produce significant cumulative risk. Lamberson *et al.* (2000) give the following example: if demographic stochasticity results in lower than average recruitment of female kits into a population for three consecutive years, and this is followed by two heavy-snow winters and one large fire, the population may quickly become in jeopardy of local extinction. Wisely and others (in litt. 2003) "have demonstrated isolation among populations with limited exchange suggesting that populations on the Pacific coast have little demographic buffer from variation in the population growth rate. Immediate conservation action may be needed to limit further erosion of the unique genetic architecture found in this one-dimensional metapopulation.''

In summary, unregulated trapping for furs began in the 1700s; predator bounties began in the 1800s and extended to 1960; extensive, lethal predator control programs were used until the mid-1970s. These factors have likely impacted fishers for nearly two centuries and were exacerbated by loss and fragmentation of habitat from urban growth and development, forest management activities, and road construction. The remaining two populations are threatened with extirpation due to their size and isolation. There is substantial information indicating that the interaction of all the factors above may cause the populations of fishers in their west coast range to become significantly at risk of extirpation.

## Conservation Activities

This fiscal year, the Pacific Region (Region 5) of the U.S. Forest Service is due to complete a conservation assessment for the fisher in the Sierra Nevada Mountains. This effort is part of the Sierra Nevada Framework planning document and is a collaborative effort including scientists from the State and Federal agencies. The assessment may be used to develop a conservation strategy for the Sierra Nevada fisher populations in California.

The timber industry and their representatives, including Sierra Pacific Industries, Simpson Timber Company and the California Forestry Association have indicated willingness to develop a conservation strategy to, if appropriate, conduct a reintroduction and/or relocation strategy in California. Their participation could include funding, staffing, and assistance with analysis and planning.

The State of Washington has completed a reintroduction feasibility study and has identified several sites in the Washington Cascades and the Olympic peninsula where sufficient potential habitat exists to support a fisher population. Reintroduction efforts and evaluation by the State are ongoing and would potentially compliment efforts to establish additional populations throughout the range of the fisher.

## Finding

We have carefully assessed the best scientific and commercial information available regarding the past, present, and future threats faced by this species. We reviewed the petition, available published and unpublished scientific and commercial information, and information submitted to us during the public comment period following our 90-day petition finding. This finding reflects and incorporates information we received during the public comment period and responds to significant issues. We also consulted with recognized fisher experts and Federal and State resource agencies. On the basis of this review, we find that the West Coast population of the fisher constitutes a valid DPS, which is both discrete and significant under our DPS policy, and that listing the fisher in its west coast range is warranted but precluded by pending proposals for other species with higher listing priorities.

In making this finding, we recognize that there have been declines in the distribution and abundance of the fisher in its west coast range, primarily attributed to historical overtrapping and habitat alteration. Much of the fisher's historical habitat and range has been lost. There is substantial information indicating that the habitat of fishers continues to be threatened with further loss and fragmentation resulting in a negative impact on fisher distribution and abundance. Mortalities and injuries from incidental captures of fishers may be frequent enough to prevent local recovery of populations, or prevent the re-occupation of suitable habitat. Removing important habitat elements such as cover could allow predation to become a significant threat. Other factors considered to be threats to the fisher include mortality from vehicle collisions, a decrease in the prey base, and increased human disturbance. Fisher populations are low or absent throughout most of their historical range in Washington, Oregon, and California. Because of small population sizes and isolation, fisher populations on the West Coast may be in danger of extirpation.

Federal, State, and private land management activities may affect key elements of fisher habitat; reduction of any of these key habitat elements could pose a risk to the fisher. Current regulations provide insufficient certainty that conservation efforts will be implemented or that they will be effective in reducing the level of threat to the fisher. We, therefore, believe that existing regulatory mechanisms are not sufficient to protect the DPS as a whole from habitat pressures.

We conclude that the overall magnitude of threats to the West Coast DPS of the fisher is high, and that the overall immediacy of these threats is non-imminent. Pursuant to our Listing Priority System (64 FR 7114), a DPS of a species for which threats are high and non-imminent is assigned a Listing Priority Number of 6. The threats occur across the range of the DPS resulting in a negative impact on fisher distribution and abundance. The threats are non-imminent as the greatest long-term risks to the fisher in its west coast range are the subsequent ramifications of the isolation of few, small populations. While we conclude that listing the West Coast DPS of the fisher is warranted, an immediate proposal to list is precluded by other higher priority listing actions. During Fiscal Year 2004 we must spend nearly all of our Listing Program funding to comply with listing actions required by court orders and judicially approved settlement agreements, which are now our highest priority actions. To the extent that we have discretionary funds, we will give priority to using them to address emergency listings and listing actions for other species with a higher priority. We expect that our discretionary listing activity in Fiscal Year 2004 will focus on addressing our highest priority listing actions.

There are currently efforts underway to implement a conservation strategy to reintroduce the fisher into its former range along the Pacific Coast. Additional populations of fishers will reduce the probability that a stochastic event would result in extirpation of these species. We will evaluate a completed conservation strategy in accordance with our Policy on Evaluating Conservation Efforts (68 FR 15100, March 28 2003) to determine whether it sufficiently removes threats to the fisher so that it no longer meets the definition of threatened under the Act.

We will add the West Coast DPS of the fisher to the list of candidate species upon publication of this notice of 12-month finding. We request that you submit any new information, whenever it becomes available, for this species concerning status and threats. This information will help us monitor and encourage the conservation of this species. Should an emergency situation develop with this or any of the candidate species, we will act to provide immediate protection, if warranted.

We intend that any proposed listing action for the West Coast DPS of the fisher will be as accurate as possible. Therefore, we will continue to accept additional information and comments from all concerned governmental agencies, the scientific community, industry, or any other interested party concerning this finding.

## Resource Report 3- Fish, Wildlife and Vegetation

| To Verify Compliance with this Minimum FERC Filing Requirement: | | See the Following Resource Report Section: |
|---|---|---|
| 1. | Describe commercial and recreational warmwater, coldwater, and saltwater fisheries in the affected area and associated significant habitats such as spawning or rearing areas and estuaries. | Section 3.3 |
| **2.** | Describe terrestrial habitats, including wetlands, typical wildlife habitats, and rare, unique, or otherwise significant habitats that might be affected by the proposed action. Describe typical species with commercial, recreational or aesthetic value. | Section 3.1<br>Section 3.2<br>Section 3.4 |
| **3.** | Describe and provide the acreage of vegetation cover types that would be affected, including unique ecosystems or communities such as remnant prairie or old-growth forest, or significant individual plants, such as old-growth specimen trees. | Section 3.1<br>Section 3.2 |
| **4.** | Describe the impact of construction and operation on aquatic and terrestrial species and their habitats, including the possibility of a major alteration to ecosystems or biodiversity, and any potential impact on state-listed endangered or threatened species. Describe the impact of maintenance, clearing and treatment of the project area on fish, wildlife and vegetation. Surveys may be required to determine specific areas of significant habitats or communities of species of special concern to state or local agencies. | Section 3.1<br>Section 3.2<br>Section 3.3<br>Section 3.4 |
| **5.** | Identify all federally listed or proposed endangered or threatened species and critical habitat that potentially occur in the vicinity of the project. Discuss the results of the consultation requirements listed in §380.13(b) at least through §380.13(b)(5)(i) and include any written correspondence that resulted from the consultation. The initial application must include the results of any required surveys unless seasonal considerations make this impractical. If species surveys are impractical, there must be field surveys to determine the presence of suitable habitat unless the entire project area is suitable habitat. | Section 3.4 |
| **6.** | Identify all federally listed essential fish habitat (EFH) that potentially occurs in the vicinity of the project. Provide information on all EFH as identified by the pertinent Federal fishery management plans that may be adversely affected by the project, and the results of abbreviated consultations with NMFS, and any resulting EFH assessments. | Section 3.3 |
| **7.** | Describe site-specific mitigation measures to minimize impacts on fisheries, wildlife, and vegetation. | Section 3.1<br>Section 3.2<br>Section 3.3 |
| **8.** | Include copies of correspondence not provided pursuant to paragraph (e)(5) of this section, containing recommendations from appropriate Federal and state fish and wildlife agencies to avoid or limit impact on wildlife, fisheries, and vegetation, and the applicant's, along with response to the recommendations. | Appendix A.3 |

## 3. INTRODUCTION

Jordan Cove Energy Project, L.P. (JCEP) is requesting authorization from the Federal Energy Regulatory Commission (FERC) to site, construct, and operate a natural gas liquefaction and export facility (LNG Terminal or Project), located on the bay side of the North Spit of Coos Bay, Oregon. The Project will provide a facility capable of liquefying natural gas and storing the liquefied natural gas (LNG) for export. Once the Project facilities are completed and placed in service, natural gas will be delivered to the LNG Terminal via the proposed Pacific Connector Gas Pipeline (PCGP), which will connect the Project with existing interstate natural gas pipeline systems. The authorization required for the PCGP will be addressed in a separate application filed by PCGP pursuant to Section 7(c) of the Natural Gas Act (NGA).

Natural gas received at the LNG Terminal will be cooled into liquid form and stored in two 160,000 cubic meter ($m^3$) full-containment LNG storage tanks. The proposed Project facilities will have the capability to allow export of six million metric tons per annum (MMTPA). Approximately 90 LNG carriers per year will be required to transport the LNG to locations in the United States (U.S.) and around the world.

The following facilities will be constructed for the Project:

- A pipeline gas conditioning facility consisting of two feed gas cleaning and dehydration trains with a combined natural gas throughput of approximately 1 Bscf/d;
- Four natural gas liquefaction trains, each with the export capacity of 1.5 MMTPA;
- A refrigerant storage and resupply system;
- An Aerial Cooling System (Fin-Fan);
- An LNG storage system consisting of two full-containment LNG storage tanks, each with a net capacity of 160,000 $m^3$ (1,006,000 barrels), and each equipped with three fully submerged LNG in-tank pumps sized for approximately 11,600 gallons per minute (gpm) each;
- An LNG transfer line consisting of one 2,300-foot-long, 36-inch-diameter line that will connect the shore based storage system with the LNG loading system;
- An LNG carrier cargo loading system designed to load LNG at a rate of 10,000 $m^3$ per hour ($m^3$/hr) with a peak capacity of 12,000 $m^3$/hr, consisting of three 16-inch loading arms and one 16-inch vapor return arm;
- A protected LNG carrier loading berth constructed on an Open Cell® technology sheet pile slip wall and capable of accommodating LNG carriers with a range of capacities;
- The improvement of an existing, on-site unimproved road and utility corridor to become the primary roadway and utility interconnection between the LNG Terminal and South Dunes sites, including between the pipeline gas conditioning units on the South Dunes Power Plant site and the liquefaction trains on the LNG Terminal site;
- A boil off gas (BOG) recovery system used to control the pressure in the LNG storage tanks;

- Electrical, nitrogen, fuel gas, lighting, instrument/plant air and service water facility systems;
- An emergency vent system (ground flare);
- An LNG spill containment system, a fire water system and various other hazard detection, control, and prevention systems; and
- Utilities, buildings and support facilities.

The following facility, although not jurisdictional to FERC, will also be constructed to support the Project:

- The South Dunes Power Plant, a 420 megawatt (MW) natural gas fired combined-cycle electric power plant inclusive of heat recovery steam generator (HRSG) units for the purpose of powering the refrigeration systems in the natural gas liquefaction process and supplying steam to the conditioning units.

**Purpose of Report**

The purpose of this Resource Report is to review and characterize existing scientific information for vegetation, wildlife, fish, and aquatic resources, and to identify potential direct, indirect, and cumulative effects to these resources from the construction and operation of the Project. This report also identifies mitigation, enhancement, and protection measures that can be implemented to avoid or minimize potential adverse impacts to these resources and their associated habitats.

The goal of this report is to provide a comprehensive reference document utilizing the best scientific information available for use in making sound decisions with respect to Project planning, environmental reviews, and permitting. It is intended for use by federal and state resource managers, permitting agencies, professionals engaged in habitat assessment activities, the regulatory community, and the public.

**Agency Communications**

In the preparation of this Resource Report, communications have occurred with the U. S. Fish and Wildlife Service (USFWS), the National Oceanic and Atmospheric Administration (NOAA) - National Marine Fisheries Service (NMFS), the Oregon Department of Fish and Wildlife (ODFW), the Oregon Biodiversity Information Center (ORBIC), and the Oregon Department of Agriculture (ODA) to identify significant terrestrial and marine biological resources, including significant habitats, federally-listed species, state-listed species, and the occurrence of Essential Fish Habitat (EFH) within the Project area. A summary of key agency contacts is presented in Table 1.8-1 (Resource Report 1 - General Project Description). Coordination and consultation with these agencies, along with surveys and assessments conducted, is documented in the attached botanical, wildlife, and fisheries reports completed for the Project.

**Report Organization**

This Resource Report is organized into five major sections and a references section. Section 3.1 discusses Vegetation, Section 3.2 Wildlife, Section 3.3 Fisheries and Marine Resources, and Section 3.4 Federal and State Threatened and Endangered Species (including proposed species and Critical Habitat). Section 3.5 briefly summarizes the overall impacts of the proposed Project, and overall mitigation, enhancement, and protection measures to address the primary impacts. References used in the development of this Resource Report are presented in Section 3.6.

**Project Area Characterization**

As discussed in Resource Report 1 – General Project Description and shown in Figure 1.1-1, the Project is located across two parcels of land on the bay side of the North spit of Coos Bay. All jurisdictional facilities except the pipeline gas conditioning facilities will be located on the western parcel (LNG Terminal site), the South Dunes Power Plant and the pipeline gas conditioning facilities will be located on the eastern parcel (South Dunes Power Plant site). The two sites will be connected by the utility and access corridor (in the aggregate, the Project site). It will include a temporary construction worker camp and compensatory mitigation sites, including the Kentuck site for wetland and estuarine resources; the Panhandle mitigation site for wetland and wildlife habitat impacts; and an eelgrass mitigation site southwest of the Southwest Oregon Regional Airport in North Bend.

## 3.1 VEGETATION

The Project will encompass a number of ecological systems that support diverse vegetation communities. The overall location was selected on the basis of avoiding, to the extent practical, unique vegetation communities and higher value wetlands. Selection of temporary construction areas was purposely restricted to upland areas to avoid impacting wetlands. Federal and state-listed threatened or endangered species observed or with the potential to occur in or near the Project vicinity are included in the description of vegetation associations presented below, as applicable, and are discussed further in Section 3.4.

### 3.1.1 Existing Resources

Extensive surveys have been conducted at the Project site for botanical resources. The Project site was initially surveyed and evaluated extensively in 2005 and 2006 for the previously proposed LNG import facility. Additional surveys were conducted in 2012 and 2013 to supplement the previous surveys and ensure that all existing botanical resources are included in this evaluation. A preliminary botanical survey of the construction worker camp site across the bay was conducted in April 2013.

Vegetation in the area to be affected by construction of the Project is generally typical of vegetation and associated habitats found on the North Spit of Coos Bay. The site consists of a number of different plant associations, as well as disturbed areas resulting from the placement of fill from historical dredging operations and previous industrial use.

The proposed Kentuck and Panhandle wetland mitigation sites are also included in the discussion of the various plant communities that occur for the Project. The Kentuck site is addressed in more detail in Resource Report 2 – Water Use and Quality, which evaluates the site for use as mitigation for impacts to wetlands by the Project. The Panhandle mitigation site will be evaluated further as the use of the site for wildlife habitat and wetland mitigation moves forward.

Vegetation associations have been grouped into four main categories: forest, woodland, shrubland, and herbaceous associations (Figure 3.1-1). These classifications are based on the National Vegetation Classification System (NVCS) used for *Plant Associations of the Oregon Dunes National Recreation Area* (Christy et al. 1998), a U.S. Department of Agriculture (USDA) publication. Forests are defined as associations where tree species make up at least 60 percent of the vegetation cover. Woodland associations are defined as open stands, usually without crowns touching, and cover varies from 25 to 60 percent. Communities that generally consist of at least 25 percent shrub cover are classified as shrubland associations. Conversely, communities that generally have less than 25 percent shrub cover are defined as herbaceous associations. These associations are discussed in Section 3.1.2.

In addition to the above vegetation associations, dune forests that occur within these associations at the Project site have been classified as A through E. Dune Forest B is the largest and is slated for removal to create the access channel and slip for the LNG facility. Dune Forest C is smaller and is located north of Dune Forest B, immediately south of the Trans-Pacific Parkway. There is a sand trail that separates the two. Dune Forest A, the highest in dune forest habitat value, is located west of Jordan Lake and runs approximately 800 feet down from the utility corridor. It consists of Port Orford cedar and shore pine-Sitka spruce communities.

Additional dune forests D and E occur in shore pine/Douglas fir associations. Dune Forest D is located on the northwestern tip of the overall site, immediately south of the Trans-Pacific Parkway. Dune Forest E is located in the western portion of the South Dunes Power Plant site, immediately east of Jordan Cove Road.

Dune forests also occur in areas that will not be impacted by the Project, including in the forested wetland mosaic complex (east of Dune Forest C and north of the Roseburg Forest Products wood chip export facility) and in upland forest sites along the ridgelines throughout the complex. These dune forests are interspersed among the wetlands and consist of shore pine-Sitka spruce, shore pine-Douglas fir, and shore pine/slough sedge.

### 3.1.2 Associations

#### 3.1.2.1 Forest Associations

Forest associations are defined as trees with crowns overlapping and generally a cover of 60 to 100 percent. Evergreen forests in this association have greater than 75 percent tree cover. Forest associations within the Project site are dominated by coniferous species with scattered hardwoods that occur generally along ridges and the toe of slopes. Forests vary in seral (intermediate ecological) and mature stand stages. The youngest forests are generally located along the northern perimeter of the developed portions of the LNG Terminal site and adjacent to the Trans-Pacific Parkway. The more successionally mature forests are located in the interior portions of the site, on stabilized dune ridges, troughs, and dry deflation basins. Forest types included in this association that occur at the Project site are described below.

**Shore Pine-Douglas Fir/Wax Myrtle-Evergreen Huckleberry (Evergreen, Upland)**

Shore pine (*Pinus contorta*) and Douglas fir (*Pseudotsuga menziesii*) forests in this association occur near previously developed areas such as roads, fill sites, or industrial sites. They have been noted to occur most frequently on warm, dry ridges, and slopes on the dunes; primarily with south to west facing aspects (Christy et al. 1998). This association is characteristic of younger forest sites north of Jordan Cove. They occur in areas where dune stabilization has been achieved through recruitment of vegetation, most notably European beachgrass (*Ammophila arenaria*) and Scotch broom (*Cytisus scoparius*). This association has an open overstory dominated by shore pine with scattered Douglas fir. The shrub layer is dominated by Scotch broom and coyote bush (*Baccharis pilularis*), with scattered hairy manzanita (*Arctostaphylos columbiana*), wax myrtle (*Myrica californica*), and evergreen huckleberry (*Vaccinium ovatum*). Dominant herbaceous species include European beachgrass, silver hairgrass (*Aira caryophyllea*), little hairgrass (*A. praecox*), hairy cat's ear (*Hypochaeris radicata*), braken fern (*Pteridium aquilinum*), and sheep sorrel (*Rumex acetosella*).

Shore pine and Douglas fir forests were observed in portions of Dune Forests A, B, and C where adjacent landscapes have been altered by human or natural influences.

**Shore Pine-Sitka Spruce/Evergreen-Huckleberry (Evergreen, Upland)**

This association is common in more successionally mature forests. Stands are generally dominated by shore pine and Douglas fir, but also include Sitka spruce (*Picea sitchensis*), western hemlock (*Tsuga heterophylla*), and scattered Port Orford cedar (*Chamaecyparis lawsoniana*). The shrub understory layer ranges from dense to nearly impenetrable and is dominated with evergreen huckleberry, salal (*Gaultheria shallon*), and wax myrtle, with scattered Pacific rhododendron (*Rhododendron macrophyllum*). The herbaceous layer varies from being depauperate (diminished) to moderately covered with candy-stick (*Allotropa virgata*), rattlesnake plantain (*Goodyera oblongifolia*), and bracken fern along edges or gaps in the overstory. Dune Forest B, the largest dune forest identified within the LNG Terminal site**,** occurs within this association and consists of a mix of shore pine, Sitka spruce, and Douglas fir.

