The 2014 savings estimates and reported deemed savings values were unchanged from the 2013 values. During 2014, the RTF reviewed the savings models for DHP with updates occurring in May, June, and December around the calibration of savings models, screening for supplemental fuel use, and the assumptions around other efficiency measures occurring in DHP homes. The RTF's decisions and resulting changes in savings will be applied in 2015. Idaho Power calculated the participant costs for the TRC by averaging one-unit installations that occurred in Idaho Power's service area over the two-year period 2013 to 2014. The average installation cost over the time period was $4,285.

In 2014, Idaho Power included RTF-approved NEBs, accounting for annual avoided supplemental fuel costs and avoided capital expenses of A/C purchases that would have occurred in the absence of the installation of a DHP system. A current sub-committee was formed in 2014 to address the possible inclusion of NEBs for decreased health impacts from reduced wood-burning emissions. In November, the RTF presented its findings and recommendation on the inclusion of health benefits to be part of the cost-effective benefits in the cost-effective analysis of measures and programs. The RTF is waiting the council's guidance on the issue.

After including the RTF-approved NEBs, the DHP measure is not cost-effective from a TRC perspective. However, Idaho Power determined DHPs meet at least one of the cost-effectiveness exceptions outlined in OPUC Order No. 94-590. Idaho Power originally filed UM-1710 to request cost-effectiveness exceptions with the OPUC on November 4, 2014, and subsequently re-filed it on February 11, 2015. The case is still pending. For cost-effective details, see *Supplement 1: Cost-Effectiveness*.

## Customer Satisfaction and Evaluations

As part of the DHP Pilot, Idaho Power's third-party contractor conducted on-site verification (OSV) on at least 10 percent of the completed installations in Idaho Power's service area in 2014 to ensure installations complied with program requirements. The OSVs were beneficial for customers and the contractors. The inspector provided customers with information about how to maximize the benefits of their new DHP. The contractors received feedback from the inspector and reviewed the installation requirements of the DHP Pilot.

In 2014, NEEA provided two reports updating the DHP Pilot. The following are highlights from the reports.

### NEEA Report E14-274, released February 2014

NEEA published a summary report addressing five key components of the DHP Pilot. The report includes market progress, laboratory testing, field monitoring, billing analysis, and cost analysis/NEBs. Each component is described individually in the report with detailed summaries. Several NEEA reports were published since the beginning of the DHP Pilot in 2009 addressing the five components. The February report recapped prior information and discussed DHP products, potential energy savings,

and potential sustainability of DHPs in the Northwest region. A copy of the NEEA Report E14-274 is included on the CD accompanying *Supplement 2: Evaluation*.

### NEEA Report E14-278, released April 2014

This report was the third MPER for NEEA's Northwest DHP Initiative (the Initiative). The report presents the findings of surveys and interviews conducted with a mix of homeowners who owned or did not own DHPs. Feedback collected from installing contractors, utilities, wholesalers, and manufacturers is presented in the report. The report details the effectiveness and progress of the Initiative's ability to transform the target market. A copy of the NEEA Report E14-278 is included on the CD accompanying *Supplement 2: Evaluation*.

## *2015 Program and Marketing Strategies*

Idaho Power will sponsor and provide training sessions and orientations to the DHP Pilot program for new and existing contractors to assist them in meeting program requirements and further their product knowledge.

Expanding the network of participating contractors remains a key strategy for the DHP Pilot. The goal is to support contractors currently in the DHP Pilot while adding new contractors. Performance of the DHP Pilot is substantially dependent on the contractor's ability to promote and leverage the DHP Pilot. Frequent individual contractor meetings will be held in 2015.

The strategy to promote the residential adoption of the DHP technology in Idaho Power's service area includes communicating with the complete supply chain. To accelerate the wholesaler's ability to increase contractor awareness of DHPs and the DHP Pilot, Idaho Power will meet with the wholesalers and share information.

The 2015 marketing strategy will include proven tactics previously used and new methods. Since homeowners make more improvements to their home during the first two years of ownership, the company plans to continue to target new customers in their first six months of new-home ownership. Postcards will be mailed to these new customers, raising awareness of the incentives available to them. The strategy will include many marketing tactics, such as bill inserts, print ads in newspapers, and direct-mail letters. Social media, such as Facebook, will be used. A DHP display will be used at several residential home and garden and home improvement trade shows.

New marketing pieces will be added to the contractor portal over time as needed.

## *Description*

The Energy Efficient Lighting program strives for residential energy savings through the replacement of less-efficient lighting with more efficient technology. The most recent studies indicate consumer usage patterns. According to the *NEEA 2011 Residential Building Stock Assessment: Single-Family Characteristics and Energy Use* study, the average Idaho home has 63 bulb sockets. The *2010 Idaho Power Residential End-Use Survey* shows 88 percent of customers have less than 20 compact fluorescent light (CFL) bulbs installed, indicating there is still potential to install more energy-efficient bulbs. Changing these bulbs represents a low-cost, easy way for all customers to achieve energy savings.

ENERGY STAR® qualified energy-saving bulbs, including CFLs and LEDs, are a more efficient alternative to standard incandescent and halogen incandescent light bulbs. Bulbs come in a variety of wattages, colors, and styles, including bulbs for three-way lights and dimmable fixtures. ENERGY STAR bulbs use 70 to 90 percent less energy and last 10 to 25 times longer than traditional incandescent bulbs.

The Energy Efficiency Lighting program follows a markdown model that provides incentives directly to the manufacturers or retailers, with savings passed on to the customer at the point of purchase. The benefits of this model are low administration costs, better availability of products to the customer, and the ability to provide an incentive for specific products.

## 2014 Program and Marketing Activities

In 2014, the Energy Efficient Lighting program provided almost 61 percent of all energy savings derived from residential energy efficiency customer programs.

Idaho Power continued to participate in the Bonneville Power Administration (BPA) Simple Steps, Smart Savings™ promotion focusing on ENERGY STAR CFL and LED bulbs and LED light fixtures. CLEAResult managed the promotion. CLEAResult is responsible for retailer and manufacturer contracts, marketing materials at the point of purchase, and providing support and training to retailers.

In 2014, Idaho Power continued to respond to recommendations made in the 2013 process evaluation conducted by TRC Energy Services. TRC Energy Services found that the program is generally successful. Since the inception of this program in 2010, the program has consistently exceeded kWh savings goals. The recommendations and Idaho Power's actions and considerations in 2014 are described below.

One recommendation was to continue to investigate options to bring LED products into the program while maintaining cost-effectiveness. In February 2014, Idaho Power added LED bulbs into the promotion in Oregon and Idaho service areas. LED bulbs comprised 13 to 29 percent of light bulb sales each month. LED fixtures were introduced in the Idaho service area March 2014 and comprised less than 1 percent of lighting sales each month through the rest of the year.

TRC Energy Services recommended increasing coordination with retailers to find mutually beneficial in-store advertising solutions and to speak with corporate representatives from a few large retailers to understand the restrictions on advertising, then work with retailers to overcome these barriers. Through its contractor, Idaho Power reached out to corporate representatives to find mutually beneficial advertising solutions. In 2014, all but two of the retailers in the Simple Steps, Smart Savings promotion allowed for some form of in-store advertising. All but five allowed for utility logos. Those that did not allow for utility logos allowed for wording such as "brought to you by your local utility." Retailers cited shopper consistency across the nation and protecting their brand as reasons to set advertising guidelines.

In addition, in 2014, Idaho Power continued to work with the region to address utility programs within the retail sector through participation in the Northwest Regional Retail Collaborative (NWRRC) facilitated by NEEA and by following promotions initiated by the Western Regional Utility Network (WRUN). Both the NWRRC and WRUN sought to develop collaborative approaches to working with manufactures and retailers to increase uptake of energy-efficient products in the retail market.

Through CLEAResult, several special promotions were conducted at the retail stores through Simple Steps, Smart Savings. These promotions generally involved special product placement and signs. For example, in March and September, Fred Meyer stores had special endcap displays with promotional products. Costco used pallet displays in February. Home Depot held a truckload event in September. These types of promotions and special product placement help increase the visibility and sales of promotional products. CLEAResult staff also conducted 1,017 store visits in 2014 to check on stock, point-of-purchase signs, and displays.

TRC Energy Services recommended Idaho Power further investigate opportunities to bring more grocery chains and small retailers into the program or to work with participating retailers of these types to overcome participation barriers and increase program sales. In 2014, Idaho Power worked with 18 participating retailers, representing 144 individual store locations throughout Idaho Power's service area. The majority—63 percent of retailers in the program—are smaller grocery, drug, and small hardware stores.

Regionally, the *2012–2013 Northwest Residential Lighting Market Tracking Study* shows the majority of customers purchase light bulbs at do-it-yourself, mass merchants, and wholesale club stores. Smaller stores have lost market share for lighting products. Regionally, lighting sales at smaller stores have decreased from 28 percent in 2006 to 14 percent in 2012, the most recent year data is available. Larger stores tend to have a larger product selection and more competitive pricing.

Instead of focusing on increasing sales at smaller stores, Idaho Power evaluated its distribution of retail stores to ensure customers had access to promotional products. Idaho Power studied the geographic distribution of participating retailers and confirmed there were participating stores located throughout Idaho Power's service area with the exception of the Salmon area.

In addition, to help facilitate customer access to the promotion under Simple Steps, Smart Savings, Idaho Power launched its first online offering with Costco. With this offering, Idaho Power customers who purchased bulbs online through Costco could access Idaho Power incentives. For the Costco promotion, after selecting the shipping zip code, the customer was prompted to pick their utility service area, thereby emphasizing the tie between Idaho Power and the discounted price.

TRC Energy Services recommended Idaho Power consider adopting changes in RTF metrics for future cycles (not retroactively). In early 2015, Idaho Power established a policy that as a general rule, beginning for 2014 reporting of energy savings from energy efficiency programs, Idaho Power will freeze the savings metrics annually. This means that all savings for a given year will not be changed mid-year. This policy conforms to recommendations from third-party evaluators and seems consistent with other energy efficiency providers in the region.

Another recommendation from TRC Energy Services was to consider assigning the task of reviewing the invoices to junior or administrative staff so the program specialist would have more time to follow other recommendations provided. Idaho Power reviewed this recommendation and believes it is important that the staff with the most expertise review invoices to ensure customer funds are prudently spent; therefore, the program specialist continued to perform the invoice review in 2014. Furthermore, the specific process referenced by TRC Energy Services is a control that is necessary to meet the financial reporting requirements of the *Sarbanes–Oxley Act of 2002* (SOX). Idaho Power has fiduciary responsibility and must ensure all of its legal and regulatory requirements are met.

TRC Energy Services recommended Idaho Power ensure consistent language and terminology for product type categories through drop-down menus or similar strategies and provide future contractors with a data dictionary or other description of database terms. Idaho Power's program database is standardized to the promotion. The database covers program participation from 2009 onward and reflects several different promotions and promotion implementers. As a result, the data classifications tie directly to the original classifications used by the implementer at the time of sale. This allows Idaho Power to differentiate between different promotions and timeframes and tie data directly back to the original source files. A data dictionary will be developed in 2015.

Additional activities in 2014 included education and marketing. Idaho Power and CLEAResult conducted four education events at Costco stores in Pocatello, Twin Falls, Nampa, and Boise. At each event, Idaho Power and CLEAResult personnel talked with customers and staffed a table with literature, promotional items, and a lighting display.

Additional marketing and customer education by Idaho Power included the company's website, a redesigned program brochure, and discussions with customers at community events. The program brochure, which focused on how to shop for an energy-efficient bulb, was redesigned to include LEDs

and the Federal Trade Commission-required *Lighting Facts Label*. This label makes it easier for consumers to choose between different light bulbs by displaying common metrics (energy used, lumens, and color temperature.)

The September issue of Idaho Power's *Connections* customer newsletter and the *Fall/Winter Energy Efficiency Guide* featured lighting. Topics in both publications included understanding how to shop for the right bulb, lighting design basics, LEDs, and lighting controls. In the November *Connections*, the back page promoted the guide with the image of a large LED light bulb. The weekly media *News Briefs* email included stories on energy-efficient lighting on October 28 (guide focuses on lighting), December 1 (tips for safe holiday lighting), and December 8 (LED holiday lights use less energy). In addition, monthly energy efficiency segments on the afternoon KTVB-TV news program (broadcast in Boise and Twin Falls) mentioned energy-efficient lighting on October 27, November 13, and December 9—reaching from 20,000 to 30,000 viewers per program.

Additional 2014 program activities included customer education through distribution of bulbs to customers. Through Idaho Power's local events, bulbs were given directly to customers at a range of venues. Venues included energy efficiency presentations at senior centers and environmental and health fairs. In 2014, 1,524 CFL bulbs and 3,234 LED bulbs were distributed through this route. This included 2,500 LED bulbs distributed along with educational materials at the FitOne Expo in Boise.

## Cost-Effectiveness

Throughout 2013, the RTF analyzed the savings for residential LED bulbs. Savings were finalized in October 2013. Idaho Power reviewed the savings and cost assumptions and determined residential LEDs are cost-effective. LEDs were added to the program in early 2014.

In 2014, the RTF updated and revisited the assumptions for both CFLs and LEDs to standardize and reduce the number of measures. The number of lamp types was reduced from 10 to 5 categories. The lumen categories within each bulb type were merged and reduced from six groups of lumen ranges to three groups. All other assumptions regarding baseline bulb, hours of use, lamp life, lamp cost, room type, and space conditioning remained the same. In grouping these measures, the RTF used a weighted average from the Residential Building Stock Assessment (RBSA).

Several lamp types were included in the program that had no corresponding savings or cost assumptions available from the RTF. These non-RTF lamp types include high-lumen CFL bulbs and LED reflector fixtures. In Tetra Tech's evaluation of the 2013 program activities, the evaluators recalculated the energy savings Idaho Power associated with the high-lumen bulbs. After the evaluation, Idaho Power requested that Tetra Tech review the non-RTF bulbs included in the program. Tetra Tech recommended that the RTF savings and cost assumptions for either the "general purpose and dimmable" bulbs or the "reflector and outdoor" bulbs be assigned to the LED reflector fixtures. After reviewing the hours of use for reflector bulbs and discussing the potential uses of reflector fixtures, Idaho Power decided to assign the "reflector and outdoor" LED bulb savings to these fixtures.

As discussed in the Introduction, Idaho Power reviewed its policy of updating savings and cost assumptions and decided to freeze savings at the beginning of each year. However, this decision was made after efforts had been made to re-map the bulbs sold in 2014 to the new RTF categories. As a result, the savings for this measure reflect the changes approved by the RTF in mid-2014. For detailed cost-effectiveness assumptions, metrics, and sources, see *Supplement 1: Cost-Effectiveness*.

## Customer Satisfaction and Evaluations

In 2014, Idaho Power administered an impact evaluation of 2013 ex-ante energy savings using third-party Tetra Tech to validate ex-post results. Overall, Tetra Tech found the program has well-established design and delivery processes, supported by the program tracking systems, program documentation, and savings tools and that processes are operating efficiently and with careful attention to detail.

The impact evaluation indicated ex-post verified savings were 10,047,811 kWh compared to 9,995,753 kWh ex-ante claimed savings, resulting in a gross realization rate of over 100 percent. The driver of the difference in the overall kWh realization rate from 100 percent was an adjustment made to non-RTF high-wattage lamps.

To facilitate more accurate, transparent, and consistent program reporting, Tetra Tech identified the recommendations below for program improvement.

Tetra Tech recommended working with the administration contractor to track allocation methods and negotiations that relate to allocations. While the administration contractor included the allocation used for each monthly report for each retailer and product model number, Tetra Tech stated Idaho Power should receive and retain a full accounting of Idaho Power's and the administration contractor's understandings of allocation and resolve any variances as part of monthly quality assurance (QA) checks.

Idaho Power reviewed this recommendation and found no action was necessary. Idaho Power already receives the full Regional Sales Allocation Tool (RSAT) used by CLEAResult, which includes a full accounting of the assumptions used to assign allocations. The tool is commissioned by the BPA and is updated approximately once per year. Idaho Power receives newly released versions and reviews the allocations for its retailers. Idaho Power has the opportunity to work with the tool developer to address any concerns. Idaho Power has always and will continue to verify allocations applied to sales as part of its monthly verification check.

Another recommendation by Tetra Tech was to consider updates to the Energy Efficient Lighting program tracking system. Tetra Tech stated that with the recent shift in RTF deemed savings amounts for lighting from wattage to lumen based, Idaho Power should consider adding lumens to the tracking database for each stock keeping unit (SKU) and work to identify future RTF changes in collaboration with the administration contractor. Idaho Power added lumens to the program database in January 2014.

Additionally, Tetra Tech recommended Idaho Power continue to comprehensively track retailer reports and RTF savings but consider a shared system that aligns all specifications that lead to reported energy savings. Tetra Tech also said to consider a database or similar system that the administration contractor and Idaho Power could share to enable additions of SKUs and available technical data to drive consistency between administration contractor reporting and Idaho Power tracking data for all factors.

Idaho Power reviewed this recommendation and found that new reports developed by CLEAResult in 2014 address this concern. Starting in 2014, Idaho Power began to receive a monthly current products list of all potential models in the promotion. Data includes lumens, model numbers, and bulb/fixture descriptions. Since the promotion began, Idaho Power has received detailed sales data directly from the contractor database each month with its invoice. The monthly invoice detail will continue to be compared against the raw sales data as reported by the retailer or manufacturer as part of the invoice reconciliation process.

Tetra Tech suggested Idaho Power consider alternative reviews of unique non-RTF lamps and characterizations. They stated that when identifying lamps that are not identified by the RTF, Idaho Power should take care when lamps are substantially different from an RTF category and verify lamp efficacy against manufacturer specifications and general performance. Idaho Power reviewed this recommendation and found quality concerns are covered by the program requirement that all lamps in the promotion be ENERGY STAR certified. Those without a deemed savings tend to be styles with specialty applications, such as high wattage. Due to lack of data, the RTF set the savings to not applicable (N/A) for some product categories. However, bulbs without deemed RTF savings values, "non-RTF lamps," have passed the ENERGY STAR qualifications for certification. These qualifications include testing procedures, general performance requirements, and minimum efficiency standards.

For non-RTF lamps, Tetra Tech recommended Idaho Power consider directly calculating energy savings using standard industry approaches or working with others to develop region-wide savings values. They stated that for lamps that fall well beyond the RTF categories or *Energy Independence and Security Act of 2007* (EISA) affected baseline lamps, Idaho Power should consider several options, including 1) working with NEEA and/or the RTF to develop lamp adjustment factors and baseline assumptions based on regional market knowledge; 2) conducting independent market research to understand the use of these lamps; and/or 3) using energy savings calculations based on general engineering principles and underlying RTF market adjustment and performance factors. In response to this recommendation, Idaho Power contracted with Tetra Tech to evaluate savings for non-RTF lamps using general engineering principles and the underlying RTF market adjustment and performance factors. Results will be available in early 2015.

A copy of the complete report is included in *Supplement 2: Evaluation*.

## 2015 Program and Marketing Strategies

Idaho Power will continue to participate in Simple Steps, Smart Savings in 2015. CLEAResult was awarded the BPA implementation contract for 2015. Idaho Power will enter into a new promotion contract with CLEAResult beginning April 1, 2015. No disruption in services will occur.

Idaho Power will continue to monitor the number of participating retailers and geographic spread of these retailers. The company will reach out to stores in the Salmon area and invite them to participate in the promotion. Idaho Power will also work regionally to develop online promotions that allow customers to access promotional pricing regardless of location.

In 2015, Idaho Power will participate in the NWRRC and follow the work of WRUN. Involvement in the NWRRC and WRUN will help facilitate research into transitioning the Energy Efficient Lighting program to a more comprehensive retailer markdown program with additional product categories and will help Idaho Power test online retail platforms.

Marketing and education tactics in 2015 will focus on helping customers purchase the right bulb for their need. CLEAResult will continue to manage marketing at retailers, including point-of-purchase signs, special product placement, and displays.

## *Description*

The Energy House Calls program gives homeowners of electrically-heated manufactured homes an opportunity to reduce electricity use by improving the home's efficiency. Specifically, this program provides free duct-sealing and additional efficiency measures to Idaho Power customers living in Idaho or Oregon in a manufactured or mobile home using an electric furnace or heat pump. Participation is limited to one time per premise.

Services and products offered through the Energy House Calls program include duct testing and sealing according to Performance Tested Comfort System (PTCS) standards set by the RTF and adopted by the BPA; installation of a CFL bulb; two replacement furnace filters with installation instructions; testing water heater temperatures for the proper setting; and energy efficiency educational materials appropriate for manufactured-home occupants. The value of the service to the customer is dependent on the complexity of the repair. Although participation in the program is free, a typical cost for a similar service call would be $400 to $600. Idaho Power provides the customer with the contractor contact information via the Idaho Power website and marketing material. The customer then schedules an appointment directly with one of the recognized, certified sub-contractors specifically trained to provide these services in their region. The contractor verifies the customer's eligibility by initially testing the home to determine if it qualifies for duct-sealing. The actual energy savings and benefits realized by each customer depend on the measures installed and the repairs and/or adjustments made.

## 2014 Program and Marketing Activities

Energy House Calls serviced 297 manufactured homes during 2014, resulting in 579,126 kWh savings. An additional 33 homes were serviced with a test only. Of the homes served, 44 percent were located in the Treasure Valley and 56 percent were outside the Treasure Valley, with 34 percent east of Ada County and 22 percent west of Canyon County. Idaho Power marketed the program, coordinated sub-contractors' performance of local duct-sealing and energy efficiency services for this program, processed sub-contractor paperwork, and paid sub-contractors directly for work performed.

Participation declined in 2014 relative to 2013, with 297 and 411 homes completed, respectively. During the 11 years the program has been active, 10,779 homes have been serviced. Although it is difficult to pinpoint market saturation, there is a concern the program may be in its declining years. Concern over declining numbers prompted specific action in 2014, including an increase of marketing activities planned for the upcoming year and a review of new measures that may provide an increase in savings and encourage reluctant customers.

A variety of marketing tactics were employed to cultivate and capture the interest of a declining target audience. In the first quarter of 2014, 1,225 flyers were sent to churches, senior centers, and mobile home parks to enlist their aid in recruiting participants through their networks.

In spring 2014, Idaho Power tested advertising on Facebook based on results from a Foremost Insurance study that reported 79 percent of residents living in manufactured homes use Facebook and 42 percent visit social media multiple times per day. The results were positive, with 146,663 impressions and 515 click-throughs to the program landing page. The CTR was 0.029 compared to a good industry average of 0.02 to 0.024. Due to the CTR, the ads were rescheduled for November 1 through December 31.

In August, the non-participant survey was distributed to 4,000 potential participants with marketing and contact information in the packet. Contractors reported an uptick in scheduled appointments shortly after the survey was fielded. Collateral was redesigned to emphasize that program participation is free—a concern brought forward by respondents of the non-participant survey.

A September bill insert was sent to all residential customers in Idaho and Oregon. In November, 10,592 postcards were sent directly to all residents of electrically-heated manufactured homes that have not yet participated in the program. Postcards were delivered in either English or Spanish, as appropriate.

As in the past, door hangers continued to be delivered by the contractors to homes in areas where they were completing Energy House Calls visits. Idaho Power delivered postcards from the marketing campaign to Community Action Partnership (CAP) agencies for distribution to customers who need assistance but do not meet the qualifications to receive weatherization assistance through those agencies. In addition, Idaho Power CRs and customer service representatives (CSR) knowledgeable about the program continued to offer the program to qualified customers.

Although Idaho Power considered Spanish radio opportunities in Canyon County, the company decided to focus efforts on establishing monthly television segments to reach a larger audience. Television interviews began in October and are scheduled to continue into 2015. All direct-mail postcards and the participant and non-participant surveys were available in Spanish and delivered directly to homes identified in Idaho Power's database as Spanish-speaking customers.

## Cost-Effectiveness

In 2014, Idaho Power used the same RTF-deemed savings for manufactured-home PTCS duct-sealing as was used in 2013. However, the average savings per home are slightly reduced in 2014 from 2013 due to the size and location of the manufactured homes serviced. Savings are greater in colder heating zones and for double and triple-wide homes than they are for single-wide homes. For more detailed information about the cost-effectiveness savings and assumptions, see *Supplement 1: Cost-Effectiveness*.

Comments received in Case No. IPC-E-14-04 suggested Idaho Power should increase its incentive for this program due to the continued strength of its TRC ratio. Although the incentive for a free program cannot be increased, Idaho Power looked into incorporating additional measures to enhance the value for future program participants. The inclusion of these additional measures will be implemented in 2015.

## Customer Satisfaction and Evaluations

To monitor QA in 2014, third-party verifications were conducted by Momentum, LLC on approximately 6 percent of the 297 participant homes, resulting in 18 home inspections. Homes were selected at random. The QA reports indicate customers were pleased with the work sub-contractors completed in their homes. Each home inspection included an on-site visual confirmation that the reported work had been completed. Weather permitting, blower door and duct blaster tests were also conducted to verify the results submitted by the sub-contractor.

In August, a program satisfaction survey was mailed to 367 customers that had participated in the program from July 2013 through July 2014. The survey and letter were printed in both English and Spanish. The letters included a link giving the participants an option to complete the survey online. One hundred forty-three participants provided feedback, resulting in a response rate of nearly 39 percent. Key findings included the following:

- Nearly 93 percent of the respondents indicated they were either “very satisfied” or “somewhat satisfied” with their overall program experience, and nearly 88 percent were “very likely” to recommend the program to friends or family.
- When asked to select their reasons for participating in the program, just over 92 percent of respondents indicated that reducing energy costs was a motivating factor.
- Nearly 86 percent of respondents indicated it was “very easy” to participate in the program.
- Following their Energy House Calls participation, just over 57 percent of respondents had noticed a change in comfort in their home. Of those that noticed a change, nearly 98 percent reported that the comfort in their home was either “much better” or “somewhat better” following their participation in the program.
- Finally, respondents “strongly agreed” nearly 75 to 82 percent of the time that the service specialists that completed work on their home were punctual, courteous, professional, and thorough.

In August, a non-participant survey was mailed to 4,000 customers that had not participated in the Energy House Calls program. The survey and letter were printed in both English and Spanish, and the letter included a link giving customers an option to complete the survey online. The non-participant

survey had a response rate of nearly 14 percent, with 542 customers completing the survey. Key findings identified included the following:

- Just over 82 percent of respondents lived in homes built prior to 1999, 66 percent lived on private land, and just over 87 percent owned their homes.
- Approximately 12 percent of respondents indicated they had primary heating systems other than central furnaces with ducts or heat pumps. These customers are ineligible for the program.
- Nearly 84 percent of respondents indicated that based on what they knew of the program, they were "very likely" or "somewhat likely" to participate in the program.
- Nearly 82 percent of respondents indicated lowering energy costs would be a "very motivating" factor for participation. Over 77 percent indicated no/low cost to participate would also be a "very motivating" factor for participation.
- When customers were asked to identify their preferences for how Idaho Power should communicate with them about programs and issues impacting their bills, about 48 percent of respondents said they preferred "promotional material in their Idaho Power bill" and nearly 61 percent indicated a preference for a letter or postcard in the mail.
- Over 63 percent of respondents were unaware of the program prior to receiving the survey.
- For those that were aware of the program, they were asked to select all of the reasons for not participating in the program. Over 26 percent indicated they didn't know the program was free, nearly 25 percent did not fully understand the program, and almost 12 percent did not see the benefits of participating.

## 2015 Program and Marketing Strategies

During the 11 years Energy House Calls has been in operation, 10,779 electrically-heated manufactured homes have been serviced through the program. Each year, Idaho Power prepares its direct-mail marketing list by analyzing kWh use of homes designated as manufactured or mobile in Idaho Power's customer information system to find those that appear to be electrically heated. After removing those homes that had already participated in the program, the 2014 direct-mail list contained 10,808 customers, indicating that approximately 50 percent of eligible homes had already been served by the program. An additional percentage of these homes may have had their ducts sealed through Idaho Power's low-income programs, as a few respondents from the non-participant survey indicated they had already participated in a duct-sealing program. Idaho Power will continue to monitor these numbers, but as response rates continue to decline across the service area, there is concern the market may be reaching saturation.

In 2015, more products and services will be offered to program participants during each scheduled visit. Specifically, contractors will install LEDs in main living areas. When water is heated with electricity, contractors will be able to wrap the inlet/discharge pipes from the water heater tank and install high-efficiency showerheads and faucet aerators.

Marketing tactics will continue to include potential participants' most-preferred methods for receiving information—promotional materials in the Idaho Power bill or a letter/postcard in the mail. However, to boost participation in a market that is moving toward saturation, marketing efforts will

double and emphasis will be placed on the variety of services offered. Two bill inserts will advertise program benefit and expected savings, and free participation will be highlighted. A targeted mail campaign direct to residents of manufactured homes that have not yet participated in the program will be conducted in spring and fall. Contractors and CRs will continue to distribute door hangers in mobile home parks and will take every opportunity to distribute program literature at appropriate events and presentations. Additionally, flyers and posters will be mailed to organizations with constituents that may benefit from the program.

Throughout the year, the program will explore new ways to reach customers and continue to look for additional cost-effective measures that can add value to the program.

# ENERGY STAR® Homes Northwest

* Includes savings from 282 certified gas-heated ENERGY STAR homes in 2014.

## *Description*

ENERGY STAR® Homes Northwest is a regionally coordinated initiative supported by a partnership between Idaho Power and NEEA's Northwest ENERGY STAR Homes to improve and promote the construction of energy-efficient homes using guidelines set forth by the EPA. This program targets the lost-opportunity energy savings and summer-demand reduction that results by increasing the efficiency of the residential-building envelope and air-delivery system above current building codes and building practices. An ENERGY STAR certified home is a home that has been inspected and tested by an independent, third-party ENERGY STAR rater/home performance specialist (HPS) to meet the stringent ENERGY STAR requirements. This third-party rater is hired by the builder to perform these duties.

The ENERGY STAR Homes Northwest residential construction program promotes homes that use electric heat pump technology and are at least 15 percent more energy efficient than those built to standard Idaho and Oregon code. The program specifications for ENERGY STAR Homes Northwest are verified by the HPS and are certified by the Washington State University Extension Energy Program and Building Energy, Inc., organizations that conduct the certification inspections throughout Idaho and Oregon for the EPA. ENERGY STAR homes are more efficient, comfortable, and durable than homes constructed to standard Idaho building codes.

Homes that earn the ENERGY STAR label include six required specifications: 1) effective insulation, 2) high-performance windows, 3) air-tight construction and sealed ductwork, 4) energy-efficient lighting, 5) ENERGY STAR qualified appliances, and 6) efficient heating and cooling equipment.

To encourage builders to construct ENERGY STAR homes, builders participating in ENERGY STAR Homes Northwest in 2014 received a $1,000 incentive per home built to the Northwest ENERGY STAR Single and Multi-Family Homes Requirements with heat pump technology. Builders who entered their homes in a Parade of Homes received the standard $1,000 incentive plus an additional $500 marketing incentive to cover their expenses for ENERGY STAR signage and brochures. Another benefit to the builders is the right from ENERGY STAR Homes Northwest to use the logo and the ENERGY STAR name to promote themselves as an ENERGY STAR qualified builder.

The Idaho Power program collaborates with many local entities for program promotion, including ENERGY STAR Homes Northwest and builders. A large part of the program's role in 2014 was to provide marketing materials and support for the building contractors associations (BCA) throughout the Idaho Power service area.

## 2014 Program and Marketing Activities

A majority of the homes certified in 2014 were townhomes. This trend toward ENERGY STAR townhome certifications is a regional trend. In 2014, 5 of the 240 ENERGY STAR home certifications in Idaho were single-family homes. The decrease in the number of participating homes in 2014 as compared to 2013 is due to fewer ENERGY STAR Homes, employing heat pump technology, being certified in Idaho Power's service area. The trend the past couple of years has been toward an increase in multi-family construction Idaho Power's service area. In 2013, seven multi-family ENERGY STAR developments were constructed. In 2014, five multi-family ENERGY STAR developments were constructed, resulting in 61 fewer homes being certified in 2014.

The company maintained a strong presence in the building industry by supporting the Idaho Building Contractors Association (IBCA) and several of its local affiliates throughout Idaho Power's service area in 2014. The company presented the Energy Efficient Design and Construction Awards to builders who integrated energy efficiency features in their parade homes at the BCASWI Parade of Homes awards banquet. In addition, the company participated in the BCASWI builder's expo, and the Snake River Valley Building Contractors Association (SRVBCA) builder's expo. The company also supported Parade of Homes events with full-page ENERGY STAR ads in the Parade of Homes magazines of the following BCAs: The Magic Valley Builders Association Parade of Homes (MVBA), the BCASWI Parade of Homes, SRVBCA Parade of Homes, and the Building Contractors Association of Southeast Idaho (BCASEI) Parade of Homes. Bill messages were added to residential customer's billing statements informing them of Parade of Homes events in their area. In addition, the company sponsored the IBCA annual winter and summer meetings. A half-page ad was placed in the BCASWI monthly November and December newsletters to promote the program and the builder incentive.

In fall 2014, a bill insert was sent to all residential customers in the Idaho Power service area promoting the ENERGY STAR Homes Northwest program. The company ran print ads for four weeks in real estate sections of daily newspapers in Boise; Pocatello; Canyon County; and Ontario, Oregon. During this same timeframe, a digital behavioral ad campaign ran for two months across Idaho Power's service area, totaling 2,683,717 impressions/ads served and including such real estate sites as zillow.com. A letter to residential builders was mailed in spring 2014 reminding builders of the benefits of building ENERGY STAR homes and of the available builder incentive.

Idaho Power administered a process evaluation of the ENERGY STAR Homes Northwest program in 2013. This evaluation was performed by third-party contractor TRC Energy Services. In general, TRC Energy Services found the ENERGY STAR Homes Northwest program was successfully meeting goals and delivering energy savings. TRC Energy Services noted this was particularly impressive given

the challenges of the recent market downturn and the exclusion of customers with natural gas heat from the program. Based on the results of this evaluation, TRC Energy Services provided several recommendations for program improvement. The recommendations and Idaho Power's responses are described below.

TRC Energy Services recommended continued support from the company for the multi-family and townhome market, identification of other markets that could be building electrically heated homes, and targeting marketing efforts toward these sectors. In 2014, the company continued to support the multi-family ENERGY STAR homes market through certification of 235 multi-family homes and through its continued support of local BCAs.

The evaluators recommended Idaho Power develop an argument for the value of the ENERGY STAR label and verification and provide this (through talking points or a one-page flyer) to CRs, HPSs, and builders and to work with other entities to develop these talking points. Idaho Power determined the marketing materials, and the talking points developed by Idaho Power and Northwest ENERGY STAR Homes, currently available to CRs, HPSs, and builders appropriately addressed the argument for the value of the ENERGY STAR homes certification.

TRC Energy Services recommended Idaho Power provide continued support for the HPSs, meet with them one-on-one to understand their barriers to participation, and work with them to overcome these barriers. In particular, revisit the QA procedure for the program. In 2014, Idaho Power continued to maintain good relationships with the active HPSs and communicated multiple times throughout the year through email, phone calls, and face-to face visits. NEEA manages the QA function of the Northwest ENERGY STAR Homes program. While Idaho Power uses the QA results for its program compliance within the company's service area, the procedures used are dictated by NEEA. The company will encourage NEEA to communicate with the raters concerning QA procedural issues.

The evaluators recommended Idaho Power update the contractor list so it contains only builders that provide accurate information about the program, and to periodically update this list (e.g., biannually) by reaching out to contractors. In response to this recommendation, the builder list on the company ENERGY STAR Homes Northwest website is now a link to the Northwest ENERGY STAR Homes builder listing, which is current and updated frequently.

Another recommendation was to test the hypothesis reported by Idaho Power staff that multi-family builders are the primary group building homes with heat pumps by analyzing the residential nonparticipant survey results and through interviews with BCA staff. Idaho Power concluded multi-family homes with heat pumps versus single-family homes with heat pumps being submitted for ENERGY STAR Homes certification via the Northwest ENERGY STAR Homes database strongly indicated a current regional trend that multi-family builders are the primary group building heat pump homes.

The evaluators recommended using the regional program database to identify builders that are building electrically heated homes in Idaho Power's service area but do not qualify for the Idaho Power program. Idaho Power ascertained that all homes built using heat pump technology and meeting all Northwest ENERGY STAR Homes criteria currently qualify for the Idaho Power program.

TRC Energy Services recommended Idaho Power develop new relationships between the CRs, program specialist staff, key homebuilders, heat pump contractors, and heat pump suppliers and to reconnect with previously participating builders. In 2014, the program specialist and the CRs continued to establish and maintain new and existing relationships primarily through BCA builder events and industry-related meetings. The primary relationship within the ENERGY STAR Homes Northwest

program and company staff was with builders. CRs also formed relationships with heat pump contractors through the Idaho Power heating and cooling program. The company sent out a letter to all current and past ENERGY STAR Homes Northwest builder participants in April 2014 to update them on the program and the incentives offered.

Another recommendation was to provide additional builder training addressing the benefits of heat pump technology, electric heat pump home design, and design strategies to reduce electricity use in homes. While there was no on-site, heat pump specific training done in Idaho Power's service area in 2014, Northwest ENERGY STAR offered a DHP webinar in November 2014. All Northwest ENERGY STAR builder and HVAC contractor partners were encouraged to attend this event.

Last, the evaluators recommended Idaho Power provide CRs with goals for marketing the program, such as contacting a certain number of builders or presenting at a BCA meeting about the program; have CRs use the heat-pump flyer as a talking point with builders; and have CRs attend program trainings or heat-pump presentations with builders to learn about the program and develop relationships with local builders. Of note, Idaho Power CRs don't have specific goals that require them to contact a certain number of builders, but they are asked to be involved in their local BCA chapter where the opportunity to meet and establish relationships with builders is high. The CRs have been and continue to be active in the local BCA chapters where they come into direct contact with a majority of builders in their area. When program trainings are held, CRs are invited and encouraged by Idaho Power to attend.

