## MEMORANDUM REPORT

**SUBJECT: BOLIVAR COPPER COMPANY**

A preliminary examination of the holdings of the Bolivar Copper Company was made by Hollis M. Dale, Director, and Len Ramp, field geologist, on May 7, 1957. The examination consisted of one-half day on the property inspecting surface outcroppings uncovered during the exploration program of the company and a general reconnaissance of the geology.

### Location

The Bolivar Copper mine workings are in secs. 10 and 15, T. 32 S., R. 10 W.W.M. in the southeast corner of the Powers mining district and the southeast corner of Coos County, Oregon. It is about 33 miles south-east of Powers by good mountain road via Eden Valley. Access is also available from Glendale by 40 miles of road, and from Galice by 39 miles of road.

### Geologic setting

The holdings of the company are in metavolcanic rocks at the base of the Jurassic Dothan formation and near their western contact with sediments of the uppermost Jurassic Riddle formation. The zone of metavolcanics is one that has been outlined and is known to extend from west of Marial on the Rogue River northeastward to Mt. Bolivar, Gold Mountain, then westward to the northeast quarter of the Datchman Butte quadrangle, on past Nickel Mountain and up to the South Umpqua near Peel where it is covered by Tertiary volcanics of the Western Cascades. This band of volcanics, varying from one-half mile to 8 miles in width, is generally bounded on the west by a strong fault probably of deep-seated origin that has brought the volcanics up and has dropped the sediments of the Riddle and Days Creek formation down, thus protecting them. The eastern contact is gradational into sediments of the Dothan formation.

### Structural setting of mineralization

Subsidiary shears attendant to the major fault between the Dothan volcanics and the Riddle and Days Creek marine sediments are common

and mineralization in these shears has been frequently investigated. Occurrences similar to the Mt. Bolivar holdings are found at the Melody mine on upper Rice Creek near Dillard and at Brushy Butte on the drainage divide between north Myrtle Creek and the south fork of Deer Creek. The subsidiary shears have localized either intrusives into the Dothan volcanics or the more mobile constituents of the volcanics at the time of granitization. As a result, scattered mineralization is found. This mineralization invariably is copper and gold-silver. Unlike the porphyry coppers of southwest United States, the mineralization occurs in "bunches" and stringers and although it might be considered as disseminated mineralization, it is not sufficiently regular to predict the possibilities of a mineralized zone without extensive exploration work. Exploration to date in this belt of volcanic rocks has not determined a large economically minable deposit.

Development work by Bolivar Copper Company

Preliminary stripping has been done at the Bolivar Copper Company in a shear zone in which mineralization is found. Insufficient detailed exploration work has been done to disclose anything except sporadic occurrences of mineralization. Until a great deal further drilling, trenching, and sampling have been done, this property should not be considered as differing from other known prospects in this same geologic setting. Recommendations were made to the company that a competent mining engineer be retained to conduct the exploration program in order to determine if plans should be made to mine. In the meantime the property cannot be evaluated differently than covered by earlier reports on file in this Department.

**Boliver Copper Company**  
Rt. 4, Box 1570  
Roseburg, Oregon

Att: Mr. R. F. Carr, President

Gentlemen:

Pursuant to your request, I am submitting the following report on your copper property near Mt. Boliver, Coos County, Oregon. It is based on my examination of the property on April 1-3 and 17, 1937. During this time, a geophysical survey of the immediate surface area was made, using the Ruck "Scout" total magnetometer.

#### INTRODUCTION

A geological and geophysical examination was made of the Boliver Copper Company's property at the headwaters of the West Fork of Cow Creek, Coos County, Oregon, on April 1-3 and 17, 1937, with the objective of development of sufficient economic copper orebodies to justify operation of the mine. An underground mine examination was made, and a magnetometer survey was completed in the immediate vicinity of the mine.