Forests within the Panhandle mitigation site are dominated by coniferous species, generally along the toe of slopes and low lying areas adjacent to shrublands, and most closely fit this association. Forests found in the site are dominated by shore pine, with scattered Sitka spruce, and western hemlock. The shrub layer in the wetland forest sites ranges from dense to nearly impenetrable and is dominated with evergreen huckleberry, salal, and wax myrtle, with scattered Pacific rhododendron. The herbaceous layer is dominated by slough sedge (*Carex obnupta*), which is found along the edge of the tree line throughout the Panhandle mitigation site area.

**Shore Pine/Scotch Broom/European Beachgrass (Evergreen, Upland)**

Although this association at the Project site contains shore pine, it is usually observed as a shrubland due to the high density of shrubby species, including Scotch broom, with limited distribution of shore pine due to the abundance of non-native species. This association is relatively widespread throughout the LNG Terminal site of the Project area and is associated with roads and other disturbed areas. The overstory within this association is generally open, averaging less than 50 percent cover of shore pine in most areas. Scotch broom cover varies from moderately dense to very dense in areas that lack a substantial canopy cover.

The herbaceous layer varies from depauperate, where there is a significant cover of Scotch broom, to moderately vegetated in areas that lack dense shrub cover. Dominant herbaceous species include European beachgrass, red fescue (*Festuca rubra*), tall fescue (*Festuca arundinaceae*), silver hairgrass, hairy cat's ear, and sheep sorrel*.* This association occurs west of the South Dunes Power Plant, north of the Roseburg Forest Products wood chip export terminal, along previous road cuts for the Trans-Pacific Parkway, and at the temporary construction worker camp site.

**Port Orford Cedar/Evergreen-Huckleberry (Evergreen, Upland)**

The Port Orford cedar and evergreen huckleberry association is described by Christy et al. (1998) as unique. It occurs in all aspects and slopes on narrow, dry stabilized dune ridges, troughs, and seasonally dry deflation basins at the southern end of the Oregon Dunes National Recreation Area immediately north of the Project site.

Port-Orford-cedar (POC) root rot disease is caused by the fungus *Phytophthora lateralis*. The disease was first discovered in POC's natural range in 1952 and since has spread throughout the POC's (host) range. The fungus invades the roots of POC and eventually colonizes the entire root system until the tree eventually dies from girdling. POC root rot disease affects both seedlings and mature trees. Evidence of infected trees includes lighter colored foliage that eventually turns red to brown. It also dyes and discolors the inner bark. The spores live in the soil and are spread through contact with contaminated soil or via free water. The disease is primarily spread through soil disturbance and spread of the disease may occur over long distances.

A small component of a well-developed Port Orford cedar/evergreen huckleberry association is located upslope from the southwestern shore of Jordan Lake, in the center of the Project site. Port Orford cedar observed at this location includes two trees upslope from the existing access trail that travels from the Roseburg Forest Products facility to Jordan Lake. Additionally, 23 Port Orford cedars were observed at sites located adjacent to Jordan Lake, in areas that will be preserved as part of the Project. Dune Forest A occurs partially within this association. Of note, the plot plan for the Project is different from that of the previously proposed LNG import terminal. The area to be disturbed by the Project now avoids this plant association.

**Shore Pine/Slough Sedge (Evergreen, Seasonally Flooded)**

This wetland forest association occurs in depressions on deflation plains and on ancient marine terraces. It was observed in the north central wetland mosaic north of the Roseburg Forest Products wood chip export terminal and is the predominant wetland type observed in the wetland forested sites found scattered throughout the Panhandle mitigation site. The understory on mounds in and around depressions is dominated by shrub species, including wax myrtle, salal, and evergreen huckleberry. Slough sedge is the single dominant herbaceous species and was observed growing in depressions and open water habitats throughout the North Spit locations of the Project.

**Red Alder/Salmonberry/Slough Sedge-Skunk Cabbage (Deciduous, Saturated)**

Red alder/salmonberry/skunk cabbage forests occur in wetland habitats adjacent to upland forested habitats, and in low flat areas adjacent to inundated wetlands. In this association, the overstory consists entirely of red alder (*Alnus rubra*) around wet areas, but transitions to shore pine in adjacent areas. Canopy cover varies from moderate to closed (more than 50 percent). Scattered clusters of dense shrubs that include salmonberry (*Rubus spectabilis*) and Hooker willow (*Salix hookeriana*) are located under the canopy. Herbaceous coverage is generally found in wet areas and consists almost entirely of slough sedge, with scattered skunk cabbage (*Lysichiton americanus*). This association has been documented in low spots in forests east of Jordan Cove Road and along the southern edge of the wetland mosaic located in the northwest part of the LNG Terminal site.

### 3.1.2.2 Woodland Associations

Woodland associations are defined as open stands, usually without crowns touching, and generally form 25 to 60 percent cover (sometimes less). They occur on all aspects of dry, well-drained, partially stabilized dune ridges, slopes, and flats between the sand and the forest edge (Christy et al. 1998). Three woodland associations occur within the LNG Terminal site, but are not well represented. They are described below.

**Shore Pine/Bearberry (Evergreen, Upland)**

The overstory for this association consists entirely of shore pine. The shrub layer is dominated by the low growing shrub bearberry (*Arctostaphylos uva-ursi*), with hairy Manzanita in scattered patches. The shore pine/bearberry association has small portions scattered throughout the

Project site, with the most substantial occurrence on the stabilized dune ridge northwest of the Roseburg Forest Products wood chip export terminal between Dune Forests B and C.

**Shore Pine/Hairy Manzanita (Evergreen, Upland)**

The shore pine/hairy manzanita association successionally replaces the shore pine/bearberry association. The overstory is moderately open and is dominated by shore pine with scattered Douglas fir trees. The shrub layer varies from moderately dense to dense in areas where the canopy is patchy. Hairy manzanita is the dominant shrub species with scattered evergreen huckleberry and bearberry along the edges. A small area of this association can be found along the eastern boundary of Dune Forest B.

#### 3.1.2.3 Shrubland Associations

Communities that consist of shrubs greater than 0.5 meter tall with generally greater than 25 percent cover and generally less than 25 percent tree cover are classified as shrubland associations. Deciduous shrubland generally has greater than 75 percent deciduous species shrub cover. The density and distribution of the shrubland association is correlated to hydrology and topography. One of the major characteristics of the shrubland association is minor variation in topography, which affects the distribution of herbs and shrubs. The lowest lying areas are frequently inundated with water and, depending on the frequency and duration of inundation, they may be dominated with emergent hydrophyte species that generally grow partly or totally submerged in water.

Shrublands within the Panhandle mitigation site are referred to as scrub-shrub wetlands, with variations in species composition and abundance throughout the site. Extensive shrublands were observed in the areas bordering open water throughout the Panhandle mitigation site and were observed dominating the landscape from the edge of the forest community to emergent wetland sites. The overstory within this shrubland varies from patchy to dense and is dominated by Hooker willow, Sitka willow (*S. sitchensis*), and Douglas spiraea (*Spiraea douglasii*), with scattered twinberry (*Lonicera involucrata*). Coniferous trees are for the most part absent in the shrubland community but may include scattered shore pine and Sitka spruce. Slough sedge is the most abundant herbaceous species.

**Hooker Willow-Crabapple/Slough Sedge-Skunk Cabbage (Deciduous, Saturated)**

Scrub-shrub communities identified for the Project site most closely resemble Hooker willow-crabapple/slough sedge-skunk cabbage association, minus the skunk cabbage. Minor variations in hydrology and topography may change the species composition drastically. This association is further described as having dwarf shrubland with shrubs less than two feet tall that provide generally greater than 25 percent cover. Tree cover is generally less than 25 percent.

The overstory within this association varies from patchy to dense and is dominated by Hooker willow, Sitka willow, and Douglas spiraea, with scattered twinberry. Evergreen (coniferous) trees are for the most part absent in the shrubland community, but may include scattered shore pine and Sitka spruce. Slough sedge is the most abundant herbaceous species. Other species include spreading rush (*Juncus effuses*), dagger-leaved rush (*Juncus ensifolius*), toad rush (*J. bufonius*), western bent-grass (*Agrostis exarata*), creeping bent-grass (*A. stolonifera*), reed canary grass (*Phalaris arundinacea),* northern willowherb (*Epilobium ciliatum*), tall mannagrass (*Glyceria elata*), and lowland cudweed (*Gnaphalium palustre*).

Hooker willow/slough sedge shrubland and Douglas spiraea saturated shrubland were observed extensively throughout wetlands west of Jordan Cove Road and southwest of Jordan Lake. In addition, this alliance is the dominant vegetation association observed in the scrub-shrub wetland habitat located in the Panhandle mitigation site.

#### 3.1.2.4 Herbaceous Associations

Communities that have generally less than 25 percent tree and shrub cover with generally greater than 25 percent herbaceous vegetation (graminoids, forbs, and ferns) are defined as herbaceous associations. Perennial vegetation for this association generally has greater than 50 percent of total herbaceous cover.

Herbaceous associations are the most variable of all the vegetation associations located in the Project site. They range from being dominated by plants that are adapted for sand burial and desiccating winds, to species that are emergent or submergent hydrophytes. They are widespread throughout the Project site, including areas that have some active sand movement and/or anthropogenic (human) disturbance. Effects from anthropogenic disturbances are reflected in the nonnative herbaceous species composition. Vegetation communities occurring in sand dune areas of the Project site are composed almost entirely of herbaceous species of plants, with no persistent woody stems above ground.

Numerous special status plant species are known to occur in herbaceous associations and are included Section 3.1.4 for unique and special status species. Federal and state-listed threatened and endangered plant species known to occur in herbaceous associations found in coastal habitats include: pink sand verbena (*Abronia umbellate,* ssp. *breviflora*), Point Reyes bird's-beak (*Cordylanthus maritimus,* ssp. *palustris*), silvery phacelia *(Phacelia argentea)*, western lily (*Lilium occidentale*), and Wolf's evening primrose *(Oenothera wolfii).* These species and their potential to occur in or near the Project are discussed further in Section 3.4.

Plant communities that occur in herbaceous associations at the Project site are described below.

**European Beachgrass (Perennial, Upland)**

Vegetation located on the active to semi-stable sand dunes is consistent with common herbaceous dune species. Dominant dune species include European beachgrass, red fescue, silver burweed (*Ambrosia chamissonis*), sand pea (*Lathyrus japonicus*), seashore lupine (*Lupinus littoralis*), beach silvertop (*Glehnia littoralis*), and beach evening primrose (*Camissonia cheiranthifolia*).

In degraded habitats such as where fill material has been deposited in the past, and near roadsides or other industrial sites, this association includes patchy non-native shrubs species, including Scotch broom. It can begin to resemble the shore pine/Scotch broom/European beachgrass association. At these sites the herbaceous vegetation is being displaced by encroaching invasive species, including European beachgrass and Scotch broom.

This association was observed in the western part of the LNG Terminal site in the dredge spoils fill site (also known as Ingram Yard) where the slip will be located and at the construction worker camp site. It was also observed in patchy distribution throughout open dune lands located north of Jordan Lake where the access/utility corridor is proposed.

#### Red Fescue-Salt Rush (Perennial, Upland)

In grasslands found on sand or fill material, red fescue is the single dominant species. Scattered red fescue was observed west of the South Dunes Power Plant site (on fill) and north of the Roseburg Forest Products export facility (on sand). At the South Dunes Power Plant site, in an area surrounded by scattered red fescue, a portion of a small dune contained the single dominant species salt rush (*Juncus lesuerii*). Red fescue-salt rush was also observed at sites where sand burial by wind driven forces limits species diversity, including in the Ingram Yard east of Henderson Marsh (western part of the LNG Terminal site).

#### American Dunegrass (Perennial, Upland)

This association includes dune lands with the single dominant species American dunegrass (*Leymus mollis*). It can be found on beaches and in foredunes, and to a lesser extent on open deflation plains and in upper estuaries. Continual sand burial and inputs of salt spray seem necessary for American dunegrass to thrive. Stands in most locations have been overrun by European beachgrass, but American dunegrass often persists in patches among the European beachgrass, which is the case of the grasses occurring on the western half of the construction worker camp site. Scattered American dunegrass was also observed west of Dune Forest B, in the Ingram Yard grassland habitat east of Henderson Marsh on previous fill deposits. Continual sand burial at this site limits competing vegetation and inputs of salt spray create the conditions necessary for this species to thrive.

#### Pond Lily (Perennial, Semi-permanently Flooded)

Other herbaceous associations are dominated by emergent hydrophytes, as described in the shrubland association section. Dominant species in semi-permanently flooded areas include yellow pond lily (*Nuphar lutea ssp. polysepala),* floating water-pennywort *(Hydrocotyle ranunculoides),* floating-leaved pondweed (*Potamogeton natans*), parrotfeather (*Myriophyllum aquaticum*), water shield (*Brasenia schreberi*), and common bladderwort (*Utricularia macrorhiza*). Pond lily habitat was observed in deep freshwater wetlands located in the Project site. This includes wetlands immediately west of Jordan Cove Road where the access/utility corridor is proposed (Wetland 2012-2 and 2013-6) and in the southern portion of Wetland E.

### 3.1.2.5 Other Plant Associations

#### Maintained Grasslands

Maintained grassland habitats observed throughout the Kentuck wetland mitigation site include native and non-native grasses and other herbaceous species associated with manicured grasslands. This site is dominated by red fescue, Kentucky bluegrass (Poa pratensis), reed canary grass (*Phalaris arundinacea*), common rush (*Juncus effuses*), and orchard grass (*Dactylis glomerata*). Wetland habitats were observed in the drainage that flows out of the levee situated along East Bay Drive at the western edge of the site. Dominant species include common rush and common cattail (*typha latifolia*). Reed canary grass, an invasive plant species, was observed in patchy distribution in areas that bordered forest sites. Tree species were planted throughout the site and include ornamental species such as blue spruce (*Picea pungens*) and poplar (*Populus trichocarpa*), as well as native tree species such as western hemlock, Sitka spruce, and Douglas fir.

#### Common Cattail/Open Water

This association includes wetland fringe sites observed adjacent to open bodies of water. These sites are limited in species diversity due to competition from common cattail which displaces other emergent vegetation. This association was observed in wetlands surrounding the existing sludge ponds at the South Dunes Power Plant site and the wetlands observed south of the Trans-Pacific Parkway in the eastern portion of the Project site.

Wetlands that occur in the Project area include emergent, scrub-shrub, forested, and estuarine intertidal, as described briefly below. A more detailed analysis is included in Resource Report 2 – Water Use and Quality, including potential effects to wetlands and proposed mitigation.

- Herbaceous emergent wetland habitat is located in low lying areas throughout the Project area. Vegetation is typically dominated by sedges, rushes, and grasses, with wetter portions of this habitat type consisting of aquatic floating and emergent plants in relatively shallow seasonally or perennially inundated areas.
- Scrub-shrub wetland habitat is commonly dominated by Hooker willow, with salmonberry and other common coastal wetland species such as slough sedge and skunk cabbage.
- Forested wetland habitat consists of wetlands that have remained undisturbed long enough to develop a consistent tree canopy. It is dominated primarily by red alder, with some areas of tree-size Hooker willow. The shrub layer is dominated by common coastal wetland species.
- Estuarine intertidal wetlands occur along the shore of Coos Bay at the mouth of the proposed slip and in an intertidal mudflat area associated with Wetland H.

**Salt Marsh Species**

Salt marshes are located along the vegetated shoreline adjacent to Jordan Cove, towards the western end of the Kentuck wetland mitigation site in areas where tidal influence occurs, and at the construction worker camp site. Dominant species include pickleweed (Salicornia virginiana), Lyngby sedge (*Carex lyngby*), salt grass (*Distichlis spicata*), and hairgrass (*Deschampsia caespitosa*). A small occurrence of salt marsh species was observed in a portion of Henderson Marsh which is located to the west and outside of the Project site, as well as in the lightly vegetated mudflat area associated with Wetland H (see Resource Report 2) that drains from the South Dunes Power Plant site into the bay.

### 3.1.3 Noxious Weeds

Noxious weeds are non-native, aggressive, and invasive plants. Species such as European beachgrass and Scotch broom are replacing native vegetation and opportunistically becoming established on sites otherwise unoccupied by grass or shrub species. The spread of noxious weeds is altering habitats and interfering with natural succession. Resource and vegetation management is necessary to maintain natural communities, successional processes, biodiversity, and ecosystem health.

Noxious weeds are classified by the Oregon State Weed Board (OSWB) as any plant that is injurious to public health, agriculture, recreation, wildlife, or any public or private property. They have become so thoroughly established and are spreading so rapidly on private, state, county, and federally owned lands in Oregon that they have been declared by Oregon Revised Statutes (ORS) 569-350 to be a menace to public welfare.

Noxious weeds have the potential to be eradicated or controlled in the state; however, steps leading to eradication and intensive control are necessary. Eradication and intensive control rests not only on private landowners and operators, but on the county, state, and federal government. To assist in control, the Oregon Department of Agriculture (ODA) Noxious Weed

Control Program and the OSWB maintain the state noxious weed list, which covers all lands within the State of Oregon.

#### 3.1.3.1 Classification of Noxious Weeds

The Noxious Weed Policy and Classification System (ODA 2013) establishes three categories for weeds within or having potential habitat in Oregon. Noxious weeds are listed as either A or B, and may be added to the T list, as directed by the OSWB, to receive priority in implementing noxious weed control projects. These classifications are defined below.

- Class "A" weeds—a weed of known economic importance which occurs in the state in small enough infestations to make eradication or containment possible; or is not known to occur, but its presence in neighboring states make future occurrence in Oregon seem imminent.
- Class "B" weeds—a weed of economic importance which is regionally abundant, but which may have limited distribution in some counties.
- Class "T" weeds—a priority noxious weed designated by the OSWB as a target on which the Oregon Department of Agriculture (ODA) will develop and implement a statewide management plan. "T" designated noxious weeds are species selected from either the "A" or "B" list.

The Coos County Weed Board utilizes ODA's classification system; however, it distinguishes "A" weeds as those not known to occur in Coos County but its presence in neighboring counties make future occurrence in Coos County seem imminent. "T" weeds are listed as designated priority noxious weeds for the county.

#### 3.1.3.2 Noxious Weeds Sites

The current list of noxious weeds for Coos County, including their potential to occur at the Project site, is presented as Table 3.1-1. Of those species, 14 were encountered during field surveys conducted for the Project. Eight noxious weed species have been mapped for the LNG Terminal, South Dunes Power Plant, and construction worker camp sites in Figure 3.1-2. The mapped species include: Scotch broom, Himilayan blackberry *(Rubus discolor),* European beachgrass, gorse (*Ulex europaeus*), sweet fennel (*Foeniculum vulgare*), poison hemlock (*Conium maculatum*), pampas grass (*Cortaderia jubata*), English ivy (*Hedera helix*), parrotfeather, and Italian thistle (*Carduus pycnocephalus*). Gorse and parrotfeather are listed as target "T" species by both the county and State to receive priority for prevention and control.

**Project Site**

Scotch broom, Himilayan blackberry, and European beachgrass have been observed throughout the Project site. All three species in this association are dominant species in the disturbed habitats associated with the South Dunes Power Plant site and the Roseburg Forest Products wood chip export terminal site. This association was also noted to occur in the active dune lands north of Jordan Lake. Additional species include: poison hemlock, observed in the South Dunes Power Plant site along a stretch of Jordan Cove Road; pampas grass, observed scattered throughout the South Dunes Power Plant site, with additional sporadic pockets occurring along the north-south rail line westerly to, and including, the easterly side of Jordan Cove Road; and English ivy, observed along the southern South Dunes Power Plant access road to Jordan Cove Road.

The LNG Terminal site has pockets of gorse scattered throughout the lower half of the fill area at the slip site, beginning approximately 150 feet north of the gravel access road along the Coos Bay shoreline and extending approximately 1,800 feet to the north. At the northern reach, the gorse appears to have spread in a southeasterly direction to the forested dune. Gorse is also present along the eastern edge of Henderson Marsh and along the forested dune tree line to the southern gate for the site. There are a few gorse plants at the South Dunes Power Plant site, with the majority located just south of the existing power substation. Gorse has been sprayed within the past year at the sites discussed above as part of an ongoing control program recently implemented. All visible gorse is dead.