## Cost-Effectiveness

Idaho Power used the same cost-effectiveness savings assumptions from the RTF for ENERGY STAR Homes Northwest for 2014 as were used in 2013. While savings assumptions remained the same for 2014, the RTF-calculated NEBs were added to the cost-effectiveness calculations to account for water and avoided maintenance savings over the lives of these efficient homes. The inclusion of NEBs helped improve cost-effectiveness for the different building packages and climate combinations from a TRC perspective, but the townhome/multi-family homes in the Bose–Nampa–Caldwell climate zone, which is the primary home submitted since 2012, is still not cost-effective from a TRC perspective.

Idaho Power has participated in ENERGY STAR Homes Northwest, a regionally coordinated initiative, supported by a partnership between Idaho Power and NEEA, since 2004. The company has been a continued proponent and driver of the increased awareness of the ENERGY STAR Homes Northwest brand. The majority of electrically heated ENERGY STAR Homes Northwest certifications are from several large multi-family builders exclusively building homes to ENERGY STAR specifications employing electric heat pump technology.

Because of Idaho Power's support of NEEA and the ENERGY STAR Homes Northwest brand, Idaho Power is claiming savings for 282 natural gas-heated, ENERGY STAR certified homes certified in Idaho Power's Idaho service area in 2014. These savings account for 195,372 kWh of annual savings from efficient cooling equipment, insulation, windows, doors, water heating, ventilation, appliances, and lighting. NEEA does not claim these savings, and they will be included in the program savings totals in appendices 3 and 4.

For more detailed information about the cost-effectiveness savings and assumptions, see *Supplement 1: Cost-Effectiveness*.

## Customer Satisfaction and Evaluations

The HPS works with builders to ensure the ENERGY STAR homes are compliant with the Northwest ENERGY STAR Homes specification. Along with verifying the installation of building components and

equipment through on-site inspections, prior to being certified, the HPS ensures the home passes a blower door test, an air-duct leakage test, and combustion back-draft tests.

The state-certifying organizations (SCO) perform QA inspections. The Washington State University Energy Extension Program is under contract with NEEA to perform QA and technical assistance duties within Idaho. For QA purposes, 5 percent of homes certified in the ENERGY STAR Homes Northwest program are reviewed by the Washington State University Energy Extension Program. This is a technical verification of the homes. All of the homes randomly chosen for QA in Idaho Power's service area passed the QA inspection process in 2014.

In 2014, the Customer Research and Analysis team administered an impact evaluation using Tetra Tech to provide third-party analysis. The findings from this evaluation found that the ENERGY STAR Homes Northwest program has well-established program design and delivery processes that are supported by the program tracking systems, program documentation, and savings tools. The impact evaluation approach emphasized compliance with the RTF energy savings as the basis for verification of savings.

Results of the impact evaluation indicated that 2013 ex-post verified savings were 353,828 kWh compared to 365,370 kWh ex-ante claimed savings, resulting in a gross realization rate of 96.8 percent. The driver of the difference in the overall kWh realization rate was adjustments made to seven townhomes removed from the program savings.

Tetra Tech also identified several recommendations for the ENERGY STAR Homes Northwest program as a result of the impact evaluation. The evaluator recommended continuing to use the program tracking system for savings assignments and noted that in 2014, Idaho Power made recent improvements to their energy efficiency programs database to assist in automating savings assignments and prevent the need to develop savings assignments outside the database. Tetra Tech also noted that improving the database usability and allowing for the automation of look-up functions to occur within the database will also assist in reducing potential error, enhance the quality review process, and help facilitate reviews. This will also ensure other parameters are entered correctly by allowing for data checks across fields. The evaluator stated that an additional result would be avoiding misalignment between participating homes and the assigned savings values. In response, in 2014 Idaho Power enhanced database functionality and will continue to automate database tracking systems as needed.

Tetra Tech recommended the continued use of RTF categories and continued use of the RTF proven measure savings, but recommended Idaho Power develop savings assignments and calculations with a clear alignment with the RTF savings values for single-family and multi-family homes. Tetra Tech stated that a unified participant tracking and savings workbook could contain such information and provide an efficient and standardized approach that can address potential future program regional complexity. Idaho Power uses the RTF proven measure savings, and the independent values for single-family and multi-family savings are assigned in the DSM Customer Load and Resource Information System (CLRIS) application based on housing type.

Another recommendation was to investigate methods for obtaining project-level documentation. Tetra Tech stated the program and a future evaluation effort may benefit by having greater access to project-level details covering project eligibility and greater technical details. For the benefit of the program and evaluators, Tetra Tech recommended Idaho Power work with NEEA and their contractors to improve the level of detail captured for each project and made available to Idaho Power for the Builder Option Package inspection results for each home. In response, Idaho Power considered this recommendation and determined the documentation provided for each certified ENERGY STAR home, via the Northwest ENERGY STAR Homes database, provides the necessary detail for Idaho Power to pay incentives to builders. This documentation, the *Northwest ENERGY STAR Homes Program Report*,

denotes that all testing and inspection on the home meets or exceeds all minimum values of ENERGY STAR Home certification. This report also denotes the certified status of the home, states that each program checklist was completed successfully, and provides the performance testing results.

Last, the evaluators recommended working to increase QA inspections within the company's service area and working with NEEA and their contractors to better understand the protocols and information obtained and documented during QA inspections in Idaho Power's service area. This recommendation is to ensure appropriate home parameters are captured for the current and future needs of Idaho Power evaluations and that a minimum number of Idaho Power ENERGY STAR certified homes are QA inspected each year. The evaluator recommended that, absent the ability of Idaho Power to ensure a minimum level of service for QA, Idaho Power should consider conducting and documenting its own QA process using the same protocols as the NEEA initiative. In response to the recommendation, in 2014 Idaho Power began discussions with NEEA to ensure a representative number of QA inspections of heat pump homes in Idaho Power's service area that qualify for the Idaho Power incentive. A copy of the complete report is included in *Supplement 2: Evaluation*.

## 2015 Program and Marketing Strategies

Builders involved in ENERGY STAR Homes Northwest during 2015 in Idaho Power's service area will receive a $1,000 incentive per home built to the Northwest ENERGY STAR Homes specifications using heat pump technology standards. Builders showcasing their electric heat pump home in a BCA Parade of Homes event will receive the standard $1,000 incentive plus an additional $500 parade marketing incentive.

Idaho Power plans to continue marketing efforts to help promote ENERGY STAR homes to home builders and new homebuyers. These marketing efforts include Parade of Homes ads in parade magazines for the BCASWI, SRVBCA, MVBA, and the BCASEI. The company also plans to continue supporting the general events and activities of the IBCA and its local affiliates. Marketing materials will be available for use by builders. Bill inserts will be sent to all residential customers in May. Bill messaging is planned in June, July, and August to support the various BCA Parade of Homes events throughout Idaho Power's service area.

A direct-mail letter to builders is planned for 2015. This direct-mail piece will highlight the requirements and the Idaho Power builder incentive for building to Northwest ENERGY STAR Homes specifications. In addition, the program will be promoted in the *Idaho Business Review* in issues targeting residential contractors and builders.

NEEA is planning a 2015 transition of the Northwest ENERGY STAR Homes program to the national EPA ENERGY STAR Homes program and to local market partners/stakeholders. NEEA will continue to provide program and technical oversight of ENERGY STAR Home Northwest through 2015 with plans to then transfer oversight to the national program. The program will be available for builders if they so choose to continue building ENERGY STAR certified homes under the national program.

A second program, NEEA's Next Step Home program, is still in the pilot stage. At the end of 2014, NEEA began developing the Phase III recruitment plan to continue building participation and awareness in the Next Step Home pilot. Homes built during Phase III will incorporate Next Step Home minimum requirements, guidelines, and best practices learned from Phase I and II. Despite NEEA recruiting efforts, there are no builders who have, as of yet, signed on to build a Next Step Home in Idaho Power's service area.

## *Description*

The H&CE Program provides incentives to residential customers for the purchase and proper installation of qualified heating and cooling equipment.

The objective of the program is to acquire energy savings by providing customers with energy-efficient alternatives for electric space heating. Incentive payments are provided to both residential customers and HVAC participating contractors who install eligible equipment. The eligible measures in 2014 include air-source heat pumps, open-loop water-source heat pumps, and evaporative coolers.

Heating and A/C companies authorized by Idaho Power as participating contractors for the program are required to perform all installations, with the exception of evaporative coolers, which can be self-installed.

The H&CE Program's list of measures and incentives includes the following:

- Customer incentive for replacing an existing air-source heat pump with a new air-source heat pump is $250 for a minimum efficiency 8.5 heating seasonal performance factor (HSPF).
- Customer incentives for replacing an existing electric, oil, or propane heating system with a new air-source heat pump is $400 for a minimum efficiency 8.5 HSPF. Participating homes with oil or propane heating systems must be located in areas where natural gas is unavailable.

- Incentive for customers or builders of new construction installing an air-source heat pump in a new home is $400 for a minimum efficiency 8.5 HSPF.

- Customer incentive for replacing an existing air-source heat pump with a new open-loop water-source heat pump is $500 for a minimum efficiency 3.5 coefficient of performance (COP).

- The customer incentive for replacing an existing electric, oil, or propane heating system with a new open-loop water-source heat pump is $1,000 for a minimum efficiency 3.5 COP. Participating homes with oil or propane heating systems must be located in areas where natural gas is unavailable.

- The incentive for customers with new construction installing an open-loop water-source heat pump in a new home is $1,000 for a minimum efficiency 3.5 COP.

- The evaporative-cooler customer incentive is $150.

## 2014 Program and Marketing Activities

The expansion of Idaho Power's network of participating contractors remained a key growth strategy for the program. Idaho Power's goal was to support contractors currently in the program while adding new contractors. The company held meetings with several prospective contractors to support this strategy. Idaho Power added eight companies to the list of participating contractors in 2014.

Idaho Power held nine training sessions for contractors in 2014. For a company to be eligible to join the program as a participating contractor, they must have participated in this required training that provides general instructions on heat pumps and program guidelines. These training sessions remain an important part of the program because they create opportunities to invite additional contractors into the program.

To increase contractor participation in the program, stronger relationships with the equipment wholesalers was necessary. In Idaho Power's service area, there are numerous wholesalers supplying heat pumps to the contractors. Idaho Power met with several of these wholesalers in Idaho Power's service area to share helpful information and to encourage them to promote the program to their contracting customers.

Idaho Power uses Honeywell, Inc., a third-party contractor, to review the incentive applications and perform OSVs. This contractor provides direct support to participating contractors and the residential program participants. Honeywell offers local assistance through representative visits to contractors at their businesses as needed. Using a program database via a portal developed by Idaho Power, Honeywell reviews and submits incentive applications for Idaho Power payment. This allows Idaho Power to maintain the database within the company's system, which is secure yet accessible to the third-party contractor.

Multiple marketing tactics were used for Idaho Power's HC&E Program. Approximately 3,000 radio ads ran on over 20 radio stations for six weeks throughout Idaho Power's service area. In spring 2014, a digital behavioral ad campaign was launched and resulted in 771,211 ads displayed on pages viewed by people browsing the internet over two months.

A contractor portal was launched in 2014. The portal allowed authorized contractors access to a specific area of Idaho Power's website where they could customize pre-approved marketing pieces with their own business name, address, and phone number. Two door hangers were offered for insulation

contractors, two door hangers for window contractors, and two fliers for participating contractors in the HC&E Program. The *Demand-Side Management 2013 Annual Report* stated the contractors would be asked to comment on the portal during 2014. Comments were not pursued due to the portal launching the third quarter of the year, which limited contractors' time to try the portal in 2014.

The *Demand-Side Management 2013 Annual Report* mentioned possible changes to the HC&E webpages. Changes to the HC&E webpages were not made in 2014 because on a separate project, the company began working on a website redesign to improve navigation on the Energy Efficiency website. The decision was made to wait until that work was completed before any changes were made to HC&E webpages. The website navigation changes did not result in any changes being made to the Energy Efficiency website during 2014.

A direct-mail campaign was conducted in April 2014. Over 27,000 letters were sent to homeowners of electrically heated homes. In addition, information about the heat pump program was included in a postcard sent to people who purchased a home within the previous six months. Bill inserts and newspaper ads rounded out the ongoing marketing and promotion of the HC&E Program.

Idaho Power administered a process evaluation of the H&CE Program in 2013, performed by third-party contractor TRC Energy Services. Based on the evaluation results received in 2014, TRC Energy Services identified program trends, successes, and barriers, then developed recommendations to address the barriers.

It was recommended Idaho Power gain a better understanding of the eligible market, such as customers with electric, oil, or propane heat and their barriers for program participation, to better target marketing efforts. In response to this recommendation, Idaho Power participated in seven local trade shows and benefited from one-on-one discussions with residential homeowner attendees.

The evaluators recommended Idaho Power provide contractors with co-branded marketing materials, case studies, or cost calculation examples to assist them with their marketing efforts. A new online contractor portal was already in development and was launched on the Idaho Power website late summer 2014. This password-protected portal provided participating contractors with pre-designed colored marketing fliers printable by the contractor for distribution. Fliers could be personalized with the contractor's business name, address, logo, and phone number.

TRC Energy Services recommended Idaho Power consider requiring contractors to attend refresher training and/or deliver a minimum number of projects per year to continue to be listed on the program website. In 2014, the H&CE Program incorporated this recommendation by providing nine refresher training sessions and requiring each participating contractor to submit a minimum of one application per year beginning in 2015 to avoid being placed on inactive status.

Another recommendation was that program requirements be described clearly and prominently in marketing collateral and on the website. In response to this recommendation, all marketing collateral and web content were reviewed. Improvements were made to ensure the reader realized incentive requirements apply.

It was recommended that Idaho Power CRs be engaged in the contractor training sessions routinely provided by Idaho Power. Idaho Power invited the CRs to sessions in 2014, and several CRs attended the sessions.

TRC Energy Services recommended Idaho Power annually contact the participating contractors to ensure there is at least one installing technician trained by the program. This recommendation was made due to employee turnover experienced with some participating contractors. Idaho Power provided training where there was a lack of a trained technician.

The evaluators recommended surveys be initiated to gather various types of program feedback from participating contractors. This has not been implemented because Idaho Power decided face-to-face meetings between participating contractors, the CRs, and the program specialist gathered program feedback promptly and effectively.

It was recommended a cash-based incentive be offered to participating contractors in an attempt to drive additional and more specific types of participation. Idaho Power has not implemented this recommendation because research data was unavailable in the Idaho Power service area that identifies what the common reason is for variability in contractor participation and what the key motivation tactics should be. Going forward, Idaho Power will investigate if a contractor incentive is needed to increase participation in its programs.

## Cost-Effectiveness

Idaho Power used the same cost-effectiveness unit energy saving (UES) assumptions for the H&CE Program during 2014 as were used in 2013. For 2014, Idaho Power calculated participant-cost averages used for the cost-effectiveness analysis based on Idaho Power-specific project data over two years (2013–2014) to estimate typical project costs instead of relying on regional averages.

Due to the lower alternative costs from the 2013 IRP, water-source heat pumps and heat pump conversions to 8.50 HSPF became non cost-effective. However, Idaho Power determined that heat pumps meet at least one of the cost-effectiveness exceptions outlined in OPUC Order No. 94-590. Idaho Power filed UM-1710 to request a cost-effectiveness exception with the OPUC on November 4, 2014, and subsequently re-filed it on February 11, 2015. The case is still pending. For more detailed information about the cost-effectiveness savings, sources, calculations, and assumptions, see *Supplement 1: Cost-Effectiveness*.

## Customer Satisfaction and Evaluations

Honeywell performed random OSVs on 10 percent of the completed installations in the Idaho Power service area. These OSVs verified the information submitted on the paperwork matched what was installed at customers' sites. Overall, the OSV results were favorable with respect to the contractors' quality of work. The program specialist continues to work with contractors to help them understand the importance of accurate documentation.

## 2015 Program and Marketing Strategies

Idaho Power will sponsor and provide training to new and existing contractors in the program to assist them in meeting program requirements and further their product knowledge. Sessions will be held on-site at contractor businesses and at Idaho Power facilities.

Expanding the network of participating contractors remains a key strategy for the program because the performance of the program is substantially dependent on the contractors' abilities to promote and leverage the measures offered. Idaho Power's goal is to support contractors currently in the program while continuing to add new contractors. To meet this objective, the program specialist, along with

Idaho Power CRs, will arrange frequent individual meetings to discuss the program with contractors in 2015.

To increase participation in the program in the Idaho Power service area, the program specialist will work to strengthen relationships with equipment wholesalers. To accelerate the wholesalers' abilities to increase contractor awareness of the program, the program specialist will meet with the wholesalers and share information.

The 2015 marketing strategy will include proven tactics previously used and new methods. Since homeowners make more improvements to their home during the first two years of ownership, the company plans to continue to target new customers in the first six months of new-home ownership. Postcards will be mailed to these new customers, raising awareness of the incentives available to them. The strategy will include many marketing tactics, such as bill inserts, print ads in newspapers, and direct-mail letters. Social media, such as Facebook, will also be used.

New marketing pieces will be added to the contractor portal over time as needed. In 2015, it has not yet been determined if/when portal feedback would be formally solicited from the contractors.

## *Description*

The Home Energy Audit is an in-home energy evaluation by a certified, third-party HPS. It is used to identify areas of concern and provide specific recommendations to improve the efficiency, comfort, and health of the home. An audit includes a visual inspection of the crawl space and attic, a health and safety inspection, and a blower door test to identify and locate air leaks. In addition to the energy evaluation, some energy-saving improvements are installed at no additional cost to the customer if appropriate. After the audit is complete, the customer is supplied with a written report of the HPS's findings and recommendations. Available improvements include installation of the following:

- Up to 20 CFLs
- One high-efficiency showerhead
- Pipe insulation from the water heater to the home wall (approximately 3 feet)

The current Home Energy Audit program is based on the insights gained from the Boise City Home Audit project conducted in 2011 and 2012, as described in the *Demand-Side Management 2012 Annual Report*. To qualify for the Home Energy Audit program, participants must live in Idaho and be an Idaho Power customer of record for the home. The home must be an existing all-electric, site-built home. Renters may participate with prior written landlord permission. Single-family homes, duplexes, triplexes, and fourplexes qualify. Manufactured homes, new construction, or buildings with more than four units do not qualify. Multi-family homes heated by a central heating unit or that aren't separately metered are not eligible.

Participating customers pay $99 for the audit and installation of measures, with the remaining cost covered by the Home Energy Audit program. Energy audits of this type normally cost $300 or more, not including the select energy-saving measures, materials, and labor. The cost of the materials potentially installed at each home is approximately $84.

## 2014 Program and Marketing Activities

In January 2014, the program launched in Blackfoot with an open house at the Bingham County Senior Center. The public was invited by direct-mail letters, newspaper ads, an article in the Blackfoot Chamber of Commerce newsletter, and posters located in the Bingham County Senior Center. The open house was later written up in the *Morning News* in Blackfoot. Three additional open houses were held in Homedale, Gooding, and Salmon. In addition to letters, newspaper ads, and posters, radio spots were used in Salmon, as well as a press release sent to local media.

Participants for the program were recruited through small batches of 1,000 to 2,000 direct-mail letters. Customers interested in participating were directed to a website for additional information and the online application. Those who did not have internet access or were uncomfortable using the application online were able to call Idaho Power and apply via phone.

Seven energy audit companies were selected to serve the program. Audits were randomly assigned to the HPSs serving each area, grouping locations for each HPS to save on travel time and expense.

In 2014, 354 audits were completed, surpassing the 2014 goal of completing 300 energy audits. The average age of participating homes was 36 years old. The homes were built between 1900 and 2013. Home sizes ranged from 700 square feet ($ft^2$) to 7,920 $ft^2$, with 2,463 $ft^2$ being the average home size. Figure 10 shows the number of participating homes located in various counties, demonstrating considerable program expansion from a Boise-based audit project to a program reaching the edges of the Idaho Power service area.

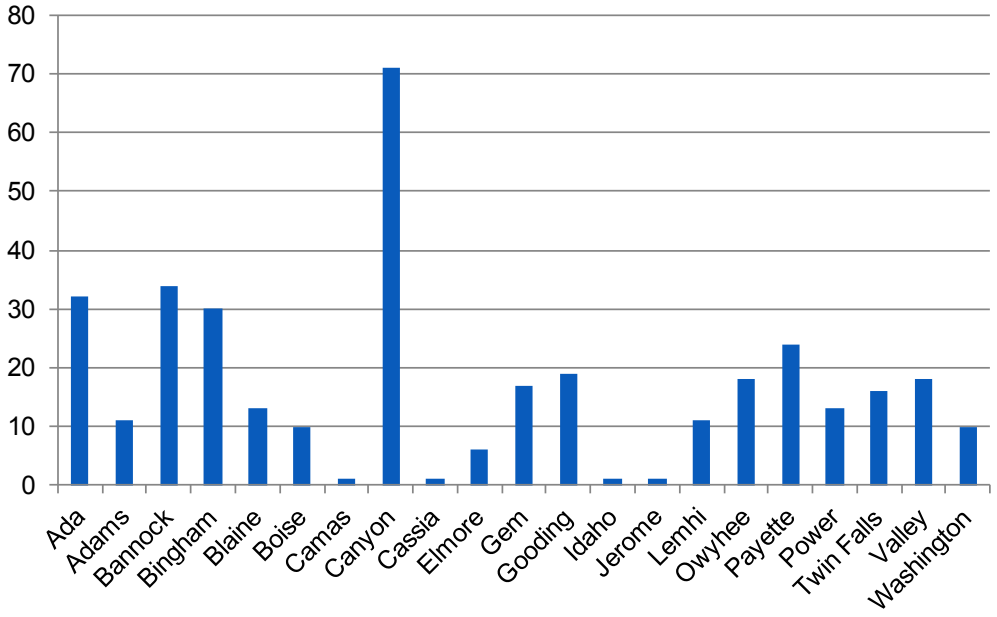

Figure 10. Summary of participating homes by county

The program was designed for all-electric homes only. All written communication sent to customers and the website included that the program was limited to all-electric homes. If the application was taken over

the phone, the customer was asked if their home had electric heat and water heating, and non-electric sources were turned down. In addition, when the HPS contacted the customer to schedule the appointment, the customer was asked if the home had electric heat and water heating. Non-electric sources were turned down. The electrically heated homes used a variety of heating styles, with heat pumps being the most common (153), then furnaces (99) and wall heaters (96). Eight of the 354 participating homes audited were not electrically heated homes, despite numerous efforts to ensure participants had all-electric homes.

Each HPS collected data on appliances and lighting in each home. The average number of incandescent lights per home was 24, and the average number of fluorescent lights was 12. When performing an audit, the HPS determined which available measures were appropriate for the home, and if the homeowner approved, those measures were installed. Figure 11 indicates the total quantity of items installed by measure.

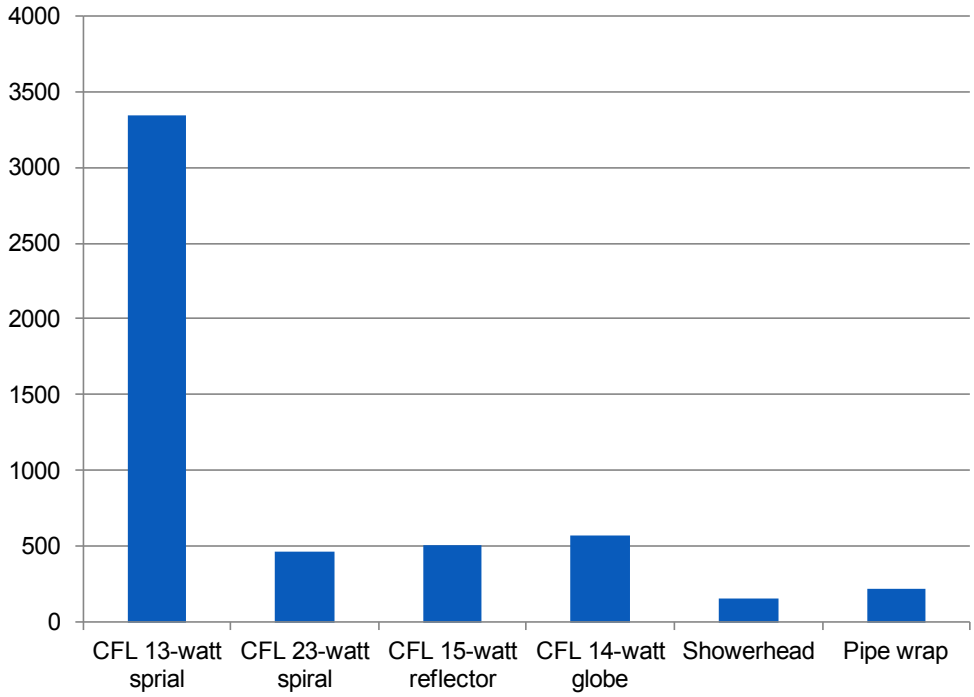

Figure 11. Measures installed in participating homes

The QA goal for the program was inspection of 10 percent of all audits, translating into approximately 35 audits in 2014. Twenty-seven QAs were completed in 2014, with all audits passing inspection. The 10 percent audit goal was unmet in 2014 because it was challenging to find participants willing to allow the auditor into their home for a 1- to 2-hour audit, especially if the participant worked outside the home.

## Cost-Effectiveness

In IPUC Order No. 32667, the commission encouraged "the Company to take other opportunities to improve customer's energy I.Q. and to educate them about the Company's energy efficiency programs." One of the goals of the Home Energy Audit program is to increase participants' understanding of how their home uses energy, and if eligible, encourage their participation in Idaho Power's energy efficiency programs. As an educational and marketing program, the traditional cost-effectiveness tests have not been applied to the program.

For the items installed directly in the homes, Idaho Power used the RTF savings for direct-install bulbs, which range 17 to 29 kWh per year. The RTF savings for 2.0 gallons-per-minute (GPM) showerheads directly installed in a home are 139 kWh per year. In Idaho Power's *Energy Efficiency Potential Study*, Applied Energy Group (AEG) estimates that pipe wraps save 150 kWh per year.

## Customer Satisfaction and Evaluations

A survey designed to assess customers' experience with program enrollment, scheduling, the auditor, the report value, and information learned was sent in July and November to a total of 225 program participants. Ninety-five participants responded to the survey, resulting in a response rate just over 42 percent. Program strengths and areas for improvement were also assessed. Participants that supplied an email address were sent the survey online. Those without an email address were sent a hardcopy of the survey with a postage-paid envelope. Results were reviewed for the program as a whole and for responses related to individual HPSs.

When asked a series of questions about their experience with the program, just under 94 percent of respondents "strongly agreed" or "somewhat agreed" they would recommend the program to a friend or relative, and just under 94 percent of respondents "strongly agreed" or "somewhat agreed" they were satisfied with their overall experience with the program.

Almost 97 percent of the respondents indicated it was "very easy" or "somewhat easy" to apply for the program. Individual program audit report results were available online, and a hard copy of the report was mailed to participants who did not supply an email address. Of the 95 survey respondents, 55 customers rated the difficulty of accessing the report online. Of those 55 customers, just under 77 percent of customers indicated that accessing the report online was "very easy" or "somewhat easy."

HPSs were rated on a number of attributes, including courteousness, professionalism, explanation of work/measurement to be performed, explanation of audit recommendations, and overall experience with the HPS. Respondents rated their HPSs as "good" or "excellent" 96 to 100 percent of the time.

When asked how strongly they agree or disagree with statements around what they learned during the audit process, just over 95 percent of respondents "strongly agreed" or "somewhat agreed" they were more informed about the energy use in their home. Almost 88 percent indicated they "strongly agreed" or "somewhat agreed" they were more informed about energy efficiency programs available through Idaho Power. Just under 87 percent indicated they "strongly agreed" or "somewhat agreed" they learned what no- to low-cost actions they could take.

After the audit, just over 51 percent of respondents indicated they visited the Idaho Power website, approximately 61 percent unplugged appliances when not in use, 42 percent signed up for myAccount, and almost 75 percent shared their experience with relatives and/or friends. Sixty-five percent of the respondents indicated they replaced additional incandescent light bulbs with CFLs or LEDs. Nearly forty-one percent indicated they serviced their heating equipment, and 38 percent serviced cooling equipment. Additional information on the actions that respondents indicated they already completed or planned to do within the next year are shown in the survey results included in *Supplement 2: Evaluation*.

Survey participants were asked to identify all of the benefits they experienced from participating in the program. Almost seventy-six percent of respondents indicated the biggest benefit they found in the audit was personal satisfaction, with nearly 71 percent citing raised awareness of energy use, just over 58 percent citing cost savings, 57 percent citing home improvement, approximately 42 percent citing

comfort, and just over 39 percent citing benefit to the environment. When survey participants were asked to identify all of the barriers they encounter when making energy-saving changes in their home, nearly 74 percent of respondents indicated the biggest barrier was cost. Figure 12 below shows benefits experienced by category and percent.

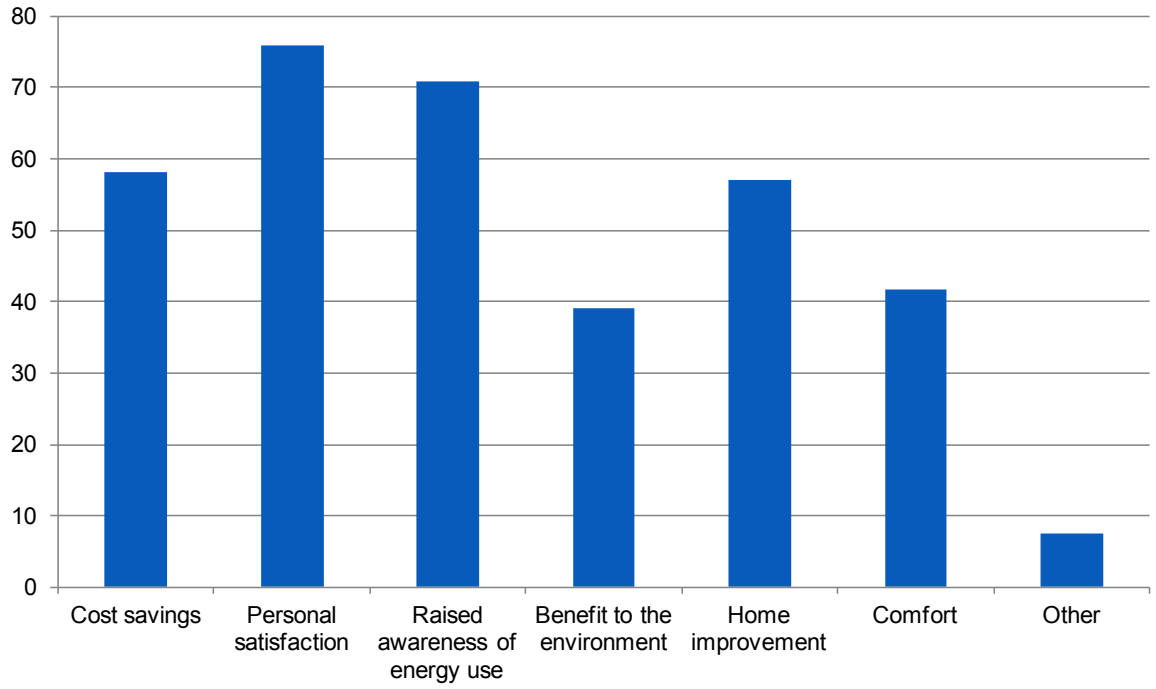

Figure 12. Program participants' benefits experienced

In 2014, Idaho Power administered a process evaluation of the Home Energy Audit program. The analysis was performed by Johnson Consulting Group. The overall conclusion of the evaluation was that the Home Energy Audit program is well designed and well run. The evaluation stated a key finding was the program had a successful launch because the design leveraged the "lessons learned" from the Boise City Audit Project. An additional finding from the evaluation was that the Home Energy Audit program incorporated most of the marketing best practices shown to be effective in promoting successful weatherization, energy audits, and "whole house" program approaches. Johnson Consulting Group also found customer and contractor feedback to be positive based on in-depth interviews. The final key finding of the evaluation was that the program participation process was quick and easy. Johnson Consulting Group's evaluation offered several recommendations for consideration. The first recommendation was to change the program name to *not* include the word audit. However, after careful review of the terms customers repeatedly used when asking for this type of service when calling or writing, Idaho Power learned that the word "audit" was the most-used term by customers. Thus, "audit" is included in the program's name.

The rest of the recommendations were around direct-install measures, customer surveys, follow up, and HPS work. For the direct-install measures, it was recommended to review the mix of measures available to ensure they are still cost-effective, appropriate, and correct for the homes. Pipe wrap had already been identified not fitting all pipes, and a larger size was made available. LEDs were also identified as a potential direct-install measure, and a cost analysis was reviewed.

Johnson Consulting Group's evaluation recommended considering a formal customer survey to assess satisfaction levels and to identify barriers preventing customer follow-through on auditor

recommendations. Idaho Power decided it wouldn't be prudent to spend additional funds for another survey because the current participant survey conducted in-house is sufficient to assess these items. Another recommendation was to develop a protocol or procedure for reaching out to customers and encouraging them to follow up on the energy efficiency recommendations. A procedure was developed to address customer follow-up and incorporated into the new HPS contracts for 2015.

The final recommendations were around additional training and guidance for the HPS. Two of the recommendations were around controlling what the HPS included in the customer's report. While guidelines are provided, such as to educate and encourage participation in energy efficiency programs, the HPSs are independent contractors and therefore have some leeway in what the contractors include in an audit. The basic parts of the audit are consistent for all auditors so all participants have a consistent experience. However, each home is different, plus the auditor is on-site inspecting the home and talking to the customer. Based on what the auditor observes and conversations with the customer, auditors need the latitude to personalize the recommendations as much as possible. Additional training on the audit software and its capabilities occurred in 2014. Although it was covered in the Statement of Work, one auditor was still unaware he was allowed to market his services to customers post-audit. That information has been directly reiterated with all auditors. The 2015 program changes resulting from a review of the process evaluation recommendations are described in detail below. A copy of the complete report is included in *Supplement 2: Evaluation*.

## 2015 Program and Marketing Strategies

With the cost of LEDs decreasing and customer interest in this technology increasing, two LEDs and 18 CFLs will be available for each participating home starting January 1, 2015. This change was made due to customer and HPS feedback and a recommendation from the process evaluation to review the mix of measures available.

Starting January 1, a new procedure for reaching out to customers to follow up on the audit recommendations as recommended by the process evaluation requires the HPS to perform a follow-up call to participants approximately 10 to 14 days after their audit. This change is expected to provide several benefits. First, the HPS will be able to verify the customers received reports. Second, the call provides a prompt and an opportunity for participants to ask their HPS additional questions. Third, the call allows the HPS to verify customers' understanding of the specific recommendations for their homes and what actions they can take next.

To account for the additional time the follow-up calls will take—and to make the fees more in-line with industry standards—the fee to the auditor will be increased in 2015 from $101 to $201. The customer fee will remain at $99.

While the HPSs were provided a program handbook to study, the program process evaluation showed it would be beneficial to provide the information verbally to each HPS. In early 2015, each HPS will take part in a live training session. The training will focus on ensuring a deep understanding of the program, including goals, standards, the timeline, and program flow. It will include information on other energy efficiency programs to promote and the use of myAccount. It will also include feedback from the surveys and areas for improvement.

A trade show booth backdrop and interactive webpages have been created using a cutaway house design to promote the Home Energy Audit program as well as demonstrate energy-saving tips for customers. These new tools will be used and promoted in 2015.

## *Description*

The Home Improvement Program offers incentives to homeowners for upgrading insulation and windows in electrically heated homes. To qualify for an incentive under this program, the home must be a single-family home, a multi-family structure three stories or under, or a manufactured home in Idaho Power's service area in Idaho. The home must have an electric heating system serving at least 80 percent of the home's conditioned floor area. The heating system can be a permanently installed electric furnace, heat pump, or electric zonal heating system. Insulation must be professionally installed between conditioned and unconditioned space by an insulation contractor.

Participating insulation contractors must successfully complete a two-day contractor training course delivered by CLEAResult and Idaho Power. Customers must use a participating contractor to qualify for the Idaho Power incentive, processed by Idaho Power.

The program details include the following:

- Customer incentives for attic insulation, wall insulation, and under-floor insulation require prescriptive air- and duct-sealing.
- Customer incentives to Idaho residential customers in the Idaho Power service area for additional insulation professionally installed are 15 cents per $ft^2$ for attic insulation, 50 cents per $ft^2$ for wall and under-floor insulation, and 30 cents per linear foot for air- and duct-sealing.

- Existing attic insulation must be an R-20 or less to qualify, and the final R-Value must meet the local energy code. Idaho Power's service area consists of climate zones 5 and 6, resulting in an R-38 requirement for climate zone 5 and R-49 requirement for climate zone 6.
- The existing insulation level in walls must be R-5 or less, and the final R-Value must be R-19.
- The existing insulation level under floors must be R-5 or less, and the final R-Value must be R-30.
- Customer incentives are $2.50 per $ft^2$ of window area to Idaho residential customers for installing energy-efficient windows and/or sliding glass doors with a U-Factor of 0.30 or lower.
- Pre-existing windows/sliding glass doors must be single- or double-pane aluminum or single-pane wood.