#### LOCATION AND ACCESSIBILITY

The Boliver Copper mine workings are in Sections 10 and 15, T. 32 S., R. 10 W., W.M. in the southeast corner of the Fowers Mining District and the southeast corner of Coos County, Oregon. It is about 35 miles southeast of Fowers by good mountain road via Swan Valley. Access is also available from Olendale by 40 miles of road, and from Galice by 50 miles of road. Fowers and Olendale both have Southern Pacific rail facilities. Economic considerations of ore or concentrate shipment would depend upon the trucking rates to each rail station and the freight rates therefrom. These narrow gravelled Forest Service roads can be used for transportation and haulage during the normal dry months of June to December. During the periods of heavy rain and snow, such maintenance and snow-plowing would have to be done. Telephone communication is reported as available over the Forestry Department system.

#### PHYSICAL FEATURES AND CLIMATE

The mine is at an elevation of 2600 feet on one of the rugged northeast-trending spur-ridges of Saddle Peak. The most prominent topographic feature of the district is Mt. Boliver with an elevation of 4500 feet. Drainage is effected by the West Fork of Cow Creek, a tributary of the Umpqua River. The topography of the area is steep and mountainous with the slopes heavily forested with conifers, with hardwoods in the

galena. Bush and soil above west of the outcrop. Annual precipitation is about 75 inches, with a minimum-maximum temperature range of 0°-100° F. Snow may remain on the higher elevations (above 8000') until late in the spring, but the local's seldom have snow for more than a few days. Water for milling is available the year round in the West Fork of Cow Creek near the camp site.

#### LABOR SUPPLY AND LIVING CONDITIONS

Ordinary labor would be available from the Powers district, especially during the full periods of the local logging and milling operations. Experienced miners would have to be imported. The prevailing wage rates are high due to the seasonal lumbering operations. Businesses and the warehouses are available on the property for a small limited operation.

#### MINERAL AND EXPLORATION

The copper ore of this locality has been known for many years. Mr. J. H. Thompson located the original "Monday" claim in 1900, and followed it by several others in later years. He prospect and dug on it sporadically until it was optioned by the Hollman and Western Development Company in 1912. They completed approximately 1000 feet of exploratory shafts and crosscuts by the end of 1916. In addition, 10 underground diamond drill holes with a possible total footage of 1000 feet were completed. No information of the hole logs are available. In 1916, they put out 15 tons of high-grade ore to Okanogan for smelter shipment. It was reported to have assayed 16.9 percent copper, with minor amounts of gold and silver.

In 1927, the Powers-Okanogan road was completed. This paved within one mile of the mine and contributed to the future exploration and development of the mine. In 1928, Mr. Earle Young of Grants Pass, Oregon, mined and shipped 30 tons of ore from the fa tunnel. Results were disappointing and operations ceased.

Originally known as the "Thompson Mine", it continued under that name until 1926. The property at the present time is owned by Mr. Naboy's Assistant of the Estate of J. H. Thompson, and under option to the Hollman Copper Company, Mr. H. F. Carr, President, P. O. Box 1370, Roseburg, Oregon.

#### THE PROPERTY

The property consists of 24 unpatented mining claims and 3 mill sites in the Grandy National Forest. The combined area is 495 acres. These claims imply cover the entire ore-bearing structure. The 3 mill sites available are located along the West Fork of Cow Creek below the camp site, and have plenty of gravity hillside, water, and room for tailings disposal.

The property is equipped for surface mining on a small scale. Equipment on the site at the present time includes: 2 trucks (dump), 1 TD-12 bulldozer, 1 Hollman surface diamond drill equipped for air drilling, 1 3/8-hp shore, 1 15-hp electric generator, and 1 portable air compressor.

Sufficient lumber, principally fir and cedar, is available on the property for construction and mining purposes. It is reported that a

small custom tunnels to located within 4 miles, where mine and mill construction there could be made.

#### MINE WORKINGS

There is 1050 feet of underground workings on the property. This includes a 1 1/2' mine in #1 Tunnel and a 1 1/2' inclined shaft above #3 Tunnel. All the work is exploration and development drifts and crosscuts. Most of it is in good condition, with the exception of about 100 feet just beyond the portal of #1 Tunnel, which is partly caved and in poor condition, notwithstanding possible. A small amount of drifting was done in the #2 Tunnel workings by Mr. Earle Young in 1928. Ten diamond drill (BX) holes with a possible total footage of 1000' can be seen in the fusion and cross-cuts of #1 Tunnel workings. No record of their logs is available.