**Construction Worker Camp**

The eastern portion of the construction worker camp site contains an infestation of Scotch broom, Himalayan blackberry, and European beachgrass. This area is an abandoned industrial site created on dredge spoils that was most recently utilized as a log deck. Noxious weeds are the dominant vegetation cover at this site. Immediately west is another former dredge spoils site separated by lowlands and tidal influence that has created a separate peninsula resembling an island. This site is covered with the singular dominant species European beachgrass. Both sites are adjacent to high quality estuarine marshlands that necessitate protection from herbicide applications for the control of noxious weeds.

### 3.1.3.3 State and Federal Action Plans

At the state level, the Oregon Invasive Species Council (OISC) was created by the Oregon legislature (ORS 561.685) to conduct a coordinated and comprehensive effort to keep invasive species out of Oregon and to eliminate, reduce, or mitigate the impacts of invasive species already established in Oregon. The council began official business on January 1, 2002. Four main functions identified by the statute for the council include: 1) creating and publicizing a system for reporting sightings of invasive species and referring those reports to the appropriate agencies, 2) undertaking educational activities to increase awareness of invasive species issues, 3) developing a statewide plan for dealing with invasive species, and 4) funding eradication and education projects.

The OISC Action Plan for 2012-2016 (Appendix H.3) includes the mission, vision, and core values of the council, as well as key strategic actions the OISC seeks to engage in during that period. The action plan is the result of a planning effort following a statewide invasive species summit in 2011 and the completion of a management assessment of invasive species in Oregon. Each year the OISC provides an updated list of the 100 most dangerous invaders to keep out of Oregon. The list is comprised or micro-organisms, aquatic plants, land plants, aquatic invertebrates, land invertebrates, and fish species.

At the federal level, the U.S. Department of Interior's Bureau of Land Management (BLM), Coos Bay District, oversees lands in the vicinity of the Project and has lists of noxious weeds of concern described in its various resource management plans, including its *Final North Spit Plan* (2006). The BLM objective for weeds is to contain and/or reduce noxious weed infestations with an integrated pest management approach (e.g., chemical, mechanical, manual, and/or biological) and to avoid introducing or spreading noxious weed infestations in any areas. This is outlined in the BLM's multi-state environmental impact statement *Northwest Area Noxious Weed Control Program* (1985) and its supplements.

### 3.1.4 Unique and Special Status Species

Special status native vegetation classifications used for this analysis are based on the Oregon Wetland Explorer At Risk Wetland Associations Database (ORBIC 2009) and the Classifications of Native Vegetation of Oregon (ORBIC 2004). Rare vegetation classifications include both state rank (S) and global rank (G) for ORBIC Natural Heritage Ranking and are given the following numerical codes:

1. Critically imperiled because of extreme rarity or because it is somehow especially vulnerable to extinction or extirpation (gone from a portion of its former range), typically with 5 or fewer occurrences.
2. Imperiled because of rarity or because other factors demonstrably make it very vulnerable to extinction or extirpation, typically with 6-20 occurrences.
3. Rare, uncommon, or threatened; but not immediately imperiled, typically with 21-100 occurrences.

Rare forest associations observed in the Project area include the shore pine-Douglas fir/wax myrtle-evergreen huckleberry (G3S3), shore pine-Sitka spruce/evergreen huckleberry (G3S3), and critically imperiled Port Orford cedar/evergreen huckleberry (G1S1). As previously noted, two Port Orford cedars are known to occur within the Project site that would be impacted. The Port Orford cedar/evergreen huckleberry forest association is sensitive because it is being decimated throughout its limited range by the POC root rot disease. In addition, the forested wetland (shore pine/slough sedge) east of Dune Forest C and the northern portion of Dune Forest B is considered rare/uncommon in ORBIC.

The shore pine/bearberry woodland association is sensitive due to its limited distribution, which is restricted to a thin band adjacent to the coastline, and the fact that it is easily damaged by human disturbances. Rare woodland associations include shore pine/bearberry (G1S1) and shore pine/hairy manzanita (G1S1). Both associations are found in limited distribution at sites associated with Dune Forest B where openings occur within the forest canopy. These associations were also observed in the Panhandle mitigation site, most notably at the interface between dune and forest habitats.

Rare herbaceous associations include red fescue-salt rush (G3S3) and American dunegrass (G1S1). Both of these rare associations were observed on significantly disturbed habitat associated with the dredge spoils fill site located east of the Henderson Marsh.

A list of the individual special status botanical species that have the potential to occur within forested, woodland, shrubland, and herbaceous associations referred to above is included in Table 3.1-2, including numerous lichen species. The list includes BLM special rankings and ORBIC state and global rankings. Federal and state-listed threatened or endangered species observed or with the potential to occur in or near the Project site are not included in the list, as they discussed in detail in Section 3.4.

### 3.1.5 Along the Waterway

Vegetative communities along the route of the LNG carriers are typical of the Coos Bay region for estuaries and shorelines. Vegetated areas within the Zones of Concern consist of forest, woodland, shrubland, and herbaceous plant associations with a component of wetland areas (salt and freshwater marshes). The most prominent vegetation within this area includes a mix of herbaceous sand dunes, shore pine forests, Sitka spruce forests, salt marshes, and freshwater marshes. Marine, estuarine, lacustrine, and palustrine wetlands occur along the LNG carrier transit route. The southeastern side of the bay is urbanized and native vegetation has been modified by residential and commercial developments.

### 3.1.6 Environmental Consequences (Construction and Operation)

The majority of vegetation that will be impacted by the Project is forested associations, with minor impacts to shrublands and herbaceous wetland associations. Direct impacts are expected to include removal of a portion of the overall habitat. The most substantial direct impact to botanical resources within the study area is a reduction in the quantity of plant species (including trees) that occur in the dune forests and adjacent areas impacted. In addition, the Project would result in impacts to natural resources within the intertidal and shallow subtidal zone of Coos Bay, and a small area of freshwater emergent wetland would also be impacted. These resources provide important ecological functions to the greater Coos Bay ecosystem. Table 3.1-3 includes details on the types and amount of vegetation that will be impacted by the Project, including the acreage volumes, per 18 CFR Part 380.12(e)(3).

The Project is not expected to have a long-term significant impact to vegetation resources, as the areas that will be graded and cleared for construction are relatively common and widespread throughout the North Spit and the Project vicinity. The Project footprint was selected on the basis of avoiding, to the extent practical, unique vegetation communities and higher value wetlands. Selection of temporary construction sites was purposely restricted to upland areas to avoid impacting wetlands.

The Project will affect approximately 1.74 acres of forested wetlands and approximately 35 acres of non-forested wetlands during construction and 1.73 acres of forested wetlands and 34.34 acres of non-forested wetlands during operation (Table 2.2-1 of Resource Report 2 – Water Use and Quality). This is the total wetland area of wetlands affected, both terrestrial and non-terrestrial, and includes those wetlands that will require mitigation as well as those that do not, as described further below. In addition to the total area of wetlands affected, totals are presented in Table 2.2-1 for affected terrestrial and non-terrestrial wetlands, and for terrestrial and non-terrestrial wetlands that will require mitigation.

The approximately 35 acres of non-forested wetlands affected by construction and approximately 34 acres affected by operation include 13.07 acres of intertidal and shallow subtidal, 15.24 acres of deep subtidal, and 2.49 acres of eelgrass affected by the slip and access channel and the construction dock. Acreage-based mitigation for impacts to the 15.24 acres of deep subtidal habitat by creating new deep subtidal habitat is not proposed. Dredging the access channel will deepen existing deep subtidal habitat. Also, new deep subtidal habitat will be created as a product of excavating the slip, but this is not viewed as mitigation.

Approximately 1.75 acres of wetlands F and G are associated with the waste treatment ponds remaining from the remedial action at the now demolished Weyerhaeuser linerboard mill. While these wetlands are considered jurisdictional under Section 404, mitigation for the 1.75 acres will not be required as the filling of these wetlands has been authorized in the ODEQ site closure plan.

The Project site also includes approximately 45.4 acres of land with 32.3 acres of delineated wetlands that will not be disturbed by the Project and will in fact be preserved as a result of the Project. Approximately 10.9 acres (Area E3 on Figure 1.2-1 in Resource Report 1 – General Project Description) of these 45.4 acres of preserved wetlands include Henderson Marsh and are included as part of the Project site property simply to provide sufficient property under the direct control of JCEP for the thermal radiation exclusion zones. The thermal radiation exclusion zone is a modeled indication of an area that could be affected in the highly unlikely event of an LNG spill or fire at the Project site. There are no thermal radiation or vapor effects from the Project that would have an adverse effect on the wetlands during the normal operation of the Project.

The liquefaction facilities and the access/utility corridor will affect approximately 2.58 acres of forested, scrub shrub, emergent and ponded wetlands during construction and approximately 1.51 acres during operation (as indicated in Table 2.2-1). The loss of these wetlands will be mitigated by the preservation and enhancement of areas owned by JCEP and located to the north of the Project site and the Trans-Pacific Parkway. This area is referred to as the Panhandle mitigation site and will be described in detail in the mitigation plan referenced below.

The loss of 9.69 acres of intertidal and 3.38 acres of shallow subtidal wetlands, due to the construction of the slip and access channel and the construction dock, will be mitigated by the restoration of wetlands at a former golf course. This area is now known as the Kentuck wetland mitigation site. The loss of approximately 2.49 acres of eelgrass will be mitigated at a proposed eelgrass mitigation site south of the west end of the Southwest Oregon Regional Airport. Alternative eelgrass mitigation sites are currently being evaluated, with one of those areas being in Jordan Cove.

Specific impacts to dune forests occurring at the Project site and the potential for root rot disease to occur in Port Orford cedar are discussed below.

#### 3.1.6.1 Dune Forests

Dune Forest A will be impacted with the construction of the access/utility corridor and the control building/plant warehouse/maintenance building. The majority of this dune forest will be unaffected by the development of the Project. Impacts will include the removal of 1.8 acres of shore pine-Sitka spruce/evergreen huckleberry forest, 0.3 acres of shore pine-douglas fir/wax myrtle-evergreen huckleberry, and 1.9 acres of Port Orford cedar/evergreen huckleberry, including two Port Orford cedars observed northwest of Jordan Lake.

Dune Forest B will be impacted by the development of the slip, LNG loading berth, liquefaction process area, LNG storage tank area, refrigerant storage area, flare area, and laydown area. Dune Forest B includes approximately 61.4 acres of shore pine/Sitka spruce/evergreen huckleberry forest.

Nearly half of Dune Forest C is located in the sand dune area (E2), which will be partially impacted by fill during construction. A total of 5.8 acres of shore pine-Douglas fir/wax myrtle-evergreen huckleberry forest is located in this area and has the potential to be impacted. Permanent impacts to the site are proposed to affect 6.3 acres of shore pine-Douglas fir/wax myrtle-evergreen huckleberry forest with the development of the laydown area.

The LNG Terminal site access and fill area will impact 3.4 acres of Dune Forest D, including shore pine-Douglas fir/wax myrtle-evergreen huckleberry forest.

Dune Forest E will be affected by the construction of the access/utility corridor and the ancillary Southern Oregon Regional Safety Center (SORSC) just east of Jordan Cove Road. The affected area includes 4.5 acres of shore pine-Douglas fir/wax myrtle-evergreen huckleberry forest and 0.6 acres of red alder/salmonberry/slough sedge-skunk cabbage forest.

#### 3.1.6.2 Port Orford Cedar

Spread of the POC root rot disease has the potential to occur at the Project site from contaminated equipment. Surveys for POC root rot disease were not conducted in the Project area, but based on what is known about the disease, it is likely to be present in the Coos Bay area, regardless of whether infected trees have been identified.

### 3.1.7 Mitigation, Enhancement, and Protection Measures

Site areas that are disturbed by construction of the Project will be stabilized by applying Best Management Practices (BMPs) for temporary sediment and erosion control measures until construction is complete, unless covered by equipment, gravel, or other covering. Site areas that are disturbed only by temporary construction activities (i.e., will not be permanently affected by a Project component) will be restored using non-invasive native plant species, to the extent practicable, to achieve stabilization of the sites and to prevent erosion of the areas disturbed.

Environmental monitoring would be conducted in all of the areas disturbed and would focus upon stabilization and prevention of erosion. This would be an ongoing activity on the Project site. In areas temporarily disturbed by construction, environmental monitoring will continue until a sufficient vegetative cover has become established. All construction activities and the operation of the facility will meet the requirements of JCEP's Upland Erosion Control, Revegetation, and Maintenance Plan (Plan) and JCEP's Wetland and Waterbody Construction and Mitigation Procedures (Procedures), including the implementation of Project-specific plans and procedures.

In addition, following the dredging activities to create the slip, all disturbed areas will be stabilized immediately with a dunegrass seed mixture compatible with Natural Resources Conservation Service (NRCS) criteria as being capable of surviving in highly permeable substrates in order to withstand seasonal soil moisture changes, loose sand, and burial and deflation from aeolian (wind) processes. Wind may erode, transport, and deposit materials, and particularly needs to be addressed in areas of the Project site with sparse vegetation and a large supply of unconsolidated sediments.

Native species will be used and if any non-native species are required for specific problem areas, species will be selected that will not become nuisance species to the surrounding areas. Should there be any areas disturbed by the excavated material haul truck road, the heavy equipment haul road, or the hydraulic slurry/decant water return pipelines that do not become part of the access and utility corridor for the LNG Terminal, they will be restored to pre-construction condition.

Impacts to wetlands will be mitigated through the implementation of an approved compensatory wetland mitigation plan. Compensatory mitigation is a method of offsetting adverse effects and is considered only after all measures to avoid and minimize impacts have been exhausted. A compensatory wetland mitigation plan has been prepared in accordance with the Oregon Department of State Lands administrative rules to address impacts to wetlands. It is provided as Appendix M.2 in Resource Report 2 – Water Use and Quality.

#### 3.1.7.1 Control of Exotic, Invasive Species

JCEP will implement treatments to remove exotic and noxious species. In addition, to avoid introducing or spreading noxious weeds or invasive species, JCEP will conduct a pre-construction survey of the Project site to identify noxious species listed by the ODA that persist despite recent and previous control efforts. Following the survey, JCEP will employ standard removal practices as approved by the BLM for the species identified on the Project site. Methods for removal that would not aid in the dispersal of these species will be used and will include the use of integrated BMPs such as fire, mechanical or manual removal, and herbicide application, as appropriate. Treated areas would be restored by spreading native seed and planting native plants. BMPs would also be implemented to prevent the further spread of noxious weeds.

JCEP will follow the BLM's existing policy and procedures for ongoing noxious weed control. Construction equipment that will be used off the Project site will be cleaned to prevent the export and spread of noxious weed species and seeds. JCEP will also use herbaceous and native dune seed mixes to limit germination of noxious weeds during the stabilization and restoration of the Project during and following construction. Once the overall Project site is stabilized and in operation, the site will be checked for noxious weed infestations and control measures will be implemented that are consistent with ODA, OISC, and BLM noxious weed control plans and policies, as applicable.

#### 3.1.7.2 Control of Diseases

JCEP will take precautions during the construction of the Project to minimize the introduction or spread of POC root rot disease from contaminated earth moving equipment. Surveys will be conducted prior to construction to identify whether the disease occurs on site and if so, measures will be taken to decontaminate equipment before leaving the site and to prevent cross contamination between soil and water. In addition, all equipment will be decontaminated before beginning work on the site. If the disease is found during pre-construction surveys, maps with precise locations will be provided to all contractors and site construction personnel to minimize and help prevent the spread of the disease to off-site locations. To ensure adequate conservation measures to address POC root rot disease are in place and implemented, JCEP will follow the BLM's existing policies and procedures.

## 3.2 WILDLIFE

A number of habitats exist on the Project site that support a variety of wildlife species as temporary or permanent residents. Approximately 178 tetrapod species (amphibians, reptiles, birds, and mammals) were recorded on or adjacent to the Project site during surveys conducted in October 2012 and during previous surveys from June to December 2005 and in early 2006 (Table 3.2-1). Terrestrial species include approximately 115 species. Approximately 151 seasonal or year-round resident bird species occur in the Project site area, and a variety of habitats suitable for migratory birds exists within the Project site boundaries. Also, as would be expected for the area, species utilizing aquatic habitats comprise the greatest occurrence by an individual species or by the number of individuals within a species. Species types and densities are directly related to season of year, preferred habitats, food resources, and protective cover.

The Project also includes compensatory mitigation sites outside of the Project footprint at Kentuck and the Panhandle for wetlands, wildlife, and estuarine habitat impacted by the Project. Although no degradation in the quality of the habitat at the mitigation sites is anticipated, they are included in this review to determine a baseline habitat.

Federal and state-listed threatened or endangered species observed or with the potential to occur in or near the Project vicinity are presented in this section and discussed in detail in Section 3.4.

### 3.2.1 Wildlife Habitat Characterizations

Characterizations of wildlife habitats potentially affected by construction of the Project were based on resource agency consultation, habitat surveys, and published reports, in accordance with the habitat categories described in the Oregon Department of Fish and Wildlife (ODFW) Fish and Wildlife Habitat Mitigation Policy (OAR 635-415-0025). The ODFW has established the following six classifications for habitats, based on dominant plant, soil, and water associations of value to the support and use of fish and wildlife:

Category 1 – irreplaceable, essential habitat

Category 2 - essential habitat

Category 3 - essential or important habitat

Category 4 - important habitat

Category 5 - habitat having a high potential to become essential or important habitat

Category 6 - habitat that has a low potential to become essential or important habitat

The ODFW habitat categories have been used to characterize wildlife habitats occurring on the Project site (Table 3.2-2). Habitat classifications for the Project site were qualified with ODFW personnel concurrence following field reconnaissance beginning in November 2006. Approved wildlife habitat categories were memorialized in November 2012 (DEA 2012). For the Project, Category 2 habitat occurs in open water, emergent wetland, forested/shrub wetland, and algae/mud/sand subtypes for surface water. The accepted ODFW wildlife habitat types and assigned categories for the Project site are shown in Figure 3.2-1 and summarized below. The Project does not have any Category 1 habitat.

#### 3.2.1.1 Upland Habitat

Upland wildlife habitat types found in the Project site are typical of the North Spit area of Coos Bay. Shore pine and Sitka spruce forests constitute the habitat with the greatest structural complexity on the North Spit and support the greatest diversity of wildlife species. The trees, snags, and down logs not found in other plant communities provide important breeding, foraging, and cover habitat for a variety of wildlife species. Upland amphibians seek cover in down logs, and many bird species (including raptors, woodpeckers, and songbirds) nest and forage in these habitats.

Emergent, shrub, and forested wetlands occurring in upland habitat are classified as Category 2 as essential wildlife habitat that is limited, but is replaceable through mitigation. Coastal dune forest and riparian forest habitats are classified as Category 3 because they are essential to wildlife but not limited. Although the unvegetated sand upland habitat formed by dunes is generally devoid of vegetation, it still provides important and essential, though not limited, habitat for a variety of wildlife and is therefore classified as important in Category 4. Upland grasslands and shrublands are also classified as Category 4.

#### 3.2.1.2 Open Water/Wetland Habitat

Open water habitats on the Project site and adjacent land are comprised of several freshwater lakes, ponds, and tidally influenced marshes on the terrestrial side of the shoreline. The marine open water environment consists of the Coos Bay estuary to the mouth of the bay, continuing westward into the open sea along the Pacific coast, and is discussed further in Section 3.3 for fisheries and marine resources. Habitats found in this environment support a rich wildlife community.

Herbaceous emergent wetland, scrub-shrub, and forested wetland habitat are all classified as Category 2 because they are essential for wildlife and limited, but can be replaced through mitigation. These habitats are used by various amphibians, birds, and invertebrates. The amount of cover and available prey or plant foods determine which species occur in these habitats. Black-tailed deer and rabbits occur throughout these communities, and songbird species feeding on plant seeds and insects take cover in the dense shrubbery. Mammalian predators such as skunks, foxes, coyotes, raccoons, mink, and bobcats prey on small mammals, birds, eggs, reptiles, and insects occurring in these habitats.