## 2014 Program and Marketing Activities

At the beginning of the year, webpages for the Home Improvement Program were updated and improved to make customer navigation easier. A contractor portal was launched in 2014. The portal allowed contractors access to a specific area of Idaho Power's website where they could customize pre-approved marketing pieces with their own business name, address, and phone number. Currently offered on the portal for use are two door hangers for insulation contractors, two door hangers for window contractors, and two fliers for HVAC contractors. New marketing pieces will be added over time as needed. A video was produced at the beginning of the year to highlight program measures and to provide customers with a visual of how the upgrades are performed. This video can be viewed at idahopower.com/homeimprovement. A Facebook ad campaign ran from June to September, reaching approximately 310,563 customers. A series of newspaper ads ran multiple times during 2014. Newspaper ads were placed in publications that serve rural areas where there is a higher concentration of electrically heated homes (a program eligibility requirement). Digital behavioral ads ran during mid-March to the end of May. The number of impressions/ads served totaled 771,024. Two information bill inserts were sent out, one in February and one in June, and a targeted direct-mail letter was sent in fall 2014. In addition, window clings and retail signage were created and used in retail locations in eastern Idaho.

## Cost-Effectiveness

In 2014, Idaho Power used the same savings and cost-effectiveness assumptions as were used in 2013. For all measures, deemed-savings values specific to Idaho Power's heating and cooling climate zones the company used published by the RTF, including cooling savings based on the RTF's deemed-savings specifications for single-family home weatherization UES values. Incremental costs for the calculation of TRCs were estimated from customer project data for insulation projects, while regional RTF cost averages were used for efficient windows. Idaho Power did not have adequate window costs for baseline efficiency windows. For more detailed information about the cost-effectiveness calculations and assumptions, see *Supplement 1: Cost-Effectiveness*.

## Customer Satisfaction and Evaluations

For QA purposes, third-party contractors performed random reviews of 5 percent of all installations completed in the Home Improvement Program. QA contractors verified the correct installation of

measures. In addition, the QA contractor assisted and educated the contractors on program requirements. Of the 37 QA inspections completed in 2014, no issues were reported.

The program incentive application form included an optional question asking customers how they heard about the program. Of the 555 applications, 506 customers answered the marketing question. The results are as follows:

- 219 respondents (43%) heard about the program from a program contractor.
- 148 respondents (29%) heard about the program from an Idaho Power bill insert.
- 58 respondents (11%) heard about the program from the Idaho Power website.
- 44 respondents (9%) received a referral from a friend or acquaintance.
- 9 respondents (2%) heard about the program from a home improvement show or fair.
- 6 respondents (1%) heard about the program from a newspaper or online ad.
- 22 respondents (4%) heard about the program from a direct mailer.

## *2015 Program and Marketing Strategies*

Numerous marketing activities are planned for 2015. Two informational bill inserts are planned. A targeted direct-mail letter is scheduled for February. Online ads will include both Facebook and behavioral network ads. Print ads will be placed in rural publications to target customers with electrically heated homes. The contractor portal will be populated with additional marketing pieces. Marketing materials will be updated as needed.

## *Description*

The Home Products Program provides an incentive payment to Idaho and Oregon residential customers for purchasing ENERGY STAR® qualified appliances. ENERGY STAR qualified appliances and products must meet higher, stricter efficiency criteria than federal standards. In 2014, the measures and related incentives included ENERGY STAR qualified refrigerators ($30) and freezers ($20).

Participants have two options to submit their application. They may complete a mail-in incentive application and submit it to Idaho Power with an itemized copy of the sales receipt or submit an online application and scanned copy of their receipt via email. If the purchase qualifies, the customer receives an incentive check by mail.

The Home Products Program also includes promotions using retailer markdowns and retailer/manufacturer incentives. Markdowns reduce retail-end prices to the customer at the point of purchase. Retailer/manufacturer incentives drive the manufacture, distribution, and promotion of more energy-efficient consumer products at the retail level. One measure offered through the retailer markdown model is low-flow showerheads. Low-flow showerheads are part of the Simple Steps, Smart Savings™ markdown promotion administered by the BPA. Simple Steps, Smart Savings is coordinated by CLEAResult.

Idaho Power works in collaboration with NEEA on the Retail Products Platform (RPP). This initiative launched in 2014 and provides a direct incentive to retailers for selling the most energy-efficient products.

## 2014 Program and Marketing Activities

Through the Home Products Program, Idaho Power paid 3,292 appliance incentives during 2014, resulting in 77,574 kWh annual savings. Ninety percent of incentives were for refrigerators, and 10 percent were for freezers. Additionally, Idaho Power paid incentives on 6,769 showerheads sold under the regional BPA Simple Steps, Smart Savings promotion, resulting in 574,555 annual kWh savings. This promotion uses the same retailer markdown model used in the Energy Efficiency Lighting program.

In 2014, Home Products Program participation decreased by 27 percent compared to 2013 participation. This is due primarily to the inclusion of clothes washers in the program through the first quarter 2013. In 2013, 20 percent of participation was due to incentives paid on 2,624 clothes washers. Idaho Power also found that purchases came from fewer stores in 2014. Some retailers, such as the Pocatello Sears, closed. However, retailers may have become less engaged when clothes washers were removed from the program.

In 2014, incentive processing was brought in-house. This decision was due in part to the removal of clothes washers from the promotion in 2013, resulting in fewer applications.

An option on the application allowed customers to donate their entire incentive to Project Share, an energy assistance partnership between Idaho Power and the Salvation Army. In 2014, Home Products Program participants donated $1,340 to this cause. The Home Products Program sent a Project Share donation thank-you card to customers who donated their incentive.

Idaho Power promoted the program to residential customers via retail store salespeople, a bill insert in July, and the Idaho Power *Connections* newsletter. Idaho Power staff promoted the program directly to customers through community events and other outreach activities. Historically, bill inserts account for about 4 to 5 percent of program enrollments. One bill insert detailing the program was mailed to all residential customers in July 2014. However, a bill insert was also sent in November 2013, which also impacted participation in 2014. As a result, 14 percent of program participants reported hearing about the program from bill inserts in 2014.

Home Products Program marketing efforts included online display ads and visual ads that pop up based on specific search behaviors, such as previous visits to Idaho Power's website or appliance-related searches. The campaign ran from September 25, 2013, through January 7, 2014, and could have influenced 2014 program participation. The campaign resulted in 771,884 impressions and 3,029 clicks for a CTR of 0.39 percent. The industry average for this type of online advertising is 0.07 to 0.10 percent.

In 2014, Idaho Power participated in the NWRRC, facilitated by NEEA, and followed the work by the WRUN. The NWRRC identifies and pursues opportunities that can best be achieved by working collaboratively in the region. WRUN is a network of western utilities, primarily serving California. Both the NWRRC and WRUN seek to develop collaborative approaches to working with manufacturers and retailers to increase the uptake of energy-efficient products in the retail market.

With WRUN, Idaho Power participated in its first upstream appliance promotion with Sears and Samsung, offering an incentive on select Samsung clothes washers. The promotion was coordinated by WRUN. Utilities such as Idaho Power were allowed to opt-in. Under the promotion, Sears and Idaho Power each offered a $50 incentive, giving the customer a $100 discount taken at the point of purchase. Sears provided utility-branded tent cards to display on qualifying units. The promotion ran from

September 12 to 26 at three Idaho Sears stores located in Boise, Twin Falls, and Pocatello. However, the Pocatello Sears store was in the process of closing during the promotion and had no sample stock available on the floor. In total, four qualifying models were sold during the promotion. While this may represent a small number of total units, the promotion allowed Idaho Power to gain valuable experience in upstream appliance promotions, including establishing contracts with a national retailer, managing in-store point-of-purchase materials, and training retail staff.

In 2014, NEEA launched the RPP. The RPP is based on the Consumer Electronics Energy Forward Initiative, which ended in 2013. The RPP uses mid-stream incentives to influence retail stocking practices, ultimately driving manufacturing and standards for a portfolio of energy-efficient products sold through the retail channel. For more information on the initiative, view the *NEEA Residential Activities in Idaho* section of this *Demand-Side Management 2014 Annual Report*.

In 2014, new federal appliance standards for refrigerators and freezers went into effect. As a result, Idaho Power began to explore new cost-effective program delivery options. Two models were explored. The first continued a mail-in incentive program, providing incentives based on a qualified products list using the Consortium for Energy Efficiency product tiers. Idaho Power also proposed an upstream model similar to the Simple Steps, Smart Savings lighting promotion. Upstream promotions can often be delivered at lower administrative costs than mail-in rebate programs.

Both program designs were presented at the EEAG August 19 meeting. After the new efficiency standards were enacted, the RTF published new deemed savings values for refrigerators and freezers. Idaho Power determined the qualified products list approach would not meet its cost-effectiveness thresholds. Idaho Power again met with EEAG November 12 and propose retiring the current measures and moving toward upstream promotions in 2015.

## Cost-Effectiveness

Idaho Power used the same cost-effectiveness UES assumptions as were used in 2013 for the refrigerators, freezers, and showerheads.

In September 2014, the federal standards for refrigerators and freezers increased 20 to 30 percent depending on the product class. The RTF discussed the impact of these federal standard changes, which raised the baseline used to calculate the electric energy savings estimates. As a result of these higher standards, the annual gross energy savings for refrigerators dropped from 29 to 21 kWh per year, and freezers dropped from 40 to 23 kWh per year. The lower alternate costs from the 2013 IRP as well as the lower savings estimates from the RTF resulted in the measures no longer being cost-effective under the mail-in incentive model. Idaho Power will continue to evaluate the cost-effectiveness of these measures under other program delivery methods that may be less expensive than the mail-in incentive model.

For detailed information for all measures within the Home Products program, see *Supplement 1: Cost-Effectiveness*.

## Customer Satisfaction and Evaluations

Due to program changes in 2014, a planned customer satisfaction survey was re-evaluated. As mentioned above, with the updated savings assumptions for freezers and refrigerators from the RTF and the new 2013 DSM alternative costs from the IRP, freezers and refrigerators were determined not to be cost-effective. The measures will no longer be available to customers beginning January 2015,

and the program will transition away from a mail-in incentive request format. As a result of these changes, a program satisfaction survey was not administered.

Information collected from a question on the incentive application form indicated salespeople are a proven marketing channel. Sixty-three percent of program participants that submitted an incentive application reported hearing about the program from a retail sales person. To support this channel, Idaho Power CRs visited participating retailers multiple times in 2014 to distribute program applications and discuss program requirements. Figure 13 indicates how customers heard about the program in 2014.

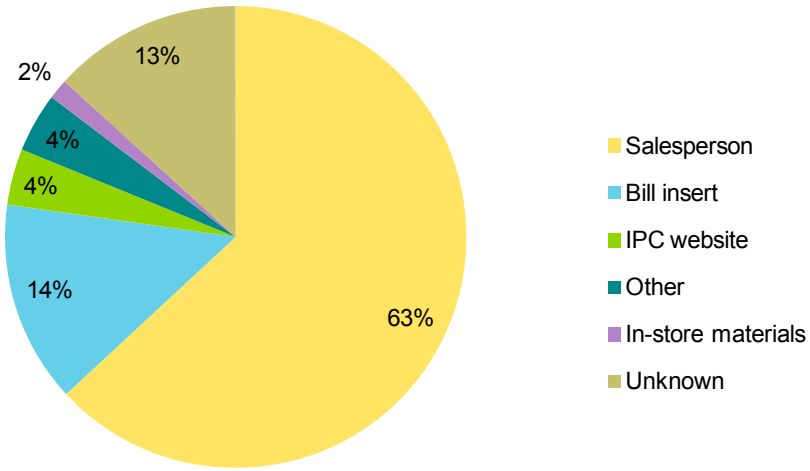

Figure 13. How customers heard about program, 2014

## 2015 Program and Marketing Strategies

Beginning January 1, 2015, Idaho Power will no longer offer incentives on refrigerators and freezers to its Idaho customers. Incentives will be paid on qualifying appliances purchased on or before Dec. 31, 2014. Beginning January 14, 2015, Idaho Power will no longer offer incentives on refrigerators and freezers to its Oregon customers. Incentives will be paid on qualifying appliances purchased on or before January 13, 2015. Applications must be received within 120 days of purchase.

In December 2014, the BPA announced changes to its Simple Steps, Smart Savings program. The program will continue to be administered by CLEAResult. BPA anticipates that clothes washers, refrigerators, and freezers will be brought into the Simple Steps, Smart Savings program beginning June 2015. Idaho Power expects to have the details of the appliance promotion at the end of first quarter of 2015 and will run the appropriate cost-effectiveness tests. If cost-effective, Idaho Power plans to opt in to the regional appliance promotion.

In 2015, Idaho Power will continue to participate in the NWRRC, follow the work by WRUN, and serve on NEEA's work group.

# Oregon Residential Weatherization

| | 2014 | 2013 |
|---|---|---|
| **Participation and Savings** | | |
| Participants (audits/projects) | 13 | 14 |

## *Description*

Idaho Power offers free energy audits for electrically heated customer homes within the Oregon service area. This is a statutory program as required by Oregon Revised Statute (ORS) 469.633 offered under Oregon Schedule 78. Upon a customer's request, an Idaho Power CR visits the home to analyze it for energy efficiency opportunities. An estimate of costs and savings for specific measures is given to the customer. Customers may choose either a cash incentive or a 6.5-percent interest loan for a portion of the costs for weatherization measures.

## *2014 Program and Marketing Activities*

During May, Idaho Power sent every Oregon residential customer an informational brochure about energy audits and home weatherization financing. Thirteen Oregon customers responded. Each customer returned a card from the brochure indicating interest in a home energy audit, weatherization loan, or incentive payment. Thirteen audits and responses to customer inquiries to the program were completed, with five incentives paid.

Idaho Power issued five incentives totaling $1,614.61 for 11,032 kWh savings. Three incentives and related savings were for ceiling insulation measures. One incentive was for floor insulation, and one incentive was paid for a combination of wall and floor insulation. There were no loans made through this program during 2014.

## Cost-Effectiveness

The Oregon Residential Weatherization program is a statutory program described in Oregon Schedule 78. The cost-effectiveness of this program is defined within this schedule. Pages 3 and 4 of the schedule list the measures determined to be cost-effective and the specified measure-life cycles for specific measures. This schedule also includes the cost-effective limit (CEL) for measure lives of 7, 15, 25, and 30 years.

Thirteen audits were conducted with five savings projects completed. Projects consisted of increasing attic, floor, and wall insulation. The projects combined for an annual energy savings of 11,032 kWh at a levelized TRC per kWh of 4.9 cents over the 30-year attic-insulation measure life as defined by Oregon Schedule 78.

The CEL for insulation (30-year measure life) is $1.30 per annual kWh saved. Since the actual levelized cost of energy savings for the 2014 projects was 4.9 cents from the TRC perspective, these projects are considered cost-effective.

## 2015 Program and Marketing Strategies

Plans for the upcoming year include notifying customers in their May bill about the program. Idaho Power will complete requested audits and fulfill all cost-effective incentive and loan applications.

# Rebate Advantage

| | 2014 | 2013 |

## *Description*

The Rebate Advantage program helps Idaho Power customers with the initial costs associated with purchasing a new, energy-efficient, ENERGY STAR® qualified manufactured home. This enables the homebuyer to enjoy the long-term benefit of lower electric bills and greater comfort provided by these homes. The program also provides an incentive to the sales consultants to encourage more sales of ENERGY STAR qualified homes and more discussion of energy efficiency with their customers during the sales process.

In addition to offering financial incentives, the Rebate Advantage program promotes and educates buyers and retailers of manufactured homes about the benefits of owning energy-efficient models. The Northwest Energy Efficient Manufactured (NEEM) housing program establishes quality-control (QC) and energy efficiency specifications for qualified homes. NEEM is a consortium of manufacturers and state energy offices in the Northwest. In addition to specifications and quality, NEEM tracks the production and on-site performance of ENERGY STAR qualified manufactured homes.

Idaho Power residential customers who purchased a new, all-electric, ENERGY STAR qualified manufactured home in 2014 and sited it in Idaho Power's service area were eligible for $1,000 through the Rebate Advantage program. Salespersons received $200 for each qualified home they sold.

## *2014 Program and Marketing Activities*

During 2014, Idaho Power paid 44 incentives on new manufactured homes, which accounted for 269,643 annual kWh savings. In 2014, all Rebate Advantage collateral was updated, including table-top

posters, brochures, call-out cards for inside model homes, and outdoor vinyl banners. A bill insert, shared with Energy House Calls, was sent to all Idaho and Oregon Customers in September 2014. Idaho Power tested a digital advertising campaign with this target market because according to the *2014 Manufactured Home Market Facts Report* by Foremost®, 79 percent of manufactured home residents use Facebook and 42 percent visit social media multiple times per day. A digital advertising campaign was run from December 15, 2014, to January 15, 2015. Total impressions were 541,400 with 846 clicks for a CTR of 0.16 percent. Generally, in the digital advertising industry, the average CTR is 0.07 percent to 0.10 percent.

Idaho Power continued to support dealerships in 2014 by providing them with Rebate Advantage brochures and applications as needed. CRs visited these dealerships to distribute material, promote the program, and answer salespersons' questions.

## Cost-Effectiveness

In 2014, Idaho Power used the same savings and assumptions as were used in 2013. All cost-effectiveness analyses were based on the January 2011 approval decision by the RTF. The measures remained cost-effective for 2014. The measure is currently under review, and the RTF extended the sunset date for the measure until March 2015. For details, see *Supplement 1: Cost-Effectiveness*.

## 2015 Program and Marketing Strategies

Customers who purchase a new, all-electric, ENERGY STAR qualified manufactured home in 2015 and site it in Idaho Power's service area will continue to be eligible for $1,000. Salespersons will continue to receive a $200 incentive for each qualified home they sell.

In 2015, Idaho Power intends to continue the digital advertising due to a very solid response in 2014. Two informational bill inserts are planned for 2015. The first one will be distributed in February, and the second distributed in the fall. An informational direct-mail letter will be sent to manufactured home dealerships in August. In addition, targeted direct online ads will be placed. Program collateral will be updated throughout 2015 as needed.

# See ya later, refrigerator®

## *Description*

The See ya later, refrigerator® program acquires energy savings through the removal of qualified refrigerators and stand-alone freezers in residential homes throughout Idaho Power's service area.

Idaho Power contracts with JACO to provide most services for this program, including customer service and scheduling, unit pickup, unit recycling, reporting, marketing assistance, and incentive payments. Marketing assistance is provided by JACO through Runyon Saltzman Einhorn (RSE). RSE is a marketing company that assists utility appliance recycling programs throughout the country. Idaho Power provides participant confirmation, additional marketing, and internal program administration.

Applicants enroll online or by phone. Idaho Power screens each applicant to confirm eligibility. JACO screens each applicant to confirm the refrigerator or freezer unit under consideration meets all program eligibility requirements, including being residential-grade, a minimum of 10 cubic feet ($ft^3$) as measured using inside dimensions, no larger than 30 $ft^3$, and in working condition. Customers receive a $30 incentive check mailed after the removal of the unit. The program targets older, extra units for maximum savings.

## *2014 Program and Marketing Activities*

The program reclaimed or recycled up to 95 percent of the components of each unit collected. In 2014, this amounted to more than 435,000 pounds of materials. Reclaimed materials may include oils or refrigerants that can be distilled and reused. See ya later, refrigerator® program participation declined by

3 percent between 2013 and 2014. This represents the natural ebb and flow of programs, demonstrated in Figure 14.

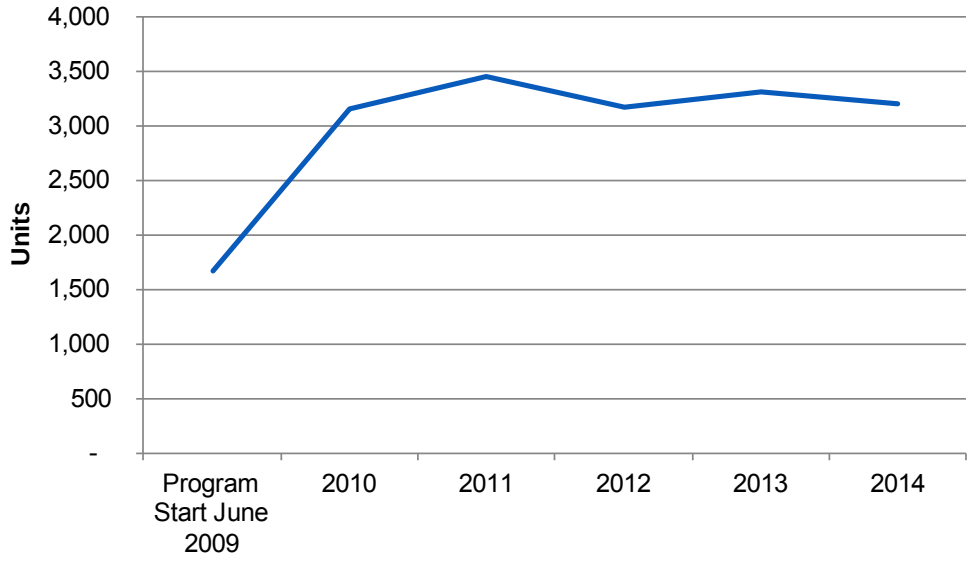

Figure 14. See ya later, refrigerator® participation by year June 2009

Idaho Power continued to offer See ya later, refrigerator® participants the option to receive their $30 incentive or donate it to Project Share. Project Share is an energy assistance program in partnership with the Salvation Army that helps customers who need help paying for energy services, including fuel bills and furnace repairs. In 2014, over 4 percent of Idaho Power's See ya later, refrigerator® participants chose this option, raising $4,230 for Project Share.

Idaho Power used an integrated, layered approach to market the program in 2014. All marketing tactics in 2014 used like imagery and messaging to build awareness and recognition. The messaging focused on convenience. Survey data showed 52 percent of participants reported they received the most value from the convenience of the program. Idaho Power and RSE used bill inserts, newspaper advertising, radio, direct mail, and earned media through two television spots to promote the program.

Bill inserts were sent during February, March, April, June, July, August, and October. In late May, a direct-mail postcard was sent to a highly targeted audience. The target audience for the program has been identified as older, empty-nesters who own their home. The mailing was sent to higher energy users and longer-term customers of Idaho Power that were likely to represent the target audience. The direct-mail had a response rate of approximately 1 percent. Program cards were included in energy-kits given to low-income customers.

Awareness tactics, such as radio and newspaper ads, ran from April through August. Handheld fans with program information were distributed at summer events, including several county fairs. In July, Idaho Power representatives and JACO staff appeared in live television broadcasts in the Twin Falls and Pocatello/Idaho Falls markets promoting the program and demonstrating how materials from refrigerators can be recycled and reused.

RSE managed a nine-month online Google AdWords™ campaign. Google AdWords™ brings up an ad based on specific combinations of search terms. The campaign resulted in 8,497 impressions and a CTR of nearly 6 percent.

## Cost-Effectiveness

Idaho Power used the same savings and other cost-effective assumptions for the 2014 reporting year as were used in 2013. However, with the implementation of acknowledged 2013 IRP avoided costs, the program measures for both decommissioning freezers and refrigerators became not cost-effective in 2014 from the UC and TRC perspectives. For details and program assumptions, see *Supplement 1: Cost-Effectiveness*.

Looking forward, the company evaluated different program options to increase the program's cost-effectiveness for 2015. Two options explored included restricting the ages of qualifying units and changing incentive levels. At the August 19 and November 12, 2014, EEAG meetings, Idaho Power discussed proposed program changes for 2015.

For cost-effective details and assumptions, see *Supplement 1: Cost-Effectiveness.*

## Customer Satisfaction and Evaluations

No formal evaluations were conducted in 2014 for this program. However, JACO tracks individual statistics for each unit collected, including information on how customers heard about the program and when customers enrolled. Statistics about the unit collected include the age of the unit, its location on the customer's property, and other data.

The 2014 unit data showed that 21 percent of units the program picked up were stand-alone freezers, and 79 percent of the units were refrigerators. Fifty-eight percent of the units were secondary, 29 percent were primary, and 13 percent were unknown. In 2014, 50 percent of the units collected were manufactured from 1965 to 1990, which generally represents the least efficient years of refrigerator manufacturing. By comparison, in 2013, 55 percent of the units were of this vintage.

JACO and Idaho Power also track data related to the marketing effectiveness of the program. Results of customer tracking information indicate 49 percent of customers learned of the program through bill inserts. Nineteen percent of customers learned of the program through a friend or neighbor. Although appliance retailers also refer customers to the program, Idaho Power does not pursue this marketing channel because the program focuses on the removal of secondary units rather than replacing existing units. Retailers sell new units to replace older units. In addition, a retailer selling a new unit will usually pick up and recycle the old one.

Seventy percent of customers who enrolled used the toll-free telephone number, and 30 percent used the online enrollment form. Idaho Power uses the customer information JACO collects and the surveys from Idaho Power evaluations to target future marketing efforts and increase the effectiveness of marketing.

Figure 15 indicates ways customers heard about the program. The Other category includes sources, such as community events, repeat customers, the truck wrap ad, and unknown sources.

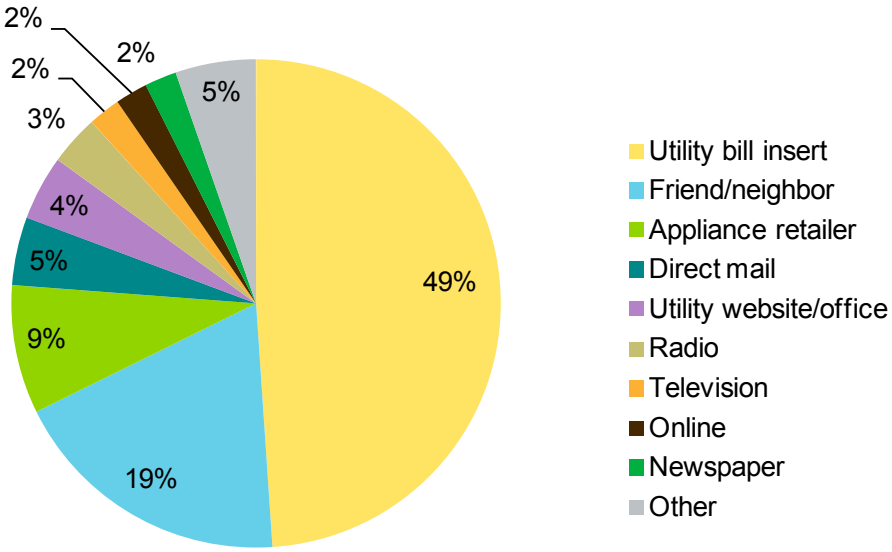

Figure 15. How customers heard about See ya later, refrigerator®

## 2015 Program and Marketing Strategies

Idaho Power will contract with JACO to provide services in 2015. To increase program cost-effectiveness, starting February 1, Idaho Power will no longer offer participants a $30 incentive for participating.

Marketing tactics in 2015 will include six bill inserts. The truck that picks up the refrigerators will continue to display a truck wrap—a large Idaho Power See ya later, refrigerator® ad—on its side. The truck wrap will be redesigned in January. This low-cost marketing tactic is expected to account for about 1 percent of program participation. Program information will continue to be included in over 2,000 energy kits distributed to low-income customers. The program will be promoted at community events and by Idaho Power's CRs. Idaho Power will also focus on online marketing tactics, including promotional advertising on Idaho Power's website, Facebook postings, and Google AdWords.

## *Description*

The Shade Tree Project began as a pilot in 2013. According to the US Department of Energy (DOE), a well-placed shade tree can reduce energy used for summer cooling by 15 percent or more. Utility programs throughout the country report high customer satisfaction with shade-tree programs and an enhanced public image for the utility related to sustainability and environmental stewardship. Other utilities report energy savings between 40 kWh per year (coastal climate San Diego) and over 200 kWh per year (Phoenix) per tree planted.

To be successful, trees should be planted to maximize energy savings and ensure survivability. Two developments in urban forestry—the state-sponsored Treasure Valley Urban Tree Canopy Assessment and the Arbor Day Foundation's Energy Saving Trees tool—provided Idaho Power with the tools to develop a shade tree project.

The Shade Tree Project was launched in Ada and Canyon counties, offering free shade trees to residential customers. Participants enroll using the online Energy Saving Trees Tool and pick up their tree at specific events. In the fall 2013 pilot, 220 trees were distributed to residential customers.

In 2014, the Shade Tree Project expanded. Idaho Power distributed 2,041 shade trees to residential customers.

## *2014 Program and Marketing Activities*

The best time to plant shade trees is in the spring and fall. Therefore, Idaho Power held two offerings in 2014. The spring shade tree offering was held in April 2014 and resulted in 1,058 trees distributed. The fall offering was held in October, and 983 trees were distributed.

Trees were purchased from regional growers in advance of each event. Species offered depended on availability at time of purchase. Idaho Power worked with its own arborists, along with city and state arborists, to select a range of tall growing, deciduous trees that should work well with the climate and soils of the two counties.

Idaho Power used direct mail to market this program in 2014 and used the state-sponsored Treasure Valley Urban Tree Canopy Assessment to develop a mailing list. The assessment is a geographic information system (GIS)-based study that mapped land use throughout the Treasure Valley including existing trees and vegetation, buildings, roads, waterways, and parking lots. The study identified areas where a tree can be planted and if that tree can be a large-growing shade tree. Idaho Power used the study to identify potential planting sites on residential properties situated to the west of the home. The mailing list was created from the results.

To enroll, customers accessed an online Energy Saving Trees Tool developed by the Arbor Day Foundation. Using this tool, participants mapped their home, selected from a list of available trees, and evaluated the potential energy savings associated with planting in different locations. During enrollment, participants learned how trees planted to the west and east save more energy over time than trees planted to the south and north. In 2014, customers could reserve up to two trees.

Participants picked up their tree at prescheduled events held throughout the Treasure Valley. Four pickup events were held in the spring and three in the fall, conducted on different days at different locations. By offering several pickup days, locations, and times, about 90 percent of participants enrolled and picked up their tree.

Ensuring the tree is planted properly helps it grow to provide maximum energy savings. At the tree pickup events, participants received additional education on where to plant trees for maximum energy savings and other tree care guidance from experts. Local specialists included city arborists from Boise, Kuna, Nampa, and Meridian; Idaho Power utility arborists; Canyon County master gardeners; and College of Western Idaho (CWI) horticulture students.

## *Customer Satisfaction and Evaluations*

In early 2014, a survey was emailed to 205 customers that participated in the first Shade Tree Project offering in fall 2013. The response rate was just over 63 percent with 130 respondents. Survey participants were asked, “How likely would you be to recommend Idaho Power’s Shade Tree Project to a friend or relative?” Just over 89 percent indicated they “definitely would” and just over 10 percent indicated they “probably would.” After reviewing these survey results, the survey was revised to remove questions with little value and to capture additional information from participants. The revised survey was sent in summer 2014 to 577 customers that participated in the spring 2014 offering. The response rate was nearly 61 percent with 351 respondents. When asked how much they would agree or disagree with statements about the Shade Tree Project, just over 95 percent of respondents “strongly agreed” and just over 4 percent “somewhat agreed” they would recommend the project to a friend or family. Nearly 93 percent indicated they “strongly agreed” and just over 6 percent “somewhat agreed” they were satisfied with their overall experience with the Shade Tree Project.

In 2014, the Customer Research and Analysis team administered a process evaluation contracting with Johnson Consulting Group for analysis. The findings from the process evaluation were, overall, the Shade Tree Project is well designed and well managed. Key findings and recommendations from the evaluation, along with Idaho Power’s responses, are described below.

The evaluators found Idaho Power successfully leveraged industry best practices to design and develop the Shade Tree Project. Program design was developed by combining internal resources from a diverse group of Idaho Power staff with input from critical external stakeholders involved in urban forestry projects throughout the region.

Evaluators indicated Idaho Power staff are responsive and flexible and have adapted this project based on both experience and customer feedback. The staff continues to refine the program delivery model, increasing the number of trees offered to customers and improving the program marketing and educational materials. In addition, the Shade Tree Project delivery strategy is consistent with the industry best practices for shade tree programs.

Johnson Consulting Group determined the online program enrollment was quick and easy. Citing Idaho Power's survey of program participants, nearly two-thirds, 60 percent, of the survey respondents were able to enroll in the program in ten minutes or less. Nearly three quarters, 72 percent, of survey respondents found the online enrollment tool very easy to use. Overall, the participants reported high satisfaction rates for the Shade Tree Project and were very satisfied with both the planting care and education they received at the distribution events.

Johnson Consulting Group noted a few respondents were dissatisfied with the quality of the trees provided. Upon further review, Idaho Power found that the comments around quality of tree related to the size of the tree. Trees came in 3- to 5-gallon containers and ranged in size from approximately 4 to 10 feet. The trees were sized so participants could safely transport and plant the trees. To address this concern, information on tree size was added to the direct-mail letter and main program landing webpage to help set participant expectations.

Based on the process evaluation findings, the Johnson Consulting Group evaluation team developed the following recommendations to improve program operations.

They recommended Idaho Power staff should standardize the current program evaluation questionnaires to allow for consistent feedback and tracking across all program events. This includes asking questions to all customers to assess satisfaction, determining the actual planting locations for all trees provided, and exploring more fully the reasons for participation.

Idaho Power agrees with this recommendation and plans to use a consistent survey starting in 2015. The company ran a small Shade Tree pilot in 2013 and issued a survey to all participants. After that survey, some small modifications were made to the survey questions with the intent of clarifying questions to obtain better data and seeking new information that would be relevant to a larger program design. Idaho Power will issue a third survey in early 2015 to capture participant feedback from the fall 2014 offering and will again refine a few questions based on specific feedback from Johnson Consulting Group. Specifically, the survey was designed in 2013 around one tree per participant. In 2014, the program was expanded to allow two trees per participant. Survey questions were adjusted for this program change. The company does not anticipate any future survey modifications but will maintain the flexibility to ensure the survey captures the data needed to manage and improve the program.

Johnson Consulting Group recommended Idaho Power staff develop a pre-screening tool to maximize energy savings potential at the initial application stage. The evaluator stated given both the survey responses and the experience with other shade tree programs, Idaho Power staff should try to maximize energy savings at the initial screening by incorporating the strategies used by other shade tree programs, such as pre-screening for customers who do not intend to plant trees with western, northwestern,

or southwestern orientation. The evaluator suggested Idaho Power staff should also assess actual free ridership rates through customer surveys in future program evaluations.

While Idaho Power agrees it is important to maximize energy savings and has taken several steps throughout the program design to do so, the company looked at other shade tree programs and has not yet found a pre-screening solution that would result in west planting locations that does not increase the cost of the project. Programs that require specific planting locations conduct one or more site visits to each participant's home and/or plant the tree for customers. For example, the Sacramento Municipal Utility District's program conducts up to three site visits—one to determine proper placement; one to deliver trees; and, for some customers, a third visit to verify planting.

Idaho Power also has concerns that a screening question at the time of enrollment alone may not lead to the desired results. Without site verification at the time of tree delivery and planting, it would be difficult to verify customers would answer a screening question truthfully.

Idaho Power uses many methods to encourage customers to plant in the most optimum location for energy efficiency. First, the program is marketed to those customers identified using the urban tree canopy assessment as having a western planting location. Messaging throughout the program includes the phrase *West is Best*. The enrollment tool uses community-based social marketing techniques, including interactive feedback, commitments, and prompts to promote western planting locations.

Second, although western planting locations result in maximum energy savings, significant savings can occur to the east and some, albeit less, savings can be achieved planting to the south and north. Idaho Power will continue to look for opportunities to maximize energy savings and promote plantings to the west of the home. The company will continue to monitor other shade tree programs and delivery models for best practices to minimize free ridership and maximize energy savings.

Johnson Consulting Group recommended Idaho Power staff should implement a QA/QC process to provide ongoing tracking of the distributed trees and that this QA/QC process should include follow up with all program participants via a customer survey and a sample of on-site visits to verify planting orientation and tree health. The evaluator noted the QA/QC process can also help to provide more accurate estimates of actual tree planting locations and therefore provide a more accurate estimate of overall program effectiveness.

Idaho Power agrees with this recommendation and currently has QA/QC procedures in place. The company follows up with all participants through an online survey after the each offering. In 2015, Idaho Power plans to conduct site visits to a subset of participant homes to measure tree planting location, planting quality, and tree health.

Two of the evaluators' recommendations regarded data collection. First, according to Johnson Consulting Group, the Shade Tree Project should develop a standard database that consistently tracks the disposition of trees and key program metrics in a standard manner. The evaluator stated that as this program evolves from a pilot to a full-scale program, it is critical to develop a standardized program tracking tool that tracks key program milestones, customer feedback, and electric and non-electric savings and allows easy comparison between offerings.

Second, Johnson Consulting Group also recommended Idaho Power staff should try to quantify the non-electric benefits associated with this program as a way to enhance its overall cost-effectiveness. The evaluator noted the technical assessments included detailed models demonstrating the significant non-electric benefits that shade tree programs provide and Idaho Power staff should leverage this

information and include the quantification of program non-electric benefits attributed to this project, including reductions in carbon emissions, carbon sequestration, and other benefits quantified in the US Forest Service (USFS) i-Tree™ model.

In regard to these two recommendations, Idaho Power continues to build upon prior work to move toward the evaluators' recommendation around data in the following manner. Idaho Power has captured program metrics for each offering, including customer data, tree type, tree planting location, marketing tactics, event pickup location, and enrollment date, as well as 20-year energy benefits (as determined by the model). In 2014, Idaho Power worked with the Arbor Day Foundation to create additional reports for each offering to track energy savings and environmental benefits. The Arbor Day tool is based on the i-Tree model, in which benefits for each tree distributed are calculated based on species and planting location. Benefits are forecasted for years 5, 10, 15, and 20. Environmental benefits include carbon benefits per pound, storm water runoff mitigated per gallon, and air pollutants per pound. Once these reports were finalized in fall 2014, Idaho Power merged the data with the other program metrics to create a central tracking system. In 2015, Idaho Power will create a data dictionary—describing each term and field used—for this database and will continue to add results from each offering going forward.