#### DESCRIPTION OF THE DEPOSIT

Miller says:

"Samples should be made of the copper ore that has been found in a mineralized belt nearly 2 1/2 miles to the northwest in the vicinity of Mount Hollwar, the west prominent peak in the Greenhorn belt that is shown near the northwest corner of the map. The greenstone of this belt is impregnated at a number of places by pyrite, chalcopyrite, and hematite and contains numerous veins of quartz and calcite. The most important copper prospect noted in this region is on the west fork of our creek at the locality known as the Thompson mine. It has been exploited by several tunnels and ladders and yielded at least 50 tons of ore, chiefly chalcopyrite and hematite. The waste were closed at the time of my examination, but the occurrence of so much ore on the dump apparently shows the existence of ore bodies of considerable size. This prospect, although only 1 1/2 miles from the main line of the southern Pacific railroad at West Fork and all down grade, is reached by trail only. Numerous prospects have been opened in this mineralized belt between Mount Hollwar and Hugo River, but none of greater promise than that already noted has yet been found."

Dr. F. G. Wells, in an unpublished memorandum, has reintepreted this above "greenstone" of Miller to be the Dohren metamorphosis of upper Jurassic age. This mineralized belt has a north-south-west trend for some 2 1/2 miles, with widths up to 2 miles. In the vicinity of the Thompson mine, it is 2 miles wide. The mine workings are apparently in the north corner of this belt. Contact on the northeast near the West Fork creek is with the Franciscan formation, in this case being a dark gray to black shale and slates.

Evidence of the basal origin of the formation around the Thompson mine is apparent. It weathers to various shades of green or yellow-brown color. A fresh specimen of the basal is green and fine-grained, and often shows a porphyritic structure. Some specimens are angular, with the angular (epherical) commonly filled with white or light-green chalcedony, green crystalline epidote, chlorite, or secondary copper

minerals (chrysocholla, malachite, etc.). Feldspar crystals about 1 mm long, light green hornblende, and some stubby pyroxene crystals were noted with the hard lens. Occasional specks of magnetite and epidote were also noted. The metabasite is observed in places to a dark-green phyllitic rock, which has the appearance of dark serpentinite.

Ore minerals observed were chiefly bornite and chalcocyanite, with minor amounts of chalcocite. The usual secondary copper minerals were in evidence near the surface outcrop of the mineralized zone. They consist of malachite, azurite, chrysocholla, with minor to trace amounts of cuprite, tenorite, and native copper. Hypogene sulfides are present within a few feet of the surface outcrop, and any secondary enrichment zone appears to be negligible. Gangue minerals in the ore zones were quartz, calcite, and barite. A talcose zone with very fine-grained homogeneously disseminated pyrite was observed in the #8 tunnel cross-cut in the north wall. Sample #5 was taken here.

Re well-defined vein structures were observed; rather the copper minerals were scattered indistinctly over a large area as mineralized fault zones and possible replacement deposits. Underground development of the mine would necessarily be expensive, and ore tonnage production low. Most of the apparent ore occurs in irregular bunches and masses. Usually that which appears to be an ore vein extends only a short distance and pinches out. Sample ore taken in the ore zones indicate this sporadic nature. Please refer to Appendix I, and samples follow #1-5, #6, and follow #7 through #11.

Due to the irregular outline of the deposits and because the ore shoots terminate abruptly, mining and development will proceed more or less discontinuously, and hence very little ore will be proved in advance of mining except by diamond drilling. Because of the nature of the deposits, projections of ore bodies and veins as a basis of tonnage estimates of ore in place are extremely hazardous and not reliable.