Flora and fauna usage of open water habitats occurring at the Project site (wetlands, estuarine, or marine) are generally specialized, or show strong preference for one habitat type over another. However, there are dozens of species associated with the Project area that are very well adapted to utilizing one, two, or all three of these open water habitats, as seasonal conditions warrant. Mudflats and sandflats found on the North Spit’s bay side are tidally-inundated and provide foraging habitat for a variety of birds and mammals. Resident and migrant shorebirds congregate there, especially during low tides, to forage on the invertebrates in the shallow waters and exposed mudflats. The concentration of shorebirds and wading birds in these habitats provide prey for bald eagles, northern harriers, and peregrine falcons. Ravens, gulls, raccoons, mink, and skunks forage in these areas for shellfish and invertebrates. The portion of the open water habitat that will be impacted by the construction and operation of the Project is classified as Category 2 because it is essential for wildlife, and limited, but can be replaced through mitigation.

#### 3.2.1.3 Developed Habitat

Developed areas include portions of the Project site that have been significantly disturbed by previous development and industrial use, including land use activities such as demolished mill foundations/concrete pad, roads, unvegetated cut slopes, rocked yards, and maintenance building footprints. This includes paved roads, parking lots, gravel roads, concrete lay down areas, log deck storage areas, and sandy roadside areas. They have limited potential to become important or essential in the foreseeable future and are therefore classified as Category 6.

#### 3.2.1.4 Regional Wildlife Management Areas

The North Spit Area of Critical Environmental Concern is approximately 5 miles southwest of the Project site and is administered by the BLM. No other federal wildlife refuges, state game, or wildlife management areas exist in the immediate Project vicinity. Marine reserves, wildlife refuges, and coastal management areas are discussed further in Section 3.3.

### 3.2.2 Existing Resources

The proposed Project site provides suitable habitat for a number of wildlife species associated with the coastal, mid-coastal, interior foothills, and mountain terrains that construction and operation of the proposed Project could affect. The majority of wildlife species detected on or adjacent to the Project site during the 2005/2006 and 2012 surveys were birds. Approximately 107 out of 151 bird species recorded were located within the Project area. Project areas surveyed and assessed in 2012 are shown in Figure 3.2-3.

#### 3.2.2.1 Amphibians and Reptiles

The BLM recognizes 11 species of amphibians (8 salamanders, 3 frogs) occurring on the North Spit (BLM 2005). Despite the presence and continual threat of invasion by non-native bullfrogs

(*Rana catesbeiana*), native amphibians were observed within suitable habitat during the wildlife surveys conducted in 2005 and 2006 for the LNG Terminal site. Northern red-legged frogs (*Rana aurora aurora*) and northwestern salamanders (*Ambystoma gracile*) are abundant within some wetlands within the Project site. It is likely that where bullfrog have not been introduced or invaded, native amphibians are present.

The BLM has observed at least 10 species of reptiles on the North Spit (BLM 2005), including the northwestern pond turtle (*Clemmys marmorata marmorata*). However, northwestern pond turtle was not observed during limited pre-construction wildlife surveys of the Project site area (LBJ 2006). Palustrine wetlands are relatively common on the North Spit so it is likely that a substantial amphibian and reptile assemblage exists. With the exception of sea turtles, amphibians and reptiles would likely occur in terrestrial habitats along the LNG carrier transit route.

#### 3.2.2.2 Birds

The Project is located in the statewide Pacific Flyway path for migratory birds. The Southern Oregon coast provides wintering and migratory habitat for birds and Coos Bay is one of a number of important areas for shorebirds between San Francisco Bay and British Columbia. Key areas for migrating shorebirds include the bay and shoreline, along with wetlands and deflation plains found throughout the North Spit. Coos Bay's extensive eelgrass beds, productive sloughs, intertidal algal flats, and substantial tidal marshes (1,726 acres) provide valuable habitat for thousands of shorebirds.

The BLM has documented 275 avian species using habitats on or near the North Spit of Coos Bay (BLM 2005). In addition, LBJ Enterprises (2006) documented 151 avian species during pre-construction surveys of the Project site, including two additional species not documented by the BLM. A mosaic of habitat types occurs within and near Coos Bay within the LNG carrier transit route zones. Some of the most important habitat types for birds include nearshore rocks and islands, beaches, dunes, coastal forests, and Palustrine and estuarine wetlands. The location of migratory bird habitat occurring within the zones of the LNG carrier transit route is shown in Figure 3.3-7, which also includes marine mammals.

Federal and state-listed threatened, endangered, or proposed species, including the brown pelican, bald eagle, short-tailed albatross, streaked horned lark, and western snowy plover are discussed in Section 3.4. Forests further inland from the Project provide habitat for the northern spotted owl and the marbled murrelet and these two species are also discussed in Section 3.4.

**Shorebirds**

Foraging habitat for shorebirds includes intertidal mudflats, rocky intertidal, estuaries, salt marshes, and beaches. Shorebirds are most often associated with exposed mudflats for foraging and salt marshes for resting and preening. The vast majority of shorebirds are migratory and non-breeders in Coos Bay. An important exception would be the western snowy plover (*Charadrius alexandrinus nivosus*), which nests on upper beaches on the North Spit of Coos Bay. Shorebirds are most likely to be encountered along the beaches of the North Spit and within the bay along tidal mudflats, salt marshes, and other exposed estuarine habitat in the 0.3 and 1.0 mile zones.

**Waterfowl**

Waterfowl habitat is as diverse as the birds themselves, varying from ocean surf to fields and open meadows to upland streams (USFWS 2007a). Coos Bay has long been recognized as an important migration and wintering waterfowl location. Waterfowl are most likely to be encountered within Coos Bay and the immediate nearshore habitat within the LNG carrier transit route zones.

**Passerines (Song Birds)**

Breeding and feeding habitat for migratory passerines is associated with terrestrial and wetland habitat within Coos Bay. Important habitat includes coastal scrub-shrub, coastal dune forest and Palustrine wetlands. In the case of swallows, human-made structures can be important structures for nesting colonies. Passerines are most likely encountered in suitable terrestrial habitats along the LNG carrier transit route 2.2 mile zone.

**Wading Birds**

Several wading bird species are residents within the Coos Bay area and the North Spit. Wading birds are typically colonial when nesting and therefore are sensitive to human disturbance. Wading birds hunt in a variety of habitat types from fields and meadows to Palustrine and estuarine wetlands. At least two historic great blue heron (*Ardea herodias*) rookeries occur within close proximity to the Project site LBJ 2006) and are discussed in Section 3.4.2 for unique and special status species. Recent field surveys have indicated that the rookeries are currently not occupied by species. Wading birds are most likely to be encountered along the LNG carrier transit route zone. A discussion of the current status of these historic rookeries is provided below.

**Birds of Prey**

Predatory birds are abundant year round residents in Coos Bay. The BLM has observed 14 species (BLM 2005), and surveys conducted by LBJ (2006) detected both peregrine falcons (*Falco peregrinus*) and bald eagles (*Haliaeetus leucocephalus*) near the Project area. Coos Bay and the North Spit provide a mosaic of habitat types with abundant prey for raptors. White-tailed kites (*Elanus leucurus*) were regularly observed during 2005 surveys, especially near Henderson Marsh. Osprey (*Pandion haliaetus*) are relatively common near river estuaries and bays and nest on human-made structures including the Roseburg Forest Products facility lights.

Predatory birds (i.e., hawks and owls) are most likely to be encountered within Coos Bay in terrestrial habitats. Osprey, falcons, and eagles may be encountered in nearshore habitats along the LNG carrier transit route. Falcons in particular are likely to be associated with salt marsh and tidal mudflats where shorebirds are likely to be abundant.

**Sea Birds**

Although the length of the Oregon coast is less than a quarter of the entire Washington, Oregon, and California coastline, over one-half of the nesting seabirds of this coastline are found along the Oregon coast (Oregon Ocean Resources Management Task Force 1991). Thirteen sea bird species breed along Oregon's coast, with offshore rocks and islands providing critical nesting habitat and important rest-over locations. Seabirds depend on relatively undisturbed coastal nesting habitats and on the rich coastal waters for food. Foraging habitat can differ by species; some species such as the sooty shearwater (*Puffinus griseus*) and the northern fulmar (*Fulmarus glacialis*) are found primarily along the mid and outer shelf, while California and western gull (*Larus californicus, L. occidentalis*) occur only in the nearshore (Oregon Ocean Resources Management Task Force 1991). Foraging sea birds can be encountered along the entire LNG carrier transit route in the 0.3 and 1.0 mile zones. Nearshore rocks and islands are of greatest importance to sea birds for nesting habitat.

**Migratory Bird Treat Act**

The Migratory Bird Treaty Act (MBTA) of 1918, as amended, provides federal protection for migratory birds, their nests, eggs, and body parts from harm, sale, or other injurious actions. The MBTA protects nearly all of the native species of birds. The only exceptions are introduced species, including English (house) sparrow, starlings, and rock dove (commonly known as park pigeons). There is no federal protection for upland game species (chuckar, pheasant, quail, and grouse), but most states protect these species. U.S. Fish and Wildlife Service (USFWS) permits are required to take, capture, relocate, or possess any of the protected species of birds or their parts, nests, or eggs. The MBTA includes a 'no take' provision and consultation with the USFWS is required if an action is determined to cause a potential take of migratory birds. The consultation determines measures to minimize or avoid these impacts.

Birds and nests are protected under MBTA, but habitat is not. Habitat is only protected when there is an active nest (a nest with chicks or eggs being tended by an adult). Empty/abandoned nests and nonviable eggs are not protected, but cannot be taken into possession without a permit during the nesting season. Outside of the nesting season, permits are not required to remove an empty or abandoned nest, or to remove or alter the structure the nest is built in or on. The MBTA policy excludes eagle nests and nest trees, which are protected under the Bald and Golden Eagle Protection Act, as amended in 1962, and threatened or endangered species, which are protected under the Endangered Species Act.

The USFWS advises that large clearing projects be conducted prior to March 1 or after August 31 to ensure most nesting birds have fledged. If construction activities occur during the nesting season, trees should be surveyed for the presence of any active nests. If there are none in the trees or the immediate area, and there are no active nests close enough for the activity of taking down trees to disturb the nesting birds, they can be removed without permits. If there should be a nest in one tree, the tree should be marked and activity limited around that area until the birds fledge, perhaps leaving that tree for the last of the project.

Unless the nests are in a location to pose a risk to human safety or the birds, there is no permit the USFWS can issue. Examples of human safety issues are permits issued to airports to protect air traffic and nests built on active power equipment which pose a fire hazard. There are no 'incidental take' permits under the MBTA. Any activity that involves habitat destruction during nesting season should proceed with caution.

### 3.2.2.3 Mammals

The BLM has documented 58 mammal species on the North Spit (BLM 2005). Pre-construction wildlife surveys conducted in the area of the Project site in 2005 and 2006 documented 16 mammal species (LBJ 2006). The Coos Bay area and North Spit provide a substantial amount of high quality habitat allowing for a diverse assemblage of mammals. For example, nine species of bats are known to occur on the North Spit (BLM 2005). While bat specific surveys were not completed during the pre-construction wildlife surveys, the mosaic of habitat types and abundant over-water foraging habitat present within the Coos Bay area suggest bat presence is high. The Pacific fisher (*Martes pennant pacificus*) and American marten (*Martes Americana*), as well as large mammals such as mountain lion (*Felis concolor*), Roosevelt elk (*Cervis elaphus roosevelti*), and black bear (*Ursus americanus*) have been documented on the North Spit (BLM 2005).

With the exception of pinnipeds (i.e., seals, sea lions) and unlikely but possible whale occurrences, all mammals encountered along the proposed LNG carrier transit route would be in terrestrial habitat types on the North Spit and the southwestern side of the bay. Bats may be encountered at any point along the proposed transit route within Coos Bay itself.

### 3.2.3 Wildlife Occurring in Project-Specific Sites

Wildlife that has the potential to occur in each major component of the Project is described below.

#### 3.2.3.1 Project Site

The natural habitat in the immediate area of the LNG Terminal has been altered by the historic use of this property, including the area east of Henderson Marsh (referred to as the Ingram Yard) that has been altered by the historical Henderson Ranch settlement and past placement of dredged material; the current Roseburg Forest Products wood chip export terminal; and the former Weyerhaeuser linerboard (paper) mill site (South Dunes Power Plant site). East of Ingram Yard, the Project site includes a dune forest where the majority of the site's natural habitats, as described in Section 3.1, remain unaltered by industrial activity. Structures located immediately adjacent to the Project site include two large buildings (Roseburg Forest Products Company north and south buildings), a few small outbuildings, and a substantial concrete lay down area east and south of the two buildings. Additionally, there are two large water tanks on the Project site within Dune Forest B along the ridgeline (see Figure 3.1-1). A dirt road provides access to the water tanks from the developed area.

East of Dune Forest B and north of the Roseburg Forest Products facility, the Project site includes an access/utility corridor that crosses along the northern boundary of the Roseburg Forest Products property and includes mature dune forests and an area of active dune. This corridor includes utilities supporting the disposal of industrial wastewater from the landfills located on the South Dunes Power Plant site. The South Dunes Power Plant site includes asphalt surfacing, gravel access roads, and previously disturbed grassland habitats. Immediately west, a mosaic of emergent and scrub-shrub wetlands interspersed in coastal dune forests occurs. This area also includes a portion of Jordan Cove Road. With the exception of the access/utility corridor, the entire Project site is bordered by the Trans-Pacific Parkway on the northern perimeter.

#### 3.2.3.2 Construction Worker Camp

The temporary construction worker camp site includes two distinct areas (eastern and western) intersected by North Point Slough. The eastern half of the site includes an abandoned industrial area that is the remains of a logging deck used to store logs until recently. The western half of the site includes a historical dredge spoils site. The highly disturbed eastern half has been filled and road prisms (gravel) have been built throughout the majority of the site. The former dredge spoils site on the western half lacks infrastructure and is occupied with an abundance of non-native weedy species, including dominant species European beachgrass and Scotch broom. High quality estuarine habitat was observed in the North Point Slough that intersects the site.

Wildlife habitat observed at the construction worker camp site includes foraging habitat for numerous species that can exist without tree cover. Breeding habitat is limited to species adapted to breeding in disturbed habitats that lack a significant tree cover. Wildlife observed (including sign) at the site include American robin (*Turdus migratorius)*, common raven (*Corvus corax*), western gull (*Larus occidentalis*), turkey vulture (*Cathartes aura*), and black-tailed deer (*Odocoileus hemionus*). Typical bird species that have potential to use the site include common species associated or adapted to disturbed habitat types, including but not limited to, common raven, American robin, foraging peregrine falcon, white-tailed kite (*Elanus leucurus*), American goldfinch (*Carduelis tristis)*, and western gull. Mammals likely to use the site include, but are not limited to, opossum (*Didelphis virginiana*), black-tailed deer, striped skunk (*Mephitis mephitis*), and raccoon (*Procyon lotor*).

### 3.2.3.3 Compensatory Mitigation Sites

The eelgrass mitigation site is discussed under Section 3.3 for fisheries and marine resources.

**Kentuck Wetland Mitigation Site**

Kentuck Slough has been identified as an estuarine and wetland mitigation site for the Project. This site includes a previously maintained golf course that closed down several years ago and is currently being used sporadically for cattle grazing. The area consists of former golf course infrastructure that includes roads, trails, fencing, and landscaping and is surrounded by semi-rural housing.

Wildlife species observed at the site include numerous wading, ground foraging, and aerial foraging species. The diversity in habitat types present (wetland, grassland, and patchy forest sites) makes this area ideal habitat for many local species. Species observed include American crow (*Corvus brachyrhynchos)*, barn swallow (*Hirundo rustica)*, great egret (*Ardea alba)*, mallard duck (*Anas platyrhynchos)*, marsh wren (*Cistothorus palustris)*, and song sparrow (*Melospiza molodia)*. Wildlife species with potential to use the site include numerous species, including common mammal species associated with rural residential areas such as black-tailed deer, black bear (*Ursus americanus*), striped skunk, and raccoon. Numerous bird species with potential to use the site for foraging include Canada goose, great egrets, waterfowl, shorebirds, wading birds, and many more. Potential nesting habitat for raptors and other breeding birds was observed in forest sites bordering Kentuck to the south and southwest, and includes potential nesting habitat for osprey, bald eagles, and red-shouldered hawks.

On any given morning or evening, numerous bird species can be observed foraging in the Kentuck Slough immediately west of East Bay Drive that separates the estuary from the site. It is not uncommon to see numerous great egrets, geese, ducks, smaller shorebirds, and occasional great blue herons in this area. The former golf course, with its grasslands still mowed and maintained, often sits empty in comparison. If opened up to expand the estuarine and subtidal area at the site, the now marginal Kentuck site inland has the potential to become an extremely productive site where even more amphibian, bird, and mammal species would seek its shelter and prime foraging and nesting habitat.

**Panhandle Mitigation Site**

The Panhandle is a proposed wildlife and wetland mitigation site for the Project and contains habitat types typical of deflation plains found throughout the North Spit. Habitats observed at the site include forest, shrubland, and herbaceous communities.

Wildlife species with potential to occur in the Panhandle include species that require or utilize forests, shrubland, open water, and/or sand dune habitats. This habitat is exceptional for amphibian species such as northern red-legged frogs and Northwestern salamander. Bird species expected to occur include waterfowl species such as wood duck (*Aix sponsa*), Eurasian wigeon (*Anas platyrhynchos*), herons and egrets such as great egret (*Ardea alba*), and great blue heron (*Ardea herodias*), as well as numerous song birds including brown creeper (*Certhia americana*), and marsh wren (*Cistothorus palustris*). This habitat has the potential to provide nesting and foraging habitat for raptor species such as Cooper's hawk (*Accipiter cooperii*) and sharp-shinned hawk (*Accipiter striatus*). Mammal species with the potential to occur in the

Panhandle mitigation area include black bear and American beaver (*Castor Canadensis*), to name a few.

### 3.2.4 Unique and Special Status Species

Special status wildlife species occurring in Coos County are listed in Table 3.2-3, along with their rankings for local, state, national, and global occurrences. In addition, Table 3.2-4 lists the potential for occurrence of these species at various sites for the Project, including general habitat requirements.

#### 3.2.4.1 Amphibians and Reptiles

**Clouded Salamander**

The clouded salamander (*Aneides ferreus*), known to occur on the North Spit and listed as state sensitive-vulnerable, was not found during site surveys, but the dune forests in the Project area could support this species.

**Northern Red-legged Frog**

The northern red-legged frog is a federal species of concern. Habitat for the northern red-legged frog includes the vicinity of permanent waters of marshes, ponds, and other quiet bodies of water. This frog regularly occurs in damp woods and meadows some distance from water, especially during wet weather. All age classes of this species were observed at the eastern edge of Henderson Marsh and high concentrations of northern red-legged frogs were observed in multiple freshwater wetland sites throughout the Project site (LBJ 2006, SHN 2012). American bullfrogs, a known predator of the northern red-legged frog, were observed during surveys in wetlands conducted in 2005-2006, but were not observed in 2012. Though not observed, this species is a long-lived and highly adaptive species that is an opportunistic predator of small animals, including other amphibians.

**Northwestern Pond Turtle**

The northwestern pond turtle is listed as a federal species of concern and state sensitive–critical. Even though this species was not found on the Project site, it is known to occur on the North Spit. Jordan Lake and other wetlands and adjacent dunes on the Project site seem to be suitable for this turtle, although the soil may be too sandy to allow turtles to nest.

**Western Toad**

This species (state sensitive–vulnerable) was not found on the Project site and is not listed by the BLM as occurring on the North Spit.