## 2015 Program and Marketing Strategies

Idaho Power plans to continue the Shade Tree Project in 2015, using the Arbor Day enrollment tool and events to distribute the trees. Idaho Power will continue to market the program by direct mail and focus on customers identified using the urban tree-canopy assessment. In addition, Idaho Power maintains a waiting list of customers that either heard about the program through a friend or relative or did not enroll in the fall offering before it subscribed. Idaho Power will reach out to these customers through direct mail or email. Should enrollment response rates not be as successful as past years, Idaho Power will consider targeted advertising on Facebook.

This project relies on strong partnerships with the cities, counties, CWI, and others. These groups provide guidance on tree selection and donate volunteer hours. Together, Idaho Power, local arborists and others interested in green infrastructure have formed the Treasure Valley Canopy Network (Network) to enhance the region's urban forest. The Network, through the Southwest Resource Conservation and Development and Idaho State Department of Lands, received a Western Competitive States Grant through the USFS. The grant proposal was the top ranked proposal submitted. Grant funds will be used to support urban tree planting for energy savings, develop local resources for tree procurement and storage, and develop additional educational materials. In 2015, the grant funds will offset some Idaho Power costs and allow Idaho Power to explore ways to procure trees locally at a lower cost. It will also be used to sustain the partnerships needed for this project.

Idaho Power will continue to collect metrics to evaluate program success and effectiveness. A survey will be sent in early 2015 to the fall 2014 participants. A survey will be sent to participants in the spring and fall 2015 offerings. In summer 2015, Idaho Power will conduct site visits to a statistically valid sample of past participant homes to confirm planting location and evaluate tree planting quality and tree health. This data will help inform assumptions used to evaluate energy savings from this program. Idaho Power is collecting data to evaluate energy savings from this project. With the available costs and savings assumptions, shade trees were added as a measure in the 2014 potential study that was prepared for the 2015 IRP. Based on currently planned tree distributions, it was estimated that just over 5 million kWh could be saved over 20 years.

## *Description*

The WAQC program provides funding to install weatherization measures in qualified, owner-occupied and rental homes that are electrically heated. In 2014, qualified households included those with incomes up to 200 percent of the federal poverty-level guidelines. Energy efficiency enhancements allow qualified families to maintain a comfortable home environment while saving energy and money otherwise spent on heating, cooling, and lighting. Participants receive energy efficiency education to help save energy in their homes. Funding is also provided for the weatherization of buildings that house non-profit organizations who serve special-needs populations. In compliance with IPUC Order No. 29505, Idaho Power funds the CAP agencies to administer the WAQC program in its service area.

WAQC is modeled after the DOE weatherization program. The DOE program is managed through the Idaho Department of Health and Welfare (IDHW) in Idaho and by the Oregon Housing and Community Services (OHCS) in Oregon. Federal funds are allocated to the IDHW and OHCS, then to CAP agencies based on US Census data of population and poverty levels within each CAP agency's geographic area. The CAP agencies serve as the administrators of the state Weatherization Assistance Program (WAP) and oversee local weatherization crews and contractors, providing services and measures that improve energy efficiency of the homes. The WAQC funding provided by Idaho Power allows these state agencies to leverage their federal weatherization dollars and serve more Idaho Power customers who heat their homes with electricity by supplementing federal Low Income Home Energy Assistance Program (LIHEAP) weatherization funds.

Energy-saving home measures provided by this program include upgrades to windows, doors, wall insulation, ceiling insulation, floor insulation, infiltration, ducts, water heaters, and pipes;

furnace tune-ups, modification, and replacement; and the installation of CFL bulbs. The Idaho WAP calculates savings with the EA5 energy audit program (EA5). Consistent with the Idaho WAP, WAQC offers several measures that have costs but do not save energy or for which savings cannot be measured. Included in this category are health and safety, vents, furnace repair, and home energy audits. Health and safety measures are necessary to ensure weatherization activities do not cause unsafe situations in a customer's home or compromise a household's existing indoor air quality. Other non-energy-saving measures are allowed under this program to help facilitate the effective performance of those measures yielding energy savings.

Energy-saving measures provided to non-profit buildings under this program include upgrades to windows, doors, wall insulation, ceiling insulation, floor insulation, infiltration, ducts, water heaters, and pipes; furnace tune-ups, modification, and replacement; and the installation of CFL bulbs. Non-profit building measures that have costs but do not save energy or for which savings cannot be measured are health and safety, vents, furnace repair, and energy audits.

For more details on the WAQC program, view the most recent regulatory report, *Weatherization Assistance for Qualified Customers 2013 Annual Report*, dated April 1, 2014, located in *Supplement 2: Evaluation*. The new *Weatherization Assistance for Qualified Customers 2014 Annual Report* will be filed on April 1, 2015.

## 2014 Program and Marketing Activities

During 2014, CAP agencies weatherized 239 electrically heated homes in Idaho and 11 in Oregon, totaling 250 weatherized homes. Five Idaho buildings housing non-profit organizations that serve special-needs populations were also weatherized in 2014.

Idaho Power continued the focus on addressing recommendations from a 2012 impact evaluation conducted by D&R International and a 2013 process evaluation conducted by Johnson Consulting. A contract was signed with Kearns ENTerprises™ to develop a Home Audit tool to be used in Idaho Power's Weatherization Solutions for Eligible Customers program starting in 2015. The updated tool was designed to capture key data and more details regarding measures installed for health and safety. Updated calculations for estimates of energy savings and measure information to more accurately report program effectiveness were built into the program. The new WxSol Home Audit Tool (HAT 14.1) was distributed in January 2015 to contractors participating in the Weatherization Solutions for Eligible Customers program and will be tested throughout 2015 in that program. The WAQC program will use the tool if the state adopts it.

In January 2014, in Oregon, Idaho Power moved funds from the non-profit pooled fund to the fund used to weatherize homes of electrically-heated qualified customers. This funding shift allowed additional funds to be spent on home efficiency improvements of qualified customers in Oregon.

Idaho Power marketed WAQC throughout 2014 at resource fairs, community special-needs populations' service provider meetings, and CAP agency functions to reach customers who may benefit from the program. Marketing for this program was conducted in cooperation with weatherization managers. Working with the CCOA—Aging, Weatherization and Human Services (CCOA), a Weiser project was identified to be featured in an internal *eNews* video. Once produced, it was released on YouTube and promoted through social media in October.

## Cost-Effectiveness

The WAQC program has been proven to provide real and substantial per-home savings, but due to the costs of comprehensive whole-house weatherization, the program remains not cost-effective from either a UC or TRC perspective. In 2014, additional billing analysis was conducted on 2012 participants' billing data. This analysis was based on a recommendation from the 2012 impact evaluation conducted by D&R International. The evaluation recommended using a control group to account for non-weather related changes in energy use not attributable to the program's weatherization measures. The 2012 impact evaluation performed a billing analysis on 2011 projects. The average realized annual savings in all housing types was 2,684 kWh per home. For the update billing analysis, Idaho Power wanted to know if savings could be further differentiated between housing stock (single family versus manufactured home), occupant size, heating footprint of the home, and the number of occupants in the home. All billing analysis and data preparation was done in accordance with the *Whole-building Retrofit with Consumption Data Analysis Evaluation Protocol* document published in April 2013 by the DOE (energy.gov/eere/about-us/ump-protocols).

Analysis results showed that manufactured home savings per home were similar to the previous 2012 evaluation results at 2,568 kWh per year. Single-family homes, when analyzed independently from manufactured homes, revealed fewer savings than the 2012 evaluation results at 1,551 kWh per year per home. The effects of further segregating savings analyses by the heating footprint of the home, number of occupants, and climate was shown not to be statistically significant. Idaho Power plans to continue to monitor savings from this program through further billing analyses. Additionally, the RTF contract staff is analyzing manufactured home audit data from 2011 to 2012 that will provide useful insights into how to potentially incorporate the measure-level audit data into future billing analyses.

To analyze program cost-effectiveness, the recommendations from IPUC staff's report and IPUC Order No. 32788 are used for cost-effectiveness analysis for 2014. For further details on the cost-effectiveness assumptions, see *Supplement 1: Cost-Effectiveness*.

## Customer Satisfaction and Evaluations

Idaho Power used two independent, third-party verification companies to randomly check approximately 10 percent of weatherization jobs submitted for payment by the program. These verifiers discussed the program with participating customers and confirmed installed measures in their homes. Home verifiers visited 43 homes for feedback about the program. When customers were asked how much they learned about saving electricity, 32, or over 74 percent, answered they learned "a lot" or "some." When asked about how many ways they tried to save electricity, 34, or approximately 79 percent, responded "a lot" or "some."

As recommended by Johnson Consulting Group in a 2013 process evaluation, a new customer survey was developed to assess major indicators of customer satisfaction and program operations consistently throughout the service area. The 2014 Weatherization Programs Customer Survey was provided to all WAQC participants in all regions upon completion of weatherization in their homes. Survey questions gathered information about how customers learned of the program, reasons for participating, how much customers learned about saving energy in their homes, and the likelihood of household members changing behaviors to use energy wisely. Demographic information was gathered to determine future marketing strategies.

Idaho Power received survey results from 237 of the 250 households weatherized by the program in 2014. Of the 237 surveys received back from customers, 228 were from Idaho customers and 9 were from Oregon customers. Some key highlights include the following:

- Over 47 percent of respondents learned of the program from a friend or relative, and another almost 15 percent learned of the program from an agency flyer. Nearly 6 percent learned about the weatherization program by receiving a letter in the mail.

- Almost 90 percent of the respondents reported their primary reason for participating in the weatherization program was to reduce utility bills, and over 45 percent wanted to improve the comfort of their home.

- Almost 74 percent reported they learned how air leaks affect energy usage, and just over 65 percent indicated they learned how insulation affects energy usage during the weatherization process. Another almost 57 percent of respondents said they learned how to use energy wisely.

- Over 79 percent reported they were very likely to change habits to save energy, and almost 80 percent reported they have shared all the information about energy use with members of their household.

- Over 86 percent of the respondents reported they think the weatherization they received will significantly affect the comfort of their home, and nearly 94 percent said they were very satisfied with the program.

- Over 86 percent of the respondents reported that the habit they were most likely to change was turning off lights when not in use, and over 61 percent said that washing full loads of clothes was a habit they were likely to change to save energy. Turning the thermostat up in the summer was reported by nearly 51 percent, and turning the thermostat down in the winter was reported by almost 58 percent as a habit they and members of the household were most likely to change to save energy.

A summary of the report is included in *Supplement 2: Evaluation*.

Idaho Power participates in the Idaho state monitoring process, which involves representatives from the CAP agencies, Community Action Partnership Association of Idaho, Inc. (CAPAI), and IDHW reviewing homes weatherized by each of the CAP agencies. Results of the state monitoring review show all CAP-agency weatherization departments are weatherizing in accordance with federal guidelines.

Additionally, the DOE audits state agencies each year. The DOE audits include field work, paperwork, and billing audits, which show that the Idaho WAP and therefore, WAQC, is in compliance with DOE standards.

## 2015 Program and Marketing Strategies

WAQC will continue using DOE guidelines and leveraging each weatherization job with state WAP funding on each job. The budget and projected number of jobs for 2015 will remain the same as 2014.

Idaho Power will continue working in partnership with the IDHW, OHCS, CAPAI, and individual CAP agency personnel to maintain the targets and guidelines and improve the cost-effectiveness of the WAQC program.

Idaho Power will continue involvement with the State of Idaho's Policy Advisory Council that serves as an oversight group for weatherization activities in Idaho. Through this forum, Idaho Power participates in the weatherization policy for the State of Idaho.

The company plans to continue to selectively market WAQC throughout 2015. The program will be promoted at resource fairs, community special-needs populations' service provider meetings, and CAP agency functions to reach customers who may benefit from the program. Marketing for this program will be conducted in cooperation with weatherization managers.

# Weatherization Solutions for Eligible Customers

## *Description*

Weatherization Solutions for Eligible Customers is an energy efficiency program designed to serve Idaho Power residential customers who are below poverty level, at poverty level, or slightly above poverty level. The program is designed to mirror WAQC. Potential participants are interviewed by the contractor to determine household eligibility as well as ensure the home is electrically heated. If the home is eligible, an auditor inspects the home to determine what energy-saving upgrades will save energy, improve indoor air quality, and increase comfort for the residents. The installation of energy efficiency measures and repairs are allowed as long as the improvements have a savings-to-investment ratio (SIR) of 1.0 or higher. The amount spent on each home is limited to an annual average of Idaho Power's portion of the cost per home. Homes considered for this program are electrically heated and either owned or rented. If rented, the landlord's permission is needed to perform the upgrades, along with an agreement to maintain the unit's current rent for a minimum of one year.

Idaho customers eligible for this program have earned incomes between 175 percent and 250 percent of the federal poverty level. These customers typically do not have expendable income to participate in other residential energy efficiency programs, and they live in similar housing as WAQC customers.

## *2014 Program and Marketing Activities*

The program served customers in Idaho Power's service area in Idaho, including Canyon, Southern, and Capital regions, as well as most of the Eastern region. In 2014, the program participation decreased from 166 in 2013 to 118 in 2014. This was due to some challenges in finding income-eligible customers in portions of Idaho Power's service area. Income guidelines overlap between the Weatherization Solutions

for Eligible Customers program and WAQC, therefore some of those eligible customers were served by WAQC. Additionally, reliance on word-of-mouth communication between prior customers and potential customers, which was a helpful method in the past, was less effective in 2014. Future marketing activities will be increased by Idaho Power and weatherization managers to locate more customers eligible to participate in the Weatherization Solutions for Eligible Customers program.

Table 10 shows the number of jobs and costs associated with measures installed in homes (production costs). Also shown are job average costs and total payments to contractors for the year.

Table 10. 2014 weatherization solutions financial breakdown

| Contractor | Number of Jobs | Production Costs | Average Job Cost | Administrative Payment to Contractor | Total Payment |
|---|---|---|---|---|---|
| Energy Zone | 55 | $ 317,757 | $ 5,777 | $ 31,776 | $ 349,533 |
| Home Energy Management | 35 | 185,276 | 5,294 | 18,528 | 203,803 |
| Power Savers | 23 | 130,176 | 5,660 | 13,018 | 143,194 |
| Savings Around Power | 5 | 28,994 | 5,799 | 2,899 | 31,894 |
| **Total** | **118** | **$ 662,204** | **$ 5,612** | **$ 66,220** | **$ 728,424** |

**Note:** Average Job Cost calculations based on the direct cost of installed measures without the administrative payment.

In response to the 2012 impact evaluation and the 2013 process evaluation, Idaho Power contracted with an outside programmer to complete a new home audit tool for use in the program. Throughout 2014, Idaho Power staff worked with Kearns ENTerprises™ to incorporate the evaluation recommendations into an audit tool for use in 2015. In January 2015, the new tool, WxSol Home Audit Tool (HAT 14.1), was distributed to the four program contractors for use in 2015.

Updates in the audit tool include more specific housing types, the most current measure life of individual measures, and an updated chart of heating degree days. LED lighting was added to the CFL measure to incorporate new bulbs and associated savings. A health and safety menu was included to better capture non-energy saving upgrades necessary to the weatherization process and to further research and quantify NEBs of the program. A percentage limit was programmed for contractor support costs on each measure, and a 10-percent funding participation mandate was added for landlords when a home is not owner occupied. The refrigerator replacement measure was updated to reflect more accurate savings.

In 2014, Idaho Power contracted with the University of Idaho IDL to develop a Weatherization HVAC Replacement Savings Calculator that is interactive with each measure upgraded in a home that receives a new HVAC system. This tool is expected to be completed in early 2015, and Idaho Power will use it to compare savings reported by the new WxSol Home Audit Tool (HAT 14.1) in anticipation of improving the accuracy of savings being reported by the program.

Marketing approaches in 2014 included a newsletter, bill inserts, and ads. For example, an energy efficiency edition of the *Connections* customer newsletter was in the February bill; a bill insert was added in April and September mailings, an ad ran in *Idaho Senior News*, and a three-day ad ran in the *Idaho State Journal*.

Contractor personnel left flyers with previous participants to spread information about the program to families and friends who might be eligible. Word-of-mouth continued to be a helpful marketing tool for the program in 2014. Several articles about the program were featured in various local publications. The program was promoted at Idaho Power and CAP agency outreach booths and resource fairs.

One of the target customer groups for Idaho Power's Weatherization Solutions program is seniors. To more directly focus on this customer group, information about the program was emailed to a number of resources used by seniors. This resulted in an assisted living provider with facilities throughout southern Idaho supplying program information in their monthly newsletter to residents, families, business partners, and healthcare providers. A health/hospice program included Idaho Power program information in their newsletter emailed to professionals/resources that work with senior citizens. Idaho Power placed print ads in the *Idaho State Journal* in October to promote program participation in eastern Idaho.

## Cost-Effectiveness

The billing analysis conducted in 2014 by Idaho Power on 2012 projects showed higher savings over the results published in the 2012 impact evaluation conducted by D&R International. However, due to the costs of comprehensive whole-house weatherization, the program remains not cost-effective from either a UC or TRC perspective. In 2014, Idaho Power conducted an additional billing analysis on 2012 participants. The company applied the recommendation from the 2012 impact evaluation by using a control group to account for non-weather related changes in energy use not attributable to the program's weatherization measures. The 2012 impact evaluation performed a billing analysis on 2011 projects. The average realized annual savings in all housing types was 1,826 kWh per home. For the update billing analysis, Idaho Power wanted to know if savings could be further differentiated between housing stock (single family versus manufactured home), occupant size, heating footprint of the home, and the number of occupants in the home. All billing analysis and data preparation was done in accordance with the *Whole-building Retrofit with Consumption Data Analysis Evaluation Protocol* document published in April 2013 by the DOE (energy.gov/eere/about-us/ump-protocols).

Analysis results showed that manufactured homes savings per home exceeded the previous 2012 evaluation results at 3,426 kWh per year. Single-family homes, when analyzed independently from manufactured homes, revealed higher savings than the 2012 evaluation results at 2,108 kWh per year per home. The effects of further segregating savings analyses by heating footprint of the home, number of occupants, and climate was shown not to be statistically significant.

To analyze program cost-effectiveness, the recommendations from IPUC staff's report and IPUC Order No. 32788 are used for cost-effectiveness analyses for 2014. For further details on the cost-effectiveness assumptions, see *Supplement 1: Cost-Effectiveness*.

## Customer Satisfaction and Evaluations

Two independent companies continued to perform random verifications of weatherized homes and visit with customers about the program. In 2014, 28 homes were verified, and 21, or 75 percent, of those customers reported they learned "a lot" or "some" about using energy wisely in their home. Twenty-six, or 93 percent, reported they had tried "a lot" or "some" ways to save energy in their home.

As recommended by Johnson Consulting Group in the 2013 process evaluation, a new customer survey was developed to consistently assess major indicators of customers' satisfaction and program operations throughout the service area. The 2014 Weatherization Programs Customer Survey was provided to all program participants in all regions on completion of weatherization in their homes. Survey questions gathered information about how customers learned of the program, reasons for participating, how much customers learned about saving energy in their homes, and the likelihood of household members changing behaviors to use energy wisely. Demographic information was gathered to determine future marketing strategies.

Idaho Power received survey results from 115 of the 118 households weatherized by the program in 2014. Some key highlights include the following:

- Almost 34 percent of respondents learned of the program through a letter in the mail and another almost 26 percent learned of the program from a friend or relative.
- Over 84 percent of the respondents reported their primary reason for participating in the weatherization program was to reduce utility bills.
- Just over 70 percent indicated they learned how insulation affects energy usage during the weatherization process, and 68 percent reported they learned how air leaks affect energy usage. Another almost 61 percent of respondents said they learned how to use energy wisely.
- Over 68 percent reported they were very likely to change habits to save energy, and almost 65 percent reported they have shared all of the information about energy use with members of their household.
- Almost 89 percent of the respondents reported they think the weatherization they received will significantly affect the comfort of their home, and nearly 96 percent said they were very satisfied with the program.

A summary of the report is included in *Supplement 2: Evaluation*.

## 2015 Program and Marketing Strategies

Contractors will use the new WxSol Home Audit Tool (HAT 14.1) throughout 2015.
The Weatherization HVAC Replacement Savings Calculator developed by the IDL will be used to compare energy savings of the WxSol Home Audit Tool (HAT 14.1) when an HVAC system is upgraded in a home. As recommended in former program evaluations, the new calculator will provide more accurate savings estimates for the program.

In 2015, marketing plans include emails, ads, bill inserts, and distribution of the program brochures. Targeting various customer segments with bill insert and direct mailings has been helpful in the past in increasing program participation and will be used in 2015. A printed bill message is scheduled for May, and bill inserts will go out in February and again in the fall. Webpages for the Weatherization Solutions for Eligible Customers program will be refreshed during the coming year.

Idaho Power will create a program brochure and provide it to contractors for use in their individual regional marketing campaigns. Idaho Power will mail a letter to customers in April, July, and September whose energy consumption indicates electrically heated homes. The program will be promoted at senior centers and resource and energy fairs throughout the year, and a redesign of the energy efficiency pages of the Idaho Power website is scheduled.

Publications dedicated and directed to senior readers that have not been used in the past will be used in 2015. *Senior Goldmine* is a monthly publication delivered to 10 senior centers and over 100 other locations in the Treasure Valley. It is also hand-delivered to over 700 Meals-on-Wheels recipients. The company will also advertise in the *Senior Blue Book*, a semi-annual resource directory mailed to over 28,000 seniors and healthcare professionals. In 2015, February, May, August, and November ads in the *Idaho Senior News* are scheduled. This publication focuses on a demographic of senior readers ages 50 and older with a readership of over 80,000 statewide.

# COMMERCIAL/INDUSTRIAL SECTOR OVERVIEW

## Description

Idaho Power's commercial sector consists of over 67,522 customers. In 2014, the commercial sector's number of customers increased by 788, an increase of a little over 1 percent from 2013. The energy usage of commercial customers varies from a few kWh each month to several hundred thousand kWh per month. The commercial sector represents 30 percent of Idaho Power's total electricity usage in 2014.

The industrial and Special Contracts customers are Idaho Power's largest individual energy consumers. There are approximately 116 industrial customers. These customers can use millions of kWh a month and account for 17.9 percent of Idaho Power's total electricity usage in 2014.

Three major programs targeting different energy efficiency projects are available to commercial/industrial customers in the company's Idaho and Oregon service areas. Easy Upgrades offers a menu of typical retrofit measures with prescriptive incentive amounts for lighting, HVAC, building shells, variable-speed/frequency drives (VFD), plug loads, and food-service equipment. These energy-saving measures give customers the option of choosing the best selections for incorporating energy efficiency into their business. The Custom Efficiency program offers financial incentives for large commercial and industrial energy users undertaking more complex projects to improve the efficiency of their electrical systems or processes. Incentive levels are 70 percent of the project cost or 18 cents per kWh for first-year savings, whichever is less. During 2014, Idaho Power combined how the Easy Upgrades and Custom Efficiency programs treat lighting projects so they are processed together and the incentives and criteria are the same. The Building Efficiency program is available for new construction projects and large remodels. These projects typically capture lost-opportunity savings and encourage business owners to incorporate energy efficiency measures that are more efficient than current commercial building codes require. This program continues to be successful, incorporating qualified energy-saving improvements for lighting, cooling, building shells, and energy-management control options.

Idaho Power continues to offer the statutory Oregon Commercial Audits program to medium and small commercial customers. The program identifies opportunities for commercial building owners to achieve energy savings.

In 2014, FlexPeak Management, a demand response program, was offered to Idaho and Oregon commercial and industrial customers. Idaho Power contracted with EnerNOC, Inc., a third-party aggregator, to reduce peak demand at critical times. EnerNOC, in turn, contracted directly with Idaho Power's commercial and industrial customers to achieve demand reduction. For 2015, Idaho Power has proposed to internally run and manage the program.

The Custom Efficiency program continued to represent the highest total energy savings among commercial and industrial programs in 2014, with a total savings of 50,363 MWh. The Easy Upgrades program continued to lead the sector in projects completed with 1,095 projects. Combined, all programs completed 1,295 projects that achieved 78,940 MWh of energy savings. Table 11 shows a summary of savings and expenses from the three commercial and industrial energy efficiency programs that produce direct savings and one demand response program.

# Programs

Table 11. 2014 commercial/industrial program

| Program | Participants | Total Cost | | Savings | |
|---|---|---|---|---|---|
| | | Utility | Resource | Energy (kWh) | Demand (MW) |
| **Demand Response** | | | | | |
| FlexPeak Management | 93 sites | $ 1,563,211 | $ 1,563,211 | n/a | 40 |
| **Total** | | **$ 1,563,211** | **$ 1,563,211** | | **40** |
| **Energy Efficiency** | | | | | |
| Building Efficiency | 69 projects | 1,258,273 | 3,972,822 | 9,458,059 | 1.2 |
| Easy Upgrades | 1,095 projects | 3,150,942 | 5,453,380 | 19,118,494 | |
| Custom Efficiency | 131 projects | 7,173,054 | 13,409,922 | 50,363,052 | 5.6 |
| **Total** | | **$ 11,582,269** | **$ 22,836,124** | **78,939,605** | **6.8** |

**Note:** See Appendix 3 for notes on methodology and column definitions.

Although 2014 was a good year for Idaho Power's commercial and industrial energy efficiency programs, Idaho Power program managers recognized early in 2014 that some changes needed made to the programs. The company took action by increasing incentives to most measures in all three programs, removing non-cost effective measures, modifying how lighting retrofit projects were processed, adding trade ally outreach for lighting, and offering a cohort to wastewater treatment plants.
The commercial and industrial programs continued to develop and strengthen Idaho Power's strategic partnerships. These partnerships include the IDL, engineering and architectural firms, a vast network of trade allies, the Northern Rockies Chapter of International Facilities Managers Association, the IBOA, and most importantly, Idaho Power customers. Training and education continued to be an important aspect of the company's programs in 2014. Trade ally meetings included training on lighting design and lighting controls. These training classes qualified for continuing education credits for eligible, licensed trade allies. Building Efficiency sponsored a number of outreach training sessions conducted by the IDL. Last, Custom Efficiency continued to offer a host of industrial training sessions that were well attended.

The Green Rewind offering is available to Idaho Power's agricultural, commercial, and industrial customers. The sectors' combined 29 Green Rewind motors achieved a total annual savings of 91,582 kWh in 2014, with 14 commercial/industrial sector motors contributing 56,499 kWh per year and 15 irrigation sector motors contributing 35,083 kWh per year.

Twenty-one service centers in Idaho Power's service area have the necessary equipment and training to participate in the Green Rewind offering. An estimated 1,200 motor rewinds are occurring annually within these service centers. Currently, four service centers have signed on as Green Motors Practice Group (GMPG) members in Idaho Power's service area. The GMPG will also expand the number of service centers participating in the GMPG's Green Motors Initiative, leading to market transformation and additional southern Idaho and eastern Oregon kWh savings.

Motor service centers are paid $2 per horsepower (hp) by the GMPG for each National Electrical Manufacturers Association (NEMA) Standard hp-rated motor up to 5,000 hp for industrial and agricultural uses that receive a verified Green Rewind. Customers are paid $1 per hp from the service center that completed their rewind. The GMPG requires all service centers to sign and adhere to the GMPG Annual Member Commitment Quality Assurance agreement. The GMPG follows up with a quality check and QA.

Idaho Power continued research on the potential to expand incentives in the Building Efficiency program in 2014 for multi-family dwellings in new construction and major remodel projects. In 2013, it was determined that most multifamily construction uses natural gas as a heat source, resulting in minimal electricity savings based on cooling measures alone. Because of this, multi-family projects do not pass Idaho Power's cost-effectiveness tests.

Customer satisfaction research by sector includes the Idaho Power quarterly customer relationship surveys that ask questions about customer perceptions related to Idaho Power's energy efficiency programs. Sixty percent of Idaho Power's large commercial and industrial customers surveyed in 2014 for the Burke Customer Relationship survey indicated Idaho Power was meeting or exceeding their needs in offering energy efficiency programs. Fifty-six percent of survey respondents indicated Idaho Power was meeting or exceeding their needs with information on how to use energy wisely and efficiently. Seventy-three percent of respondents indicated Idaho Power was meeting or exceeding their needs by encouraging energy efficiency with its customers. Overall, 77 percent of the large commercial and industrial survey respondents indicated they have participated in at least one Idaho Power energy efficiency program. Of the large commercial and industrial survey respondents who have participated in at least one Idaho Power energy efficiency program, 94 percent are "very" or "somewhat" satisfied with the program.

The results from surveying Idaho Power's small business customers indicated 52 percent of these customers said Idaho Power was meeting or exceeding their needs in offering energy efficiency programs. Fifty-one percent of survey respondents indicated Idaho Power was meeting or exceeding their needs with information on how to use energy wisely and efficiently. Sixty percent of respondents indicated Idaho Power was meeting or exceeding their needs with encouraging energy efficiency with its customers. Overall, 22 percent of the small business survey respondents indicated they have participated in at least one Idaho Power energy efficiency program. Of small business survey respondents who have participated in at least one Idaho Power energy efficiency program, 82 percent are "very" or "somewhat" satisfied with the program.

Customers' familiarity with Idaho Power's business energy efficiency programs meets or exceeds the average of its peer utilities according to the J. D. Power and Associates Electric Utility Business Customer Satisfaction Study. Idaho Power has exceeded the average of its peer utilities every year in the last four years with its awareness of business programs.

## *Description*

The Building Efficiency program enables customers in Idaho Power's service area to apply energy-efficient design features and technologies in new commercial or industrial construction, expansion, or major remodeling projects. The program offers a menu of measures and incentives for lighting, cooling, building shell, controls, appliances, and refrigeration-efficiency options. These measures may otherwise be lost opportunities for savings on customers' projects. Commercial and industrial customers taking service under, or who will take service under, Schedule 7 (Small General Service), Schedule 9 (Large General Service), Schedule 19 (Large Power Service), or Special Contracts customers are eligible to participate. Program marketing is targeted toward architects, engineers, and other design professionals.

Twenty prescriptive measures are offered through this program. The measures are interior-light load reduction, exterior-light load reduction, daylight photo controls, occupancy sensors, high-efficiency exit signs, efficient AC and heat pump units, efficient variable refrigerant flow (VRF) units, efficient chillers, air-side economizers, direct evaporative coolers, reflective roof treatment, energy-management control systems, guest room energy management systems, HVAC VFDs, efficient laundry machines, ENERGY STAR® under-counter dishwashers, ENERGY STAR commercial dishwashers, refrigeration head pressure controls, refrigeration floating suction controls, and efficient condensers.

The IDL has been a useful resource for the Building Efficiency program. Idaho Power is a primary sponsor of the IDL, which provides technical assistance and training seminars focused on energy efficiency to local architects, engineers, and designers through Lunch & Learn sessions and the

Idaho Building Simulations Users Group (BSUG). Sessions are outlined in the IDL section of *Supplement 2: Evaluation*.

## 2014 Program and Marketing Activities

The Building Efficiency program completed 69 projects, resulting in 9,458,059 kWh in annual energy savings in Idaho and Oregon. Although the program showed a slight decrease in total kWh savings from 2013, the program increased the total number of projects by 17 percent from 59 projects in 2013. New construction and major renovation project design and construction life is much longer than small retrofits and often encompasses multiple calendar years.

The Building Efficiency program was modified in 2014, adding six new incentive measures. Idaho Power contracted with ADM to provide a technical reference manual (TRM) to address recommendations provided in the ADM impact evaluation in 2012. The TRM was completed in 2014 and provided updated savings for existing measures and savings for new measures that were added to the program.

Research conducted at the end of 2012 revealed that one barrier to participation is the amount of uncompensated time it took to fill out and submit supporting project documentation. Idaho Power addressed this barrier in 2014 by adding a "Professional Assistance Incentive" equal to 10 percent of the participant's total incentive, up to a maximum amount of $2,500, to improve participants' satisfaction with the incentive process. Modifications to the program were posted on Idaho Power's website, in the fall edition of the *ENERGY@WORK* commercial newsletter, and in a letter mailed directly to engineers and architects throughout Idaho Power's service area. Idaho Power worked with the American Institute of Architects—Idaho Chapter to have the program revisions posted to their website at aiaidaho.com/.

Idaho Power marketing and program staff participated in bi-monthly conference calls in support of the Kilowatt Crackdown™ competition. A video highlighting positive participant experiences was produced by the company and shown at the 2014 BOMA Symposium. In addition to the video, Idaho Power was a symposium sponsor and as such, had a full-page ad in the program magazine. The Kilowatt Crackdown™ Awards luncheon held April 16 recognized the top three highest-performing buildings, the top three most improved buildings, and two special recognition rewards. Idaho Power issued a news release that day to recognize the winners and encourage additional coverage of the competition. Idaho Power scheduled two additional training sessions with BOMA members in 2014.

Building Efficiency was marketed as a single program and as part of Idaho Power's suite of commercial energy efficiency programs. Ads that include all of Idaho Power commercial programs appeared in association directories, *Horizon Air* magazine, Boise Metro Chamber of Commerce monthly magazine, the *Business Insider*, the *Idaho Business Review*, and bill inserts.

Additional commercial/industrial sector success stories were added to the Idaho Power website in 2014, with one specific to a Building Efficiency program new construction project titled *CSHQA architects and engineers design sustainability into their own offices*. Copies of the 2014 success stories are provided in *Supplement 2: Evaluation*.

In 2014, Idaho Power created a new commercial video showing how energy efficiency can be incorporated into new construction or as a retrofit. The Hailey Interpretive Center, a Building Efficiency program participant, was one of three projects featured on the video. The IDL was also featured in the video.

Technical training and assistance continue to be important in educating design professionals in energy efficiency design for new construction and major renovations. Influencing a project early in the design phase will have the most impact and least amount of lost opportunity. Twenty technical training lunches were completed in 2014, with 281 attendees, including architects, engineers, interior designers, and project managers. Technical training sessions were held in Boise, Pocatello, and Ketchum. The Building Efficiency program, in conjunction with the Custom Efficiency program, sponsored the Idaho BSUG through the IDL. Topics and sessions are outlined in the IDL section of *Supplement 2: Evaluation*.

The Building Efficiency program supports a number of associations and events, including placing ads in the American Institute of Architects (AIA) directory and sponsoring the AIA Honor awards, Grow Smart awards, BOMA symposium, and ASHRAE Technical Conference.

## Cost-Effectiveness

To calculate energy savings for the Building Efficiency program, Idaho Power verifies the incremental efficiency of each measure over a code or standard-practice installation baseline. Savings are calculated through two main methods. When available, savings are calculated using actual measurement parameters, including the efficiency of the installed measure compared to code efficiency. Another method for calculating savings is based on industry-standard assumptions when precise measurements are unavailable. Since Building Efficiency is a prescriptive program and the measures are being installed in new buildings, there are no baselines of previous measureable kWh usage in the building. Therefore, industry-standard assumptions from the International Energy Conservation Code (IECC) are used to calculate the savings achieved over how the building would have used energy absent of efficiency measures.

Building Efficiency incentives are based on a variety of methods depending on the measure type. Incentives are calculated mainly through a dollar-per-unit equation using square footage, tonnage, operating hours, or kilowatt reduction.

In 2014, under contract with Idaho Power, ADM completed a TRM for Building Efficiency, which provides savings and costs related to existing and new measures for the Building Efficiency program. The TRM was evaluated in 2014, and cost-effectiveness analyses were performed on all measures addressed through the TRM. The analyses resulted in modifications to several existing measures, the removal of one measure, and the addition of six measures to the updated 2014 Building Efficiency program.

Several measures that are not cost-effective remain in the program. These measures include daylight photo controls, high-efficiency A/C units, and high-efficiency heat pump units. After reviewing these measures, Idaho Power determined these measures met at least one of the cost-effectiveness exceptions outlined in OPUC Order No. 94-590. These modification and cost-effectiveness exceptions were approved by the OPUC in Advice No. 14-10 for 2014 and went into effect in Idaho in July 2014 and in Oregon in November 2014. Complete measure-level details for cost-effectiveness can be found in *Supplement 1: Cost-Effectiveness*.

## Customer Satisfaction and Evaluations

Building Efficiency continued random installation verification on 10 percent of projects in 2014. The purpose of the verifications is to confirm program guidelines and requirements are adequate and ensure participants are able to provide accurate and precise information with regard to energy efficiency

measure installations. The IDL completed on-site field verifications on 7 of the 69 projects, which encompass approximately 10 percent of the total completed projects in the program. Out of the seven projects verified, six projects were installed with only minor or no discrepancies compared to how they were declared on the final application. The minor discrepancies resulted in a total increase of energy-efficient measures for six of the seven projects. Only one project was installed with less energy-efficient measures than declared. The project involved the installation of additional lighting fixtures and did not meet the program guidelines. Random project installation verification will continue in 2015.

## 2015 Program and Marketing Strategies

The following strategies are planned for 2015:

- Continue to perform random post-project verifications on a minimum of 10 percent of completed projects.
- Continue to sponsor technical training through the IDL to address the energy efficiency education needs of design professionals throughout the Idaho Power service area.
- Continue to support Kilowatt Crackdown participants through continued coaching and technical support to further energy efficiency projects.
- Support organizations focused on promoting energy efficiency in commercial construction.
- Place print ads in the *Idaho Business Review* when the editorial content is dedicated to commercial property developers and engineers/architects.
- Actively support the 2015 Idaho Energy and Green Building Conference as a member of the conference planning committee. Participate in planning the conference agenda and energy efficiency sessions.
- Continue to sponsor the BOMA symposium and offer energy efficiency training and support to the real estate market.

# Custom Efficiency

* Includes 56,499 kWh from Green Motors projects.

## *Description*

The Custom Efficiency program targets energy savings by implementing customized energy efficiency projects at customers' sites. The program is an opportunity for commercial and industrial customers in Idaho and Oregon to lower their electrical usage and receive a financial incentive by completing energy efficiency projects. Incentives reduce customers' payback periods for projects that might not be completed otherwise. Program offerings include training and education regarding energy efficiency, energy auditing services for project identification and evaluation, and financial incentives for project implementation.