#### MINING AND MILLING

To develop an economically feasible copper mine at the present time from this property, it will be necessary to block out by grid-pattern diamond drilling (for sinking by open pit methods) sufficient tonnage of good quality copper ore to justify the installation of a small concentrating mill. The minimum requirements in the ore zone, commensurate with the capital investment of the mill installation, would be 30,000 tons of 3% copper ore on a 90 ton-per-day scale. This is also predicated upon the high metallurgical recovery of the 3% copper ore into a good drying concentrate, and using a simple flotation flow sheet.

#### DEVELOPMENT DIAMOND DRILLING

In order to develop this commercial orebody, diamond drilling should proceed on a grid pattern of 25 feet, progressing outward to delineate the orebody, with holes to a minimum depth of 90 feet. In this case, assuming solid 3% ore in the 90-foot holes, it would take approximately 10,000 square feet, or a square 100' on a side. To completely outline this possible orebody would require 16 90-foot holes.

Agency results of the intervals of the 2 completed diamond drills

holes are tabulated in Appendix I. These samples were given to us for assay, and were reported as being representative of the two holes. #1 hole appears to be of uniformly good ore, with chalcopyrite and bornite observed in the sludge sand. The two sample intervals from #2 hole appear to be very low grade mineralization, and not commercial ore at the present time. It is recommended that diamond drilling be resumed in the vicinity of #1 Hole, with the objective of blocking out an orebody of comparable grade and character to the interval assays of this first hole. Please refer to Appendix I and assays Bolivar #15 through #19.

Sludge and all core from development drill holes should be carefully saved for a metallurgical test sample. Sludge should be kept covered with water to prevent surface oxidation of the ore minerals. Ore dressing testwork on a representative and composite sample of ore should be started as soon as it is apparent that a commercial orebody possibly exists.

#### MAGNETOMETER SURVEY

The immediate area of the mine was covered by a grid of 50' stations. Out roads and trails were utilized wherever possible in order to speed the set-ups. Results indicate a geologic structure of fairly uniform magnetic character.

The magnetic susceptibility of the copper ore was variably higher than the Dothan metavolcanic country rock. This was probably due to the small amounts of magnetite disseminated throughout the ore, wherever noted.

One positive magnetic anomaly was outlined in the vicinity of the old inclined shaft above and to the southwest of #3 Tunnel. Please refer to Magnetic Survey Map and anomaly marked MA #1. This 500 gamma anomaly corresponds to the area containing the most of the best copper ore outcrops. Two vertical diamond drill holes have already been drilled in this area, one with good and the other with poor results. (Please refer to Appendix I for interval assays).

The magnetometer used during this examination was a Rush "Scout" model, having an accuracy of 25 gamma per scale division, and equipped with compensating magnets to give a maximum range of 15,000 gamma.

#### RECOMMENDATIONS AND CONCLUSIONS

1. Magnetic anomaly MA #1 should be diamond drilled by a 25' grid pattern to delineate the ore body. At the present time, drilling depth need not be more than 50', or enough to plan an efficient open-pit operation for the initial production stage of the operation.
2. In the future, representative samples of the drilling progress should be taken at 5' intervals and assayed for copper content. This is in addition to saving all the sludge and core for metallurgical testing.
3. Ore dressing testwork on a representative and composite sample of ore should be initiated as soon as it is apparent that a commercial ore body possibly exists. Results of this testwork would be the basis for the mill design.

**Page 6 - Bolivar Copper property**

It is recommended that caution be exercised in the development of this property. The outlining of a commercial orebody by diamond drilling as previously mentioned is only "good insurance" that a future continuous and profitable operation can be assured. Standard procedures in this phase are recommended.