#### 3.2.4.2 Birds

Fifteen special status bird species were observed throughout the Project area during wildlife surveys conducted in 2005-2006 and in 2012 (Figure 3.2-4). Detections of special status birds during surveys include species of grebes, waterfowl, hawks, nightjars, pigeons, flycatchers, and swallows. Special status waterfowl and grebes observed in Coos Bay and associated wetland and grassland habitats include the following species: Clark's grebe (*Aechmophorus clarkia*) and western grebe (*Aechmophorus occidentalis*), observed at sites near the bay adjacent to the Project; Aleutian cackling goose (*Branta hutchinsii leucopareia*), federally delisted, observed foraging near the airport and flying over the Project site; bufflehead (*Bucephala albeola*), observed just offshore of the Project site; horned grebe (*Podiceps auritus*), common in Coos Bay and observed offshore near the Project site; and red-necked grebe (*Podiceps grisegena*), state critical, observed offshore near the Project site.

Special status hawk and nightjar were observed at several locations at or near the Project area and were recorded as flying over or foraging. They include the following species: common nighthawk (*Chordeiles minor*), a single occurrence observed as a fly-over at the Project site; American peregrine falcon (*Falco peregrinus anatum*), federally delisted and state vulnerable, observed foraging above the southwest edge of Henderson Marsh and at the Project site; and white-tailed kite (*Elanus leucurus*), observed over Henderson Marsh and the Jordan Cove area multiple times. In addition, the Arctic peregrine falcon (*Falco peregrinus tundrius*), state sensitive–vulnerable, is reported as a rare visitor to the Oregon Coast and Coos County.

Additional special status birds include pigeon, passerine, quail, and meadow lark. They include the following species: band-tailed pigeon (*Patagioenas fasciata*), federal species of concern, recorded once at the Project site; purple martin (*Progne subis*), federal species of concern and state critical, observed multiple times during the breeding season, with active nests within view of the Project site; olive-sided flycatcher (*Contopus cooperi*), federal species of concern and state vulnerable, recorded singing near the LNG Terminal site; little willow flycatcher (*Empidonax traillii brewsteri*), state vulnerable, recorded near the South Dunes Power Plant site, mountain quail (*Oreortyx pictus*), federal species of concern and state vulnerable, observed in Dune Forest B near the water tanks; and western meadowlark (Sturnella neglecta), state critical, observed once at the Project site.

Special status bird species that are considered likely to occur (moderate to high potential for occurrence) in the Project area but have not been detected include the following: upland sandpiper (*Bartramia longicauda*), federal species of concern and state critical; black oystercatcher (*Haematopus bachmani*), federal species of concern and state vulnerable; yellow-breasted chat (*Icteria virens*), federal species of concern and state critical; acorn woodpecker (*Melanerpes formicivorus*), federal species of concern and state vulnerable; Oregon vesper sparrow (*Peoecetes gramineus affinis*), federal species of concern and state critical; western bluebird (*Sialia mexicana*), state vulnerable; Arctic peregrine falcon (*Falco peregrines tundris*), BLM sensitive; bobolink (*Dolichonyx oryzivorus*), BLM sensitive; dusky Canada goose (*Branta canadensis occidentails*), BLM sensitive; pileated woodpecker (Dryocopus pileatus), state vulnerable; and trumpeter swan (*Cygnus buccinators*), BLM sensitive.

Special status bird species considered likely to occur (moderate to high potential for occurrence) along the waterway where vessels will be traveling include the following species: Cassin's auklet (*Ptychoramphus aleuticus*), state vulnerable; rhinoceros auklet (*Cerorhinca monocerata*), state vulnerable; and tufted puffin (*Fratercula cirrhata*), state vulnerable.

In addition to the unique and special status birds discussed above, the American peregrine falcon and great blue heron warrant additional analysis, as discussed below.

**American Peregrine Falcon (Federal Delisted and State Sensitive–Vulnerable)**

The American peregrine falcon nests widely in coastal and montane areas throughout Oregon, possibly including the Coos Bay area (Adamus et al 2001). Nesting has been confirmed in the Bandon area (Adamus et al. 2001). The BLM reported it to be an uncommon, year-round resident of the North Spit (USDI 2005), while observations by local birders and ODFW local wildlife biologists indicate that it is common on the North Spit. Its habitat is difficult to characterize, as it may occur virtually anywhere and is quite variable and adaptable in its nesting and feeding habits. The American peregrine falcon requires concentrations of prey such as shorebirds, starlings, pigeons, and small ducks; elevated perch sites; and for nesting, a relatively secluded ledge on a bridge or cliff (Henny and Pagel 2003).

Ample food and nest sites occur around Coos Bay, and the McCullough Bridge could be considered a potential nest site. The Project site area itself probably does not offer any suitable nest sites, but peregrine territories are large and the site is used regularly by many prey species. There were seven sightings of this species during field surveys, including several in the Project site, and no seasonality was apparent.

**Great Blue Heron**

There is a historic great blue heron (*Ardea herodias*) rookery approximately 300 feet from Jordan Cove Road near the beginning of the road, situated approximately 2,000 feet to the east of the LNG Terminal site. This rookery was visited on November 1, 2006, during a site visit with ODFW and BLM biologists and was found to be inactive, but it still contained some nests. At that time, the BLM biologist noted that it had been inactive the previous two breeding seasons. The location of the rookery is in an area that will not be affected by the construction of the Project; however, it would be subject to construction traffic noise. It is currently subject to truck and railroad car traffic delivering chips to the Roseburg Forest Products wood chip export facility. If it were to become active again, the nesting birds could be disturbed by the existing Roseburg Forest Products traffic, as well as construction traffic for the Project.

Another historic rookery is located adjacent to the Project site on the south side of Henderson Marsh. It has not been active for several years (BLM biologist, pers comm.). Great blue herons have been observed foraging at this site during pre-construction surveys in 2005/2006 and in 2012, although no evidence of breeding in the area has been observed.

Surveys for nests were conducted on April 11, 2013, to determine if historic rookeries are being utilized this breeding season. It was determined during the survey that the rookeries are not active at this time. No nests or nest building activities were observed, although numerous detections of the great blue herons were noted foraging along the tidal flats and flying north past Jordan Cove.

### 3.2.4.3 Mammals

Special status mammals that are considered likely to occur (moderate to high potential for occurrence) include terrestrial and arboreal rodents, bats, and weasel species, the majority of which are associated with mature forest sites with sources of water.

Special status rodents with the potential to occur in the Project area include white-footed vole (*Arborimus albipes*), federal species of concern, and red tree vole (*Arborimus longicudus*), federal species of concern and state vulnerable. White footed voles are associated with stands of alders generally found in riparian areas. Red tree voles occur in old-growth stands of Douglas fir and various other mesic forest sites (i.e., that require a moderate amount of moisture).

Special status bats include the following species: Townsend's western big-eared bat (*Corynorhinus townsendii townsendii*), federal species of concern and state critical; silver haired bat (*Lasionycteris noctivagans*), federal species of concern and state vulnerable; California myotis (*Myotis californicus*), state vulnerable; long-eared myotis bat (*Myotis evotis*), federal species of concern; and Yuma myotis bat (*Myotis yumanensis*), federal species of concern. Bats are generally associated with a variety of habitat types, including caves, forests, open grasslands, and water. Due to the prevalence of freshwater habitats and forests, it is likely that special status bat species exist at the Project site.

Special status weasels include the American marten (*Martes Americana*), state vulnerable, and fisher (*Martes pennanti*),candidate for federal listing and state as sensitive–critical. The American marten is associated with large tracks of mature forests and has a habitat range that overlaps that of fishers. Dune Forest B and the Panhandle are noted to contain potential American marten habitat. The fisher is discussed in further detail below.

**Fisher (Federal Candidate Species, State Sensitive-Critical)**

The fisher is a large weasel which inhabits forests with high canopy closure, large trees and snags, large woody debris, large hardwoods, and multiple canopy layers (USFWS 2004). Fishers are known to have very large home ranges and to wander widely. They avoid areas lacking overhead canopy cover and disturbance by humans. Fishers also occupy and reproduce in some managed forest landscapes and forest stands not classified as late-successional that provide some of the habitat elements important to the species.

The fisher was nearly extirpated from Oregon by logging and trapping and is now very rare. Reintroductions have been attempted in several inland counties and there have been recent sightings in the mountains east and west of the Willamette Valley (Csuti et al. 2001). The BLM Coos Bay District wildlife sightings database contains several fisher observations in Coos County. None of these sightings were in the vicinity of the North Spit. An adult was seen near Daniels Creek just below Wren Smith Creek (about 10 miles from the Project area) in 1991 (ORNHIC). The presence of the fisher on the North Spit is unlikely given the rarity of the species and the lack of large, well-connected tracts of mature forest with continuous canopies (BLM 2006). Most forested areas on the North Spit are interspersed with areas of open sand and research indicates that fishers are reluctant to cross openings greater than 25 meters (Powell and Zielinski 1994). Furthermore, fishers on the North Spit would be separated from Coast Range populations by Highway 101, human developments, and fragmentation of mature forest. It is uncertain the extent to which fishers can recover from extirpation given that their populations are isolated and their apparent inability to colonize unoccupied areas (Aubry and Lewis 2003).

Although the species is considered of potential occurrence on the North Spit (ODFW 2012 pers comm.), and porcupines, one of the fisher's preferred prey items, are present in the Project area, there are no records of its presence and no fisher was observed during focused Project surveys. Moderate habitat for this species was found in the forested hillside and riparian areas within the Project study area; however, it is assumed that there is too much disturbance and that the forest is too immature and fragmented for the site to be used by fishers.

### 3.2.5 Environmental Consequences (Construction and Operation)

The overall area affected by the construction of the Project encompasses a total of approximately 406.8 acres, including the 251.9 acres for the Project facilities, 64.0 acres for the non-jurisdictional facilities, and 90.9 acres of temporary construction areas (Table 1.2-1, Resource Report 1, General Project Description). An additional 45.4 acres of adjacent emergent and forested wetlands (including a portion of Henderson Marsh) will not be impacted and will be avoided and preserved. These avoided habitats do not require mitigation and are not considered further. Some wildlife currently inhabiting the upland habitats on the Project site will most likely be displaced or experience some direct mortality during construction. Several areas of the Project site will remain open and can be restored to higher value habitat by contouring, landscaping, and vegetation plantings typical of the coastal dune setting of the North Spit. Restored construction areas will be converted to ODFW Habitat Category 4. A summary of habitat lost and post-construction habitat categories is listed in Table 3.2-5 and shown in Figure 3.2-2.

Direct effects to animals in terrestrial habitats along the waterway for LNG carrier traffic could include direct mortality if they were not able to flee from a spill, or the loss and/or modification of habitat in the event of an accident. It is possible that an oil or fuel leak from the LNG carriers in transit to or from the LNG Terminal could affect either aquatic or terrestrial wildlife, with the level of intensity dependent on the scope and size of the spill. These potential environmental consequences are discussed further in Section 3.5.

### 3.2.5.1 Amphibians and Reptiles

Amphibians and reptiles, including special status species, are likely to be impacted by fill activity in 2.58 acres (LNG Terminal site, access/utility corridor, and construction worker camp) of low to mid quality wetlands impacted by fill activities. Removal of dune forest for the Project will reduce habitat for the clouded salamander, should this species occur in these areas. The sand dunes adjacent to Jordan Lake and other wetlands on the Project site will not be affected by the construction of the Project. Hence, the northwestern pond turtle should not be affected and no mitigation is proposed for this species. Jordan Lake and nearby wetlands on the east side of the Project site area may offer suitable breeding habitat for the western toad, although the species was not found on the Project site. None of these areas will be affected by the Project and no mitigation is proposed.

### 3.2.5.2 Birds

#### American Peregrine Falcon

Potential effects to American peregrine falcon populations will be minimal. The species may lose some foraging habitat with the removal of the tidal flat during slip construction, but the species is adaptable in its feeding habits. The Project site does not offer any suitable nest sites.

#### Sensitive Breeding Birds

Ospreys nest on one of the tall lights in the Roseburg Forest Products Company yard on the east side of the Project site area. This nest is in a highly disturbed area and the birds are habituated to a high level of disturbance. It is likely that Project construction activity will agitate the birds initially, but it is expected that they will become habituated to it as well.

The forested portions of the Project site area are suitable breeding habitat for the olive-sided flycatcher, a federal species of concern, and this bird was detected regularly in small numbers during summer surveys. Some suitable nesting habitat may be lost as a result of Project construction. Specific mitigation is not proposed for this species.

#### Wading Birds and Shorebirds

The impact of the construction of the slip and access channel on wetlands will be the permanent loss of approximately 9.69 acres of intertidal, 3.38 acres of shallow subtidal, and 2.49 acres of eelgrass. These are all habitat for wading birds and shorebirds. The loss of this habitat will be offset by the construction of in-kind mitigation (intertidal algal flats and intertidal unvegetated mud flats) proposed by the JCEP at the Kentuck estuarine and wetland mitigation site.

#### Migratory Bird Treaty Act

Nesting habitat for migratory birds occurs within areas that will be cleared for the Project. The Project would alter and disturb breeding and non-breeding habitat and could affect food fish populations. To a certain extent the Project has the potential to contribute to pollution levels or contamination of marine waters. Focused pre-construction surveys will allow JCEP to comply with the MBTA by ensuring that impacts to nesting birds are avoided. The loss of the approximately 9.69 acres of intertidal and 3.38 acres of shallow subtidal habitat may reduce the migratory bird feeding opportunities, although the mitigation of these losses at compensatory mitigation sites should minimize the losses and reduce the overall impact.

#### 3.2.5.3 Mammals

**American Marten**

The American marten (state sensitive–vulnerable) occurs in mature, closed-canopy forests and travels through openings if sufficient cover exists. Although unlikely, occasional dispersing individuals could wander into forested portions of the Project site. Thus, loss of dune forest for the Project could potentially reduce this species' habitat should this species occur in these areas. If potential occurrence is detected during pre-construction surveys, coordination with resource agencies and monitoring of American marten would be conducted, likely following the protocol developed by the U.S. Forest Service (USFS) for detecting carnivores (USDA 1995).

**Bats**

Specific bat surveys have not been conducted, but potentially suitable foraging habitat for many species occurs in the Project area, particularly around wetlands where insect prey is probably most numerous. Unidentified bats were observed in one of the buildings on the Roseburg Forest Products Company property on July 21, 2005. Breeding and roosting sites are likely very limited due to the existing high level of industrial activity and disturbance in the Project area, as well as the absence of more typical bat habitat such as cliffs, rock outcrops, bridges, caves, mines and large snags. Habitat for those species that nest under bark is available in the Project area.

**Fisher**

Potential adverse effects to fisher populations would be unlikely. There are no records of its occurrence on the North Spit, the site is separated by U.S. Highway 101 from inland forested habitat, there is too much disturbance from previous fill deposits and industrial use of the site, the forest is too immature and fragmented, and the species is too rare in the region for Project site use to be likely.

**Big Game**

Black bear and Roosevelt elk are fairly common on the North Spit and both have been sighted in the Project area. Black-tailed deer are also numerous in the Project area and use the site regularly. The development of the Project will reduce the amount of habitat for big game species and increased vehicle traffic during construction will increase the potential for collisions. However, due to the already disturbed nature of the Project site and existing industrial activities, it is not anticipated that the Project will have any significant adverse effects on these species.

### 3.2.6 Mitigation, Enhancement, and Protection Measures

Mitigation, enhancement, and protection measures for wildlife species that have been observed or are likely to utilize habitats in the Project area include specific measures, as defined below. These measures have been developed to avoid or limit potential impacts. As defined in the Fish and Wildlife Habitat Mitigation Policy (OAR 635-415-0010), the ODFW requires or recommends, depending upon the habitat protection and mitigation opportunities provided by specific statutes, mitigation for losses of fish and wildlife habitat resulting from development actions. Pursuant to the Fish and Wildlife Habitat Mitigation Policy, the Project will provide mitigation for lost fish and wildlife habitat by developing compensatory mitigation plans, including the Kentuck and Panhandle mitigation sites for wildlife species. Wildlife mitigation will be carried out at ratios agreed upon with the ODFW.

#### 3.2.6.1 Amphibians and Reptiles

The mitigation measures below will be implemented for construction and vegetation removal activities that may impact freshwater wetlands, including ponds, ditches, and other freshwater habitats that provide habitat for these species.

1. Suitable habitat that will be impacted by construction activities has been identified for further pre-construction surveys. A qualified biologist will survey the Project site 30 days prior to construction activities to determine if the northern Pacific pond turtle, northern red-legged frog, or the clouded salamander are in or near the action area and could be impacted by construction activities. Surveys will be in accordance with current species protocols. Areas that do not contain suitable habitat for these species will be released for construction without additional requirements.
2. The JCEP and ODFW will consult regarding the location of freshwater habitats for the relocation of amphibians or reptiles discovered during pre-construction surveys at the Project site. These habitats will provide areas for species relocation outside of construction areas where habitats are either being removed, modified, or managed for Project needs. Areas identified will be mapped and agreed to prior to construction.
3. Immediately prior to construction (within 4 hours) in areas identified as potential habitat, a qualified biologist will conduct surveys for the northern Pacific pond turtle, northern red-legged frog, and the clouded salamander. Species that are found during the survey will be captured and transported to suitable habitats outside of the construction areas, as pre-determined in consultation with the ODFW. Appropriate authorizations for capture and collection will be secured by the biologist prior to pre-construction surveys.

#### 3.2.6.2 Birds

To ensure compliance with the MBTA, clearing of Project area and any activity that involves habitat destruction, including staging and grading areas, if the construction schedule allows, will be conducted prior to March 1 or after August 31 to ensure most nesting birds have fledged. If construction activities must occur during the nesting season, JCEP will conduct focused pre-construction surveys to determine if there are active migratory bird nests present to ensure that impacts to nesting birds are avoided. The surveys will be conducted within the construction limits and within 100 feet (200 feet for raptors) of the construction limits. If active nests are encountered within the limits of the survey, construction and vegetation removal activities will be halted in the immediate vicinity until a qualified biologist has determined that the individuals have fledged from the nest (evacuated). JCEP will coordinate with the USFWS prior to proceeding with construction and any consultation exchange with the USFWS will be provided to FERC.

For construction activities during the nesting season, if no active nest is encountered within the limits of the survey, construction and vegetation removal will proceed with caution with an eye out for active bird nests. Empty or abandoned nests will not be taken into possession without a permit. During the non-nesting season, permits are not required to remove an empty or abandoned nest, or to remove or alter the structure the nest is built in or on.

Structures associated with the proposed Project would be monitored to discourage use by avian predator species. Frequent inspections would ensure that nests are not being constructed and all nests found would be removed immediately. It is anticipated that there would be sufficient inspections and other activities mandated by safety and security requirements to keep the structures nest free. However, in the unlikely event that a nest becomes established and it is not discovered until young birds are present, the disposition of the nest would be handled in accordance with the provisions of the MBTA.

LNG carriers along the transit route could affect migratory birds should an LNG spill occur while birds are flying directly through the spill area if the birds come in direct contact with either the unignited or ignited spill, or should an ignited spill affect the habitat of the migratory birds. In order for an unignited spill to affect a bird species flying through the vapor cloud, the bird would have to be flying at a level close to the spill where the vapor concentrations would be high enough to cause asphyxiation. This is unlikely unless the spill occurs in the route to the habitat to which the bird was descending and no other habitat was available. Given the amount of migratory bird habitat along the LNG carrier transit route, this would be an unlikely scenario. If the spill was ignited, it is likely that the birds would avoid the heat and smoke of the fire. The way that an effect could occur is if the vapor cloud ignited at the exact same time that the bird flew through it. The probability of this occurring is extremely remote.

If the release of LNG near a migratory bird habitat was in the presence of an ignition source, the resulting fire could injure the habitat within the 0.3 mile zone depending on the time of the year and conditions existing at the time of the fire. Heat from such a fire would have less of an effect on habitat vegetation within the 1.0 mile zone, and no effect from a pool fire is anticipated on wetland vegetation in the 2.2 mile zone. Even if vegetation is impacted by the fire, root structures would remain and allow the plants to become re-established.

The maximum flammable range for a vapor cloud could extend to the outer limits of the 2.2 mile zone and if an ignition source were present, the resulting fire could burn back to the source of the spill, directly injuring any habitat in the path. Again, this could result in injury to parts of the habitat plants, but would not result in long term damage to the plant or the plant community. The probability of these scenarios occurring is low given the marine transit safety and security measures employed and the unlikelihood of a spill of LNG cargo due to collisions and potential terrorist attacks.