Interested customers submit pre-applications to Idaho Power for potential projects that have been identified by the customer, Idaho Power, or by a third-party consultant. Idaho Power engineers work with customers and vendors to gather sufficient information to support the energy-savings calculations.

Project implementation begins after Idaho Power reviews and approves a pre-approval application finalizing the terms and conditions of the applicant's and Idaho Power's obligations. A payment application is later submitted when the project is installed and operating. In some cases, large, complex projects may take as long as two years to complete. Every project is verified post-completion by Idaho Power staff or an Idaho Power contractor. Lighting projects are typically pre- and post-inspected by an Idaho Power contractor or an Idaho Power representative. Incentive levels for the Custom Efficiency program were increased from 12 cents per kWh per year saved to 18 cents per kWh per year saved in July 2014; however, the 70-percent project cost cap remained in place. The lighting incentives for Custom Efficiency changed in July 2014. All standard lighting measures are now paid at

the stated prescriptive amount, which were revised in July 2014. All non-standard measures for interior lighting are now paid at the rate of 18 cents per kWh for first-year savings, up to 70 percent of the cost. All non-standard measures for exterior lighting are paid at the rate of 12 cents per kWh for the first-year savings, up to 70 percent of the cost.

## 2014 Program and Marketing Activities

Custom Efficiency had a very successful year in 2014. A total of 131 projects, including nine Oregon projects, were completed by 95 customers. Program energy savings increased in 2014 by 135 percent over 2013, from 21,370 MWh to 50,306 MWh.

Savings for the Custom Efficiency program can vary greatly based simply on the timing of projects as evidenced by the drastic difference in program savings year to year. In 2014, 145 new applications were submitted, totaling 64,729 MWh. There were 150 submitted projects in the pipeline for Custom Efficiency at the end of 2014, representing almost 67,665 MWh of potential future savings.

The Custom Efficiency program may also have reached some level of saturation through program maturity, as over 95 percent of the large-power service customers have engaged in the program. With the high percentage of industrial customers that have completed projects in the program, deeper energy savings will be challenging to achieve.

Table 12 indicates the program's 2014 annual energy savings by primary project measures.

Table 12. 2014 Custom Efficiency annual energy savings by primary project measure

| Program Summary by Measure | Number of Projects | kWh Saved |
|---|---|---|
| Lighting | 53 | 11,107,700 |
| Refrigeration | 19 | 24,158,395 |
| HVAC | 4 | 1,247,404 |
| Compressed air | 12 | 3,446,633 |
| Fan | 10 | 3,326,987 |
| Controls | 2 | 1,850,541 |
| Pump | 3 | 1,629,045 |
| VFD | 27 | 2,733,098 |
| Other | 1 | 806,750 |
| Total[a] | 131 | 50,306,553 |

[a] Does not include Green Rewind project counts and savings.

Key components in facilitating customer implementation of energy efficiency projects are facility energy auditing, customer technical training, and education services. The 2014 activities in the key components are described below.

### Facility Energy Auditing

In 2014, five scoping audits and seven detailed audits were completed on behalf of Idaho Power customers. These audits identified over 24,000 MWh per year of savings potential, and most of the customers engaging in these audits have used the information to move forward with projects or have expressed interest in moving forward in the near future. A Scoping Audit and an Energy Management Assessment was provided to 11 facilities as part of the Wastewater Energy Efficiency Cohort (WWEEC) offering.

### Customer technical training and education services

Technical training and education continue to be important in helping Idaho Power industrial customers identify where they may have energy efficiency opportunities within their facilities. The training is coordinated by the NEEA Industrial Training Project, and Idaho Power is a co-sponsor. Idaho Power provides funds for extra NEEA trainings in the Idaho Power service area. Additionally, Idaho Power pays customers' attendance fee in the classroom-based training sessions. Seven technical classroom-based training sessions were completed in 2014. Two of these classes were two-day classes, and the rest were one-day classes. Topics included compressed air, air-cooled refrigeration systems, pump systems, and fan system efficiency. A schedule of training events is posted on Idaho Power's website.

The level of attendance in 2014 remained high, with 115 Idaho Power-sponsored seats for customers and various Idaho Power staff, consultants, and trade allies out of the 119 total attendees. Customer feedback indicated average overall satisfaction levels of 99 percent.

Additionally, 2014 encompassed Phase IV of the webinar pilot plan coordinated by NEEA. Three webinars were presented free to all attendees. Topics included VFDs, efficient industrial lighting, and energy auditing and troubleshooting. There were 24 Idaho Power end-use customers, multiple Idaho Power personnel, and various consultants attending the webinar recordings. Idaho Power posted the webinar recordings and PDFs on the commercial and industrial training page on the Idaho Power website.

Figure 16 shows the number of Idaho Power-sponsored attendee seats filled as compared to other utility companies for the 2014 in-class NEEA industrial trainings. This figure uses data from ECOVA™'s summary of the trainings provided in the *NEEA Regional Industrial Training Update, December 2014* included in *Supplement 2: Evaluation*.

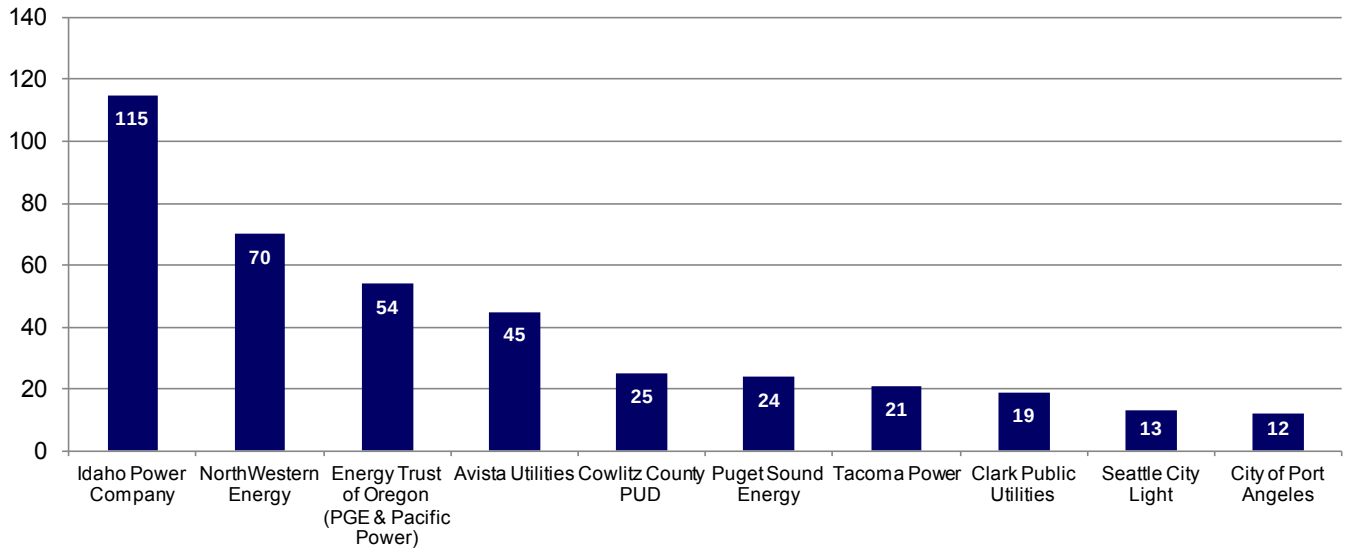

Figure 16. NEEA chart of attendees (in-class seats filled) by attendee sponsor[1]

Figure 17 shows the number of Idaho Power-sponsored attendee seats filled as compared to other utility companies for the three 2014 webinar-based NEEA industrial trainings. This figure uses data from ECOVA's summary of the trainings provided in the NEEA Regional Industrial Training Update, December 2014, included in *Supplement 2: Evaluation*.

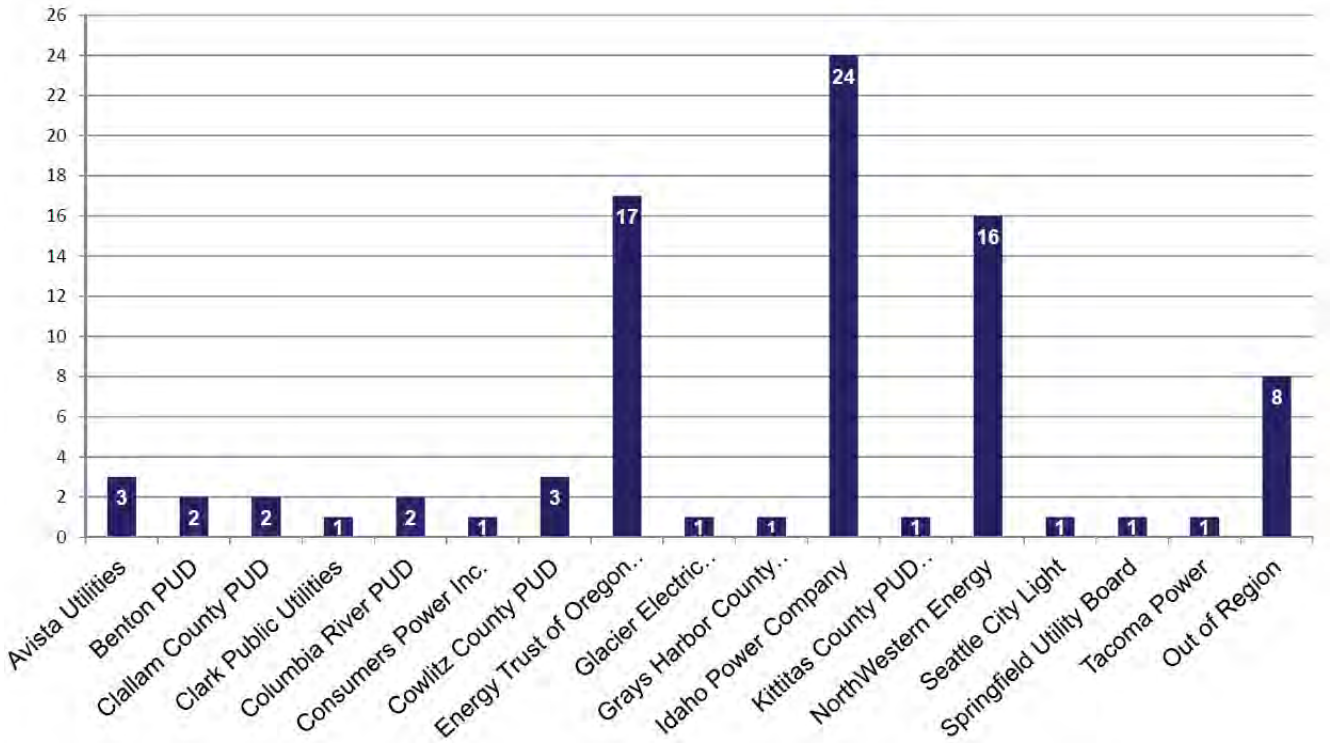

Figure 17. NEEA chart of attendees (webinar-based seats filled) by attendee sponsor[2]

In 2014, Idaho Power sponsored a Refrigeration training at the CWI during the September Treasure Valley Refrigerating Engineers and Technicians Association (RETA) chapter meeting.

In November in Boise, Idaho Power also co-sponsored a two-day RETA Certified Refrigeration Energy Specialist (CRES) review class training with NEEA with 13 customers in attendance. The purpose of the training was to review refrigeration energy efficiency concepts and to prepare the attendees for the RETA CRES exam. The requirement for signing up for the free training was for the students to apply for the CRES exam.

Custom Efficiency program engineers and the MCRs set up numerous target visits with the large commercial and industrial customers in 2014. The visits ranged from commercial/industrial efficiency program training to a comprehensive targeted technical training session for a larger audience on potential energy-savings opportunities for different measure types, such as refrigeration, pumps and fans, compressed air, HVAC, lighting, etc. Because of WWEEC, Custom Efficiency program engineers also set up multiple program marketing meetings with the area civil engineering firms specializing in water and wastewater designs to educate them on the efficiency programs, audit process, energy efficiency opportunities, and tools and resources available to them.

[2] Data source: NEEA Regional Industrial Training Update, December 2014

Under the IDL, Idaho Power participated in the BSUG. The goal was to facilitate the Idaho BSUG, which was designed to improve the energy efficiency-related simulation skills of local design and engineering professionals. In 2014, 11 sessions were hosted by the IDL. For one session, the IDL hosted the remote viewing of sessions taught by the Building Energy Simulation Forum in Portland. The sessions were made available remotely and were attended by 179 professionals in-person and 318 professionals remotely. Details regarding BSUG topics and additional details are located in the Other Programs and Activities section of the report and in *Supplement 2: Evaluation*.

The IDL provided a Tool Loan Library (TLL). The goal was to operate and maintain a measurement equipment tool loan library, including a web-based equipment tool loan tracking system, and provide technical training on how each tool is intended to be used. There were a total of 286 tools loaned in 2014 as part of 37 total loans. Fourteen new tools were purchased or acquired in 2014. Details regarding the types and number of loans, types of tools, and additional IDL activities are located in the Other Programs and Activities section of the report and in *Supplement 2: Evaluation*.

As stated in the sector overview, Green Rewind is available to Idaho Power's Custom Efficiency customers. This measure maintains the motor's original efficiency by ensuring certain standards and methods in the motor rewind process. There were 14 Green Rewind motors in the commercial/industrial sector in 2014, contributing 56,499 kWh in annual savings.

In 2013, Custom Efficiency launched two new offerings to increase the total program savings in 2014 and beyond. Early in 2013, the ROCEE offering was rolled out to Idaho Power's larger customers with complex refrigeration systems in the western half of Idaho Power's service area. This was a two-year engagement with the eight participating customers. ROCEE provided a series of technical training workshops with a cohort cluster training approach. Workshops included visits to participants' refrigeration engine rooms to gain hands-on experience viewing and discussing energy efficiency concepts. The goal of the training was to equip refrigeration operators with the skills necessary to identify and implement energy efficiency opportunities on their own and to ensure these energy and cost savings are maintained long term. Sessions included technical training, hands-on learning exercises to demonstrate simple low- and no-cost actions to diagnose problems and save energy, and peer-to-peer sharing of lessons learned as the classes progressed.

ROCEE provided energy audits of the participants' facilities in conjunction with a qualified refrigeration system expert. Customers were able to immediately implement low-cost and no-cost energy efficiency improvements by actions as simple as processing set-point changes. Participants had technician and engineering support between each workshop, facilitated by an expert team of energy engineers. Energy savings were tracked via an energy model that was constructed for each participating facility using third-party energy management software that Idaho Power provided as part of the cohort. In some cases, bottom-up calculations or sub-system data logging captured the savings. The incentives and the energy savings for year one of the offering totaled $13,886 and 3,678,985 kWh per year. In all cases, the incentive was capped on 70 percent of the eligible costs. Year two incentives and savings will be processed in 2015. Additionally, some ROCEE participants completed capital projects that were encouraged and discussed in the workshops and energy audits. These projects' savings are captured in the main Custom Efficiency program savings.

The second program offering rolled out in 2013 was SCE. This offering targets projects that may have typically been too small to participate in the Custom Efficiency program due to the resources required to adequately determine measure savings. Idaho Power has contracted SCE out to a company to manage the data collection and analysis for each project. SCE provides custom incentives for small compressed air system improvements, fast-acting doors in cold-storage spaces, refrigeration controllers for walk-in

coolers, and process-related VFDs. In 2014, the SCE offering processed 46 projects, totaling 4,698,478 kWh per year of savings and $540,375 in incentives paid.

In January 2014, Custom Efficiency launched the WWEEC program offering to increase the total program savings. Similar to ROCEE, WWEEC is a cohort training approach to low-cost or no-cost energy improvements. WWEEC is a two-year engagement with 11 Idaho Power service area municipalities. WWEEC provided a series of five technical training workshops with a cohort training approach. In addition, WWEEC provided energy audits in conjunction with a qualified wastewater system expert and an Energy Management Assessment conducted by a Strategic Energy Management professional for each participating facility. Customers were able to immediately implement low-cost and no-cost energy efficiency improvements by actions as simple as turning off equipment or adjusting control points for systems. They also implemented many energy management principles, including forming an energy team, setting energy goals, and establishing energy policies in their organization for persistence of savings. Energy savings were tracked via Idaho Power provided third-party software and an individual energy model for each facility. WWEEC contributed several capital projects to Idaho Power incentive programs from some of the WWEEC participants. Additionally, pre-planning meetings were held with consultants and municipalities for upcoming new wastewater construction projects.

2014 was the third year the Idaho Power CR&EE department filled a summer internship position with a university mechanical engineering student. A Custom Efficiency engineer served as the intern mentor. The intern was involved with many aspects of the day to-day program operation, including, but not limited to, measurement and verification of energy efficiency aspects related to Custom Efficiency program lighting projects; attendance at customer meetings related to energy efficiency; familiarization with, and communication for, all three commercial incentive programs; calculation and review of energy-saving projects; exposure to program marketing and planning activities; and administrative work related to the Custom Efficiency program.

The Custom Efficiency program has achieved a high service-area penetration rate. As stated previously, through 2014, over 95 percent of the large-power service customers have submitted applications for a project. Idaho Power staff met with all of the Special Contracts customers to discuss energy efficiency programs and opportunities. Specifically, only 2 of the 107 large-power service customers have not submitted an energy efficiency project, and all three Special Contracts customers have submitted projects. The company staff are actively working to support these customers in new ways.

Idaho Power's Custom Efficiency program is unique from the company's other energy efficiency programs by providing individualized energy efficiency solutions to a somewhat limited number of customers. Idaho Power's MCRs often act as the company's sales force. Marketing supports the MCRs by providing collateral to help them inform customers of the measures and benefits available to them.

The Custom Efficiency program was updated in July 2014, increasing incentive rates to 18 cents per kWh for first-year savings from 12 cents per kWh for first-year savings. As a result, marketing materials and web content were updated to reflect programmatic changes. A letter was sent to MCRs to distribute to their customers to increase awareness of changes to the commercial/industrial programs. Also, a PowerPoint presentation was created for the engineers and MCRs to use as part of their target visits with customers to highlight ongoing program activities and program changes.

In 2014, two new pieces of collateral were created for the Custom Efficiency program: 1) a flyer describing the types of incentives available under the Streamlined Custom Efficiency offering, and 2) a general overview brochure described the Custom Efficiency program. The flyer detailed the

types of improvements that fit under the Streamlined Custom Efficiency program offering, eligibility, and the application process. A new Custom Efficiency brochure was created to easily provide an overview of the program without reading through pages of text. Both of these documents were designed with the same look and feel. MCRs took flyers and brochures with them on customer visits. Both documents are available at idahopower.com/EnergyEfficiency/Business/Programs/CustomEfficiency/default.cfm.

As incentives were received, some commercial customers wanted to publicize the work they have done to become more energy efficient. Upon request, Idaho Power created large-format checks that are used for media events and or board meetings. Idaho Power also worked with customers on coordinating media events.

In early January, Idaho Power reached out to administration offices of cities in the company's service area participating in the Custom Efficiency WWEEC in Boise to encourage media opportunities in their communities. An alert was sent to all press outlets on January 27, the first day of the workshop, in the form of a media advisory, to inform the media of a public relations opportunity, with contact information for each city's public information officer and/or mayor's office representative. At the workshop, Idaho Power interviewed participants for testimonials to be included in an internal *eNews* video that was posted on YouTube in April and the link shared with workshop participants and promoted on social media. The video is titled *Partnering for Efficiency—Wastewater Plants* and is posted at youtube.com/watch?v=ES46PET3B70. In September, a press release was sent to all media on the day of the last of the five workshops held in Boise providing more information about the work being done by Idaho Power partnering with participants to improve energy efficiency throughout the service area. The press release included a link to the YouTube video. Local media was invited to join a tour of one of the local wastewater treatment plants; video footage was taken during the tour and a link to the footage was provided to any media that did not attend. In October, Idaho Power helped create a press release template for the participants to report out their results to local media.

Custom Efficiency has been marketed as a single program and also as part of Idaho Power's suite of commercial energy efficiency programs. Ads that include all Idaho Power commercial programs have appeared in association directories, *Horizon Air* magazine, Boise Metro Chamber of Commerce monthly magazine, the *Business Insider*, the *Idaho Business Review*, and bill inserts. Also, industry-specific energy efficiency brochures were developed in 2014 for several industries, including grocery stores, convenience stores, offices, hotels, restaurants, and healthcare facilities. These brochures are being distributed by CRs and MCRs and are available on the company's website here: idahopower.com/EnergyEfficiency/Business/Tips/eeBusinessSpecificTips.cfm.

## Cost-Effectiveness

All projects submitted through the Custom Efficiency program must meet cost-effectiveness requirements, which include TRC, UC, and PCT tests from a project perspective. The program requires that all costs related to the energy efficiency implementation and energy-savings calculations are gathered and submitted with the program application. Payback is calculated with and without incentives, along with the estimated dollar savings for installing energy efficiency measures. As the project progresses, any changes to the project are used to recalculate energy savings and incentives before the incentives are paid to the participant. To aid in gathering or verifying the data required to conduct cost-effectiveness and energy-savings calculations, third-party engineering firms are sometimes used via a scoping audit, detailed audit, or engineering measurement and verification services available under the Custom Efficiency program. Details for cost-effectiveness are in *Supplement 1: Cost-Effectiveness*.

## Customer Satisfaction and Evaluations

Each project in the Custom Efficiency program is reviewed to ensure energy savings are achieved. Idaho Power engineering staff or a third-party consultant calculate the energy savings. Through the verification process, end-use measure information, project photographs, and project costs are collected.

On many projects, especially the larger and more complex projects, Idaho Power or a third-party consultant conducts on-site power monitoring and data collection before and after project implementation. The measurement and verification process helps ensure the achievement of projected energy savings. Verifying applicants' information confirms that demand reduction and energy savings are obtained and are within program guidelines. If changes in scope take place in a project, a recalculation of energy savings and incentive amounts occurs based on the actual installed equipment and performance. The measurement and verification reports provided to Idaho Power include a verification of energy savings, costs, estimates of measure life, and any final recommendations to ensure the persistence of savings.

Because the customers who participate in the Custom Efficiency program are some of Idaho Power's largest customers, program managers or MCRs solicit customer satisfaction feedback for the Custom Efficiency program. This is authenticated in customers' willingness to allow posting the customers' success stories on the Idaho Power website. In 2014, seven new success stories described energy efficiency projects submitted by Custom Efficiency program participants. An example of a success story posted in 2014, *A chilling story of ON Semiconductor and Idaho Power incentives*, refers to a project ON Semiconductor completed. Idaho Power provided $53,255 in incentives for energy efficiency measures that reduced costs. The facility expects to save over $25,000 in annual utility bills. Copies of the 2014 success stories are provided in *Supplement 2: Evaluation*.

Qualitative research for the Custom Efficiency program began in late 2013. MDC was selected through a competitive request for proposal (RFP) process. The research served to provide a deeper understanding of customers' awareness and knowledge of the program offering and benefits as well as gauge customer satisfaction with the program and equipment installed. Customer feedback was collected on the program processes and preferred method of communication. The research involved one-on-one interviews with program participants based on the nature of the equipment installed and the industry. MDC interviewed 26 large commercial and industrial program participants in several industries, such as manufacturing, services, and retail trade. In addition, MDC conducted one-on-one interviews with 10 eligible commercial and industrial customers that have not yet participated in the Custom Efficiency program.

As a qualitative study, the following key findings only reflect the general thoughts of those that participated in the interviews and are not representative of the entire program. Overall, the 26 participants were "highly satisfied" with the Custom Efficiency program processes. Some participants cited their own internal processes as more difficult than the program's steps. The "vast majority" that worked directly with an Idaho Power representative were "highly satisfied." The consensus was that when an Idaho Power representative is involved, they tend to "fully drive the process." For both participants and non-participants, the return on investment (ROI) is the primary factor considered before participating. The 10 non-participants interviewed believed they would be "somewhat likely" to participate in the program in the future. They need more guidance around the qualified equipment, probable ROI, and probable upfront costs to help make that decision. Respondents were mixed on an "ideal" outreach strategy; however, most would pay attention to an in-person visit from Idaho Power.

Comprehensive results of all findings related to the Custom Efficiency program research were delivered in early 2014, and a copy of the report is provided in *Supplement 2: Evaluation*.

## 2015 Program and Marketing Strategies

Additional program offerings are currently under consideration for implementation in 2015. These efforts will be targeted at maintaining a high level of customer participation as well as achieving year- over-year program goals.

Items currently under consideration include the following: additional contractors for energy studies and measurement and verification (M&V) efforts; retro-commissioning offering; and new cohorts including ROCEE II (target Southern Region), Compressed Air (could be a stand-alone offering), Data Centers (could be a stand-alone offering), and Water Supply Energy Efficiency Cohort (WSEEC).

The second year of energy savings for the ROCEE offering will be reported and incentives paid in 2015. The first year of energy savings for the WWEEC offering will be reported and incentives paid around mid-year 2015.

The SCE offering will continue to be offered in 2015, and new measures, processes, and other improvements will be evaluated to continuously improve the effectiveness of this offering.

In addition, Idaho Power plans to continue expanding the Custom Efficiency program through a number of activities and continued development of strategic partnerships. These activities will include direct marketing of the Custom Efficiency program by Idaho Power MCRs to further educate customers on Idaho Power energy efficiency programs, including identification of potential ways the customer can reduce energy costs and drive program participation. A target visit brochure will be developed for the MCRs to use with their customers. The brochure will allow the customer to customize the visit by letting Idaho Power know the type of training and energy information they would like to know more about.

Idaho Power will continue to provide site visits by Custom Efficiency engineers and energy scoping audits for project identification and energy-savings opportunities; M&V of larger complex projects; technical training for customers; funding for detailed energy audits for larger, complex projects; and delivery of NEEA-sponsored Strategic Energy Management improvement practices to customers.

In 2015, additional industry-specific energy efficiency tip brochures will be revised and mailed to targeted customers, along with an insert highlighting possible incentives.

In 2015, an article on the WWEEC offering will be created to discuss the cohort approach on energy efficiency and energy management training with the municipal wastewater segment. A brochure outlining energy efficiency tips and benefits for the wastewater sector will be produced and posted to a new Idaho Power webpage. Hard copies will be printed and distributed at events and through CRs and MCRs as needed.

Each year, the company designs and pays for a “Top 10” ad that appears in the *Idaho Business Review*. This ad publicly congratulates companies that had the most energy savings throughout the year. The company will continue this tradition in 2015. Success stories will continue to be written and produced throughout 2015. These stories focus on businesses that took advantage of Idaho Power’s Custom Efficiency program and the resulting benefits. Success stories are posted on Idaho Power’s website so the highlighted businesses can print and use them to publicize their energy-efficient projects. Idaho Power will continue to assist customers with public relations opportunities by creating certificates for display within the building and having an Idaho Power representative speak at press events if requested.

The Custom Efficiency team will be mentoring another engineering intern in 2015. These internships are important mechanisms that help drive work-force development in the energy efficiency profession.

Idaho Power will continue to support the IDL in 2015. In addition to the specific tasks outlined in the IDL description in the Other Program and Activities section of the main report and in *Supplement 2: Evaluation*, the IDL provides foundational services to customers in the Idaho Power service area. The IDL will provide energy modeling assistance for large, new-construction projects. The energy modeling is used by the Custom Efficiency team to support the claimed energy savings that are not covered by the existing measures through the Building Efficiency program.

The Custom Efficiency team will continue to support the Center for Advanced Energy Studies (CAES) Industrial Assessment Center (IAC) by marketing their IAC services during both customer site visits and at technical training workshops. The IAC is part of the CAES's Energy Efficiency Research Institute (CEERI), which is a collaboration between Idaho's three state research universities where students provide energy audits and general recommendations to improve operations for mid-sized, local, manufacturing companies.

## *Description*

Easy Upgrades is Idaho Power's prescriptive measure program for the commercial and industrial retrofit market. Customers can also apply for incentives for non-standard lighting incentives. The program encourages commercial and industrial customers in Idaho and Oregon to implement energy efficiency retrofits by offering specific incentives on a defined list of measures, except for the non-standard lighting. Eligible measures cover a variety of energy-saving opportunities in lighting, HVAC, building shell, VFDs, food-service equipment, and other commercial measures. A complete list of the measures offered through the Easy Upgrades program is included in *Supplement 1: Cost-Effectiveness*.

Idaho Power commercial and industrial customers and Special Contracts customers are eligible. For projects with expected incentive payments of $1,000 or more, or Complete Lighting Upgrade projects, applicants must submit a pre-approval application prior to installing the project. For projects not requiring pre-approval, customers may elect to skip the pre-approval application process and submit the payment application and accompanying documentation. Customers may assign their incentive payment to a third party (e.g., their contractor or supplier), as approved by Idaho Power.

## *2014 Program and Marketing Activities*

To increase customer and trade ally participation in the Easy Upgrades program, several changes were made to the program in 2014. Idaho Power increased incentives for numerous measures, added new measures, adjusted processes to enhance project submission and review, and added more trade ally outreach support.

The following are highlights of the modifications to lighting measures:

- For purposes of encouraging/rewarding more robust energy savings per project, and after considering how to adopt a form of a comprehensive lighting incentive in the program, Idaho Power added the Complete Lighting Upgrade bonus incentive. This new incentive applied to projects where all the interior inefficient lighting was retrofitted with more cost-effective, efficient technologies, including the incorporation of controls, where applicable. The Complete Lighting Upgrade was a bonus incentive given in addition to the calculated incentive on the lighting tool.

- To increase trade ally and customer participation, the program reviewed all lighting measures to determine if incentive increases could be made. The review resulted in increased incentives on several standard incentive measures and an increase to the non-standard incentive for interior lighting retrofits.

- The program segmented lighting incentives based on an interior or exterior application installation.

- To expedite project submission and reduce trade ally wait time to begin a project, the program eliminated the requirement for projects less than the $1,000 incentive with non-standard measures to be submitted for pre-approval. This change was heartedly received by participating trade allies and has resulted in quicker turnaround of project implementation.

In 2013, Idaho Power contracted with ADM to review the non-lighting Easy Upgrades measures and compile a TRM for these measures. Based on information provided by ADM and the RTF measure list, changes were made to several non-lighting measures. Highlights of the modifications to the non-lighting measures are described below.

New measures were added to the program, such as non-process chillers, electric combination and convection ovens, fryers, steamers, energy-free stock tanks, efficient electric water heaters, and commercial showerheads.

Some measures were removed from the program due to no longer meeting cost-effective criteria. Discontinued measures include refrigeration cases, refrigerators, door gasket repair, roof insulation, standard windows, and window shade screens.

Several measures were modified to reflect the updated TRM data and subsequent cost-effectiveness analysis. Idaho Power increased incentives for refrigeration line insulation, auto-closers, and floating head/suction pressure controls. The company moved VFDs installed on process applications to the Custom Efficiency program due to the highly variable nature of those applications. Idaho Power revised the eligibility and incentive level for qualifying efficient air conditioners, heat pumps, and HVAC controls.

The primary reason the project count decreased in 2014 compared to 2013 can be attributed to the delay in rolling out the 2014 program changes. Idaho Power announced the proposed program changes to participating lighting trade allies beginning in March. At that time, the expected effective date for the changes was the end of May; however, due to various delays, including the filing of OPUC Advice No. 14-06, and the company's desire to have uniform programs in both Idaho and Oregon jurisdictions, the program changes did not become effective until the end of July. Most trade allies and customers

delayed implementing lighting retrofit projects until the program changes became effective because of the increased incentive offered.

In addition to the reduction in lighting project submissions, the program experienced reduction in HVAC and food-service applications. The reason for the decline in these areas is attributed to the program changes in these categories (e.g., the removal of several measures for cost-effectiveness and/or adjustment to incentive or requirements). In 2013, the program had 140 food-service projects. In 2014, the program had 55 (the gasket seal measure went away). In 2013, there were 86 HVAC projects, and in 2014 there were 47.

Following the success from the *It's So Easy Lighting Campaign* targeted-town approach offered to the Pocatello area in fall 2013, the Easy Upgrades program expanded this offer to the Payette/Ontario and Twin Falls areas in spring 2014. In preparation for each week-long event, Idaho Power CRs and interested local trade allies in the two areas identified customers who would benefit from a lighting retrofit. The customers were offered a free facility lighting audit, a lighting consultation, or an expedited inspection of a proposed energy efficiency project. The local lighting trade allies were informed of the event and asked to participate.

The *It's So Easy Lighting Campaign* resulted in many positive outcomes for the program. Ninety-one visits were made to customer facilities in the participating two areas. Customers were appreciative of the offer made to them by Idaho Power. Customers gained tangible project information for decision-making with regard to undertaking a lighting retrofit. Trade allies appreciated the dedicated support the program gave them during the events.

The Easy Upgrades program facilitated 17 program workshops and technical classes across the Idaho Power service area targeting lighting trade allies, electrical contractors, and large customers. Offerings included six program workshops, one lighting 101 class, two lighting controls classes, and eight power quality classes. The program received feedback from trade allies requesting power quality education. The trade allies involved with energy efficiency projects involving VFDs were required to comply with power quality requirements. Idaho Power's power quality engineers developed a class to address this need, and the program facilitated delivery of the classes in 2014. The technical lighting and power quality classes qualified for continuing education credits for licensed electrician and electrical contractor trade allies. These classes and workshops resulted in 470 attendees receiving valuable industry-related training.

In addition to the formal training classes held, Idaho Power staff contacted over 110 trade allies in the field, via telephone, at the trade ally's business, or at a customer location to further educate them on program criteria and to respond to their inquiries. Contacts were made to strengthen relationships, encourage program participation, increase knowledge of the Easy Upgrades program, and to receive trade ally feedback about the market, the program, and trade allies' experiences. This targeted outreach was to electrical contractors, electrical distributors, and HVAC contractors.

Idaho Power also partnered with the IDL by sponsoring Daylight Harvesting Controls System classes. These classes provided education and training for electrical contractors and the design community on the concepts of daylight-harvesting control systems. IDL details are located in a description in the Other Programs and Activities section of the *Demand-Side Management 2014 Annual Report* and in *Supplement 2: Evaluation*.

Idaho Power continued to contract with Evergreen Consulting Group, LLC to provide ongoing lighting specialist expertise, project support, and trade ally training. In fall 2014, Idaho Power expanded its

contract with Evergreen Consulting Group to locate personnel in Idaho Power's service area to perform ongoing trade ally outreach to lighting trade allies. The trade ally outreach position enabled Idaho Power to increase support to its largest trade ally group—those working on lighting retrofit projects. Idaho Power continued to contract with Honeywell, Inc., to perform non-lighting project reviews and pre- and post-non-lighting project inspections. Idaho Power continued to contract with RM Energy Consulting to support lighting project review, lighting inspections, and audits for the targeted-town events.

Some inspections matched the information in the submitted paperwork, while other inspections showed discrepancies in submitted paperwork. To ensure projects in the program met program specifications and to verify conditions in the field were as stated on the program application, the Easy Upgrades program conducted 297 pre-inspections and 419 post-inspections, representing 552 unique customers in 2014. The program adjusted the incentive and kWh savings on projects with discrepancies to reflect actual field findings. Idaho Power took various steps to increase the accuracy and thoroughness of incoming paperwork to the program. Program personnel communicated the importance of being accurate on project submittals with trade allies at its annual program update workshops, as well as during communications with trade allies throughout the year. Program staff commended trade allies on submitting accurate and thorough paperwork as well as provided feedback and encouragement to trade allies whose paperwork would benefit from increased accuracy. The new trade ally support person began meeting with trade allies on a more frequent basis to provide ongoing education on program processes, paperwork submittal, and program requirements. In addition, the new outreach support person met with contractors who were new to the program to help them gain a thorough understanding of the program and requirements.

Several marketing tactics were used to promote and create awareness of the Easy Upgrades program in 2014. These included traditional approaches, such as running print ads in the *Business Insider* and *The Idaho Statesman* business section, a cover story in the fall edition of Idaho Power's commercial newsletter *ENERGY@WORK*, and marketing Easy Upgrades in combination with Idaho Power's other commercial/industrial energy efficiency programs. In fall 2014, a full-page Easy Upgrades ad appeared on the back cover of the *Small Business Administration's Resource Guide*. Ads that included all Idaho Power commercial/industrial programs appeared in various association directories, *Horizon Air* magazine, Boise Metro Chamber of Commerce monthly magazine, *Business Insider*, *Idaho Business Review*, and bill inserts.

The program implemented targeted direct mailing as a new strategy in 2014. A direct-mail letter was sent to 22,000 business customers announcing the 2014 program changes. This direct-mail strategy proved most successful in terms of getting customers to act. The letter briefly notified customers of the recently implemented program changes, included several customer testimonials, and specifically listed the Idaho Power CR and the CR's phone number for that particular recipient. Customers were encouraged to call their CR and find out more information about the Easy Upgrades program. Because the direct-mail letter was targeted and specific, customers did not need to look up anything—they were able to make a phone call and find out information right away.

In fourth quarter 2014, a targeted mailing was sent to hotel and motel businesses. The mailing included the brochure *Energy Efficiency Tips for Hotels*. A flyer was inserted in the middle of the brochure that outlined specific Easy Upgrades incentives relevant to the lodging industry market segment.

As part of its Commercial Lighting work group, NEEA continued work on its Reduced Wattage Lamp Replacement (RWLR) Pilot Initiative and development of the Top Tier Trade Ally Initiative Program.

An Idaho Power employee was on this working group, and the company is updated on progress at periodic conference calls and meetings. Details are provided later in the NEEA section of this report.

Idaho Power contracted in 2013 with Opinion Dynamics to conduct an Easy Upgrades process evaluation. Based on the results, the following recommendations were addressed in 2014.

Opinion Dynamics recommended Idaho Power consider adding or shifting staff resources (or subcontractors) to contractor-related outreach. The program contracted with Evergreen Consulting Group for local trade ally outreach support.