In conclusion, it is possible that a small commercial orebody can be developed, and I can recommend only a limited investment in this preliminary phase. Procedure from there is dependent upon the results obtained from it.

|                                 |  |
|---------------------------------|--|
| <u>28-51.3</u><br><u>1134</u>   | Very oxidized RX. ??   |
| <u>51.3-62.1</u><br><u>1135</u> | Very oxidized Rx. ??   |
| <u>62.1-67</u><br><u>1136</u>   | Very oxidized Rx - diorite or andesite?  |
| <u>67-72</u><br><u>1137</u>     | Less oxidized - andesite? Minor magnetite<br>olivine   |
| <u>72-77</u><br><u>1138</u>     | As above.  |
| <u>77-82</u><br><u>1139</u>     | As above. Heavy iron mangenes.   |
| <u>82-87</u><br><u>1140</u>     | As above.  |
| <u>87-92</u><br><u>1141</u>     | As above. One main shear vertical.   |
| <u>92-97</u><br><u>1142</u>     | Rx more fresh. Fine grained H.B.<br>Very minor pyrite FeS <sub>2</sub> .<br>94' change - feldspar more chloritic, more<br>white mineral. |
| <u>97-102</u><br><u>1143</u>    | As above except some of the black mafic looks<br>like biotite? Minor pyrite and chalco.  |
| <u>102-107</u><br><u>1144</u>   | Light green-grey fine grained andesite.<br><u>Note 103' breccia.</u> 105' no visible sulfides  |
| <u>107-112</u><br><u>1145</u>   | As above. Some <u>breccia.</u> Visible sulfides<br>FeS <sub>2</sub> . Pyrite. <u>White and pink zeolites?</u><br>No reaction with HCL.   |
| <u>112-117</u><br><u>1146</u>   | As above. Pyrite heavier. No visible<br>chalco or pyrite. Rock auto-brecciated.<br>Fragments same material as ground mass.               |
| <u>117-122</u><br><u>1147</u>   | As above.  |
| <u>122-127</u><br><u>1148</u>   | Contact 45°. Contact at 125'.<br>Chloritic schist. Same as<br>124-127 very chloritic basalt unit.<br>sheared almost gouge.               |

- 127-132  
1149 Less shear as above. 130'-131'  
heavy wine maroon colored altered zeolite?  
Very lightly pyritized. Magnetite and  
olive green mineral.
- 132-137  
1150 Note change 135'. Porphyritic andesite?  
Visible pyrite and chalcopryrite. Pyrite  
predominates. 137' massive pyrite, very minor chalco.
- 137-142  
1151 Porphyritic andesite. 140' massive pyrite  
6" band offset by small fault.  
Cu Au Some minor qtz.
- 142-147  
1152 As above. Massive sulfide pyrite at 143'.  
Cu, Au and AG.
- 147-152  
1153 Porphyrite andesite. Massive 6" band of  
Pyrite with blotches of chalcopryrite.
- 152-157  
1154 Porphyritic andesite. No visible sulfides.
- 157-162  
1155 As above. 160'-162' more altered  
chloritic schists with numerous white  
stringer of zeolite.
- 162-167  
1156 As above.
- 167-171.5  
1157 As above. TD

REPORT ON THE DIAMOND DRILL PROGRAM BOLIVAR COPPER PROSPECT  
SEC. 10, TWP. 32 S, R 10, WWM, COOS COUNTY, OREGON  
JULY 18 TO AUGUST 31, 1974

REPORT ON THE DIAMOND DRILL PROGRAM BOLIVAR COPPER PROSPECT  
SEC. 10, TWP. 32 S, R 10, WWM, COOS COUNTY, OREGON  
JULY 18 TO AUGUST 31, 1974

I SUMMARY

A total of 742 ft. of NX drilling consisting of 5 holes were drilled in the immediate pit area of the Bolivar Copper prospect. The drilling indicates that the copper mineralization consists primarily of bornite ( $\text{Cu}_5\text{FeS}_4$ ) with minor amounts of chalcocite ( $\text{Cu}_2\text{S}$ ) and chalcopyrite ( $\text{CuFeS}_2$ ). The host rocks are pillow basalts and chloritic basalts of the Rogue formation of Jurassic Age.