**Great Blue Heron Rookery**

Ongoing surveys of the two (currently abandoned) great blue heron rookery sites near the Project site would be conducted prior to construction. Although both rookeries have been documented to be abandoned, reuse by this species can occur. Pre-construction surveys will be conducted during seasonally appropriate nesting periods. If coordination with the ODFW and BLM determines that these agencies are conducting rookery surveys, JCEP may suspend surveys and use the results of these agency surveys. In the event that a rookery becomes active, JCEP, in consultation with ODFW biologists, will develop an appropriate mitigation plan depending on the status of construction and the potential for indirect effects. No mitigation for potential impacts will be required as long as the rookery is inactive.

### 3.2.6.3 Mammals

Relocation of mammals ranging from small to big game species will occur as these species typically relocate from sites impacted by construction. To avoid inadvertent return of these species to the construction site, vegetation clearing will occur in a progressive manner, to encourage species to move out of the Project site to more natural lands managed by the USFS. As areas of the Project site are cleared, fencing will be installed to discourage foraging activities back onto the construction site.

#### 3.2.6.4 ODFW Wildlife Habitat

On the basis of the Oregon Administrative Rules habitat categorization scheme (OAR 635-415-0025), ODFW Fish and Wildlife Habitat Mitigation Policy (OAR 635-415-0000), and coordination with the ODFW, habitat values lost to the construction of the Project will be replaced in-kind. Replacement of the lost habitat will include the following;

- Approximately 2.49 acres of eelgrass (Habitat Category 2) will be replaced by constructing eelgrass across the bay south of the runway for the Southwest Oregon Regional Airport.
- Approximately 13.9 acres of estuarine resources (Habitat Category 2), including intertidal unvegetated sand, shallow intertidal and algal/mud/sand flats, will be mitigated by the construction of mud flat estuarine wetlands in the Kentuck wetland mitigation site.
- Approximately 2.4 acres of additional Habitat Category 2 impacted by the construction of the Project will be mitigated in accordance with Oregon Division of State Lands Wetland Mitigation requirements (OAR Division 85 and Division 90) on neighboring North Spit property owned by JCEP.
- The loss of approximately 80.8 acres of terrestrial habitat (predominately coastal dune and riparian forests) classified as Habitat Category 3 will be mitigated by in-kind habitat replacement on neighboring North Spit property. Neighboring property to be used for in-kind replacement for lost habitat will be valued in accordance with OAR 635-415-0025 as agreed upon by consultation with the ODFW.
- The loss of approximately 62.9 acres of terrestrial habitat (Habitat Category 4; predominantly grassland, shrub, herbaceous, and herbaceous shrub upland) will be mitigated by in-kind or better habitat replacement on neighboring North Spit property. Neighboring property to be used for in-kind replacement of lost habitat will be valued in accordance with OAR 635-415-0025 as agreed upon by consultation with the ODFW.

## 3.3 FISHERIES AND MARINE RESOURCES

The Coos Bay estuary is the second largest estuary in Oregon and covers approximately 54 square miles of open channels and periodically inundated tidal flats. It ranges from a mile to a mile and a half wide by 15 miles long and has approximately 30 tributaries. The major tributary flowing into Coos Bay is the Coos River. Coos Bay and its connecting waterways provide foraging, migratory, spawning, and juvenile nursery habitat to numerous species of fish and invertebrates. This area also contains important crab, clam and salmon resources, as well as marine fish such as flatfish and rockfish. It is a major migration corridor for salmon and steelhead that spawn and rear in the Coos River systems.

The fish community consists of species that are adapted to salinity fluctuations characteristic of the Coos Bay estuary, with the number of species increasing down river through the estuary towards the ocean. Some estuarine fish such as kelp greenling and starry flounder spend their entire lives within the estuary, whereas other species are seasonal. Anadromous fish species occurring in the Project area include Chinook salmon, coho salmon, chum salmon, steelhead, and coastal cutthroat trout. Anadromous salmon are generally transitory, passing through the bay in the fall as adults to Coos River, while juveniles primarily outmigrate in the spring and summer. Other seasonal inhabitants include white and green sturgeon, American shad, Pacific lamprey, surfperch, lingcod, rock greenling, sculpin, surf smelt, Pacific herring, English sole, eulachon, longfin smelt, Pacific tomcod, sand sole, and topsmelt. In addition, clams, crabs, oysters, and shrimp make up important invertebrate components of the bay. Table 3.3-1 provides a list of commonly occurring fish and invertebrate species in Coos Bay.

Historically, dredged materials have been deposited in Coos Bay in the bay, marshes, and flats to provide fill for development or to store it outside of the navigational channels. Major historical alterations of Coos Bay include dredging and in-bay spoil disposal located at approximate CM 3.0, between CM 4.0 and 5.0, below CM 6.0, and between CM 8.0 and 9.0. Jefferts (1977) reported that dredging has a relatively minor influence on the fauna of the lower reaches of the estuary, which primarily consists of coarse sediment type. The marine habitats affected by the construction of the slip and access channel and the construction dock will be approximately 9.69 acres of intertidal, 3.38 acres of shallow subtidal, 15.24 acres of deep subtidal, and 2.49 acres of eelgrass.

Along the western shore of the bay from CM 6.0 to CM 8.0 (including Jordan Cove) the narrow sandy shore drops off quickly into the subtidal zone and the deeper navigational channel. Ebb and flow currents through the deeper portion of the bay are swift and scour the shores so that attached vegetation is absent. Five pile dikes have been installed along the shore to retard erosion (USACE 1973). This area is an important feeding area for English sole, topsmelt, surfsmelt, herring, anchovy, coho salmon, and Chinook salmon. Fish feed on material in the water column from adjacent productive areas. Closer to shore, herring spawn at the Roseburg Forest Products Co. dock and on eelgrass beds in Jordan Cove. In addition, west of the railroad bridge at Jordan Point is a sandy area where the ODFW seines and samples large numbers of fish.

A total of over 14,000 acres of habitat is present in Coos Bay, including some 1,500 acres of eelgrass beds, an important habitat component for major estuarine resources. The flat inner portions of the bay are used by most species found in the bay. These regions are where most eelgrass beds are found.

Eelgrass habitats are common in the lower bay subsystem. These submerged aquatic vegetation (SAV) areas appear to exhibit great species diversity and are preferred by many aquatic species. Most fish species within Coos Bay utilize the flats of the lower bay at some time during the year, where a majority of the eelgrass beds exist. Color infrared aerial photographs taken near the Project site area reveal a narrow band of sparsely populated SAV near the low tide line and partially submerged along the beach west of the Roseburg dock. Field surveys indicated that approximately 9.69 acres of intertidal, 3.38 acres of shallow subtidal, 15.24 acres of deep subtidal, and 2.49 acres of eelgrass occur at the slip and access channel and the construction dock site (Figure 3.3-1). It is recognized that eelgrass is an annual aquatic plant and production can vary widely from year to year. However, the aerial photography and field verification provides an indication of the extent of the eelgrass within the Project area.

Salinity and other water quality characteristics vary with proximity to the estuary mouth and with the volume of freshwater entering sloughs. In general, the lower bay (below CM 9.0) is dominated by higher salinity from ocean water while the upper bay water is affected by freshwater influx that varies seasonally. Tidal flux constantly changes the salinity of the water in the channel. South Slough, at CM 1.3, is relatively saline whereas Catching Slough at approximate CM 15.5 is brackish with a much lower salinity. The abundance of fish in the lower bay increases in the summer due to higher salinity.

The Fish and Wildlife Coordination Act (FWCA) was enacted to protect fish and wildlife when federal actions result in the control or modification of a natural stream or body of water. JCEP consulted with the ODFW, USFWS, and NMFS regarding potential impacts to fish and wildlife as part of the overall state and federal permitting and authorization process for the Project.

The Oregon Parks and Recreation Department (OPRD) has statutory authority for managing Oregon's ocean shore, which includes public beaches and other intertidal areas along the entire coast. The ocean shore is defined as the land lying between extreme low tide of the Pacific Ocean and the statutory vegetation line or the line of established upland shore vegetation, whichever is farther inland (ORS 390.605). The ocean shore does not include estuaries.

### 3.3.1 Existing Habitat

#### 3.3.1.1 Coos Bay Estuarine Habitat

Much of the Coos Bay shoreline and subtidal habitat consists of unvegetated mud and sand, mixed with areas of various algae species. Algae/mud/sand flat habitat is inundated with water more frequently and for a longer duration than intertidal unvegetated sand habitat and is therefore more likely to support aquatic organisms. Clam and/or burrowing shrimp holes occur within this habitat, with varied abundance and diversity. The habitat is classified as Category 2 by the ODFW because it is essential for fish and marine species, and limited, but can be replaced through mitigation. Based on conversations with ODFW personnel, habitat at the site is limited due to its location within the Coos Bay ecosystem.

Many of the managed groundfish species occur in estuarine waters and are included under Essential Fish Habitat. Juvenile and adult life stages of cabezon can be found in shallow water bays and estuarine areas. All life stages of kelp greenling and starry flounder are found in estuarine areas. Several species of rockfish occur in estuarine areas during their juvenile and adult life stages. These include black, brown, copper, and quillback rockfish that are usually found near kelp beds off the coast in later stages. Other groundfish species that may be found in estuarine and coastal areas include Pacific cod, Pacific whiting, sablefish, bocaccio, English sole, Pacific sand dab, and rex sole which utilize nearshore nursery areas.

Salt marshes exist on the transition zone between the land and the sea in protected low-energy areas such as estuaries, lagoons, bays, and river mouths. Marsh ecosystems, like all wetlands, are a function of hydrology, soil, and biota. Tidal cycles allow salty and brackish water to inundate and drain the salt marsh, circulating organic and inorganic nutrients throughout the marsh. Water is also the medium in which most organisms live. The marshes are strongly influenced by tidal flushing and stream flow, which affect the inundation and salinity regimes of salt marsh soils. In areas with enough runoff, salt marshes transition into brackish and freshwater marshes.

Sand- and mudflats occur at extreme low water, whereas salt marsh vegetation develops where soils are more exposed to the air than inundated by tides, usually above mean sea level. Sedges, salt grasses, beach grasses, and eelgrasses dominate the shallow intertidal and subtidal habitats. Salt marshes are of paramount ecological importance because they 1) export vital nutrients to adjacent waters; 2) improve water quality through the removal and recycling of inorganic nutrients; 3) absorb wave energy from storms and act as a water reservoir to reduce damage further inland; and 4) serve an important role in nitrogen and sulfur cycling (Mitsch and Gosselink 1993, Thayer et al. 1981).

Marshes and sloughs in Coos Bay provide rearing habitat for coho salmon and brackish-water estuarine areas may also be used by juvenile coho. The Coos estuary is estimated to contain less than 10 percent of its original salt marsh habitat, due to filling, dredging, and other development. Significant portions of the salt marshes remaining are in the South Slough National Estuarine Research Reserve, a 5,000 acre natural area near Charleston, which has approximately 550 acres of intertidal habitat and contains large expanses of eelgrass beds alongside its meandering, shallow channels, providing essential habitat for many fish and shellfish species, including Dungeness crab.

The LNG carrier transit route zones within Coos Bay overlap South Slough, Pony Slough, and North Slough/Haynes Inlet. Slough habitat varies depending on the location and amount of freshwater inputs. For example, salinity and other characteristics vary with proximity to the estuary mouth and the volume of freshwater entering sloughs. In general, sloughs provide habitat for a number of estuarine fishes, commercial shellfish, and invertebrates, many of which are important food sources for salmonids. Many marshes bordering sloughs have been diked, restricting tidal flush and flow of nutrient-rich organic material into the estuary.

South Slough enters the main channel of Coos Bay less than two miles from the estuary mouth and has a high shoreline to surface area ratio resulting in diverse habitats. The upper reaches of South Slough have been set aside as a research sanctuary. Because of its proximity to the ocean, it receives more marine influence than the other slough subsystems and its north-south orientation makes it susceptible to strong north-northwest winds. South Slough is an area of sediment deposition. The marine influence, coarse sediments, and relatively undisturbed nature of the upper portion provide habitat for more species of invertebrates and fish than are found in other slough subsystems in Coos Bay. Commercial oyster culture is a major commercial use in South Slough.

Pony Slough, across the bay from Jordan Cove (near CM 9), has subtidal areas with unconsolidated bottoms, intertidal mud flats, sand-mud flats, eelgrass beds, algal beds and marshes. Eelgrass is distributed along the intertidal areas near the slough entrance and through part of the main channel. Mud flats are populated by burrowing mudflat organisms including *Corophium spinicorn,* an important amphipod in the diet of juvenile salmonids. Tide flat users harvest soft shell clams and ghost shrimp.

The North Slough subsystem extends approximately three miles north from the main body of Coos Bay at CM 9, near Jordan Cove. The Trans-Pacific Parkway separates the slough from full exposure to the main bay, and the diked system reduces tidal circulation. Water quality sampling has shown high temperatures, high coliform counts, and excessive turbidity. Low summer stream flows, incomplete mixing, livestock, log storage, and waste are thought to contribute to degraded water quality. Ghost shrimp, lugworms, American shad, shiner perch, staghorn sculpin, and starry flounder have been documented in the slough (Cummings and Schwartz 1971). Coho salmon spawn in North Creek, a tributary to the North Slough.

Eelgrass habitats are common in the lower bay subsystem and they appear to exhibit great species diversity and are preferred by many aquatic species. Previous studies (Akins and Jefferson 1973) reported that Coos Bay has 1,400 acres of lower intertidal and shallow subtidal tide flats covered by eelgrass meadows. In 1979, the ODFW conducted habitat mapping in Coos Bay and documented intertidal and subtidal aquatic beds, including documentation of SAV in Jordan Cove and across the bay from the proposed LNG Terminal in and near the mouth of Pony Slough. The largest and most contiguous beds of submerged grasses are located in both the lower and upper bay, in the North and South Sloughs, and in Haynes Inlet. Eelgrass in

Pony Slough is distributed along the intertidal areas near the slough entrance and through part of the main channel. In the fall and winter, as much as 75 percent of the eelgrass blades die back and decompose, supplying estuarine food webs with essential nutrients. In spring and summer, eelgrass beds sprout and grow, renewing the annual cycle of production.

Submerged grass meadows provide cover and food for a large number of organisms including burrowing, bottom-dwelling invertebrates; diatoms and algae; herring that deposit egg clusters on leaves; tiny crustaceans and fish that hide and feed among the blades; and larger fish, crabs, and wading birds that forage in the meadows at various tides. Eelgrass in Coos Bay provides shelter for a variety of fish and may lower predation, allowing more opportunity for foraging. The protective structure attribute of eelgrass is primarily for smaller organisms and juvenile life history stages of fishes. Orth et al. (1984) reported that shoot density, patchiness, leaf area, leaf morphology, along with the thickness, structure, and proximity of the rhizome layer to the sediment surface are the primary characteristics that affect predation rates. Structural complexity is related to fish abundance and species richness. Fish diversity and eelgrass biomass were also significantly correlated in surveys conducted in Craig, Alaska (Murphy et al. 2000).

Field surveys of the Project site conducted in September 2006 verified the extent and species composition of SAV previously identified from aerial photography as occurring in the area of the slip and access channel and construction dock. The narrow strip of SAV was found to be comprised of eelgrass (*Zostera marina*) and algae. It is recognized that eelgrass is an annual aquatic plant and production can vary widely from year to year. However, the aerial photography and field verification provides an indication of the areal extent.

#### 3.3.1.2 Along the LNG Marine Transit Route

Oregon, along with nearly every other coastal state, has jurisdiction over the seabed and its resources out to three geographical (or nautical) miles. First proposed in 1793 by then-Secretary of State Thomas Jefferson as a "temporary" seaward boundary for the United States, state jurisdiction over the "territorial sea" was finally established by Congress in the 1953 Submerged Lands Act (43 USC 1301-1315). Where offshore islands occur within the three miles, the Territorial Sea extends another three miles beyond. The Oregon Territorial Sea is 950 square nautical miles. In 1991, the Oregon Legislature required that the Territorial Sea also include the ocean shore, which is defined in state law (ORS 390.605) as the land lying between extreme low tide of the Pacific Ocean and the line of vegetation (also known as the beach zone line).

**Riparian Zones and Streams**

The LNG carrier transit route zones within Coos Bay overlap tributaries and riparian zones draining into Coos Bay. An abundance of streams drain into Coos Bay from mixed-conifer forests and developed areas. Chinook and coho salmon spawn in freshwater tributaries of Coos Bay in select areas such as pool tailouts, runs, and riffles during the fall or winter (Vronskiy 1972, Burger et al. 1985, Healey 1991). Riparian zones are typically lined with red alder, willows, and ferns. The transit route zones within Coos Bay overlap multiple small freshwater tributaries flowing into South Slough within lower Coos Bay including Hayward Creek, Day Creek, Elliot Creek, and Joe Ney Creek. In addition, lower Pony Creek is within the transit route zones that reach into the upper bay. Miner Creek and Big Creek are within the LNG carrier transit route zones along the coast, and drain directly into the Pacific Ocean near Gregory Point just north of Sunset Bay.

**Shoreline Habitat**

Sandy beaches are transitional areas between subtidal soft sediments and the terrestrial dunes or sedimentary bluffs. Ecotypes include high intertidal and mid to low intertidal areas. Fauna of sandy beach habitat are transitory and move up and down with the tides. Fish use these areas for foraging and invertebrates burrow in sand during periods of exposure. Fish utilizing submerged sandy beach habitat include surf smelt, English sole, night smelt, roughback sculpin, Pacific sand lance, and Pacific staghorn sculpin. Species utilizing the mid to low intertidal zones along sandy beaches include Dungeness and red rock crab, various species of clams, Pacific sand lance, surfperch, night smelt, and bay rays.

The shoreline in the vicinity of Coos Bay is dominated by geological features distinctive of the Klamath Mountain metamorphic province, as well as rocky shores of uplifted and tilted marine sediments. Rocky shore habitat exists south of Coos Bay, including diverse intertidal habitat, shore-associated reefs, offshore reefs, offshore rocks, and islands. Cape Arago and Gregory Point research reserves provide coastal intertidal and kelp forest habitats. The coastline just north of Coos Bay is sandy beach habitat. Nearshore environments vary from low-energy sheltered environments to more exposed coastline, subjected to high-energy wave and tidal action. Numerous groundfish species, salmon, and a number of coastal pelagic species are found in nearshore habitat. These include juvenile and adult life stages of Pacific mackerel, which occur off sandy beaches. In open bays, eggs and paralarvae of market squid are found in shallow, semi-protected nearshore areas (PFMC 1998a).

The transit route also overlaps soft bottom subtidal areas off of Coos Bay, which have primarily sandy substrates. Communities are dominated by burrowing invertebrates such as worms with shrimp, crabs, snails, bivalves, sea cucumbers, and sand dollars living on the sediment surface. Common fish include flatfish, sand lance, and burrowing sandfish.

**Rocky Shore Habitat**

The LNG carrier transit route zones overlap rocky shore habitat south of the entrance to Coos Bay. Rocky shore habitat includes all hard substrate areas along the shoreline that are alternately exposed and covered by the tides. Rocky shores contain the following ecotypes: high intertidal, mid-intertidal, low intertidal, and intertidal artificial substrates (jetties, etc.). The physical characteristics of nearshore rocky reefs reflect local shoreline geology, exposure, and currents as well as biological influences. South of Coos Bay, the coastal geology produces the complex of cliffs, reefs, and rocks of Cape Arago, which are tilted layers of sedimentary rocks. The physical environment of intertidal areas changes dramatically as the tide rises and falls, and habitat is either covered by salt water or exposed to air and the sun. Rocky intertidal habitats have an abundant and diverse biological community, including algae and other marine plants (surfgrass), attached and mobile invertebrates (sponges, anemones, barnacles, bryozoans, tunicates, mussels, crabs, snails, sea stars, urchins, brittle stars, nudibranchs, chitons, worms), fish (sculpins, gunnels, pricklebacks), marine mammals, and sea birds. Rocky shore habitat fish species include cabezon, black rockfish, and other species of rockfish.