The evaluators recommended increasing the Easy Upgrades marketing and outreach budget. Opinion Dynamics stated that "A prudent use of additional marketing funds would be to boost contractor outreach." This recommendation was implemented in 2014 by securing dedicated trade ally outreach support and by increasing the Easy Upgrades marketing budget for 2015.

Opinion Dynamics recommended Idaho Power consider workflow and customer relationship management tools to help staff administer the program to increase efficiencies. Opinion Dynamics recommended it would be ideal to have all program management functions take place within one system. Opinion Dynamics recommended Idaho Power investigate what types of enhancements could be made to CLRIS so the management functions could happen with the existing system or, alternately, they noted there are a number of software packages available with workflow and customer relationship management capabilities. Idaho Power believes it is more reasonable and economical to enhance its existing system, which is tied into Idaho Power's customer billing system, than to invest in a third-party developed system. The company is constantly making enhancements to CLRIS and continues to explore further development.

## Cost-Effectiveness

In 2014, Idaho Power reviewed and modified most of the measures offered in the Easy Upgrades program. Idaho Power contracted with Evergreen Consulting Group to review the assumptions within the lighting tool for all the current and proposed standard lighting measure offerings. For the lighting measures, Idaho Power segmented the lighting incentives based on an interior or exterior application installation. Based on the difference in hours of use and end-use load shapes, the benefits associated with the energy savings with interior lighting measures are greater than comparable exterior lighting applications. The incentives for many interior lighting measures were increased to reflect the higher value of these lighting applications. The incentives for exterior lighting measures remained the same. The initial analysis of the standard lighting measures within the tool showed the measures to be cost-effective based on the average input watts and hours of operation. The actual savings for each lighting project are calculated based on the input watts of existing light fixtures, the replacement light fixture, and the actual hours of operation. As a result of these changes, there are over 100 lighting combinations under Easy Upgrades' Standard Lighting Incentives worksheet. In *Supplement 1: Cost-Effectiveness*, these lighting measures have been grouped under 26 similar categories.

In 2014, ADM completed a TRM for Easy Upgrades that provides savings and costs related to existing and new non-lighting measures for the Easy Upgrades program. The TRM was evaluated in 2014, and cost-effectiveness analyses were performed on all measures addressed through the TRM. Additionally, Idaho Power reviewed the list of commercial measures with deemed savings from the RTF that were not currently offered in the program. The analyses resulted in modifications to several existing measures, the removal of non cost-effective measures, and the addition of several measures as listed under the 2014 Program and Marketing Activities section.

Several lighting and non-lighting measures that are not cost-effective remain in the program. These measures include several lighting combinations with mostly exterior applications, high-efficiency A/C units, high-efficiency heat pump units, and wall insulation. After reviewing these measures, Idaho Power determined the measures met at least one of the cost-effectiveness exceptions outlined in OPUC Order No. 94-590. These modifications and cost-effectiveness exceptions were approved by the OPUC in Advice No-14-06 for 2014 and went into effect in Idaho in July and in Oregon in August 2014.

Complete measure-level details for cost-effectiveness can be found in *Supplement 1: Cost-Effectiveness*.

## Customer Satisfaction and Evaluations

Although the program did not solicit formal customer satisfaction surveys in 2014, the program received unsolicited customer and trade ally comments throughout the year indicating their satisfaction with the program. In addition, CRs and program staff asked customers about their experience with the program, their contractor, and their retrofit project during inspection visits and phone conversations.

In 2014, three new success stories describing energy efficiency projects were developed and posted to the company's website. The first 2014 success story, titled *Industrial detergent manufacturer cleans up with Idaho Power Easy Upgrades incentive*, references the lighting retrofit project completed at detergent formulator, Technichem Corporation. Company president, Brian Rencher, said, "I would recommend the Easy Upgrades program to anyone who has been hesitant about it, or has an old building. Or even a not-so-old building."

The second success story, titled *Using less energy to create better lighting is a win/win for Riverstone International School*, speaks of another lighting upgrade project. Todd Predovich, Riverstone International School's facilities manager, said, "When I got the proposal and I saw what Idaho Power's incentive was going to be, it felt like a win/win kind of deal." He said they took out half the bulbs and still got brighter classrooms. Todd described that the first day of class after they installed the new lights, the middle school art teacher asked what was done to her classroom. She noticed the difference in the quality of the light, which, in the case of new lighting technologies, can resemble daylight.

The third success story posted in 2014, titled *North Star Charter School graduates to a better lighting system*, refers to the lighting upgrade in North Star Charter School's gymnasium. Dan Conti, the school's athletic director, noted the gym is used for varied and wide purposes—from chess tournaments, quilt shows, and weddings to sports. Dan said, "We got our [incentive check] less than two weeks after the project was completed, so we could use the money to pay the contractor. It worked out nice." Copies of the 2014 success stories are provided in *Supplement 2: Evaluation*.

## 2015 Program and Marketing Strategies

Idaho Power will evaluate the viability to implement new program offerings and strategies and will look at ways to increase penetration in hard-to-reach small businesses. A customer satisfaction survey is planned to be implemented in 2015.

Marketing strategies for 2015 may include some or all of the following: trade ally trade show, direct mail to small and medium businesses, focus on trade ally outreach, program update workshops, print ads in the *Idaho Business Review* and/or major regional newspapers highlighting customer success stories and trade ally thank you ads, and Idaho Power monthly newsletter and bill inserts.

## *Description*

FlexPeak Management is a demand response program administered by Idaho Power through a third-party aggregator. It is a voluntary program available in Idaho and Oregon service areas designed for Idaho Power's industrial and large commercial customers capable of reducing their electrical energy loads for short periods during summer peak load days. The program objective is to reduce the demand on Idaho Power's system during periods of extreme peak electricity use. The program is active June 15 to August 15 between 2:00 p.m. and 8:00 p.m. on non-holiday weekdays. Customers receive notification of a demand-reduction event two hours prior to the start of the event, and events last between two and four hours. Reduction events may be called a maximum of 60 hours per season.

In November 2008, EnerNOC, Inc. was selected through a competitive RFP process to implement the program. Idaho Power entered into a five-year contract with EnerNOC in February 2009. In May 2009, the IPUC approved the contract in Order No. 30805. In June 2010, the program was approved by the OPUC in Order No. 10-206.

EnerNOC is responsible for developing and implementing all marketing plans, securing all participants, installing and maintaining all equipment behind Idaho Power's meter used to reduce demand, tracking participation, and reporting results to Idaho Power. Idaho Power initiates demand response events by notifying EnerNOC, who then supplies the requested load reduction to the Idaho Power system.

EnerNOC meets with prospective customers to identify their potential to reduce electrical energy load during active program hours with minimal impact to their business operations. Customers initially enroll in the program by entering into a contract with EnerNOC. EnerNOC then installs energy-monitoring

equipment at the customer site, simulates a demand response event to ensure customer satisfaction and performance, and officially enrolls the facility in the program.

Each week during the active season, EnerNOC commits a demand-reduction amount in MW to Idaho Power that EnerNOC is obligated to meet during a demand-reduction event. EnerNOC is subject to financial penalties for failing to reach the committed MW reduction.

When Idaho Power anticipates the need for capacity, it notifies EnerNOC of the date and time of the event. Idaho Power has access to near real-time energy-usage data and can continuously monitor the success of the demand-reduction event in aggregate. Customers can also continuously monitor their demand-reduction performance using their individual, near real-time energy-usage data through EnerNOC's proprietary software. This metering data and software are available to participating customers throughout the year.

## 2014 Program and Marketing Activities

In 2014, Idaho Power worked with EnerNOC to implement changes that would better align the program with the Settlement Agreement approved by the IPUC in Case No. IPC-E-13-14. The changes included extending the contract termination date through the end of 2014, reducing payments to EnerNOC, amending the payment structure, removing the lower bound of EnerNOC's committed load reduction, modifying the program availability dates to June 15 through August 15, and allowing notification of dispatch of a demand response event to occur through a web portal.

During the first week of the program, EnerNOC committed to provide a meter-level reduction of 29.6 MW. This weekly commitment, or nomination, was comprised of 92 facility sites, of which 90 participated in the program in 2013, and two were added in 2014. The weekly nomination at the end of the season was 25.7 MW and was comprised of 93 facility sites.

EnerNOC was contractually obligated to commit to provide a maximum meter-level reduction of 35 MW for each week in 2014. Their weekly commitments ranged from 25.6 MW to 30 MW. Their commitment peaked the first week in July at 30 MW.

Idaho Power called three demand response events for the FlexPeak Management program in 2014. The first two events occurred in July, and the third event occurred in August. EnerNOC exceeded the committed MW reduction in two of the three events. For the third event, EnerNOC did not reach their committed MW reduction; performance was 96 percent of the committed level. The highest hourly reduction achieved was 39.6 MW, calculated using 9.7-percent line losses (36.1 MW at the meter).

## Cost-Effectiveness

The methods used to determine the cost-effectiveness of the demand response programs was updated in 2014. As part of the public workshops in conjunction with Case No. IPC-E-13-14, Idaho Power and other stakeholders agreed on a new method for valuing demand response. The settlement agreement, as approved in IPUC Order No. 32923, defined the annual cost of operating the three demand response programs for the maximum allowable 60 hours must be no more than $16.7 million. This $16.7 million value is the levelized annual cost of a 170 MW deferred resource over a 20-year life. In 2014, the cost of operating the three demand response programs was $10.6 million. It is estimated that if the three programs were dispatched for the full 60 hours, the total costs would have been approximately $13.8 million, and the programs would have remained cost-effective because there is no variable incentive paid for events beyond the three required events.

The FlexPeak Management program was dispatched for 12 event hours and achieved a maximum demand reduction of 40 MW. The total expense for 2014 was $1,563,211.

## Customer Satisfaction and Evaluations

EnerNOC sent a post-season survey via email to 93 participants representing all the sites enrolled in the program for 2014. Thirteen participants responded for a 14-percent response rate. All of these responses were slightly down from the previous year:

- When asked how prepared they felt for the demand response event on a scale of 1 to 10, 10 being "fully prepared," the average response was 9.2.
- When asked how likely they were to recommend EnerNOC to a peer or business partner on a scale of 1 to 10, 10 being "definitely will," the average response was 8.7.
- When asked how clear the initial notification they received from EnerNOC was on the day of the event on a scale of 1 to 10, 10 being "very clear," the average response was 8.2.
- When asked how satisfied they were with how EnerNOC managed the demand response event on a scale of 1 to 10, 10 being "very satisfied," the average response was 8.8.

A summary of the results is in *Supplement 2: Evaluation*. Also included in the supplement is the *FlexPeak Management Annual Report*.

## 2015 Program and Marketing Strategies

Idaho Power has proposed to internally run and manage the FlexPeak Management program, changing the name to the Flex Peak program starting in 2015. As of December 31, 2014, Idaho Power's contractual obligation agreement with EnerNOC ended. Idaho Power reviewed and received feedback from EEAG on the idea of running the program internally during a conference call on January 9, 2015. Idaho Power filed an application with the IPUC on February 4, 2015 (IPUC Case No. IPC-E-15-03), and filed an advice with the OPUC on March 10, 2015. Prior to this decision in fall 2014, the company conducted an informal inquiry with 25 of the largest participants in the FlexPeak Management program. The company asked them how they might respond to a change in the way the program was designed and managed. The responses generally indicated they would likely participate even if the program changed and they were not provided with the same monitoring and coaching services EnerNOC had provided. The feedback supported Idaho Power's proposal to internally run the Flex Peak Program. Current Flex Peak Program customers were notified on February 11, 2015, that EnerNOC would no longer be managing the program and that the company had filed an application with the IPUC to internally manage the Flex Peak Program.

There are several benefits to a company-managed program. First, the company has identified significant annual cost savings. These cost savings directly impact customer-provided funds. Second, the company-offered program would require each participating customer to adhere to the terms and conditions, and receive payments, as available under the Idaho and Oregon tariff schedules publically available. Last, the company welcomes any opportunity to cross-market energy efficiency programs and strengthen the communication and relationship with its customers directly.

Pending IPUC and OPUC approval, the Flex Peak Program will be available from June 15 through August 15, Monday through Friday, from 2:00 p.m. to 8:00 p.m., excluding holidays. Each dispatch

event will last up to four hours per participant within the available program hours. Dispatch events will not occur more than 60 hours per season. In the event of a system emergency, demand response capacity from the Flex Peak Program will be available. Idaho Power will conduct a minimum of three dispatch events per season. There will be two hours of advance notice to participants.

As per the settlement agreement, Idaho Power has proposed to maintain the current capacity of 35 MW during the 2015 program season. The company believes it can retain current participants and enroll new customers to meet this 35 MW amount. In 2015, Idaho Power will market the Flex Peak Program as needed to acquire enough participation to meet the 35 MW target. The marketing strategies will include a variety of channels, including field interaction by CRs and MCRs, and direct mailers.

# Oregon Commercial Audits

## *Description*

The Oregon Commercial Audits program identifies opportunities for commercial building owners to achieve energy savings. This is a statutory program as required by ORS 469.865 offered under Oregon Schedule No. 82. Through this program, free energy audits provide evaluations and educational services to customers. Annual mailings to each customer in the commercial sector communicate program benefits and offerings.

## *2014 Program and Marketing Activities*

Idaho Power sent out its annual mailing to 1,574 Oregon commercial customers in late September 2014. Customers were notified of the availability of no-cost energy audits and were provided with the Idaho Power publication *Saving Energy Dollars*. Sixteen customers requested an audit, and five customers requested only the brochure. Of the 16 audits, 12 audits were completed by Idaho Power, and 4 were completed by a third-party contractor. The costs were up in 2014 over 2013 because an ongoing invoice for audits performed late in 2013 was not paid for until early 2014.

Idaho Power contracts with EnerTech Services to perform a portion of the requested audits. Energy audits include a review of the customer's past billing data and an inspection of the building shell, HVAC equipment, operating schedules if available, and lighting systems. Additionally, specific business operating practices that can be incorporated to improve energy use are discussed. During the audits, customers receive Idaho Power energy efficiency program information.

## Cost-Effectiveness

As previously stated, the Oregon Commercial Audits program is a statutory program offered under Oregon Schedule 82. Since the required parameters of the Commercial Energy Audit Program are specified in Oregon Schedule 82 and the company abides by these specifications, this program is deemed to be cost-effective. Idaho Power claims no energy savings from this program.

## Customer Satisfaction and Evaluations

Audits provide the opportunity to discuss utility incentives available to customers who install qualifying energy efficiency measures. Both activities can lead to energy efficiency projects being undertaken. Customers are generally pleased with the audit process. This is especially true when the business owner is fully engaged in the audit. Business owners can make the decisions to change operating practices or make capital improvements designed to use energy wisely. Additionally, the audits help identify energy-saving opportunities that may not be obvious to the business owner.

## 2015 Program and Marketing Strategies

The Oregon Commercial Audits program will continue to be an important avenue for Idaho Power to help customers identify energy-saving opportunities. The audits help pinpoint favorable energy-saving actions that customers may pursue through customer behavioral changes or potential capital projects, such as replacing inefficient lighting. Additionally, the audit process will be used to introduce customers to Idaho Power's energy efficiency incentive programs. The program will be marketed through the annual customer notification.

This page left blank intentionally.

# IRRIGATION SECTOR OVERVIEW

## Description

The irrigation sector is composed of agricultural customers operating water-pumping or water-delivery systems to irrigate agricultural crops or pasturage. End-use equipment primarily consists of agricultural irrigation pumps and center pivots. The irrigation sector does not include water pumping for non-agricultural purposes, such as the irrigation of lawns, parks, cemeteries, golf courses, or domestic water supply.

In December 2014, the active and inactive irrigation service locations totaled 18,773 system-wide. This was an increase of 1.5 percent compared to 2013, primarily due to the addition of service locations for pumps and pivots to convert land previously furrow-irrigated to sprinkler irrigation systems. Irrigation customers accounted for 1,966,297 MWh of energy usage in 2014, which was a decrease from 2013 by over 6 percent due to a cooler, wetter summer. This sector represented nearly 14 percent of Idaho Power's total electricity usage and about 25 percent of the summer coincident peak demand. Energy usage for this sector has not grown significantly in many years; however, there is substantial yearly variation in usage due primarily to the impact of weather on customer irrigation needs.

Idaho Power offers two programs to the irrigation sector: 1) Irrigation Peak Rewards, a demand response program designed to provide a system peak resource and 2) Irrigation Efficiency Rewards, an energy efficiency program designed to encourage the replacement or improvement of inefficient systems and components. Idaho Power also pays incentives to customers participating in the Green Rewind offering in which motor service centers are paid $2 per hp for each NEMA Standard hp-rated motor up to 5,000 hp for agricultural uses that receives a verified Green Rewind. Participation in Green Rewind ensures the motor's original efficiency is maintained if it is rewound at an approved service center.

In 2014, the Irrigation Peak Rewards program was back in full operation after temporarily being suspended for the 2013 season to address need and cost in light of the company's load and resource balance from the *2013 IRP* showing the company had adequate resources in the near-term. In spring 2014, Idaho Power successfully marketed to the majority of prior participants to continue their participation in the programs, with only an approximated 9-percent drop in potential load reduction from 2013 even though incentives to participate were reduced.

The Irrigation Efficiency Rewards program, in operation since 2003, experienced annual savings that were nearly the same, with 18,511 MWh in 2013 and 18,464 MWh in 2014. During 2014, the Irrigation Efficiency Rewards program contributed 18,428 MWh, while the 15 motors in Green Rewind contributed 35,083 kWh per year of energy savings.

Table 13 summarizes the overall expenses and program performance for both the energy efficiency and demand response programs provided to irrigation customers.

# Programs

Table 13. 2014 irrigation program summary

| Program | Participants | Total Cost | | Savings | |
|---|---|---|---|---|---|
| | | Utility | Resource | Annual Energy (kWh) | Peak Demand (MW) |
| **Demand Response** | | | | | |
| Irrigation Peak Rewards | 2,225 service points | $ 7,597,213 | $ 7,597,213 | n/a | 295 |
| **Total** | | **$ 7,597,213** | **$ 7,597,213** | **n/a** | **295** |
| **Energy Efficiency** | | | | | |
| Irrigation Efficiency Rewards | 1,128 projects | $ 2,446,507 | $18,459,781 | 18,463,611 | 4.6 |
| **Total** | | **$ 2,446,507** | **$18,459,781** | **18,463,611** | **4.6** |

**Note:** See Appendix 3 for notes on methodology and column definitions.

Each year, the company conducts a customer relationship survey. Overall, 52 percent of Idaho Power irrigation customers surveyed in 2014 for the Burke Customer Relationship survey indicated Idaho Power was meeting or exceeding their needs in offering energy efficiency programs. Fifty-one percent of survey respondents indicated Idaho Power is meeting or exceeding their needs with information on how to use energy wisely and efficiently. Sixty percent of respondents indicated Idaho Power is meeting or exceeding their needs with encouraging energy efficiency with its customers. Overall, 40 percent of the irrigation survey respondents indicated they have participated in at least one Idaho Power energy efficiency program. Of irrigation survey respondents who have participated in at least one Idaho Power energy efficiency program, 92 percent are “very” or “somewhat” satisfied with the program.

In response to a 2013 phone survey conducted by Hansa GCR regarding non-participants of Idaho Power irrigation energy efficiency program options, in 2014 Idaho Power identified irrigation customers that had not participated in either irrigation program. The company’s agricultural representatives (ARs) contacted a few potential customers in each region to ensure awareness of the Idaho Power offerings. To provide information in detail to Idaho Power irrigation customers, in 2014 the company created two irrigation-specific newsletters. Newsletters included energy efficiency information and other important information of interest to irrigation customers.

In 2015, Idaho Power ARs will continue contacting non-participants potentially eligible for program participation and will continue providing a newsletter at least twice a year.

# Irrigation Efficiency Rewards

| | 2014 | 2013 |
|---|---|---|
| **Participation and Savings** | | |
| Participants (projects) | 1,128 | 995 |
| Energy Savings (kWh)[a] | 18,463,611 | 18,511,221 |
| Demand Reduction (MW) | 4.6 | 3.0 |

[a] Includes kWh savings from Green Rewind projects.

# Description

The Irrigation Efficiency Rewards program encourages energy-efficient equipment use and design in irrigation systems. Qualified irrigators in Idaho Power's Idaho and Oregon service area can receive financial incentives and reduce their electricity usage. Incentives for the Irrigation Efficiency Rewards program help customers recover a portion of the costs of installing a new, more efficient irrigation system or energy-efficient improvements to existing systems.

Two options help meet the needs for major or minor changes to new or existing systems. The Custom Incentive Option addresses extensive retrofits of existing systems or new irrigation systems, providing component upgrades and large-scale improvements. For new systems, the incentive is 25 cents per the first year of kWh saved above standard installation methods, not to exceed 10 percent of the new system's cost. For existing system upgrades, the incentive is 25 cents per the first year of kWh saved, or $450 per kW demand reduction, whichever is greater, but not to exceed 75 percent of the total project cost. The qualifying energy efficiency measures include any hardware changes that result in a reduction of the potential kWh usage of an irrigation system.

Idaho Power reviews, analyzes, and makes recommendations on each application. On each completed project, before final payment, all project information is reviewed. Prior usage history, actual invoices, and, in many situations, post-usage demand data are available to verify savings and incentives.

The Menu Incentive Option covers a significant portion of the costs of repairing and replacing specific components that help the irrigation system use less energy. This option is designed for systems where

small maintenance upgrades provide energy savings from 11 separate measures. These measures are as follows:

- New flow-control type nozzles
- New nozzles for impact, rotating, or fixed-head sprinklers
- New or rebuilt impact or rotating type sprinklers
- New or rebuilt wheel-line levelers
- New complete low-pressure pivot package
- New drains for pivots or wheel-lines
- New riser caps and gaskets for hand-lines, wheel-lines, and portable mainlines
- New wheel-line hubs
- New pivot gooseneck and drop tube
- Leaky pipe repair
- New center pivot base boot gasket

Payments are calculated on pre-determined average kWh savings per component.

In addition to incentives, the program offers customer education, training, and irrigation-system assessments. Idaho Power ARs sponsor, coordinate, conduct, and present educational workshops for irrigation customers, providing expert information and training across Idaho Power's service area. Energy audits conducted by Idaho Power ARs evaluate prospective customers' potential savings. ARs from Idaho Power also engage agricultural irrigation equipment dealers in training sessions, increasing their knowledge of energy efficient designs and awareness of the program and promoting the program through the irrigation equipment distribution channels. Marketing efforts include direct mailings, ads in agricultural publications, and participation in agricultural workshops and conferences.

Because the irrigation sector is a load comprised primarily of motors, Idaho Power participates in Green Rewinds. It is an opportunity that enables customers to maintain the motor's original efficiency by ensuring proper rewind of the electric motor. Motor service centers are paid $2 per hp for each NEMA Standard hp-rated motor 15 hp to 5,000 hp that receives a verified Green Rewind. The RTF approved the Green Motors Practices rewinding as an energy efficiency measure and approved a table of deemed savings for industrial and agricultural applications. In 2013, the RTF updated the deemed-savings values.

## 2014 Program and Marketing Activities

In 2012, the RTF approved a plan to re-evaluate the deemed savings for each measure under the Menu Incentive Option. Idaho Power met with the RTF in early 2013 and evaluated the research done by the University of Idaho to study the savings impacts of the measures provided in the Menu Incentive Option. In April 2013, the RTF approved the updated savings under the RTF Small Saver category. The 2013 RTF-deemed savings have a slightly different component itemization for some measures.

For example, nozzle replacements, sprinklers, and replacement regulators were combined under one sprinkler package, and gasket and drain replacements were separated into two measures. ADM conducted an impact evaluation in 2013. In this evaluation, it was recommended Idaho Power align measures to be consistent with how the RTF has deemed savings. Idaho Power presented the RTF updated savings values and proposed program changes at the EEAG meeting February 6, 2014. After the EEAG presentation, the program was filed with the OPUC as Advice No. 14-04 and was approved effective May 16, 2014. The 2014 energy savings values reflect the new RTF values for 2014.

Of the 1,128 irrigation efficiency projects completed in 2014, 1,000 were associated with the Menu Incentive Option, providing an estimated 14,051 MWh of energy savings and 2.75 MW of demand reduction. The Custom Incentive Option had 128 projects, of which 70 were new irrigation systems and 58 were on existing systems. This option provided 4,377 MWh of energy savings and 1.83 MW of demand reduction for the year. Also during 2014, irrigation customers contributed 35,083 kWh of energy savings from 15 motors participating in the Green Rewind opportunity.

Idaho Power ARs, the program specialist, and the agricultural engineer participated in training that maintains their Certified Irrigation Designer (CID) and Certified Agricultural Irrigation Specialist (CAIS) certifications. This training allows Idaho Power to maintain its high level of expertise in the irrigation industry and is sponsored by the nationally based Irrigation Association.

Idaho Power continued to market the program by varying the location of workshops and offering new presentations to irrigation customers. In 2014, Idaho Power provided seven workshops promoting the Irrigation Efficiency Rewards program throughout the service area. Approximately 250 customers attended workshops in Blackfoot, Aberdeen, Eden, Twin Falls, Mountain Home, Nampa, and Ontario. Idaho Power also accepted invitations to present the program at four workshops sponsored by agricultural groups in Shoshone, Hailey, Ontario, and Burley. Exhibitor booths were displayed at regional agricultural trade shows, including the Eastern Idaho Agriculture Expo, Western Idaho Agriculture Expo, the Agri-Action Ag show, the Treasure Valley Irrigation Conference, and the Idaho Irrigation Equipment Association show and conference. In addition, ARs made target visits or communicated with a selected number of non-program participants to increase customer education. A database of irrigation dealers and vendors was maintained for direct-mail purposes. Irrigation dealers and vendors are a key component to the successful marketing of the program; therefore, direct mailings containing the most up-to-date program information, brochures, and dealer-specific meetings ensured correct program promotion.

The Irrigation Efficiency Rewards brochure was updated in spring 2014 and distributed to all irrigation rate schedule customers using direct mail. Idaho Power ARs also distributed large quantities to irrigation dealers and vendors in the service area.

In 2014, the newsletter *Irrigation News* was created to improve customer satisfaction with all irrigation customers in Idaho and Oregon. The newsletter shares valuable information specifically for irrigation customers to help clarify processes, help customers better understand their bill, provide information on energy efficiency and energy efficiency programs, clarify rates, and provide information on safety. The newsletter stimulated numerous opportunities to communicate and dialogue with irrigation customers on the variety of topics to help improve customer relations and promote the Irrigation Efficiency Rewards program. Media outreach included an Irrigation Efficiency Rewards success story provided to Capital Press about a project in Richfield, Idaho, that upgraded a farm’s irrigation system.

The total number of print publications that marketed the Irrigation Efficiency Rewards program consisted of 10 print ads in five agricultural print publications. Idaho Power also used two opportunities

in radio advertising during Agri-Action and the Future Farmers of America (now FFA) National FFA Week. New creative advertising material was launched in fall 2014 to promote Idaho Power's Irrigation Efficiency Rewards program. Four ads were created that targeted Idaho-specific crops, including potatoes, sugar beets, hay, and corn. Digital ads using the new creative material are being tested with the target audience to determine if they respond well to digital information sources. Digital ads are running in *The Capital Press* from December 19, 2014, to January 16, 2015, with a guaranteed 60,000 impressions during the cycle.

At the end of 2014, a postcard was mailed to all irrigation dealers and vendors thanking them for the integral role they play in the success of this program.

In 2013, Idaho Power conducted an impact evaluation of the Irrigation Efficiency Rewards program. This evaluation was performed by third-party contractor ADM. Data for the study was collected through a review of program materials and interviews with participating agricultural customers, agricultural trade allies, and Idaho Power staff. Based on the results of this evaluation, ADM provided recommendations for program improvement. Their recommendations and Idaho Power's 2014 responses are described below.

The evaluators suggested Idaho Power consider including NEBs as part of a comprehensive cost-effectiveness test for the program and that currently, there is no known previously published research conducted on NEBs for irrigation systems. ADM indicated the RTF provides values for societal costs and benefits for menu components. However, Idaho Power has identified the RTF benefits being referred to are already considered as part of the power system benefits and costs and are not considered NEBs. Idaho Power converted its previous NEB assumptions to a per-kWh basis as recommended by ADM and is currently collecting customer-calculated NEBs to more accurately account for these benefits. A new brochure and application providing an opportunity for customers to identify NEBs, such as yield, labor, and other benefits, was direct-mailed to all irrigation customers in May 2014.

ADM recommended that Idaho Power update the menu component incentives and expected savings to match the RTF. ADM noted that the 2013 version of the RTF combined the existing nozzle measure, low-pressure regulator measure, and sprinkler-head measures into a new "sprinkler package" measure. The application for the 2014 irrigation program should be revised to match the measures covered under the RTF. To comply with this ADM recommendation, changes to the Irrigation Efficiency Rewards program aligning the measures and expected savings to the RTF recommendations were presented to EEAG at the February 6, 2014, EEAG meeting. These changes were filed with the OPUC and approved in Advice No. 14-04, effective May 16, 2014, and are reflected in the new program brochure.

## Cost-Effectiveness

Idaho Power calculates cost-effectiveness using different savings and benefits assumptions and measurements under the Custom Incentive Option and the Menu Incentive Option of Irrigation Efficiency Rewards.

Each application under the Custom Incentive Option received by Idaho Power undergoes an assessment to estimate the energy savings that will be achieved through a customer's participation in the program. On existing system upgrades, Idaho Power estimates the effectiveness of a project using a service point's previous five years of electricity usage history on a case-by-case basis depending on the applicant's history. On new system installations, the company uses standard practices as the baseline and determines the efficiency of the applicant's proposed project. Based on the specific equipment to be installed, the company calculates the estimated post-installation energy consumption of the system. The company verifies the completion of the system design through aerial photographs, maps, and field

visits by Idaho Power ARs to ensure the irrigation system is installed and used in the manner the applicant's documentation describes.

Each application under the Menu Incentive Option received by Idaho Power also undergoes an assessment to ensure deemed savings are appropriate and reasonable. Payments are calculated on a prescribed basis by measure. In some cases, the energy-savings estimates in the Menu Incentive Option are adjusted downward from deemed RTF savings to better reflect known information in how the components are actually being used. For example, a half-circle center pivot may use half as much energy as a full-circle center pivot, or acres irrigated using spring water for a portion of the season reduces seasonal pumping kWh usage. All deemed savings are based on seasonal operating hour assumptions by region. If a system's usage history indicates it has lower operating hours than the assumptions, like the examples above, the deemed savings are adjusted.

Based on the deemed savings from the RTF, all the measures offered under the Menu Incentive Option are cost-effective with the exception of rebuilt or new brass impact sprinklers. Idaho Power determined these brass sprinklers meet at least one of the cost-effectiveness exceptions outlined in OPUC Order No. 94-590. Idaho Power filed UM-1710 to request a cost-effectiveness exception with the OPUC on November 4, 2014, and subsequently re-filed it on February 11, 2015. The case is still pending. For details on the cost-effectiveness assumptions for the Menu Incentive Option, see *Supplement 1: Cost-Effectiveness*.

## 2015 Program and Marketing Strategies

Marketing plans for 2015 include conducting 7 to 10 customer-based irrigation workshops. Additionally, Idaho Power will continue to participate in five regional agricultural trade shows. These workshops and trade shows enable discussions between Idaho Power representatives, the company's customers, irrigation dealers, and trade allies while continually educating them about irrigation best practices, the program, and ways to participate. Each year, workshops are conducted in different local areas. Subjects and presentations are updated to offer new ideas.

Idaho Power will work closely with customers who have participated in the Irrigation Efficiency Rewards program to create success stories by highlighting efficient irrigation system designs for program promotion.

The Idaho Power *Irrigation News* newsletter will continue to provide a direct line of communication on valuable information that will clarify processes, help customers better understand their bill, provide information on energy efficiency and energy efficiency programs, clarify rates, and provide information on safety, specifically for irrigation customers.

Idaho Power will continue to work with the Scientific Irrigation Scheduling (SIS) sub-committee consisting of RTF members, utility representatives, and professional experts to determine the potential for SIS programs.

A 2015 media plan was created aimed at increasing the impact of advertising on this program. Idaho Power will continue to promote the program in print ads in agricultural-focused editions of Idaho newspapers and agriculture magazines. The effectiveness of online ads will be evaluated with this target audience.

In early 2015, Idaho Power will test the effectiveness of translating various agriculture workshops and presentations into Spanish. The company will look at how this is received and make appropriate decisions moving forward.

## *Description*

Idaho Power's 2014 Irrigation Peak Rewards program is a voluntary program available to Idaho and Oregon agricultural irrigation customers with service locations that had participated in the past. The purpose of the program is to minimize or delay the need to build new supply-side resources. By reducing demand on the most extreme load days in the most extreme summer conditions, the Irrigation Peak Rewards program can reduce the amount of generation and transmission resources Idaho Power needs to build. The program pays irrigation customers a financial incentive for the ability to turn off specified irrigation pumps with the use of one or more load control devices during the program season of June 15 through August 15. The Irrigation Peak Rewards program provides approximately 300 MW of load reduction, which is a capacity near 9 percent of Idaho Power's all-time system peak. This program, along with Idaho Power's other demand response program, has eliminated or delayed the need to build supply-side resources.

In 2013, Idaho Power filed IPUC Case No. IPC-E-12-29 to temporarily suspend the program to allow time to work with stakeholders and interested parties to determine how the program should operate in the future. These workshops resulted in settlement agreements reached in Idaho Case No. IPC-E-13-14 and Oregon UM 1653. The Irrigation Peak Rewards program was again offered as a demand response program in 2014, with some modifications. Program modifications resulted in an approximately $5 million in savings with only an approximately 9-percent drop in participation.

Per the terms in the settlement agreement, Idaho Power agricultural irrigation customers in both Idaho and Oregon that had service locations that participated in the past were eligible for participation in 2014. Customers could chose between two options: 1) an Automatic Dispatch Option that allows Idaho

Power to remotely turn off participants' pumps or 2) a Manual Dispatch Option designed for large-service locations with 1,000 hp or greater that allows participating customers, after being notified by Idaho Power, to choose which pumps to manually turn off during a load control event. Historically, customers could choose a third option, the Electronic Timer Option. In 2014, this was discontinued. Customers who had service locations that had participated in the past in the Electronic Timer Option had the ability to participate by selecting the Automatic Dispatch Option.

For customers participating in the dispatch options, load control events could occur up to four hours per day, up to 15 hours per week, but no more than 60 hours per season. Only service locations that had participated in the past were eligible to participate in the program for 2014. Participating customers were guaranteed to experience at least three events per season. Dispatchable load control events could happen between 1:00 p.m. and 9:00 p.m. on weekdays and Saturday. The incentive structure consisted of fixed and variable payments. The fixed portion was paid based on participation during each of the first three events. The variable incentive was applied based on participation in events following the first three. Customers who chose to participate until 9:00 p.m. could receive a higher variable incentive for events that occurred after the first three. A control device attached to the customer's individual pump electrical panels allowed Idaho Power to remotely control the pumps. Participants in the Manual Dispatch Option were required to nominate the amount of kW they were enrolling in the program by June 1 of the program year.

Program rules allow participants the ability to opt out of dispatch events up to five times per service point. The first three opt-outs each incur a penalty fee of $5 per kW, while the remaining two opt-outs each incur a penalty fee of $1 per kW based on the current month's billing kW. The opt-out penalty fees may be prorated to correspond with the dates of program operation and are completed through manual bill adjustments. The fees will never exceed the amount of the incentive that would have been paid.

The incentive amounts that participating customers received per participating service location are listed in Table 14.

Table 14. 2014 program incentives

| Option | Fixed Demand Credit ($/billing kW) | Fixed Energy Credit ($/billing kWh) | Variable Energy Credit ($/billing kWh) | Extended Hour Variable Energy Credit ($/billing kWh) |
|---|---|---|---|---|
| Automatic and manual options ..... | $5.00 | $0.0076 | $0.148 | $0.198 |

## 2014 Program and Marketing Activities

After the Irrigation Peak Program suspension in 2013, Idaho Power used workshops, trade shows, and direct customer mailings to make a concerted effort to encourage past participants to re-enroll in 2014. Despite reinstating the program with a reduction in incentive amounts and modifications to the event notification, most past participants re-enrolled to participate in 2014. The number of service points enrolled to participate in the program for 2014 was 2,225. This accounted for approximately 81 percent of the eligible service points. Three load control events occurred in July 2014, with the highest load reduction occurring on July 10 and providing an estimated 295 MW on July 10.

In 2014, the program was only marketed to customers who had service locations that had participated in the program in the past. Idaho Power provided information about the 2014 Irrigation Peak Rewards program at seven workshops throughout the service area. Approximately 250 customers attended workshops in Blackfoot, Aberdeen, Eden, Twin Falls, Mountain Home, Nampa, and Ontario.

Idaho Power also accepted invitations to present the program at four workshops sponsored by agricultural groups in Shoshone, Hailey, Ontario, and Burley. Exhibitor booths were displayed at regional agricultural trade shows, including the Eastern Idaho Agriculture Expo, Western Idaho Agriculture Expo, the Agri-Action Ag show, the Treasure Valley Irrigation Conference, and the Idaho Irrigation Equipment Association show and conference. Additionally, numerous one-on-one conversations with Idaho Power ARs informed customers of the 2014 program eligibility requirements and program offering.

An information flyer was made visually more appealing and easier to read by using a brochure format for existing Peak Rewards participants in December 2014. In October *Connections*, the program received recognition in the article *Demand Response Programs Ease Summer Peak*.

## Cost-Effectiveness

The methods used to determine the cost-effectiveness of the demand response programs was updated in 2014. As part of the public workshops in conjunction with Case No. IPC-E-13-14, Idaho Power and other stakeholders agreed on a new method for valuing demand response. The settlement agreement, as approved in IPUC Order No. 32923, defined the annual cost of operating the three demand response programs for the maximum allowable 60 hours must not be more than $16.7 million. This $16.7 million value is the levelized annual cost of a 170 MW deferred resource over a 20-year life. In 2014, the cost of operating the three demand response programs was $10.6 million. It is estimated that if the three programs were dispatched for the full 60 hours, the total costs would have been approximately $13.8 million, and the programs would have remained cost-effective.