Copper mineralization above 0.20% was drilled in the following holes (Ranchers Bolivar Nos. = RB Nos.):

|                |                                 |        |
|----------------|---------------------------------|--------|
| <u>RB# 1A.</u> | 5 ft., 61-66 ft. = 1.021% Cu    | Core   |
| <u>RB# 1C.</u> | 50 ft., 0-50 ft. = 0.807% Cu    | Sludge |
|                | 5 ft., 73-78 ft. = 0.718% Cu    | Core   |
| <u>RB# 2.</u>  | 20 ft., 0-20 ft. = 0.468% Cu    | Sludge |
|                | 10 ft., 27-37 ft. = 0.774% Cu   | Core   |
|                | 10 ft., 37-47 ft. = 2.808% Cu   | Core   |
|                | 10 ft., 47-57 ft. = 0.809% Cu   | Core   |
| <u>RB# 3.</u>  | 20 ft., 0-20 ft. = 0.252% Cu    | Sludge |
|                | 1 ft., 52-53 ft. = 0.819% Cu    | Core   |
|                | 6 ft., 111-117 ft. = 2.066% Cu  | Core   |
| <u>RB# 4.</u>  | 5 ft., 50-55 ft. = 0.365% Cu    | Core   |
|                | 5 ft., 65-70 ft. = 0.270% Cu    | Core   |
| <u>RB# 5.</u>  | 10 ft., 104-114 ft. = 3.744% Cu | Core   |
|                | 8 ft., 114-122 ft. = 1.391% Cu  | Core   |

Assaying was done by Union Assay Office Inc., Salt Lake City, Utah.

The drill hole spacing explored an area 350 ft. x 280 ft. = 98,400 sq. ft. The average for a composite of 70 ft. of the mineralization from the 5 holes is 82,000 tons of 1.5% Cu. The host rocks for copper mineralization appear to extend east, south and north from the drilled area.

3000 ft. southwest from pit area an exposure of basalt with stringers of bornite has been exposed in a bulldozer trench. 5000 ft. from the pit in a southwest direction another exposure of basalt with very minor amounts of bornite has been exposed in a bulldozer cut.

## II RECOMMENDATION

The following drill program is proposed to lineate the ore zone in the pit area.

|     |          |    |         |
|-----|----------|----|---------|
| P-1 | vertical | TD | 150 ft. |
| P-2 | vertical | TD | 150 ft. |
| P-3 | vertical | TD | 150 ft. |
| P-4 | vertical | TD | 100 ft. |
| P-5 | vertical | TD | 120 ft. |
| P-6 | vertical | TD | 120 ft. |
| P-7 | vertical | TD | 250 ft. |

The mineralized zone 3000 ft. southwest of the drilled area should be explored with a series of bulldozer trenches. If the zone appears to have any extent, a drill program should be planned to explore the area.

## III GEOLOGY & MINERALIZATION

Bornite is the main copper mineral in the deposit. Very minor amounts of chalcopyrite were observed. A fine coating of chalcocite forms on the bornite but no massive chalcocite was seen. Very minor amounts of malacite were observed. Zinc is not uniformly present with the copper. The highest zinc value is 0.9% in an 8 ft. section in hole RB#5. Gold is nil to trace. The ore horizon appears to be very flat.

Six rock-types appear in the pit area and in the drill holes. Five volcanic units make up the major portion of the rock-types. The writer's field classifications are as follows:

(1) Pillow Basalt. The pillow basalts are the main rock type in the pit area and one of the main mineralized units. The drilling indicates this unit may be 60 ft. thick. Bornite veinlets occur in the shearing around the pillows. There doesn't appear to be disseminated mineralization into the pillows themselves.

(2) Chloritic Basalt. This is a dark green rock made up primarily of chlorite. The unit is highly-fractured with the fractures filled with a soft white mineral. This unit contains the strongest copper mineralization found in the drilling. The bornite mineralization occurs as bands or veinlets in the highly sheared chloritic rock. The old mine workings in part followed the contact between the pillow basalts and the chloritic basalt. The sheared contact between these two units appears to be vertical.

(3) Volcanic Unit No. 3 is a fine-grained, grey-green, porphyritic rock made up of 20-30% white phenocrysts of fresh-looking feldspar crystals and a rounded white unidentified mineral. In outcropping the white rounded mineral and the feldspar crystals stand out in relief of the ground mass. Hole RB#4 was drilled in this unit which contained a 67 ft. section of weak copper mineralization in the form of bornite. The mineralized rock consisted of very tiny veinlets of bornite in the shear zones. This unit is not highly

sheared in hole RB#4. There does not appear to be any dissemination of the bornite away from the shearing.