**Rocky Reef Habitat**

The ODFW has studied a modest number of reefs along the Oregon coast. Many species are principally associated with rocky reefs and these areas are a focal point for commercial and recreational fishing. The LNG carrier transit route zones overlap portions of submerged rocky reef habitat south and north of Coos Bay, including nearshore rocky reefs near Cape Arago and deeper subtidal reefs offshore of this area, as well as a subtidal rocky reef north of Coos Bay.

Rocky subtidal habitat includes all hard substrate areas that are never exposed at low tide, including reefs, rocky reefs, rocky banks, pinnacles, and hard bottoms. Ecotypes include shallow rocky reefs with kelp beds, shallow rocky reefs without kelp beds, deep rocky reefs, and subtidal artificial substrates. Subtidal rocky reefs have a variety of microhabitats and an abundant and diverse biological community. Species utilizing shallow rocky reefs include numerous species of rockfish, greenling, sculpin, gunnel, flounder, perch, and smelt. Invertebrates include mussels, crabs, abalone, limpets, anemones, snails, sea stars, sea urchins, chitons, barnacles, and scallops. Deep rocky reefs have a rich invertebrate and fish community, with little algae. Invertebrates include sponges, anemones, snails, sea stars, and crabs. Deep nearshore reefs tend to have a higher diversity of rockfish as well as perch, lingcod, Irish lord, sole, and dogfish sharks.

**Kelp Forests**

Kelp forests are associated with rocky reefs and include subtidal marine communities that form floating canopies on the surface of the sea. Kelp forests are highly productive and create a three-dimensional aspect to the nearshore environment, providing habitat and food for hundreds of other species of plants (algae) and animals. Kelp forest ecosystems include structure-producing kelps and their myriad of associated biota such as marine mammals, fishes, crabs, sea urchins, mollusks, other algae, and epibiota (organisms living on its surface), which collectively make this one of the most diverse and productive ecosystems in the world (Steneck et al. 2002).

Kelp forests are included as SAV in subtidal marine habitat, occurring across a wide depth range, from rocky intertidal habitats to depths of 40 meters, and for some species, broad latitudinal ranges. Kelp grows on many of Oregon’s shallow rocky reefs on rocky substrates between 5 and 20 meters of water, with some extending to 25 meters (ODFW 2005b). While rocky reefs of this depth range exist all along the Oregon coast, the strip of coast from Cape Arago south contains approximately 92 percent of the state’s kelp beds (ODFW 2005b).

Distribution patterns of kelp are influenced by light, salinity, temperature, substrate type, and currents. Kelp forests supply many habitat functions, including: 1) supporting of large numbers of non-parasitic epiphytic organisms that live on them; 2) damping of waves and slowing of currents which enhances sediment stability and increases the accumulation of organic and inorganic material; 3) binding sediments with their holdfasts (roots), thus reducing erosion and preserving sediment microflora; and, 4) holdfasts and blades (leaves) provide horizontal and vertical complexity to habitat, which, together with abundant and varied food sources, support densities of fauna generally exceeding those in unvegetated habitats.

### 3.3.2 Existing Fish and Marine Species

#### 3.3.2.1 Fish

ODFW (2005) seining data at stations near Jordan Cove give a snapshot of the diversity of species that utilize habitat near the proposed slip location. Species seined in September and July of 2005 at McCullough Bridge (upper bay from the Project area) included Chinook salmon, shiner perch, walleye perch, northern anchovy, starry flounder, staghorn sculpin, speckled sand dab, and saddleback gunnel. Species seined in July 2005 from the Trestle station (just upbay from the Project site area) included coho salmon, Chinook salmon, shiner perch, staghorn sculpin, sand sole, white sea perch, surf smelt, and American shad. Species seined from the Pony Creek station (across and upbay from the Project site area) in July 2005 included coho salmon, Chinook salmon, shiner perch, staghorn sculpin, sand sole, white sea perch, surf smelt, jack smelt, and bay pipefish.

**Salmon**

The Coos Bay system provides migration, rearing, and feeding habitat for the following environmentally sensitive units (ESUs) of Pacific salmonids: federal species of concern Oregon Coast (OC) coastal cutthroat trout (*O. clarki clarki*); OC Chinook salmon (*Oncorhynchus tshawytscha*), state sensitive-critical; Pacific Coast chum salmon (*O. keta*), state sensitive-critical; OC steelhead (*O. mykiss*), state sensitive-vulnerable, which is also a federal species of concern; and OC coho salmon (*O. kisutch*), federally-listed as threatened under the Endangered Species Act (ESA) in February 2008.

### 3.3.2.2 Invertebrates

As one of Oregon's largest estuaries, Coos Bay provides habitat and rearing value for clams, crabs, and shrimp, which are of significant economic importance to the area, including Oregon's economically productive Dungeness crab fishery. Many invertebrates have not been thoroughly studied and updated population and distribution information is not available. Variations in substrate, attachment sites, sediments, salinities, temperatures, dissolved oxygen, and other physical factors in Coos Bay affect shellfish distribution. Shellfish distribution varies along the route from the proposed LNG Terminal to the Coos Bay harbor entrance, with principal subtidal clam beds and crab species found in the lower bay along the route.

Mapped clam and crab distributions shown on Figure 3.3-2 are based on the Shellfish and Estuarine Assessment of Coastal Oregon: Coos Bay (SEACOR) conducted in 2008 by the ODFW. Butter (Martha Washington, beefstake, quahog) and gaper (horse, horseneck, blue, Empire) clams are considered the most numerous in Coos Bay and studies conducted from the 1970s to 2009 have shown increased populations. Cockles and littlenecks (steamers) are less common and studies show their populations have been dropping since the 1970s. Softshell clams (non-native) are typically found further inland along the bay.

Oysters and shrimp distributions are mapped in Figures 3.3-3 and 3.3-4, respectively, and are based on distributions contained in Coos Bay by the Oregon Geographic Response Plan (U.S. Coast Guard 2004). There are two species of oysters in Coos Bay: the native or Olympia oyster (*Ostrea lurida*) and the commercially grown Pacific oyster (*Crassostrea gigas*). The Olympia oyster is the only oyster native to Oregon and Coos Bay is one of only a few bays where they exist in Oregon. Neither species is legal for recreational harvest. Native oyster populations are protected to encourage their recovery, but since Pacific oysters are only commercially grown they are private property.

Bringing the Olympia oyster back to Oregon's coastal waters has become a priority for natural resource managers, scientists, shellfish farmers, and recreationists. A team led by the South Slough National Estuarine Research Reserve in lower Coos Bay is conducting the science and forming the relationships necessary to make Coos Bay the epicenter of the state's restoration efforts. In 2010, the reserve received a federal start-up grant for a pilot restoration project. Since then they have re-introduced about 4 million juvenile oysters to South Slough. The project aims to build on existing research and relationships to establish a community stakeholder group committed to working collaboratively to bring the Olympia oyster back to Coos Bay.

### 3.3.2.3 Marine Mammals

The Marine Mammal Protection Act (MMPA) was enacted on October 21, 1972, and prohibits killing, harming, or harassing any marine mammal. It is based on the finding that some marine mammal species or stocks may be in danger of extinction or depletion as a result of human activities and that these populations must not be permitted to fall below their optimum sustainable population level. The MMPA was amended substantially in 1994 to provide certain exceptions to the take prohibition, including: 1) for small takes incidental to specified activities; 2) permits and authorizations for scientific research; and 3) access by Alaska Natives to marine mammal subsistence resources. The amended act also included a program to authorize and control the taking of marine mammals incidental to commercial fishing operations, the preparation of stock assessments for all marine mammal stocks in waters under U.S. jurisdiction, and studies of pinniped-fishery interactions.

In addition to the marine mammals listed below, other threatened or endangered marine mammals that may occur in the LNG carrier transit route zones are described in Section 3.4 and include whales and Steller sea lions.

**California Sea Lion**

California sea lions (*Zalophus* californianus) occur in nearshore waters along the Pacific coast from Vancouver Island, British Columbia, to Baja Mexico. North of southern California, the haulout grounds are occupied by males only who migrate north for the winter following the breeding season, which ends in mid-July (Maser et al. 1981) after the pups are born. Females and their pups remain in California all year. Males may often reach 850 pounds and 7 feet in length. Males develop a bony bump on top of their skull, which is called a sagittal crest. Females can weigh up to 220 pounds and reach 6 feet in length; females are lighter in color than the males. California sea lions are very social animals and rest together in tightly packed groups on haulout sites. The main haulout sites along the Oregon coast include Shell Island at the Simpson Reef. California sea lions forage within Coos Bay throughout the year and use dredge material islands as haul-out sites (BLM 2005). Occasionally they may be found on the North Spit's beaches (BLM 2005). The California sea lion may occur in the LNG carrier transit route zones.

**Harbor Porpoise**

The harbor porpoise (*Phocoena phoceoena*) is circumboreal in the northern hemisphere and occurs in ice-free waters. In the eastern Pacific Ocean, this species ranges from Point Barrow, Alaska, to San Diego, California. This species is the smallest cetacean in the eastern North Pacific Ocean and is considered abundant in waters off Washington and western Canada. Adult males reach up to 1.7 meters in length and females reach 1.8 meters. Adult harbor porpoises weigh up to 90 kilograms. In the Pacific, harbor porpoises feed on bottomfish, cod, herring, squid, clams, and occasionally crustaceans. Harbor porpoise could be found within the LNG carrier transit route zones.

**Harbor Seal**

Harbor seals (*Phoca vitulina*) occur in both the Pacific and Atlantic oceans north of the equator. In the Pacific, they range from Alaska to Baja Mexico and can often be seen in nearshore coastal waters, bays, estuaries, and on sandy beaches and mudflats. Harbor seals have spotted coats in a variety of colors, ranging from silver to dark brown or black. Males are slightly larger than females and the species reaches 5-6 feet in length and weigh up to 300 pounds. In Oregon, pups are born in April and May. Harbor seals are opportunistic feeders and take a variety of bottom fishes and rockfishes, small schooling fish such as herring, some salmon, and lamprey (Maser et al. 1981). Harbor seals spend half their time on land and half in the water, occasionally sleeping in the water. Harbor seals are year-round residents on the Oregon coast and can be found at Cape Arago. Harbor seals forage within Coos Bay throughout the year and use dredge material islands as haul-out sites (BLM 2005). Occasionally they may be found on the North Spit's beaches and are very sensitive to disturbance (BLM 2005). Harbor seals could occur within the LNG carrier transit route zones.

**Northern Elephant Seal**

Northern elephant seals (*Mirounga angustirostris*) occur in the North Pacific, from Baja Mexico to the Gulf of Alaska and Aleutian Islands. The elephant seal was almost extinct by the late 19$^{th}$ century but has repopulated throughout its range, having once received protection. During the breeding season, they live on offshore island beaches and a few remote locations on the mainland. The rest of the year elephant seals live offshore. Adult males reach up to 13 feet in length and weigh up to 5,000 pounds. The females are smaller at 10 feet in length and weighing less than 1,000 pounds. This species is the second largest seal in the world, after the southern elephant seal, and can dive to depths of 5,000 feet. Elephant seals breed in the winter and male elephant seals arrive first at their breeding beaches in Mexico and California to establish territories. Pups cannot survive in the water until eight to ten weeks after birth. The northernmost breeding site on the Pacific coast is Shell Island at Cape Arago, which is also the largest marine mammal haulout area on the Oregon Coast (USFWS 2007b). Elephant seals may occur in the LNG carrier transit route zones.

**Sea Otter**

The sea otter (*Enhydra lutris*) was extirpated from Oregon by the early 20$^{th}$ century; however, translocation attempts were made in Cape Arago in 1971 where 41 otters were released (Jameson 2007). The translocated populations failed and the last sea otter observation at Cape Arago was in 1991 (Jameson 2007). This species is currently extirpated in Oregon and will not be affected by the LNG carrier transit route zones.

### 3.3.3 Commercial and Recreational Fisheries

Commercial and recreational fish and invertebrates species found in Coos Bay are listed in Table 3.3-3.

#### 3.3.3.1 Commercial Fishing

Commercial fisheries in the Coos Bay estuary includes clams, bait fish, and ghost and mud shrimp (used for fishing bait), along with limited crabbing from September through December. Only 15 permits for commercial clam harvesting are issued per year for the entire state of Oregon. A company called West Coast Clams began regularly harvesting clams commercially in Coos Bay in March 2012 and has since opened up new markets for clams from Coos Bay.

Commercial ocean fisheries include boats (trollers and trawlers) targeting tuna, sablefish, salmon, groundfish, Dungeness crab, clams, and pink shrimp. Most vessels fishing offshore dock and sell their products in Coos Bay and a fisherman's market cooperative and a small commercial salmon fleet are located in Charleston. Shellfish fisheries (predominantly crab, shrimp, and clams) are of significant economic importance to the Coos Bay area.

In 2011, the total value of the catch at the fisherman's level reported by the ODFW at Charleston was $35.7 million. This was comprised of $12.7 million for fish, $23.1 million for crab and shrimp, $8,312 for clams, and $700 for other invertebrates. Within the fish category, albacore tuna, sablefish, and Chinook salmon were the highest valued catch of all the fish caught, at $4.2, $3.7, and $1.3 million, respectively. In 2011, the ODFW reported that Dungeness crab harvested from the ocean had a total value of $11.8 million at the fishermen's level. Pink shrimp had a value of $10.9 million, and spot shrimp, $182,264. Cockle and gaper clams, combined, account for only $7,069.

Although many shrimp species are found in waters off Oregon, the pink shrimp (*Pandalus jordani*), also known as the ocean shrimp, is the only one found in quantities large enough to be commercially harvested. The pink shrimp is a small shrimp in comparison to many shrimp and prawns seen in supermarkets and restaurants, and is often referred to as cocktail shrimp or salad shrimp. Pink shrimp have been harvested in Oregon since 1957 and are caught by trawl boats which generally fish between 450 to 750 feet deep on mud and muddy-sand substrates off the coast. Populations vary widely from year to year, which is common for many short-lived crustaceans. Landings in 2005 were 15 million pounds and have averaged 26 million pounds per year over the last 31 years.

The Oregon Division of State Lands (DSL) oversees six oyster claims in Coos Bay and leases for commercial operations are issued by the Port of Coos Bay and Coos County. There are four commercial growers that cultivate about 1,500 acres of non-native Pacific oysters, worth about $10 million each year. No oysters are allowed to be recreationally harvested in the bay. The closest commercial oyster lease occurs east of the Project, as mapped in Figure 3.3-3.

### 3.3.3.2 Recreational Fishing

The main recreational catch species of fish include coho and Chinook salmon. Other recreational catch species include American shad, shiner perch, redtail surf perch, striped sea perch, white sea perch, pile perch, black rockfish, lingcod, Cabezon, red Irish lord, Pacific staghorn sculpin, surf smelt, Pacific herring, Pacific tomcod, kelp and rock greenling, blue and cooper rockfish, California halibut, and white sturgeon.

Much of the recreational angling for salmon in Coos Bay occurs in late summer and fall. It usually begins in late summer at jetty areas and moves up the bay as fish move upstream. Bank angler access on the North Spit is limited. Boat angling occurs throughout the bay, but angling is limited in some areas at times by exposure to winds. For example, the Roseburg Forest Products Co. dock area in Jordan Cove gets less boat angling use due to exposure to wind and tidal action. Other areas of concentrated angling for fall salmon are further up the bay, beginning at the railroad bridge and extending through the Marshfield and Coos River channels.

Perch fishing begins in Coos Bay in late February to early March, depending on freshwater runoff into the bay, and can continue through July. Rocks around bridge abutments and the north jetty are targeted by anglers on the outgoing tide.

Recreational fishing for sturgeon occurs between the railroad bridge and McCullough Bridge and also above the McCullough Bridge. Green sturgeon are illegal to retain and are listed as threatened under the ESA. White sturgeon can be taken year round, but the best angling is during December through March when there is a heavy freshwater plume in Coos Bay. Sturgeon anglers target areas upstream of the McCullough Bridge away from the Project site area.

The west shore of the bay at Jordan Cove contains sand-mud flats, eelgrass beds, and a fringe of estuarine wetlands that provide habitat for recreationally important ghost shrimp and mud shrimp. These shrimp are recreationally harvested at a number of locations throughout the bay

(Figure 3.3-4) and are popular among fishermen for use as bait for species such as perch, rockfish, and various groundfish species that occur in the bay.

Recreational crabbing and clamming brings year-round tourist income to the region. Crabbing occurs in the main channel areas, largely from the BLM boat ramp on the North Spit (west of the Project) to the mouth of the bay and typically is done around slack tides. Crab harvesting by boats is very productive along the western side of the lower bay west/southwest of the BLM boat dock on the North Spit. Along the eastern side of the lower bay from the Empire area south are sand and mud flats that provide some of the highest recreational effort for clams.

Six main areas for recreational shellfish are described below (ODFW 2013):

**Area 1** (South Slough) can be reached from several access points along the west side of South Slough within Charleston. This area is a large sand/mud flat that is firm enough to walk on easily in most places. Many clam species can be found in this highly marine influenced area. In sandy areas, such as those just south of the Charleston bridge, cockle raking is popular. In muddier areas, such as the "Charleston Triangle" (between the commercial docks and the bridge), gaper clams can be found readily at good tides. In areas further up South Slough soft shell clams can be found sparingly. Other clams, such as butter and littleneck clams, are found mixed throughout.

**Area 2** (North Spit) requires a boat or 4x4 vehicle for access other than hiking. This area supports several large and productive clam beds. All species common to lower bays can be found here, including gapers, butters, cockles, and littlenecks.

**Area 3** (Fossil Point and Pigeon Point) can be accessed by many points along Cape Arago Highway from Empire to Charleston. Substrate in the area varies from sand/mud to sandstone/ gravel. In the sandier areas of Pigeon Point, gapers and cockles are easily found. In gravelly areas, such as Fossil Point, butter and littleneck clams are more common.

**Area 4** (Haynes Inlet, North Slough, and Glasgow) can be reached by the nearby banks, from Highway 101 or East Bay Drive. Soft shell clams are common throughout the intertidal areas. Ghost shrimp are common in the area. Commercial oyster operations are also nearby. The oysters are private property and cannot be harvested recreationally.

**Area 5** requires a boat for crabbing. Large sandy flats in depths of 20-30 feet provide excellent bay crabbing year round. Pots may be set anywhere within this area, using caution to avoid direct placement in navigation channels.

**Area 6** includes areas for dock crabbing. In Charleston, the primary areas for dock crabbing are the commercial docks, public crab dock, and "T" docks just south of the bridge. Another popular spot is on the docks adjacent to the Empire boat ramp. Dock crabbing is often fruitful year round, but less so than boat crabbing.

### 3.3.4 Unique and Special Status Fisheries and Marine Resources

Additional species not federally or state-listed as threatened or endangered but designated as protected or sensitive by an environmental division of the local, state, or federal government are described below.

#### 3.3.4.1 Essential Fish Habitat (federal) and Essential Salmonid Habitat (State)

The Magnuson-Stevens Fishery Conservation and Management Act (MSA) of 1976, as amended, was enacted, along with other goals, to promote the protection of Essential Fish Habitat (EFH) in the review of projects conducted under Federal permits, licenses, or other authorities that affect or have the potential to affect EFH. The MSA requires all federal agencies to protect fisheries habitat from being lost due to disturbance and degradation and to consult with the National Marine Fisheries Service (NMFS) when an action has the potential to adversely affect EFH. EFH is defined as “those waters and substrate necessary to fish for spawning, breeding, feeding, or growth to maturity” [16 USC § 1801(10)]. The EFH interim final rule, summarizing EFH regulations (62 FR 66531-66559), outlines additional interpretations of the EFH definition.

For the purpose of interpreting the definition of EFH, “waters” include aquatic areas that are used by fish and their associated physical, chemical, and biological properties, and may include areas historically used by fish where appropriate; “substrate” includes sediment, hard bottom, structures underlying the waters, and associated biological communities; “necessary” means the habitat required to support a sustainable fishery and a healthy ecosystem; “fish” includes finfish, mollusks, crustaceans, and all other forms of marine animal and plant life other than marine mammals and birds; and “spawning, breeding, feeding, or growth to maturity” covers a species’ entire lifecycle.