The Irrigation Peak Rewards program was dispatched for 12 event hours and achieved a maximum demand reduction of 295 MW. The total expense for 2014 was $7,597,213 and would have been approximately $10.8 million if the program was fully used for 60 hours.

## Customer Satisfaction and Evaluations

Each year, Idaho Power produces an internal annual report for the Irrigation Peak Rewards program. This report includes a load-reduction analysis, cost-effectiveness information, and program changes. A copy is included in *Supplement 2: Evaluation*.

In 2014, Idaho Power contracted PECI to complete an impact evaluation of the 2014 Peak Rewards program. The goals of the impact evaluation were to determine the demand reduction (in MW) during three actual called events and determine the counterfactual realization rate if an event been called on each business day during the program's June 15 through August 15 season.

PECI completed analyses of curtailment events held on July 2, July 10, and July 14, 2014, each containing four dispatch groups that curtailed enrolled irrigation pumps in rolling four-hour increments. The results of the curtailment event analyses showed maximum meter level demand reductions of 257.9 MW, 268.9 MW, and 250.5 MW, respectively, for the three events, which do not include system losses of 9.7 percent.

Due to the Irrigation Peak Rewards program suspension in 2013, annual device maintenance did not occur for nearly two years, resulting in a 7-percent device failure rate, as indicated in the evaluation report, lowering the overall realization rates. The past analysis of the program realization rates indicates they would be higher if device maintenance were at normal levels, resulting in fewer device failures.

As part of the impact evaluation, PECI developed a counterfactual realization rate analysis that demonstrated that the time period within an irrigation season has a large influence on the realization rate. With 2014 device failures excluded, realization rates ranged from 65 percent at the beginning of the program season to a peak realization rate of 74 percent during the first two weeks of July. The counterfactual realization rate in the last quarter of the season (August 1–15) dropped off significantly to 34 percent with device failures included. This was due to a high percentage of pumps being shut off during the first two weeks of August due to crop maturity and uncharacteristically extreme rainfall of 2 to 4 inches in southern and eastern Idaho. This resulted in a skewed realization rate that was an exception to what has been determined in past analyses.

The results of the impact evaluation showed Idaho Power's Irrigation Peak Rewards program functioned as intended, and, if properly maintained, can be relied on to provide dispatchable demand reduction to the electricity grid. The evaluation also identified opportunities to maximize the demand reduction benefit the program delivers to the electricity grid. First, Idaho Power may increase the program's realization rate by working to address device failure problems. The uncharacteristically high number of device failures in 2014 provided valuable information on how to identify and address device failures. In an effort to increase realization rates by minimizing device failures, Idaho Power may also decide to use more AMI devices for load control in the future.

Finally, as seen in the counterfactual realization rate analysis results, maximum load reduction potential is realized during the peak of the irrigation season. This time period generally equates to the last week of June through the middle of July, which usually correlates to Idaho Powers' overall system peaks.

## *2015 Program and Marketing Strategies*

Idaho Power will continue to work with past participants in this program who are eligible to participate in 2015 to encourage their participation.

Idaho Power will conduct 8 to 10 workshops throughout the company's regions to familiarize customers to the program details and eligibility requirements. Through direct mail, each eligible customer will receive an informational packet containing a personalized letter, sign-up worksheet, informational brochure, and contract agreement encouraging their participation for the 2015 program season. Idaho Power ARs will continue one-on-one customer contact to inform and encourage program participation.

In early 2015, Idaho Power will test the effectiveness of translating various agriculture workshops and presentations into Spanish. The company will look at how this is received and make appropriate decisions moving forward.

This page left blank intentionally.

# MARKET TRANSFORMATION

## Northwest Energy Efficiency Alliance

NEEA encourages and supports cost-effective market transformation efforts in Idaho, Oregon, Washington, and Montana. Through partnerships with local utilities, NEEA motivates the marketplace adoption of energy-saving services and technologies and encourages regional education and marketing platforms. NEEA provides training and marketing resources across residential, commercial, and industrial sectors. Idaho Power accomplishes market transformation in its service area through membership and coordinated activities with NEEA. Idaho Power has been a funding member of NEEA since its inception in 1997.

The fifth year of NEEA's current, five-year funding cycle ended in 2014. As early as 2009 Idaho Power expressed a desire to see a change in the way NEEA services were offered that would differentiate "core" services of market transformation activities from optional services, whereby utilities could elect to support projects and activities that matched their interests and needs. During 2014, the company continued to advocate for this model through multiple meetings with NEEA, by actively participating on the NEEA Board of Directors and exploring alternative funding models, and by chairing and serving on the Alternative Funding Model Working Group Committee of the NEEA Board of Directors. The end result of these efforts was that the NEEA *2015–2019 Business Plan* offered optional programs and activities. Idaho Power executed an agreement to continue its participation in NEEA and chose not to participate in some optional programs and activities where it believes it is providing or can provide the same services at a lower cost or more effectively for the 2015 to 2019 funding cycle. This delivers significant energy-savings potential and ultimately saves Idaho Power customers $3,304,560 when compared to the 2010 to 2014 funding cycle agreement.

NEEA performs several MPERs on various energy efficiency efforts each year. In addition to the MPERs, NEEA provides market-research reports, generally through third-party contractors, for energy efficiency initiatives throughout the Pacific Northwest. Each of the reports applicable to Idaho is included in the NEEA Market Effects Evaluations in *Supplement 2: Evaluation*.

Idaho Power has participated by phone, online, or in person in a variety of NEEA activities. In 2014, Idaho Power energy efficiency staff served on NEEA's Board of Directors, the Regional Portfolio Advisory Committee, Residential Advisory Committee, Commercial Advisory Committee, Industrial Advisory Committee, Irrigation Advisory Committee, Cost-Effectiveness and Evaluation Advisory Committee, Consumer Electronics Energy Forward Initiative, Conduit online community, Regional Emerging Technologies Advisory Committee (RETAC), NWRRC, Northwest Heat Pump Water Heater Group, Code Collaborative, and Regional Lighting Strategy Working Group and participated in NEEA-sponsored studies and research.

Idaho Power also participates in NEEA's Northwest Research Group. This group meets throughout the year to catalogue and coordinate energy efficiency research projects regionally. Idaho Power collaborates with regional utilities doing similar program evaluations or that may face similar program challenges.

### *Commercial and Industrial NEEA Activities in Idaho*

NEEA continued to provide support for commercial energy efficiency activities in Idaho in 2014. This included partial funding of the IDL and local BetterBricks® trainings and workshops.

Technical training and education continue to be important to Idaho Power's industrial customers, helping them identify energy efficiency opportunities within their facilities. Seven technical training classes were completed in 2014. Topics included compressed air, air-cooled refrigeration systems, pump systems, and fan system efficiency. The level of attendance at these classes remained high, with 119 participants attending the classes. See the Custom Efficiency program section for more details regarding the technical training classes.

Additionally, 2014 encompassed Phase IV of the webinar pilot plan coordinated by NEEA. Three webinars were presented free to all attendees. Topics included VFDs, efficient industrial lighting, and energy auditing and troubleshooting. There were 24 total Idaho Power region participants that attended the webinar sessions in 2014.

Idaho Power co-sponsored with NEEA a two-day RETA CRES review class training with 13 customers in attendance. The training reviewed refrigeration energy efficiency concepts and prepared the attendees for the RETA CRES Exam.

Idaho Power participated as a member of the NEEA Commercial Lighting Working Group. This group formed through collaboration with stakeholders to identify opportunities and strategic needs to support the region's success in commercial lighting. NEEA launched its first strategy from this report in November 2013, a market test of a midstream RWLR Initiative. The initiative goal is to change the pricing, stocking, and sales practices of reduced-wattage fluorescent T-8 lamps in the maintenance market. Targeted electrical distributors across the region were selected for participation. No distributor in Idaho Power's service area was selected for participation. Results of this pilot will be available in 2015. The pilot results will be used to determine whether NEEA, in coordination with stakeholders, will scale this program in 2015 across the region to try to transform this largely untapped market. NEEA's second strategy, Top-Tier Trade Ally Training, is in the development stage. This strategy will provide advanced lighting training to high-performing trade allies throughout the region, with an end result of achieving deeper energy savings in commercial lighting retrofit projects. Development of this strategy will continue throughout most of 2015, with implementation of pilot trainings in Idaho in 2016.

Idaho Power continued its partnership with BOMA of Boise and NEEA to offer continued coaching and support to the Kilowatt Crackdown™ participants in 2014. In 2013, 43 buildings competed in the competition, which included benchmarking their building in ENERGY STAR® Portfolio Manager and implementing low-cost and no-cost efficiency measures. In 2014, this effort was continued with ongoing coaching and support to further their energy efficiency efforts.

NEEA's pilot project in Idaho for their Existing Building Renewal (EBR) initiative was ongoing in 2014. This initiative is aimed at developing and testing new industry tools for commercial property owners engaging in deep energy retrofits. The Idaho project will be phased in through 2016. Idaho Power worked with The Idaho Statesman's *Business Insider* to feature the EBR initiative as their January cover story, along with other articles about *Retrofitting for the Future*. The issue appeared January 15, the same day Idaho Power issued a press release recognizing a local commercial real estate firm for its participation in the initiative.

In 2014, NEEA continued to have demonstrations on projects on variable-rate irrigation (VRI) and variable-speed irrigation (VSI) at various locations. VRI works by allowing a varied amount of water coming out of each sprinkler along an irrigation pivot. VSI is where the speed of the pivot irrigation system is varied as it makes a rotation for irrigation. The potential for energy savings exists with both technologies if different areas of the field have different water requirements. Information from NEEA indicated additional technical development was required and the adoption of the technology

would be challenging. The NEEA Board of Directors voted to remove the Initiative from the portfolio in the *2015–2019 Business Plan*. NEEA staff completed the 2014 demonstrations and a series of final reports that document the qualitative and quantitative findings from the three years of the Initiative. A copy of the reports will be included on the CD accompanying *Supplement 2: Evaluation* in next year's *Demand-Side Management 2015 Annual Report*.

NEEA also worked with Oregon State University to develop a common set of data standards for vendors or manufactures to better integrate technologies such as soil sensors, flow meters, pumping systems, and pivot systems—including VRI & VSI—to promote the combination of irrigation technologies for increased efficiency of water use. In 2015, through its scanning efforts, NEEA will continue to evaluate the usefulness and usability of the data standards.

## Residential NEEA Activities in Idaho

NEEA supported a variety of residential programs and associated activities in Idaho Power's service area in 2014. NEEA is directly involved in providing additional funding and support for ENERGY STAR® Homes Northwest, the DHP Pilot, and the Heat Pump Water Heater (HPWH) research project. Idaho Power served on workgroups for the DHP, HPWH, Retail Product Portfolio, RETAC, and a short-term dryer specification workgroup. Idaho Power participated in the Conduit online community and the Northwest Regional Retail Collaborative.

NEEA provides ENERGY STAR Homes Northwest builder and contractor training, manages the regional-homes database, develops regional marketing campaigns, and coordinates the various building specifications and requirements with the EPA and utilities in Idaho, Montana, Oregon, and Washington. Most of these activities are managed through a third-party implementer hired by NEEA.

NEEA is taking energy-efficient homes to the next step above ENERGY STAR with its Next Step Homes pilot program. The goal of this innovative pilot program is to identify the most cost-effective ways to achieve maximum energy savings in residential new construction. NEEA recruited builders throughout the Northwest to build to a high-performance specification, then installed monitoring devices in the homes to track energy-saving performance. NEEA is currently trying to recruit a Next Step Homes builder in Idaho Power's service area.

NEEA has coordinated the DHP Pilot research project since 2009, which includes data collection, design, results analysis, savings calculations, and ongoing promotional activities. Idaho Power was a member of the NEEA Ductless Heat Pump Workgroup during 2014. The goal of the pilot is to encourage the adoption of these products while displacing the use of existing electric-resistance zonal heating systems in homes. NEEA created and launched a regional marketing program, which was conducted during summer and fall 2014. The goal of the program was to increase consumer awareness of DHPs. The promotion included the use of social media, as well as radio, television, and website ads. Idaho Power currently offers a $750 cash incentive for qualified homeowners who install a qualified DHP system.

NEEA coordinated a residential HPWH research project in the Northwest region that started around five years ago. Idaho Power was represented on the NEEA HPWH Workgroup during 2014. A goal of the project is to promote the adoption of higher-efficiency HPWHs over traditional resistance-heat water heaters. Another goal is to provide a business case to the DOE encouraging the DOE to make the federal standards and test methods for domestic electric water heaters more stringent. The research project includes data collection, design, analysis, savings calculations, and promotions. NEEA's promotions included rebates to residential homeowners who had certain HPWHs installed. The promotion required

the HPWH to be installed by a contractor trained by NEEA. NEEA also arranged for a HPWH discount program to be offered through retailers. The research project was conducted in 2014 and will continue in 2015. Idaho Power is monitoring this research closely to determine when a northern tier HPWH will be developed that is reliable and applicable to Idaho Power's climate zones.

NEEA developed a baseline forecast in fall 2012 describing the naturally occurring market adoption of HPWHs over a 20-year span. The baseline forecast excluded any market influence from utilities or NEEA initiatives. NEEA published the *NEEA Heat Pump Water Heater Baseline Forecast Research*, created by Evergreen Economics, on October 23, 2014. A copy of NEEA Report E14-300 is included on the CD accompanying *Supplement 2: Evaluation*.

NEEA performed field research beginning in fall 2013 to evaluate the ability for HPWHs to provide demand response to the electric grid. Field research involved fitting 20 homes in the Northwest with HPWHs. The water heaters received communication control signals from a remote third party. Units were tested for their ability to increase and decrease water heating electric load by adjusting storage tank temperature set points. On September 29, 2014, NEEA published the *Heat Pump Water Heaters for Demand Response and Energy Storage* created by Ecofys. A copy of the NEEA Report E14-296 is included on the CD accompanying *Supplement 2: Evaluation*.

In 2014, NEEA launched the RPP. Idaho Power participated in the advisory workgroup for the RPP. The RPP is based on the Consumer Electronics Energy Forward Initiative, which ended in 2013. The RPP used mid-stream incentives to influence retail stocking practices, ultimately driving manufacturing and standards for a portfolio of energy-efficient products sold through the retail channel.

The 2014 RPP goal was to expand and test the upstream approach with different product categories and different retailer types. To maintain relationships with electronics retailers developed under the Consumer Electronics Energy Forward Initiative, the RPP offered incentives on televisions and home theaters in box/soundbars. To test the model at big box, do-it-yourself retailers, the RPP offered incentives on air purifiers and dishwashers.

Idaho Power also participated in NEEA's Residential Advisory Committee meetings and activities throughout 2014. Additionally, one member of the residential programs team, one member of the commercial/industrial programs team, and one analyst attended NEEA's Efficiency Exchange in May 2014. In September 2014, the DSM residential lighting program specialist and a DSM program analyst participated in a one-day lighting summit hosted by NEEA. Summit participants explored ways to capture full-category retail sales data for light bulbs.

Idaho Power participated in RETAC, the purpose of which is to discuss and provide feedback on various emerging technologies in the region. RETAC met twice in 2014 to review the emerging technology pipeline for BPA, NEEA, and the NWPCC *Seventh Power Plan*. Technologies of particular interest to the group include $CO_2$ heat pumps, high-performance manufactured homes, LEDs and advanced controls, and home energy management systems.

An Idaho Power residential specialist was involved with the NWRRC in 2014. This collaborative forum evaluates and coordinates regional retail strategy. Activities of this group included two multi-year pilot projects. The first was aimed at understanding market lift promotions. The second aimed at improving retail contractors' participation in utility programs. The group also serves as the advisory workgroup to NEEA's RPP initiative.

## NEEA Funding

In 2014, Idaho Power began the fifth year of the 2010 to 2014 *Regional Energy Efficiency Initiative Agreement* with NEEA. Per this agreement, Idaho Power is committed to fund NEEA based on a quarterly estimate of expenses up to the five-year total direct funding amount of $16.5 million in support of NEEA's implementation of market transformation programs in Idaho Power's service area. Of this amount in 2014, 100 percent was funded through the Idaho and Oregon riders.

In 2014, Idaho Power paid $3,305,917 to NEEA. The Idaho jurisdictional allocation of the payments was $3,140,621, while $165,296 was paid for the Oregon jurisdiction. Other expenses associated with NEEA activities, such as administration and travel, were paid from Idaho and Oregon Riders.

Final NEEA savings for 2014 will be released in June 2015. For the annual report, preliminary funder share savings for 2014 were assumed to be similar to 2013 final savings. In the *Demand-Side Management 2013 Annual Report*, the NEEA preliminary funding share savings reported were 18,346 MWh. The revised estimate included in this report for 2013 final funding share NEEA savings is 20,568 MWh. Preliminary estimates reported by NEEA for 2014 indicate Idaho Power's share of regional market transformation MWh savings for 2014 is 20,000 MWh. Idaho Power relies on NEEA to report the energy savings and other benefits of NEEA's regional portfolio of initiatives. For further information about NEEA, visit their website at neea.org.

# OTHER PROGRAMS AND ACTIVITIES

## Residential Energy Efficiency Education Initiative

Idaho Power recognizes the value of general energy efficiency awareness and education in creating behavioral change and customer demand for, and satisfaction with, its programs. The Residential Energy Efficiency Education Initiative promotes energy efficiency to the residential sector. This is achieved by creating and delivering educational materials and programs that result in wise and informed choices regarding energy use and increase Idaho Power's energy efficiency program participation.

The Residential Energy Efficiency Education Initiative continued to produce semiannual energy efficiency guides in 2014. These guides were primarily distributed via insertion in local newspapers and at events across Idaho Power's service area. Process improvements implemented in 2014 include the following:

- Enhanced design elements identified in 2013 were repeated in the 2014 guides to further the publication's identity and strengthen readership recognition.
- Idaho Power's Technical Editing team provided expertise and training to improve readability.
- All past guides were updated to encourage continued use as presentation handouts and one-on-one distribution by Idaho Power's CRs.
- Focus groups provided feedback about the guide's format and content.
- Guide circulation was increased in two ways: 1) the *New Plymouth News* was added to the list of local newspapers distributing the energy efficiency guide and 2) the guide was included with each free, non-subscriber delivery of the *Blackfoot Morning News* and *Meridian Press*.

The *Spring/Summer Energy Efficiency Guide*—Inserted into 14 newspapers and delivered to 215,539 homes on April 27, 2014. The guide focused on helping customers understand how their behavior impacts their electricity bill. The guide highlighted Idaho Power's myAccount as a tool to help learn about energy use, answered questions about how and why weather impacts energy use, offered tips for keeping costs down during extreme weather, and encouraged customers to consider the value proposition for energy efficiency when buying, selling, and remodeling their homes. It also contained a suggested "path" for becoming energy efficient at home.

The *Fall/Winter Energy Efficiency Guide*—Inserted into 16 newspapers and delivered to 237,144 homes on October 26, 2014. The guide focused on ways to keep heating bills down on a limited budget and specifically targeted lighting as an all-around energy efficiency opportunity available to all. The guide offered suggestions for benchmarking home energy use using myAccount and current energy codes. It also presented Idaho Power's various residential programs via a simple, colorful chart to help customers compare relative costs, benefits, and eligibility details for each program.

The release of each guide received public relations support through numerous communication channels, including an item in the weekly *News Briefs* email to all media (April 21 and October 28) and a feature during the monthly live studio energy efficiency segment on KTVB-TV on October 27. The November issue of Idaho Power's *Connections* customer newsletter included an image display for the guide as well.

In 2014, 10,351 additional guides were distributed at energy efficiency presentations and events, up from 3,447 in 2013. This increase is an indication of their ongoing value and success of the strategy to prolong the shelf-life of these guides. Links to current guides were given prominent positions on Idaho Power's website during the appropriate seasons. Additionally, the full selection of energy efficiency guides was made available for viewing and download via Idaho Power's website.

As part of Idaho Power's Account Manager team, the Residential Energy Efficiency Education Initiative staff played a key role by gathering research from neighboring utilities and organizing customer and employee focus groups. These groups provided insight into how customers interacted with the tool and what features might best be used to market the tool. Following the focus groups, the tool's name was changed from Account Manager to myAccount and two of three key messages for the advertising campaign were focused around educating customers about their individual home's energy use.

As a result of customer comments gleaned from the spring focus groups conducted by MDC (discussed in-depth in the Marketing section), marketing tactics were used in November to expand the distribution channels and test the demand for the *Fall Energy Efficiency Guide* and the 96-page booklet *30 Simple Things You Can Do to Save Energy*. The following marketing tactics were used to drive demand for these publications:

- A display image appeared in the November issue of the *Connections* customer newsletter, which was delivered to approximately 415,000 customers.
- Bill inserts were placed in over 40,000 residential customer bills.
- A digital ad campaign ran from October 25 to November 23.

All advertising drove customers to a webpage where they could request printed copies mailed directly to their homes. They could also view the publications online or download printable versions. For those customers without internet access, a toll-free number was provided and an order form was included on the bill insert. Based on the marketing campaign, another 587 *Fall/Winter Energy Efficiency Guides* and 582 *30 Simple Things You Can Do To Save Energy* were mailed by request directly to customers.

The Residential Energy Efficiency Education Initiative distributed energy efficiency messages through a variety of other communication methods during 2014. Increased customer awareness of energy-saving ideas was accomplished via continued distribution of the third printing of the 96-page booklet *30 Simple Things You Can Do To Save Energy*, a joint publishing project between Idaho Power and The Earthworks Group. During the year, 9,070 English and 623 Spanish copies were distributed directly to customers via community events and local libraries; by CRs during in-home visits; by participating contractors in the Home Improvement Program, Energy House Calls, H&CE Program, and See ya later, refrigerator® program; through direct web requests; and in response to inquiries received by Idaho Power's customer service center.

Idaho Power continues to recognize that educated employees are effective advocates for Idaho Power's energy efficiency programs. To keep energy efficiency top-of-mind among employees, an educational video was produced. Each employee received a personal email invitation to view the video and become an ambassador for energy efficiency by learning about the company's energy efficiency programs.

The Kill A Watt™ Meter Program remained active in 2014. Idaho Power's customer service center and field staff continued to encourage customers to learn about the energy used by specific appliances and activities within their homes by visiting a local library to check out a Kill A Watt meter. A second

hands-on table display was developed and made available to assist libraries in engaging patrons, promoting energy efficiency, and increasing circulation of the energy efficiency kits. Additionally, the Kill A Watt meters were featured during a live studio news program on KTVB-TV in Idaho Power's monthly energy efficiency segment with Idaho Power's CR&EE manager.

As in previous years, Idaho Power took the lead in strengthening the energy education partnership with secondary school educators through continued participation on the Idaho Science, Technology, Engineering and Mathematics (iSTEM) Steering Committee. In 2014, 16 teachers completed the 4-day, 2-credit professional development seminar facilitated by Idaho Power and co-sponsored by Intermountain Gas and the Idaho National Lab (INL).

Idaho Power continued its co-sponsorship of the US Green Building Council lecture series, *Sustainable Energy Sustainable Homes*. In 2014, Idaho Power provided additional support to extend the reach through web-based video broadcasting of live seminars and recorded content and PowerPoint slides available for online reference. The eight workshops, facilitated by local trade experts, provided information and expertise to encourage energy efficiency upgrades. These sessions continue to be popular with homeowners, builders, developers, and architects, with 143 attending in 2014. Idaho Power also opened discussions regarding a new partnership with the City of Meridian to produce an energy-related video emphasizing wise energy use as part of the city's *It Starts at Home* campaign.

Idaho Power continued to engage communities in energy efficiency discussions at many community events throughout Idaho Power's service area. In April, Idaho Power continued to sponsor the Portneuf Valley Community Environmental Fair and actively promoted attendance at this event with a bill message for communities surrounding Pocatello. Idaho Power's Pocatello CRs staffed the booth and promoted wise energy use and participation in energy efficiency programs.

In September 2014, Idaho Power participated in the FitOne Expo in Boise, Idaho. The event continued to be important due to the size of the audience and because Idaho Power surveys confirmed that the demographics of attendees continued to align with Idaho Power's residential energy efficiency target audience. In 2014, the booth theme capitalized on LED lighting imagery from the integrated campaign launched in August and previewed the energy efficient interactive home graphic in the background. Idaho Power staff at the event educated attendees about the benefits of LED lighting technology and distributed 2,500 LED light bulbs to an engaged and receptive audience.

Idaho Power further increased its energy efficiency presence in the community by providing energy efficiency and program information through 116 outreach activities, including events, presentations, trainings, and other outreach activities documented in the Outreach Tracking System. In addition to these activities, Idaho Power field staff throughout Idaho Power's service area delivered 164 presentations to local organizations addressing energy efficiency programs and wise energy use. In 2014, Idaho Power's Community Education team provided 67 presentations on *The Power to Make a Difference* to 1,756 students. The CERs and other staff also completed 32 senior citizen presentations on energy efficiency programs and shared information about saving energy to a total of 912 seniors in the company's service area. Additionally, Idaho Power's energy efficiency program managers responded with detailed answers to 288 customer questions about energy efficiency and related topics received via Idaho Power's website.

As part of National Energy Awareness Month in October, Idaho Power held its fourth annual student art contest in the Idaho Power service area, bringing energy education into the classroom and inspiring students and families to think more about energy. "Ways to Save Energy" was one of the categories, and both overall and regional winning students and their teachers were recognized.

The Residential Energy Efficiency Education Initiative continued to provide energy efficiency tips in response to media inquiries. In addition to supplying information for various Idaho Power publications, such as the *News Scan* weekly employee newsletter, the *Connections* customer newsletter, and Idaho Power's Facebook page, articles were written for the North End Neighborhood Association newsletter (circulation 5,300 print/341 electronic). Energy efficiency tips were provided for three of the monthly KTVB-TV news live studio interview segments.

Idaho Power also researched the possibility of working with a vendor to produce energy efficiency kits and age-appropriate curriculum for high school students. The idea was presented to EEAG as a potential new program in the August. With EEAG input, Idaho Power met with local high school teachers to refine the potential offering and revisited it with EEAG again in November. The next step in exploring this potential offering is to convene a committee of teachers for the purpose of gathering input, identifying appropriate deliverables, and preparing an RFP.

The initiative's 2015 goals are to increase program participation and promote education and energy-saving ideas that result in energy-efficient and conservation-oriented behaviors and choices. In addition to producing and distributing educational materials, the initiative will play an integral role in providing LED lighting education and distributing LED bulbs to customers. Idaho Power will improve the accessibility of educational information available to customers on the company's website and work with the Program Planning Group to explore behavioral program opportunities that may include an enhanced kit program, promotion of myAccount, home energy reports, or a pilot program to test another behavioral message, such as clothes drying rack adoption.

## Student Energy Efficiency Kit Program

The SEEK program provides fourth- to sixth-grade students in schools in Idaho Power's service area with quality, age-appropriate instruction regarding the wise use of electricity. Each child that participates receives an energy efficiency kit. The products in the kit are selected specifically to encourage energy savings at home and engage families in activities that support and reinforce the concepts taught at school.

For the 2013 to 2014 school year addressed in this report, Idaho Power partnered with the National Energy Foundation (NEF) for the 2013 fall semester and Resource Action Programs (RAP) for the 2014 spring semester. NEF's partnership for the fall 2013 semester ended Idaho Power's test year, and RAP was selected as Idaho Power's long-term partner beginning January 2014.

During the 2013 to 2014 school year, 6,312 kits were delivered to 208 classrooms in 73 schools within Idaho Power's service area, resulting in 1,491 MWh of first-year savings. In fall 2013, program participants were recruited by invitation from a regional Idaho Power CER, resulting in 2,419 student participants. In spring 2014, the program was marketed to all elementary schools with open enrollment, resulting in 3,696 student participants.

Once a class enrolled in the program, teachers received curriculum and supporting materials. Students received classroom study materials, a workbook, and a take-home kit containing three CFLs, a high-efficiency showerhead, an LED nightlight, a furnace filter alarm, a digital thermometer for measuring water, refrigerator and freezer temperatures, a water-flow rate test bag, and a shower timer. At the conclusion of the program, students and teachers returned feedback to the vendor indicating how the program was received and which measures had been installed. Each vendor used this feedback to provide a comprehensive program summary report showing program results and savings.

Teachers said they liked the program. Fall feedback indicated 97 percent of teachers said the content was good or excellent and they would recommend the program to colleagues. Spring feedback indicated 100 percent of teachers would recommend the program to other colleagues and 97 percent would conduct the program again. Student engagement was high as well—73 percent of student surveys were returned in the fall and 81 percent were returned in the spring.

Both NEF and RAP calculated annual savings based on information collected from the participants' home surveys and the installation rate of the kit items. Questions on the survey include the number of individuals in each home, water-heater fuel type, flow rate of the old showerhead, and the wattage of the bulb replaced. Based on this information, NEF estimates that fall 2013 participants saved 635,782 kWh per year. RAP estimates that spring 2014 participants saved 855,443 kWh per year. The total annual savings of 1,491,225 kWh appears under the Residential Energy Efficiency Education Initiative in the Appendices.

A copy of the complete report is included in *Supplement 2: Evaluation*.

## Easy Savings Program

As a result of IPUC Case No. IPC-E-08-10 under Order Nos. 30722 and 30754, Idaho Power committed to fund energy efficiency education for customers receiving energy assistance through the federal LIHEAP and provide $125,000 to CAP agencies in the Idaho Power service area on a prorated basis. This order specified that Idaho Power provide educational information to customers who heat their homes with electricity provided by Idaho Power. This is being accomplished through the development and distribution of kits containing low-cost, self-install energy efficiency items and educational materials.

The Easy Savings Program straddles two calendar years. The LIHEAP program starts in November each year at CAP agencies, while Idaho Power summarizes activities based on a January to December cycle. However, the following report summarizes activities from November 2013 through October 2014 and covers future plans for the 2014 to 2015 program.

Three main desired outcomes of the Easy Savings Program are to educate recipients about saving energy in their homes by using energy wisely, allow hands-on experience while installing low-cost measures, and reduce the energy burden for energy assistance/LIHEAP applicants.

Each kit contained the following low-cost/no-cost energy saving items and a survey:

- CFLs (13 W and 18 W)
- Hot-water temperature card and refrigerator thermometer
- Rope caulk and outlet draft stoppers
- Kitchen faucet aerator and high-efficiency showerhead
- LED nightlight and reminder magnets for the laundry
- *Quick Start Guide* to installation
- Mail-in survey

By April 2014, all 2,127 kits from the 2013 to 2014 program year were distributed by regional CAP agencies to Idaho Power customers approved to receive LIHEAP benefits on their Idaho Power bills.

The mail-in survey inquiring about installation experiences and actions taken to reduce energy use was included in the kits. Returned surveys were used to track the effectiveness and educational impact of the program.

There were 202 completed surveys received from customers describing their experience in installing kit items in their homes during the 2013 to 2014 program. The survey included questions about whether the customer took specific actions to reduce energy use as a result of receiving the kit as well as questions confirming the installation of kit items.

Ninety-two percent of household respondents reported they have, or will, lower their heat during the day, and 84 percent reported they will lower their heat at night. Eighty-five percent of the households reported installing both CFLs provided in the kit, and another 7 percent said they installed one of the CFLs. Eighty percent of the households reported installing the high-efficiency showerhead.

Overall, survey results showed that over 62 percent of the households that received the kits and returned a survey installed five or more kit items. Seventy-nine percent of the respondent households reported learning a lot about saving energy and money in their home after completing the *Easy Savings Quick Start Guide*. Copies of the survey and survey results can be found in *Supplement 2: Evaluation*.

During the 2013 to 2014 program, three gift certificates valued at $100 each were provided by CAPAI to encourage survey completion. A drawing from all returned surveys was held July 2014. Three households won a $100 gift certificate.

For the 2014 to 2015 program, checks totaling $125,000 were sent by Idaho Power in September 2014 to the five Idaho regional CAP agencies. Each agency used 30 percent of the agency's allotment to cover expenses for administering the program at their agency. By the end of September 2014, an order for 2,067 kits was placed by CAP agencies. Kits were shipped from the vendor and received at CAP agencies in November 2014 for distribution to customers throughout the 2014 to 2015 LIHEAP season. One LED bulb replaced the CFLs this year.

Upon completion of kit distribution and receipt of corresponding survey results for the 2014 to 2015 program, Idaho Power and CAPAI will consider program changes for the future.

## Commercial Education Initiative

Since 2008, the Commercial Education Initiative has informed and educated commercial customers regarding energy efficiency, increased awareness of and participation in existing commercial energy efficiency and demand response programs, and enhanced customer satisfaction regarding the company's energy efficiency initiatives.

This initiative is also used to educate and support trade allies and key stakeholders working in the energy efficiency market. A major strength of the initiative is the emphasis on building strategic relationships. Additionally, program specialists work closely with Idaho Power CRs assigned to commercial market segments to capitalize on their established relationships with customers.

The Commercial Education Initiative oversees the distribution of informational materials and works directly with trade allies and other market players who, in turn, support and promote Idaho Power's

energy efficiency programs. Routinely, individual site visits are conducted to educate customers on energy-saving opportunities at their business.

In 2014, Idaho Power carried out its plan to capitalize on effective customer projects by developing 11 success stories highlighting customers' energy efficiency projects for posting on Idaho Power's website. Copies of the success stories are provided in *Supplement 2: Evaluation*.

Other marketing efforts included a March and a November *ENERGY@WORK* newsletter created and mailed to all commercial customers. These newsletters had business-specific articles of interest, with an emphasis on energy efficiency. Idaho Power's customer newsletter, *Connections*, is distributed monthly in customers' bills. In 2014, two editions were devoted exclusively to energy efficiency content.

Raising the knowledge level of commercial customers in the wise use of energy in their daily operations is important to the continued success of Idaho Power's commercial energy efficiency programs. The Commercial Education Initiative works with and supports multiple stakeholders and organizations to increase customers' energy efficiency knowledge. Examples of key stakeholders include the IDL, BOMA, US Green Building Council, ASHRAE, IBOA, and the IFMA Northern Rockies Chapter. Through funding provided by Idaho Power, the IDL performs several tasks aimed at increasing the energy efficiency knowledge of architects, engineers, trade allies, and customers. Specific activities include sponsoring a BSUG, conducting Lunch & Learn sessions held at various design and engineering firms, and offering a TLL. The TLL gives customers access to equipment that enables them to measure and monitor energy consumption on various systems within their operation.

In 2014, the Commercial Education Initiative supported two organizations that provide professional accreditation to their members. The IBOA offers Building Operator Certification to train building operators in the energy efficiency operation of their facilities. The IFMA teaches four modules of its Facility Management Professional (FMP) credential. The FMP training equips facility managers with the knowledge and skill sets to promote, justify, and implement sustainable and energy efficiency projects and programs within their facilities.

Plans for 2015 include 1) working with Idaho Power marketing specialists to increase customer awareness of the company's energy efficiency programs and their specific offerings; 2) coordinating training opportunities for CRs and trade allies to increase their energy expertise; 3) continuing to support key stakeholders that train, educate, and support the advancement of energy efficiency practices; 4) conducting outreach and education activities through the IDL; and 5) supporting customers via facility walk-throughs, including energy audits.

## Regional Technical Forum

The BPA and the NWPCC established the RTF in 1999. Since 2004, Idaho Power has supported the RTF by providing annual financial support, regularly attending monthly meetings, and participating on various sub-committees.

The forum's purpose is to advise the BPA; the NWPCC; the region's utilities; and organizations, including NEEA and the Energy Trust of Oregon (ETO); on technical matters related to energy efficiency. Activities include the development of standardized protocols for verifying and evaluating energy savings and tracking conservation and resource goals. Additionally, the RTF provides feedback and suggestions for improving the effectiveness of regional energy efficiency programs. The RTF also recommends a list of eligible energy efficiency measures and the estimated savings associated with those measures. Idaho Power uses the information provided by the RTF when conducting research and

analysis on new and current measures. The RTF meets monthly to review and provide comments on analyses and other materials prepared by the NWPCC, BPA staff, and RTF contractors. Idaho Power uses the savings estimates and calculations provided by the RTF when applicable to the Idaho climate zones and load characteristics. In 2014, Idaho Power staff participated in all of the RTF's meetings and was involved in various sub-committees, including the RTF Policy Advisory Committee.

In 2014, the RTF continued efforts to bring measures and documentation in line with the protocols and guidelines put in place in 2012. Additionally, the RTF wrapped up the work began in 2013 to calibrate the residential building energy model commonly referred to as the SEEM model for existing and new construction single family homes. The results from the region-wide 2011 RBSA study, which included on-site home inspections of a regional representative sample of single-family, multi-family, and manufactured homes, were analyzed by the RTF to calibrate the SEEM model inputs. The SEEM calibration impacts all of Idaho Power's residential weatherization and HVAC measures. Idaho Power participated in the SEEM Affected Measures Workgroup throughout the process and provided feedback on the proposed methodologies and support documentation prepared by RTF contract staff. The results for SEEM calibration for manufactured-home savings are expected to be completed by RTF staff in 2015.

Additionally, Idaho Power representatives participated in the SIS sub-committee. SIS is a behavior-based agricultural program to optimize irrigation. A calculator converts water reduction to kWh savings. The current RTF SIS protocol is out of compliance with the current RTF guidelines. BPA, in partnership with the RTF, developed a research plan and standard protocol to bring the measure into compliance. BPA plans to implement the study during the 2016 growing season with the sample segmented based on the "high" and "medium to low" water-level crops within the two geographic areas in the population: the Columbia Basin and southern Idaho. Idaho Power representatives will continue to participate and lend their expertise to the sub-committee in 2015.