(4) Andesite? A light-grey, fine-grained rock, non-porphyrific makes up the outcropping to the west of the pit and appears to be interfingering with the other 3 volcanic units. This fine-grained rock may be dikes or sills within the volcanic units. This unit does not appear to be mineralized with copper.

(5) Quartz Diorite? A wedge-shaped block of very altered granitic textured rock is exposed in the pit and appears to cut through the volcanic units. The quartz diorite does not appear to be mineralized.

(6) Porphyritic rhyolite. Light colored rock with both quartz and feldspar phenocrysts. This unit makes a flat to 10° contact with the pillow basalt and chloritic basalt.

The regional mapping of the prospect area by the Oregon Department of Geology and Mineral Industries Bulletin 80, Geology and Mineral Resources of Coos County, Oregon, 1973, classifies the rocks in the prospect area as Rogue volcanics and contemporaneous diorite and gabbro stocks of Late Jurassic Age. No paragenesis of the ore deposit is made in the report and no attempt was made to divide the volcanic units.

The mine area is approximately 1000 ft. southeast of the thrust fault contact of the Rogue volcanics over the younger sediments which consist of conglomerates and sandstones of the Riddle formation.

The writer does not know if the thrust faulting has any relationship to the mineralization at the Bolivar mines; however, it is a structural feature that should be closely examined.

#### IV CONCLUSIONS

The Bolivar Copper prospect consists primarily of bornite mineralization distributed as veinlets throughout 3 volcanic units. Volcanic unit (1) consists of pillow basalt where the bornite mineralization forms veinlets in the shear zones around the pillows. There doesn't appear to be any dissemination of the bornite into the pillows themselves. The attitude of the pillow basalt unit has not been determined, nor has its relationship to the other rock types in the pit been established. This is due mainly to the complex faulting that is present in the pit area. The drilling did not delineate the pillow basalt unit. The pillow basalt and the mineralization appear to extend east, south, and north beyond the drilled area.

Bornite and minor chalcopyrite mineralization appear to be strongest in an intensely sheared and altered chloritic basalt. Bands 4" to 6" wide of massive bornite were drilled in RB#5 where a 10 ft. section assayed 3.7% Cu. The chloritic basalt was not delineated by the drilling and must be regarded as one of the most important units carrying the copper mineralization at Bolivar. This chloritic basalt unit does not appear to contain disseminated copper.

mineralization throughout the unit itself. The mineralization appears to be confined solely to bands or veinlets within the shear zones. These sheared zones vary from a few inches wide to 18 ft. wide. The attitude and the relationship of the chloritic basalt to the other rock types has not been established. This chloritic basalt unit appears to extend beyond the pit and drilled area and should be one of the main exploration targets.

Volcanic unit (3) consists of a light-grey, porphyritic rock containing very minor veinlets of bornite in minor shearing. RB#4 was drilled in this unit: 67 ft. of the hole assayed 0.19% Cu. This unit appears less altered, less sheared and less mineralized than either the pillow basalt or the chloritic basalt. In outcrop west of the pit area this unit appears to contact with and dip under the pillow basalt. The attitude of the contact is S15°E/50°NE. This contact may serve as a guide to determine the extent of the pillow basalt and the chloritic basalt. It is the writer's opinion that to determine the economic potential of the Bolivar deposit, the pillow basalt and the chloritic basalt must be lineated and assayed. A flat lying flow or sill of porphyritic rhyolite (0-10°N) occupies a portion of the ridge north and east of the drilled area and appears to cover the pillow basalt and the chloritic basalt. The rhyolite appears to be approximately 30 ft. thick. Any drilling in this area should allow for the thickness of the rhyolite. If the rhyolite is a flat lying sill, it may be an ore-control feature accounting for the flat nature of the ore horizon.

This report is respectfully submitted this 6th day of January, 1975, in Grants Pass, Oregon, by