The MSA established regional Fishery Management Councils and mandated that Fishery Management Plans (FMPs) be developed to identify and describe the habitat areas of particular concern within the EFH. When Congress reauthorized this act in 1996 as the Sustainable Fisheries Act, several reforms and changes were made. One change was to charge the NMFS with designating and conserving EFH for species managed under existing FMPs. This was intended to minimize, to the extent practicable, any adverse effects on habitat caused by fishing or non-fishing activities, and to identify other actions to encourage the conservation and enhancement of such habitat.

The Pacific Fishery Management Council (PFMC) has authority over the fisheries in the Pacific Ocean seaward of the states of California, Oregon, Washington, and Idaho. The individual FMPs addressing EFH for managed species in these areas represent the PFMC’s response to those requirements stated in Section 303(a)(7) of the MSA (16 USC §1801 et seq.). Four FMPs have been established by the PFMC, including: FMP for the groundfish in the Pacific; FMP for coastal pelagic species in the Pacific, FMP for salmon in the Pacific, and FMP for highly migratory species (tuna, sharks, and billfish). Tuna and billfish do not occur in Coos Bay but may be found seasonally offshore when the ocean’s temperature warms up.

For the Pacific salmon fishery, the PFMC identified EFH using U.S. Geological Survey hydrologic units, as well as habitat association tables and life history descriptions for each life stage. These areas encompass all streams, lakes, ponds, wetlands, and other currently viable water bodies and most of the habitat historically accessible to salmon in Washington, Oregon, Idaho, and California. In estuarine and marine areas, EFH for Pacific salmon extends from the nearshore and tidal submerged environments within state waters out to the full extent of the Exclusive Economic Zone (EEZ; 200 nautical miles).

EFH is described and identified as everywhere that species managed by the PFMC occur. Specifically, EFH is identified and described based on areas where various life stages of 90 managed species commonly occur. These include 82 species of groundfish, five coastal pelagic species (four finfish: Pacific sardine; Pacific (chub) mackerel; northern anchovy; jack mackerel and one invertebrate: market squid); and three species of salmon (Chinook, coho, and pink salmon). Table 3.3-2 lists species with designated EFH in Oregon. EFH species in Coos Bay include Chinook and coho salmon, northern anchovy, Pacific sardine, and a variety of rock and groundfish. The ODFW reports that adult and juvenile black, blue, and copper rockfish, lingcod, rock greenling, and starry flounder are found in Coos Bay year-round. It also reports that recent genetic work points to the possibility of resident copper rockfish. All habitat accessible to these managed species in the Coos Bay system is considered EFH. This includes estuarine habitat, shore environments, marsh habitat, SAV, and kelp beds. The locations of EFH within Coos Bay and the zones of the LNG carrier transit route are shown in Figure 3.3-5.

Approximately 31.5 acres of potential EFH within Coos Bay will be removed by the dredging and construction that will occur for the Project, including 29.1 acres for the slip, 1.7 acres for the construction dock, and 0.7 acre for the gas processing area. This includes approximately 9.69 acres of intertidal (unvegetated sand), 3.38 acres of shallow intertidal habitat (algae, mud, and sand), 2.49 acres of eelgrass, and 15.24 acres of deep subtidal habitat (Figure 3.3-1).

No habitat designated as EFH for species under federal management plans will be affected by the construction of the land-based elements of the Project; however, it is likely that EFH will be affected by the construction of the slip. The normal transit of LNG carriers to and from the Project will have no direct physical effect on EFH, although maintenance dredging for the access channel to the LNG Terminal ship berth will affect EFH that develops between maintenance dredging periods. Development and maintenance of the slip will temporarily affect the subtidal mudflats in the Project area; however, it will result in the production of a zone of deepwater habitat that will likely be utilized by a myriad of fish species, including the green and white sturgeon. The conversion of shore lands, grassland, and dune forest to open water for the slip will also create additional underwater habitat, which should be considered ODFW Habitat Category 3.

**Prey Dependence on EFH**

Habitat for prey items of species for which EFH has been identified in Coos Bay is essentially the same as that required by those managed species (i.e., estuarine and marine habitats). Shrimp larvae feed on phytoplankton and zooplankton. Postlarvae feed on epiphytes, phytoplankton, and detritus. Juveniles and adults prey on polychaetes, amphipods, and chironomid larvae, but also on detritus and algae (Pattillo et al. 1997). Submerged grasses are important habitat for small prey species of adult lingcod (EFH Core Team 1998).

Forage habitat components for the managed species depend to some extent on estuarine systems. Many species of groundfish and salmonids occupy inshore areas of the lower bay during juvenile stages (e.g., Chinook salmon, coho salmon, English sole, eulachon) where they feed on estuarine dependent prey, including shrimp, small fishes, and crabs. As they mature and move offshore, their diets in many cases change to include fish, although estuarine-dependent species (e.g., shrimp, crabs) can still constitute an important dietary component.

**Essential Salmonid Habitat (State)**

Pursuant to Oregon Revised Statutes (ORS) 196.810(1)(b), the Oregon Department of State Lands (DSL), in consultation with the ODFW, designates Essential Indigenous Anadromous Salmonid Habitat (ESH) areas based on field surveys and/or the professional judgment of ODFW´s district biologists. ESH is defined as the habitat necessary to prevent the depletion of native salmon species (chum, sockeye, Chinook, and Coho salmon; and steelhead and cutthroat trout) during their life history stages of spawning and rearing. The designation applies only to those species that have been listed as sensitive, threatened, or endangered by a state or federal authority, and designations are periodically reviewed and updated.

All projects proposed in ESH must be reviewed pursuant to the standards set forth in the State's Removal-Fill Law (ORS 196.600 to 196.990) and rules (OAR 141-085). An authorization from

DSL for activities involving the fill or removal of any amount of material in ESH is required unless the activity is exempt. This authorization is included in the permit issued by the DSL as part of the Joint Permit Application process with the U.S. Army Corps of Engineers. The DSL Permit for the slip and access channel has been issued to the Port. A copy is provided in Appendix O.2 of Resource Report 2 – Water use and Quality.

#### 3.3.4.2 Native American Fisheries

Historically, an essential resource for the Native Americans in Coos Bay was fish. The extensive tidal channels of the bay were habitat for dozens of species of fish. Massive spawning runs occurred in all seasons of the year, bringing salmon, herring, smelt, and other fishes in vast numbers. One of the most effective systems the local Native Americans used to harvest these fish involved weirs and traps of wooden stakes and woven lattice or basketry, often built across the mouths of tidal channels. They were typically designed to allow fish passage upstream as the tide rose, then trap the fish as the tide receded. In the mid-1900s, the stakes forming these weirs could still be observed at various sloughs in the bay. This is no longer the case, although, remnants of fishing weirs are occasionally reported by those familiar with identifying such weirs.

Modern Native Americans living in Coos Bay do fish, both recreationally and commercially, but these practices are not conducted as tribal fisheries as they are done at certain locations along the Columbia and Klamath Rivers. There is no land that is currently owned by Native American tribes in or adjacent to the Project site area. The tribes in Coos Bay currently do not have policies that regulate fishing separately from state and federal fisheries management. No information about traditional fishing sites still in use in the Project vicinity was identified during the cultural resource investigations which included consultation with tribal representatives. A more detailed discussion of the Native American fisheries is provided in the Cultural Resources Survey Report, filed as “Privileged and Confidential” (Appendix A.4 to Resource Report 4 – Cultural Resources).

#### 3.3.4.3 Marine Sanctuaries, Reserves, and Management Areas

The location of marine research reserves, reefs, and management areas along Coos Bay and within the zones of the LNG carrier transit route are shown in Figure 3.3-6 and described in the following sections. In addition, migratory marine mammal feeding and breeding grounds and bird habitat along the entire route are shown in Figure 3.3-7.

Within state waters along the coast, 1,400 offshore rocks and islands are classified as Rocks and Islands National Wildlife Refuge System, which is administered by the USFWS. There are no rocks or islands in this refuge that fall within the LNG carrier transit route zones. Shell Island which is part of the Oregon Islands National Wildlife Refuge is approximately three miles from the LNG carrier transit route and is outside of the 2.2 mile zone.

The Cape Arago headland encompasses the coastline of three OPRD parks: Sunset Bay, Shore Acres, and Cape Arago. It contains extensive, rich, and diverse intertidal and subtidal habitat, including Oregon’s largest giant kelp bed, seabird nesting sites, and large marine mammal haulouts (including threatened Steller sea lions and the only year-round elephant seal haulout in the state). Within these parks, some areas get high visitor use. More than 600,000 people visit at Sunset Bay and more than 450,000 people visit Cape Arago each year.

**Cape Arago Intertidal Research Reserve**

Marine reserves are defined by the ODFW (2006) as "areas designated to meet specific goals and are regulated to protect resources or uses from activities that may conflict with these goals." The Cape Arago Research Reserve is located just south of the mouth of Coos Bay and forms the only major rocky shoreline between Heceta Head, 55 miles to the north, and Cape Blanco, 32 miles to the south. The Reserve extends along approximately 2.5 miles of shoreline and includes North Cove, Middle Cove, South Cove and Squaw Island. Shoreline features include steep cliffs, numerous offshore rocks, extensive rocky intertidal and subtidal reefs, and small sand beaches. Sloping bedrock platforms with small surge channels are common at Sunset Bay and portions of North Cove. Steeper sloped platforms with deep surge channels are common at Middle Cove, Simpson Reef, Squaw Island, and most of North Cove. The site supports a rich and diverse community of intertidal wildlife. Several species of pinnipeds and seabirds utilize the area.

The Reserve has several prominent features. Nearshore rocks provide nesting and roosting habitat for seabirds. Squaw Island is surrounded by an extensive intertidal area. Simpson Reef, located just beyond the Reserve, provides shelter from wave energy which has resulted in a rich and extensive intertidal community. The wide variety of habitat types at Cape Arago has created a very diverse intertidal community. Cape Arago is the southernmost site in Oregon to support high densities of intertidal and subtidal purple sea urchins. Red sea urchins are also abundant here. A commercial offshore fishery exists for both urchin species but has been in decline in recent years. High diversity and abundance of algal species occur in North Cove, behind the protection of Simpson Reef. Simpson Reef is the only site in Oregon where significant kelp beds of giant kelp (*macrocystis integrifolia*) are found and kelp is extensive along much of the shoreline. Shell Island in North Cove is another unique feature, as it is entirely covered with shell fragments.

Four species of pinnipeds haulout in the reserve. Shell Island, Squaw Island, Simpson Reef and South Cove support harbor seals, California sea lions, and Steller sea lions. Shell Island has the only breeding population of elephant seals in Oregon. Peregrine falcons are also residents at the site.

According to the USFWS Oregon Islands National Wildlife Refuge website, Simpson Reef at Cape Arago is the world's northernmost pupping site for northern elephant seals, and is the largest marine mammal haulout site on the Oregon coast. Shell Island in Simpson Reef is the largest rock in the reef and is habitat for marine mammals, including the federally threatened Steller sea lion. Simpson Reef and Shell Island are located outside of the LNG carrier transit route zones, but due to their close vicinity and significant marine mammal habitat, they were included in the discussion.

**Gregory Point Subtidal Research Reserve**

Gregory Point Subtidal Research Reserve includes 57 acres of subtidal areas at Gregory Point, Lighthouse Island, and nearby Squaw Island. It is located northwest of the mouth of Sunset Bay State Park and includes all areas seaward of extreme low tide in the area. The rocky intertidal area at the site (3.5 acres) is part of the Cape Arago Research Reserve. Formations at Gregory Point are remnants of steeply upturned sedimentary rocks that underlie the Cape Arago region. Key resources of this site include seabird nesting sites on Lighthouse Island and extensive intertidal and subtidal rocky habitat between Lighthouse Island and Squaw Island. Harbor seals also use the area as a haulout. Because of its isolation, the area has been used for many years for study and research by staff and students at the nearby University of Oregon Institute of Marine Biology in Charleston.

**Marine Protected Areas**

The state of Oregon and NOAA designated the South Slough National Estuarine Research Reserve (SSNERR) as the nation's first estuarine reserve in 1974. The SSNERR is administered by the Oregon DSL, which is under the jurisdiction of State Land Board. The SSNERR is the southern extension of the Coos Bay estuary and South Slough is one of the seven inlets that combine to form the Coos Bay estuary. The SSNERR encompasses 4,765 acres and is approximately one-quarter of the South Slough watershed. The reserve includes approximately 800 acres of water and tidally influenced habitat, 115 acres of riparian habitat, and 3,850 acres of upland forest. The mixture of open water channels, tidal and freshwater wetlands, riparian areas, and forested uplands provides a diverse and biologically rich area. Several threatened and endangered and special status species occur at the reserve, including bald eagle, peregrine falcon, brown pelican, cutthroat trout, coho salmon, California pitcher plant, sea lavender, and Point Reyes bird's-beak. Management and administration at the SSNERR supports and coordinates research, education, and stewardship programs which serve to enhance a scientific and public understanding of estuaries and contribute to improved estuarine management. The SSNERR is located to the south of LNG carrier transit route 2.2 mile zone.

### 3.3.5 Environmental Consequences (Construction and Operation)

#### 3.3.5.1 Fish and Marine Species (including EFH)

Potential effects to fish and marine species are discussed below, and also in Section 3.3.5.2 for aquatic habitats and Section 3.3.5.3 for water quality. Discussion of potential effects to marine mammals is primarily included under Section 3.4.4 for environmental consequences to threatened and endangered species, as the Steller sea lion and nine species of whales are addressed in Section 3.4.

**Acoustic Effects**

All piles required for the LNG carrier berth, including docks and mooring dolphins, will be driven prior to or concurrent with the dredging of the slip on dry land. No open water pile driving will be required, thereby eliminating potential affects to fish and marine organisms from higher intensity sound waves in the water column. It is currently assumed that piles will be driven on dry land in isolation from the Bay, and soils would subsequently be removed from around them, eliminating the majority of potential land-based noise impacts.

**Impingement or Entrainment**

As discussed in Resource Report 2 – Water use and Quality, LNG carriers would re-circulate water while loading LNG at the berth and the amount of cooling water to be re-circulated is a function of the propulsion system for the vessels. Once the LNG fleet has been identified, cooling water flow rates and the amount of water required can be further addressed. It is likely that some organisms small enough to pass through the screens covering the carrier's intake port will be drawn in with the cooling water and will be lost from the population in the slip area; however, it is anticipated that the effect associated with the intake of cooling water will be minimal. Juvenile fish would need to be present in the slip area near the carrier's intake screens and be small enough to fit through the sea chests which are covered with screens composed of 4.5 mm thick bars spaced 24 mm apart and located approximately 32 feet below the water line, or 5.6 feet from the keel of the LNG carrier. The intake velocities for cooling water are low enough that it is not anticipated that any larger organisms (fish, marine mammals, or invertebrates) would be impinged on the intake screen. Generally the total water intake would occur over a 24-hour period during each loading period, about 90 times per year.

**Temperature**

Temperature effects are discussed in Resource Report 2 – Water Use and Quality. LNG vessels would re-circulate water for engine cooling while loading LNG at the berth to provide power for standard hoteling activities as well as running the ballast water pumps. Using conservative assumptions, the maximum heating of cooling water at the time of discharge is estimated to be approximately 3$^{o}$C (5.4$^{o}$F) above ambient temperature for a distance of 50 feet from the discharge point on the LNG vessel, with the difference decreasing with further distance. The creation of the slip results in the addition of approximately 40 acres of water surface to the Coos Bay estuary. This additional water surface will increase the amount of evaporative cooling, further decreasing the water temperature in the slip area. Considering the volume of Coos Bay, virtually no change in bay temperature would occur from heated water discharge. The tides would be continually exchanging the water and the cooling water would be discharged in the same localized area (the northeast corner of the slip). The warmer engine cooling water is not anticipated to have a significant adverse impact on the water temperature in Coos Bay because of mixing and other factors.

**Localized Changes in the Light Regime**

Localized changes in light regime have been shown to affect fish species behavior in a variety of ways. Disorientation may cause delays in migration, while avoidance responses may cause diversion of migratory routes into deeper, less protected waters. In some cases, increased light may attract both predators and potential prey species.

Lighting at the LNG Terminal and onshore facilities would likely include a mixture of low-power fluorescent lighting and higher intensity security lighting that would primarily be located on shore, in and adjacent to the slip. When an LNG carrier is not in the berth, the lighting would be reduced to that required for security. It would be focused upon the structures and not be in proximity to the water so as to serve as an attractant or deterrent to fish species. When an LNG carrier is at the berth, it would physically block the lighting on the berth from the slip waters and, due to its proximity to the slip wall, would block the fish from getting too close to the lighting on the berth. Lighting used would be similar to that already in place at other Coos Bay facilities.

Lighting on the tug dock would be low intensity lighting for safety, providing sufficient light for personnel movements on the trestle out to the tug berth and for movement on the berth itself. There is no intention to provide lighting near the water line or high intensity lighting that would be associated with activities other than the simple berthing of the tugs at this location. The reduced lighting levels near the water would reduce or eliminate any behavioral effects to fish in the Project vicinity. The final details of the lighting arrangement will be determined through consultation with NMFS in the Biological Opinion (BiOp) and other resource agencies to reduce these potential adverse effects.

**Ship Wake and Propeller Wash**

Shoreline erosion, wave heights and shoreline changes, and propwash scour are all discussed in Resource Report 2 – Water Use and Quality. Propeller wash from LNG vessels and tug boat propellers associated with the Project, as well as ship wakes breaking on shore, could cause increased erosion along the shoreline and re-suspend the eroded material within the water column. This may affect the diversity and health of the benthic community regarding food availability and feeding conditions for foraging and migrating fish species. At high concentrations, suspended sediments can affect oxygen exchange over the gills, resulting in weakened individuals or mortality. However, ship wakes associated with the operation of the slip are not expected to result in significant bank erosion or effects due to the low speed at which carriers would traverse the lower bay when approaching or departing the slip and the limited number of trips (approximately 90 round trips per year).

Fish stranding can occur when fish become caught in a vessel's wake and are deposited on shore by the wave generated by the vessel wake. Stranding typically results in mortality unless another wave carries the fish back into the water. A series of interlinked factors act together to produce stranding during vessel traffic and may include water surface elevations, with low tides more likely to result in strandings than high tide; beach slope, with strandings more likely on low gradients than high; wake characteristics influenced by vessel size, hull form, depth underwater (draught), and speed; and biological factors, such as numbers of small fish present near the shoreline and whether fish are strong swimmers or not.

Ship wakes produced by deep-draft vessels traveling at speeds greater than the estimates for LNG carrier speeds have been observed to cause occasional stranding of juvenile salmon (Pearson et al. 2006); however, no strandings were observed as a result of vessels traveling at speeds under 9 knots (10.4 mph). The hull geometry of the LNG carriers is such that bow wakes are minimized, especially at the slower speeds of 4 to 6 knots that would occur during most of the transit route through Coos Bay. Therefore, the LNG carriers would be traveling at speeds less than that observed (Pearson et al.) to cause stranding. In models and research conducted by the JCEP, wave heights produced by LNG carrier traffic would not exceed that of normal conditions in Coos Bay and overall waves would contribute to a small portion of the total waves that occur in the bay. In addition, the LNG carriers would be arriving and leaving at high tide, which is a period when gently sloping beaches are mostly covered and less likely dewatered from waves. Considering that LNG marine traffic would enter and leave at high slack tide, have low vessel speeds, and wave height would be in normal range, it appears unlikely that the Project would contribute to fish stranding within Coos Bay.

**Marine Sanctuaries, Reserves, and Management Areas**

LNG spills from LNG carriers in the transit route from the LNG Terminal should not have any effect on wildlife refuges as the closest refuge is the islands near Cape Arago that are part of the Oregon Island National Wildlife Refuge which extends down the coast south of the Coos Bay harbor entrance. This area is approximately three miles from the transit route and outside of the 2.2 mile zone. The likelihood of a vapor cloud from an LNG spill moving down to the refuge and then being ignited from an ignition source is very low since boats, aircraft, and humans are prohibited from the area and there are no ignition sources.