## University of Idaho Integrated Design Lab

Idaho Power is a founding supporter of the IDL. The IDL is dedicated to the development of high-performance energy-efficient buildings in the Intermountain West. Idaho Power has worked with the lab since its inception in 2004 as part of efforts to educate customers about the value of energy efficiency to businesses, as well as to the businesses' customers. On January 21, Idaho Power helped sponsor the 10th anniversary celebration of the IDL in Boise, participating in the open house and tour of the facility. Company representatives recognized the lab's commitment to high-performance energy-efficient building through research, education, and outreach efforts in the Intermountain West. Idaho Power issued a media advisory, inviting members of the press to attend the event and share the story of the IDL's success.

In 2014, Idaho Power entered into an agreement with the IDL to perform the following 14 tasks.

### *Building Metrics Labeling*

The goal of this task was to expand on the 2012 and 2013 development of Building Metrics Labeling (BML), a graphical display of four building metrics on a single sheet. The metrics displayed are Energy Use Intensity (EUI), ENERGY STAR® score, Walkability, and Space Daylit Area. The purpose of the BML sheet is to increase awareness of building energy use and promote energy efficiency during the sale or lease of commercial properties.

In 2013, a beta version web-based portal for self-directed use of a building's data to create BML sheets was created. The final version became available for public use in early 2014.

In addition to finalizing the portal, the IDL followed up with previous users of the BML sheets and supported new users. The IDL promoted the BML sheet at a BOMA monthly luncheon meeting and to the City of Boise in conjunction with an educational Lunch & Learn session. It was also marketed at the 2014 BOMA Symposium and the Kilowatt Crackdown™ Awards ceremony. The report is located in the IDL section of *Supplement 2: Evaluation*.

## Lunch & Learn

The goal of the Lunch & Learn task was to educate architects, engineers, and other design and construction professionals about energy efficiency topics through a series of educational lunch sessions. This series includes sessions outside the Treasure Valley.

In 2014, 20 technical training lunches were scheduled in Boise, Pocatello, and Ketchum. The trainings were coordinated directly with architecture and engineering firms and organizations and were attended by a total of 281 architects, engineers, interior designers, project managers, and others. Nineteen sessions were held in 2014. Due to a 2014 scheduling conflict, one remaining session is scheduled for January 29, 2015.

Fourteen sessions were offered in Boise, two in Pocatello, three in Ketchum, and one in Chubbuck. The topics of the lunch sessions (and quantity of each) were: *High Performance Retrofits* (1), *Integrated Design Principle* (2), *Integrated Design Lab Overview* (2), *Radiant System Design Considerations* (2), *Daylight Sensing Electric Lighting Controls* (2), *High Performance Classrooms* (2), *Climate Responsive Design—Tools and Methods* (1), *M&V + Tool Loan Library* (1), *Architectural HVAC Integration Strategies* (2), *Integrated Design Case Studies* (2), *Daylight in Buildings: Schematic Design* (1), *Daylight in Buildings: Getting the Details Right* (1), and *Benchmarking, M&V, + Tool Loan Library* (1). The report is located in the IDL section of *Supplement 2: Evaluation*.

## Fall Educational Series

The goal of the Fall Educational Series was to educate architects, engineers, building owners, building operators, designers, and construction professionals about energy efficiency through a series of publicly available evening lectures.

In 2014, the title of the series was *Design Decisions and Outcomes*, which focused on design decisions and strategies for energy efficiency. Four sessions were held that featured topics that supported this concept. The topics were *Developer Choices and Local Stories, Design for Off: A Seattle HVAC Case Study, Outstanding Local Projects*, and *Integrated Lighting Practices*. Each session consisted of 1.5 hours of lecture followed by time for questions. The sessions were held at Idaho Power's CHQ and were offered live, as well as broadcasted webinars. The live and remotely broadcasted presentations had 92 total participants. The report is located in the IDL section of *Supplement 2: Evaluation*.

## Building Simulation Users Group

The goal of this task was to facilitate the Idaho BSUG, which is designed to improve the energy efficiency-related simulation skills of local design and engineering professionals.

In 2014, 11 monthly BSUG sessions were hosted by the IDL. In most cases, the IDL taught the sessions themselves or brought in outside speakers. The sessions were made available remotely and were

attended by 179 professionals in person and 318 professionals remotely. Evaluations forms were completed by attendees for each session. On a scale of 1 to 5, with 5 being excellent and 1 being poor, averaging results from all seven questions, the average session rating was 4.0 for 2014.

Finally, each presentation was archived on the BSUG 2.0 website along with general BSUG-related content. The BSUG 2.0 site logged 2,150 total visits with 1,132 specific to Idaho users in 2014. The report is located in the IDL section of *Supplement 2: Evaluation*.

## Foundational Services

The goal of this task was to provide energy efficiency technical assistance and project-based training to building industry professionals and customers. When the IDL receives requests for their involvement in building projects, the projects are categorized into one of three types. Phase I projects are simple requests that can be addressed with minimal IDL time. Phase II projects are more complex requests that require more involvement and resources from the lab. Phase III projects are significantly more complex and must be co-funded by the customer.

In 2014, the IDL provided technical assistance on 37 Phase I projects, 9 Phase II projects, and 3 Phase III projects. Overall, 35 percent of the projects were on new buildings and 65 percent were on existing buildings. The report is located in the IDL section of *Supplement 2: Evaluation*.

## Building Efficiency Verification

The goal of this task was to continue random installation verification of over 10 percent of Building Efficiency applications provided incentives. This consisted of conducting a full review of documentation and complete on-site inspections to validate whether noted systems and components had been installed. The purpose of this verification was to confirm program guidelines and requirements were adequately facilitating participants to provide accurate and precise information with regard to energy efficiency measure installations.

This task also included the review of all daylight photo-control incentives to verify site conditions and improve the quality of design and installation.

The IDL completed on-site field verifications for the Building Efficiency program as summarized in the Building Efficiency program's Customer Satisfaction and Evaluations section presented earlier in this *Demand-Side Management 2014 Annual Report*. The report is located in the IDL section of *Supplement 2: Evaluation*.

## Tool Lending Library

The goal of this task was to operate and maintain a measurement equipment TLL, including a web-based equipment tool loan-tracking system, and provide technical training on how each tool is intended to be used.

The inventory of the TLL, which has been built up in previous years, now consists of over 900 individual pieces of equipment. The tools are available for customers, engineers, architects, and contractors in Idaho Power's service area to borrow at no cost to aid in the evaluation of energy efficiency projects and equipment they are considering.

There were 37 tool loan requests in 2014, which included a total of 286 tools loaned. There were 14 tools purchased or acquired in 2014 for the TLL. The tools were loaned to engineering firms or

equipment representatives, educational institutions, industrial plants, and office/commercial facilities. The report is located in the IDL section of *Supplement 2: Evaluation*.

## Simulation Quality Assurance

The goal of this task was to provide energy simulation QA by conducting pre- and post-measurements and verifications to compare modeled savings to realized savings on selected projects. The IDL accomplished this by reviewing energy simulation techniques used to estimate facility consumption, conducting on-site measurements used to calibrate and validate the energy model, performing energy management system data extraction, analyzing actual bill and weather data, and creating a report detailing findings and lessons learned from each project.

The information gained from these activities is conveyed to the local design community through other education and outreach tasks, such as the BSUG and Lunch & Learn sessions, both described above. Additionally, system issues have been uncovered and corrected due to the investigation associated with these efforts, which helps ensure persistence of energy savings. In 2014, four highly visible and innovative projects were analyzed, consisting of a local architectural and engineering firms' new radiant cooling system, a university classroom building, and two mid-sized commercial buildings. The report is located in the IDL section of *Supplement 2: Evaluation*.

## Heat Pump Calculator

The goal of this task was to develop an Excel-based heat pump analysis tool to calculate energy usage and savings based on site-specific variables for commercial buildings. It was determined there was a lack of sophisticated heat pump energy-use calculators available with the capability of comparing the energy use of heat pumps in commercial buildings against other technologies in a quick, simple fashion. The tool was developed in 2013 and underwent testing in early 2014. Feedback from validation testing has been integrated into the current version of the tool. The report is located in the IDL section of *Supplement 2: Evaluation*.

## Planning and Commissioning for Daylight Harvesting

The goal of the Daylight Harvesting task in 2014 was to expand on the previous task of creating a hands-on demonstration and training for electrical contractors by offering on-site classes for them to learn the necessary skills to successfully install and commission daylight harvesting lighting-control systems.

Nine Daylight Harvesting classes were held in 2014. These classes were attended by 29 participants, representing 102 continuing education hours. The various control systems in the IDL space provided a great venue to educate electrical contractors and the design community on daylight-harvesting technology. Classes were held in a two-part series: Part 1 provided in-class training, and Part 2 provided hands-on commissioning education. The report is located in the IDL section of *Supplement 2: Evaluation*.

## Customer Representative Training

The goal of the Idaho Power CR training task in 2014 was to develop and provide training to Idaho Power CRs to identify common energy efficiency opportunities in commercial buildings. The training consisted of three classroom style modules: Module 1: Pre-Walk Benchmarking and Analysis, Module 2: Typical Building Systems and Efficiency Opportunities, and Module 3: Specialty Systems and Efficiency Opportunities. This training was delivered across the Idaho Power

service area. The twelve classroom-style trainings had a total of 55 attendees. Nine on-site field trainings were conducted in conjunction with the classroom-style trainings and had a total of 45 attendees. The report is located in the IDL section of *Supplement 2: Evaluation.*

### Residential Heat Pump Calculator

In 2014, the IDL created a computer-based residential energy calculator. This tool calculates energy consumption for residential houses. It has the ability to accept various descriptive user inputs—for example, attic insulation and window performance in an existing house. It also enables the user to compare the energy consumption of a house with various types of heating and cooling systems. The tool will be evaluated in 2015 to determine if any enhancements are needed.

### Residential Heat Pump Calculator—Weatherization Solutions & Home Improvement Programs Module

The IDL created a computer-based residential energy calculator in 2014. This tool calculates energy consumption for residential houses for pre- and post-weatherization. The tool has the ability to accept various descriptive user inputs to calculate estimated savings based on the interaction between potential upgrades and various heat systems.

### Residential Electronically Commutated Motors

In 2014, the IDL investigated ECMs at the request of Idaho Power. These motors are sometimes used in residential forced-air heating and cooling systems. These motors can be an energy-efficient option when compared to other types of motors used in the air handlers for these systems. An air handler is a device that circulates air through ductwork. Idaho Power is evaluating the ECM motor for a potential new measure to be added to the H&CE Program. The work the IDL performed was to help determine if an ECM motor would be a suitable energy-saving replacement motor for the traditional permanent split capacitor motor. The results of their work will be reviewed in 2015. The report is located in the IDL section of *Supplement 2: Evaluation*.

The contract between Idaho Power and the IDL will continue through 2015. In 2015, the IDL will continue or expand work on the BML sheets, Lunch & Learn sessions, BSUG, foundational services, building efficiency verification, TLL, heat pump calculator, and daylight demonstrations. In addition, they will begin work on four new tasks—Commercial Real Estate Support, IBOA and IFMA Organization/Chapter Support, Targeted Energy Expansion of Daylight Pattern Guide, and Whole House Fan Energy Savings.

## Local Energy Efficiency Funds

The purpose of LEEF is to provide modest funding for short-term projects and activities that do not fit within other categories of energy efficiency programs but still provide energy savings or a defined benefit to the promotion of energy-efficient behaviors or activities. Idaho Power received three applications for LEEF in 2014 and awarded funds to one applicant.

Meridian Food Bank requested funding to replace one of their existing upright freezer units with a new, more energy-efficient unit. Idaho Power met with the Meridian Food Bank at their facility to gather more information on the project. Given the ongoing need for this type of replacement at the Food Bank and the positive community impact this operation serves, it was decided that an alternate method of funding would be more appropriate. As of December 31, 2014, the Idaho Power CR for this site worked

with the customer and Idaho Power executives to investigate a potential corporate donation to support this facility's efforts.

A high-performance builder in the Wood River Valley area submitted an application regarding substantial energy efficiency measures associated with a large, new-construction residence. Energy efficiency measures included reduced heating loads due to premium construction methods and materials, highly efficient ground-source heat pumps, and ECMs. Idaho Power convened a working group of residential and commercial engineers and cost-effectiveness analysts from Idaho Power's energy efficiency department to review the application and request additional information. Energy calculations were supported by energy modeling software, RESNET, and an estimated 95,834 kWh per year in heating system savings. After a thorough review of the details surrounding this LEEF request, the team approved funding for $9,100.

The third project submitted regarded potential lighting retrofits in Boise High School's auditorium. A brief review revealed the project would qualify for existing commercial lighting incentives. The applicant was asked to submit the project to Idaho Power's energy efficiency commercial program staff.

## Building-Code Improvement Activity

Since 2005, the State of Idaho has been on a cycle of adopting a state-specific version of the IECC. The Idaho Building Code Board convened another Energy Code Collaborative in 2013 in an effort to address implementation of the new series of building-related codes. Idaho Power participated and offered support in those collaborative meetings, which included members of the building industry, local building officials, code development officials, and other interested stakeholders. The Energy Code Collaborative is an ongoing collaborative in which Idaho Power participates.

The Energy Code Collaborative brought forth its recommendations to the Idaho Building Code Board, which included the adoption of the *2012 IECC Residential Code* with amendments and the *2012 IECC Commercial Code* in 2013. The recommendation was adopted by the Idaho Building Code Board and was presented in the 2014 legislature session. Legislature passed the rules effective March 21, 2014, and the changes will go into effect January 1, 2015.

## Idaho Power's Internal Energy Efficiency Commitment

Several Idaho Power properties were enhanced in 2014 with the goal of improving energy efficiency. During the Payette Operations Center remodel, ceiling insulation was increased from R-20 to R-38, and a Watt-Stopper lighting-control system was added. At four substation buildings across the service area, old black built-up roofs were replaced with white metal roofs for reflection purposes.

Numerous CHQ remodel projects were completed in 2014. Plaza I was remodeled, and the old T-12 and T-8 lighting fixtures were replaced with LED fixtures controlled by a lighting system. Plaza II was remodeled, and the old T-12 system was replaced with LED fixtures. The existing natural gas-fired rooftop unit was replaced with a higher efficiency rooftop packaged heat pump unit rated at an energy efficiency ratio (EER) of 16 that has a payback cost of 14 months. The Plaza II roof was replaced with a reflective, better-insulated thermoplastic polyolefin roof to open the floor plan to the rafters in the barrel-shaped building. All the three-lamp T-12 fixtures on CHQ fourth floor and sixth floor were replaced with two-lamp T-8 fixtures. The CHQ fourth floor was completely remodeled with new recycled carpet, low-VOC paint, and low-partition walls for increased light transmission throughout the floor.

An outcome of the Energy Efficiency Audit conducted at the BOC with Tikker Engineering in 2013 was the installation of building-wide direct digital control system controls at the BOC. While not all of the suggested energy efficiency measures were addressed, the company incorporated measures that would provide the most value. Total energy reduction with the changes implemented at the BOC was estimated at 300,000 kWh annually.

At BCW, the chillers and air handlers were replaced. The new equipment exceeded ASHRAE standards for efficiency and were quieter than the previous chillers. Cooling and heating problems in the Grid Operations area were corrected. While no baseline was taken from the original air handling units (AHU) and chillers, the new air handlers run at 60 percent of the amperage compared to the old equipment. Idaho Power will continue to monitor the performance of the new chillers and AHUs in 2015.

In 2015, Idaho Power will continue with a number of major remodels on the CHQ buildings downtown, starting with the remodel of parts of CHQ sixth floor and seventh floors. The company will begin remodels on the CHQ eighth floor going into 2016. Remodels will incorporate energy efficiency items, such as lower partitions, lighting retrofits, and lighting controls.

Through the Sustainability Initiative Project implemented in 2012, Idaho Power has helped fund and execute sustainable, employee-driven initiatives aimed at increasing efficiencies and lowering company costs. Each year, the Sustainability team puts out a call for projects. Qualifying initiatives must demonstrate a financial benefit to the company, as well as either an environmental or social gain, or preferably both. Approved projects are given financial assistance through “incubation funding,” and the Sustainability team provides consulting services—if necessary—to speed implementation. A new document, available in print and online, catalogues three years of sustainability initiatives, with a brief description of each. From 2012’s Greenleaf wet-meadows project to last year’s rollout of electric vehicles and charging stations, all 26 initiatives are listed.

Employee-suggested sustainability initiative projects yielded several sustainability programs in 2014, including three programs with annual energy savings. At BCW, computer room “occupancy programming” was incorporated into the building management system. This allows one of several air-conditioning units to remain idle when the system detects the room is unoccupied, bringing an annual energy savings estimate at over 33,000 kWh. Idaho Power installed VFDs at the company’s data centers, with a combined savings of over 240,000 kWh annually.

# REGULATORY OVERVIEW

Idaho Power believes there are three essential components of an effective regulatory model for DSM: 1) the timely recovery of DSM program costs, 2) the removal of financial disincentives, and 3) the availability of financial incentives. By working with its stakeholders and regulators through negotiations and filings, Idaho Power continues to seek to move DSM regulatory treatment toward achieving all of these goals.

## Timely Recovery of DSM Program Costs: Energy Efficiency Rider and Prudence Determination of Expenditures

Since 2002, Idaho Power has recovered most of its DSM program costs through the Rider with the intended result of providing a more timely recovery of DSM costs. In addition, since January 1, 2012, funding of Idaho demand response program incentives is included in base rates and tracked in the annual PCA mechanism.

### *Annual DSM Expense Review Filing and Order No. 33161*

On March 14, 2014, Idaho Power filed Case No. IPC-E-14-04 with the IPUC requesting an order finding the company had prudently incurred $25,951,486 in DSM expenses in 2013, including $21,748,331 in Rider expenses and $4,203,155 in demand response program incentive expenses. The filing included three reports: *Demand-Side Management 2013 Annual Report*, *Supplement 1: Cost Effectiveness*, and *Supplement 2: Evaluation*. Due to a previous IPUC decision in Case No. IPC-E-13-08 to decline Idaho Power's request to deem prudent the increases in the company's Rider-funded labor-related expenses for 2011, 2012, and 2013, Idaho Power did not request a prudence determination for labor-related expenses of $269,432 in the filing. In Order No. 33161, dated November 4, 2014, the IPUC deemed $25,951,486 as prudently incurred and stated:

> The Commission notes that Idaho Power issued a strong rebuttal of these claims, offering several reasons to explain the recent decline in its DSM expenditures and a defense of its marketing efforts. While the Commission is cognizant of the recent decline in energy savings, acknowledged by the Company in its Application, we are encouraged by the Company's reply comments that its commitment to cost-effective DSM has not waned and that it has a renewed interest in taking action to procure all cost-effective DSM.

### *Errata to Order No. 33161*

In an Errata to Order No. 33161, dated November 7, 2014, the Commission amended the original Order to read:

> The Commission is cognizant of the recent decline in energy savings, acknowledged by the Company in its Application, and notes that Idaho Power issued a strong rebuttal of these claims, offering several reasons to explain the recent decline in its DSM expenditures and a defense of its marketing efforts. We are encouraged that the reply comments seem to demonstrate the Company's renewed interest in procuring all cost-effective DSM.

> In this case, the Commission restricts its findings to the prudency of the Company's 2013 expenditures. The Commission agrees that the issues raised by Staff and other parties are significant and warrant a more in-depth review. We direct the parties to do so in the context of the Company's next Integrated Resource Plan filing.

## Energy Efficiency Working Group

In response to the Errata, Idaho Power organized an Energy Efficiency Working Group, inviting members of the IRP Advisory Committee (IRPAC), EEAG, and other interested parties to participate. The Energy Efficiency Working Group held two sessions to conduct an in-depth review of the issues referenced in the Errata to Order No. 33161. The sessions were open to the public and held at Idaho Power's CHQ on December 3 and 18.

The first workshop session included a discussion of a broad range of energy efficiency and resource planning issues that can be classified into two general categories: 1) strategies related to program delivery and 2) the treatment of energy efficiency in the resource planning process. Because the IRP process does not address program delivery issues, it was suggested to narrow the focus of the discussion to only the treatment of energy efficiency in the resource planning process. The strategies related to the successful delivery of programs will be better addressed by EEAG.

The second workshop session agenda included a comparison of potential studies from other regional utilities; a description about how Idaho Power's incorporates energy efficiency in the IRP; a comparison of how other regional utilities incorporate energy efficiency in long-range planning; a review of Idaho Power's investigation into including Transmission and Distribution (T&D) investment deferral into the benefits in the energy efficiency cost-effectiveness analysis; and offered an open discussion time to address other issues. The information presented at the second meeting prompted extensive discussion among participants and ultimately served to inform Idaho Power's next steps.

Idaho Power believes its current treatment of energy efficiency in the resource planning process appropriately balances the need for responsible and effective resource planning and the desire to prudently pursue all cost-effective energy efficiency. Idaho Power recognizes that achieving those balanced objectives on an ongoing basis requires continued review and evaluation of the planning process and an awareness of related industry best practices.

Idaho Power is committed to investigate the extent to which transmission and/or distribution benefits result from energy efficiency measures and programs, as well as the approximate value of such benefits. When available, the company will present the results of this investigation to the IRPAC.

The company is also committed to continue to discuss the program delivery issues identified by workshop participants and by IPUC staff and some interveners in comments filed in Case No. IPC-E-14-04. The company plans to use EEAG as the forum to provide customers, IPUC and OPUC staff, and other interested stakeholders an opportunity to provide advice and recommendations to Idaho Power in formulating, implementing, and evaluating energy efficiency and demand response programs and activities.

## Energy Efficiency Rider-Funds Transfer

On April 15, 2014, Idaho Power filed the annual PCA Case No. IPC-E-14-05 with the IPUC. As part of that case, the company proposed that the commission approve a one-time transfer of $20 million of

surplus Idaho Rider funds to customers as a credit, or reduction, in the 2014/2015 PCA on customers' bills. In Order No. 33049, the commission approved the one-time transfer.

## Removal of Financial Disincentives: Fixed-Cost Adjustment

To address the removal of financial disincentives, Idaho Power has in place a fixed-cost adjustment (FCA) mechanism in Idaho. Under the FCA, rates for Idaho residential and small general-service customers are adjusted annually up or down to recover or refund the difference between the fixed costs authorized by the IPUC in the most recent general rate case and the fixed costs Idaho Power actually received the previous year through weather-normalized energy sales. This mechanism removes the financial disincentive that exists when Idaho Power promotes energy efficiency programs that are designed to reduce customer usage. The FCA is a permanent mechanism limited to the residential and small general-service customer classes in Idaho in recognition of the fact that, for these customers, a large percentage of fixed costs are recovered through their volumetric energy charges.

On May 30, 2014, the IPUC issued Order No. 33047 approving the company's request to implement FCA rates beginning June 1, 2014, for the 2013 fixed-cost deferrals. The overall rate adjustment was a 1.18 percent increase for residential and small general-service customers to collect a combined $14.9 million. This adjustment was an increase of $6 million from the previous year's FCA. Residential customers experienced a rate increase of 0.1143 cents per kWh, while small general-service customers experienced an increase of 0.1447 cents per kWh. The rate will be in place until May 31, 2015.

## Promotion of Energy Efficiency through Electricity Rate Design

Idaho Power believes rates offered to customers should reflect their cost of service in order to provide cost-based price signals and encourage the wise and efficient use of energy.

Since 2012, Idaho Power has offered a Time-of-Day (TOD) Pilot pricing plan to residential customers in Idaho. The overall goal of this TOD pricing plan is to use the AMI system to offer customers a choice of pricing plans while providing them with better tools to manage their energy usage, provide the company with the opportunity to further study the effects of a time-variant rate on customers' usage, and help shape the company's future communication efforts. The plan provides participants the opportunity to move their usage from higher-priced, on-peak time periods to lower-priced, off-peak time periods and possibly lower their bills. Idaho Power sent out a mailing in late spring of 2014 reminding participants that higher summer rates go into effect June 1. The spring mailing promoted the use of myAccount and reminded customers to use electricity wisely. A description of this plan is at Idaho Power's website (idahopower.com/TOD).

In July 2014, Idaho Power concluded the final impact study of the residential TOD pilot. The study was a customer behavior study that evaluated how the TOD pricing impacted energy consumption for participants in the plan. Participant's response to the TOD pricing signal was determined using a quasi-experimental study design structure with a TOD participant treatment group and a closely matched non-participant control group. Idaho Power also calculated the billing revenue impact of this pilot by calculating a shadow bill for each of the customers on the TOD pricing plan versus the standard residential three-tiered pricing plan in Idaho.

Key findings are summarized below:

- There was no statistically significant change in overall energy consumption observed in the study participants on the TOD rates.

- For the study group as a whole, the data analyzed showed a **reduction** in energy use from peak time periods by the analyzed participants of the pricing plan verses the control group. All but 2 out of 12 months showed statistically significant reductions in energy use during peak periods. Over the 12-month study period, this combined reduction in peak-time-period consumption was approximately 3 percent of the total kWh use.

- For the study group as a whole, the data analyzed showed an **increase** in energy use during off-peak time periods by the analyzed participants of the pricing plan verses the control group. Five out of the 12 months showing statistically significant increases. During the 12-month study period, this combined increase in off-peak time-period consumption was approximately 1 percent of the total kWh.

- The overall response rate to the residential TOD pricing pilot plan solicitation was 1.3 percent.

- The study estimates that there was a revenue reduction of $119,000 when actual TOD energy billings of all TOD pilot participants are compared with standard plan shadow energy bill calculations for all TOD pilot participants during the 12 months of the study, September 2012 through August 2013.

As of the end of 2014, over 1,500 Idaho customers were TOD plan participants.

# APPENDICES

This report includes five appendices. Appendix 1 contains financial information for 2014, showing the beginning balance, ending balance, and the expenditures for the Idaho and Oregon Riders and NEEA payments and credits. Appendix 2 also contains financial information showing expenses by funding source for each of Idaho Power's energy efficiency and demand response programs or activities. Appendix 3 shows participation, UC, TRC, energy and demand savings, measure life, and levelized costs for Idaho Power's current energy efficiency programs and activities for 2014. Appendix 4 shows similar data as Appendix 3 but also includes data for past years' program performance and B/C ratios from the UC and TRC perspectives for active programs. Appendix 5 contains program savings and costs separated into Idaho Power's Idaho and Oregon jurisdictions and by funding source. In these appendices, the data has been rounded to the nearest whole unit, which may result in minor rounding differences.

Additional information is contained in the supplements provided in separate documents in two formats. *Supplement 1: Cost-Effectiveness* contains detailed cost-effectiveness information by program and energy-savings measure. Provided in Supplement 1 are the B/C ratios from the UC, TRC, RIM, and PCT perspectives. The *2014 DSM Detailed Expenses* by program table reports expenses by funding source and separates the company's DSM expenses by expense type, incentive expenses, labor/administration, materials, other expenses, and purchased services. *Supplement 2: Evaluation* contains copies of Idaho Power's third-party evaluations and reports. A CD is attached in Supplement 2 and contains copies of *NEEA Market Effects Evaluations*. A searchable, linked table with the title, study manager, evaluation type, and other information are included with each supplement.

| **Total DSM Expense** | | **$ 36,713,333** | | | | | | |

[a] Levelized Costs are based on financial inputs from Idaho Power's 2013 IRP and calculations include line-loss adjusted energy savings.
[b] The Total Utility Cost is the cost incurred by Idaho Power to implement and manage a DSM program.
[c] The Total Resource Cost is the total expenditures for a DSM program from the point of view of Idaho Power and its customers as a whole.
[d] Summer Peak Demand is reported where program MW reduction is calculated specifically by project. Demand response program reductions are reported with 9.7-percent peak loss assumptions.
[1] Peak demand represents the peak performance of the program.
[2] Savings claimed for gas-heated certified homes that were not provided a direct incentive payment by Idaho Power.
[3] Savings claimed for direct-install measures during home energy audits.
[4] Savings for energy kits provided as part of the Residential Energy Efficiency Education Initiative program.
[5] Custom Efficiency savings includes 15 Green Motors participants totaling 56,499 kWh of annual savings, not counted in project totals.
[6] Irrigation Efficiency includes 14 Green Motors participants totaling 35,083 kWh of annual savings, not counted in project totals.
[7] Savings are preliminary estimates. Final savings for 2014 will be provided by NEEA in June 2015.

## **Appendix 4.** Historical DSM expense and performance, 2002–2014

| Program/Year | Participants | Total Costs | | Savings and Demand Reduction | | | Measure Life (Years) | Levelized Costs[a] | | Program Life Benefit/Cost Ratios[b] | |

## **Appendix 4.** Historical DSM expense and performance, 2002–2014 (continued)

| Program/Year | Participants | Total Costs | | Savings and Demand Reduction | | | Measure Life (Years) | Levelized Costs[a] | | Program Life Benefit/Cost Ratios[b] | |
|---|---|---|---|---|---|---|---|---|---|---|---|
| | | Utility Cost[c] | Resource Cost[d] | Annual Energy (kWh) | Average Energy[e] (aMW) | Peak Demand[f] (MW) | | Total Utility ($/kWh) | Total Resource ($/kWh) | Utility | Total Resource |
| **Total Expenses** | | | | | | | | | | | |
| 2002 | | $ 2,061,375 | | | | | | | | | |
| 2003 | | 2,524,685 | | | | | | | | | |
| 2004 | | 3,969,550 | | | | | | | | | |
| 2005 | | 6,700,972 | | | | | | | | | |
| 2006 | | 11,484,013 | | | | | | | | | |
| 2007 | | 15,662,377 | | | | | | | | | |
| 2008 | | 21,193,521 | | | | | | | | | |
| 2009 | | 34,846,766 | | | | | | | | | |
| 2010 | | 45,832,851 | | | | | | | | | |
| 2011 | | 46,266,252 | | | | | | | | | |
| 2012 | | 49,326,859 | | | | | | | | | |
| 2013 | | 26,841,378 | | | | | | | | | |
| 2014 | | 36,713,333 | | | | | | | | | |
| **Total 2002–2014** | | **$ 303,423,931** | | | | | | | | | |

[a] Levelized Costs are based on financial inputs from Idaho Power's 2013 IRP and calculations include line loss adjusted energy savings.

[b] Program life benefit/cost ratios are provided for active programs only.

[c] The Total Utility Cost is all cost incurred by Idaho Power to implement and manage a DSM program.

[d] The Total Resource Cost is the total expenditures for a DSM program from the point of view of Idaho Power and its customers as a whole.

[e] Average Demand = Annual Energy/8,760 annual hours.

[f] Peak Demand is reported for programs that directly reduce load or measure demand reductions during summer peak season. Peak demand reduction for demand response programs is reported at the generation level assuming peak line losses.

[1] Savings are preliminary estimates. Final savings for 2014 will be provided by NEEA in June 2015.

## **Appendix 5.** 2014 DSM program activity by state jurisdiction

| Program | Idaho Participants | Idaho Utility Costs | Idaho Demand Reduction/ Annual Energy Savings | Oregon Participants | Oregon Utility Costs[a] | Oregon Demand Reduction/ Annual Energy Savings |
|---|---|---|---|---|---|---|
| **Demand Response** | | | **(MW)** | | | **(MW)** |

APPENDIX C
Technical Report

# Integrated Resource Plan 2015

## ACKNOWLEDGMENT

Resource planning is an ongoing process at Idaho Power. Idaho Power prepares, files, and publishes an Integrated Resource Plan every two years. Idaho Power expects that the experience gained over the next few years will likely modify the 20-year resource plan presented in this document.

Idaho Power invited outside participation to help develop the *2015 Integrated Resource Plan*. Idaho Power values the knowledgeable input, comments, and discussion provided by the Integrated Resource Plan Advisory Council and other concerned citizens and customers.

It takes approximately one year for a dedicated team of individuals at Idaho Power to prepare the Integrated Resource Plan. The Idaho Power team is comprised of individuals that represent many different departments within the company. The Integrated Resource Plan team members are responsible for preparing forecasts, working with the advisory council and the public, and performing all the analyses necessary to prepare the resource plan.

Idaho Power looks forward to continuing the resource planning process with customers, public interest groups, regulatory agencies, and other interested parties. You can learn more about the Idaho Power resource planning process at www.idahopower.com.

# INTRODUCTION

*Appendix C–Technical Appendix* contains supporting data and explanatory materials used to develop Idaho Power's *2015 Integrated Resource Plan* (IRP).

The main document, the IRP, contains a full narrative of Idaho Power's resource planning process. Additional information regarding the 2015 IRP sales and load forecast is contained in *Appendix A–Sales and Load Forecast*, and details on Idaho Power's demand-side management efforts are explained in *Appendix B–Demand-Side Management 2014 Annual Report*. The IRP, including the three appendices, was filed with the Idaho and Oregon public utility commissions in June 2015.

For information or questions concerning the resource plan or the resource planning process, contact Idaho Power:

# IRP ADVISORY COUNCIL AND MEMBERS

Idaho Power has involved representatives of the public in the IRP planning process since the early 1990s. This public forum has come to be known as the IRP Advisory Council (IRPAC). The IRPAC generally meets monthly during the development of the IRP and the meetings are open to the public. Members of the council include political, environmental, and customer representatives, as well as representatives of other public-interest groups.

As part of preparing the 2015 IRP, Idaho Power hosted a field trip to the Swan Falls hydroelectric project and museum.. Idaho Power also hosted 12 IRPAC meetings, including a resource portfolio design workshop. Idaho Power and members from the IRPAC also met in several small break-out sessions to discuss certain topics in greater detail. Idaho Power values these opportunities to convene, and the IRPAC members and the public have made significant contributions to this plan.

Idaho Power believes working with members of the IRPAC and the public is very rewarding, and the IRP is better because of the public involvement. Idaho Power and the members of the IRPAC recognize that outside perspective is valuable, but also recognize that final decisions on the IRP are made by Idaho Power.

# PUBLIC POLICY ISSUES

## Clean Air Act Section 111(d) Sensitivities Assumptions

### *Section 111(d) Sensitivities*

Because of the uncertainty associated with the EPA's proposed regulation of $CO_2$ under the *Clean Air Act of 1970* (CAA) Section 111(d), a range of sensitivities was modeled. Each sensitivity is based on multiple assumptions as provided in this section. It is noted that portfolio cost results associated with each sensitivity are contingent upon underlying assumptions of the sensitivity; stipulations for the final CAA Section 111(d) regulation may differ greatly from those assumed for these sensitivities, leading possibly to markedly different costs in practice.

#### Null Sensitivity (No CAA Section 111(d))

- No existing regulations require any modifications to operations or equipment
- No pending or future regulations (i.e., CAA Section 111(d)) will require any modifications to operations or equipment
- Analyzed to provide a comparison with portfolios complying with CAA Section 111(d)-based regulations on $CO_2$ emissions

#### State-by-State Mass-Based Compliance

- Compliance determined within state boundaries
- Compliance cannot cross state lines and plant reductions cannot be shifted across state lines
- Converting from rate base to mass base using percent reduction from rate goals established by proposed regulation
- No requirements for renewable energy or energy efficiency
- Generation is capped at the target levels
    - North Valmy targets—574,382 MWh/year for 2020-2029 and 533,343 MWh/year for 2030 through IRP planning period end
    - Jim Bridger targets—3,914,502 MWh/year for 2020-2029 and 3,675,608 MWh/year for 2030 through IRP planning period end
    - Langley Gulch target alternatives
        - 30 percent annual capacity factor for 2020 through IRP planning period end (837,018 MWh/year)
        - 55 percent annual capacity factor for 2020 through IRP planning period end (1,534,533 MWh/year)
        - 70 percent annual capacity factor for 2020 through IRP planning period end (1,953,042 MWh/year)

### System-Wide Mass-Based Compliance

- Determine total $CO_2$ reduction for Idaho Power system
- Compliance is determined by meeting Idaho Power system $CO_2$ emission target
- Compliance can cross state lines and plant $CO_2$ reductions can be shifted across state lines
- Converting from rate base to mass base using percent reduction from rate goals established by proposed regulation
- No requirements for renewable energy or energy efficiency
- Idaho Power system emissions are capped at the target levels
    - 6,332,020 tons $CO_2$ for 2020–2029
    - 5,925,874 tons $CO_2$ for 2030 through IRP planning period end
- Early shutdown of units enables other units to increase generation

### Emissions Intensity Compliance Utilizing the EPA's Compliance Building Blocks

- All building blocks required to meet compliance
- Rate reductions established based on the goal calculations by the EPA
- The state of Idaho is able to count previously constructed PURPA projects as part of building block 3
- Renewable energy (building block 3) and energy efficiency (building block 4) in Idaho grow to EPA projected levels
- No renewable energy or energy efficiency requirements for states where Idaho Power has no customers (Wyoming, Nevada)
- CAA Section 111(d) $CO_2$ attributes can cross state lines
- Affected unit generation and renewable energy/energy efficiency are variable as long as interim and final rates are met
- Idaho Power is not responsible for meeting interim or final goals for Wyoming, Nevada, or Oregon
- Since Boardman has an agreed upon closure date, Idaho Power has no rate requirements to meet in Oregon
- Interim goals are relaxed with agreed upon retirement dates for Boardman and North Valmy set at 2020 and 2025 respectively (note that pre-2025 North Valmy retirement also allows a relaxing of interim goals)
- Building block 1 (6 percent efficiency improvement) cannot be met or sustained and is reset to 0 percent
- Jim Bridger generation reduced from 2012 levels for pro-rata share of 95 MW natural gas plant under construction in Wyoming (building block 2)
- Generation capped at the target levels
    - North Valmy target—814,264 MWh/year until retirement (retirement no later than 2025)

- Jim Bridger target—4,488,392 MW/year for 2020 through IRP planning period end
- Langley Gulch target alternatives
  - 30 percent annual capacity factor for 2020 through IRP planning period end (837,018 MWh/year)
  - 55 percent annual capacity factor for 2020 through IRP planning period end (1,534,533 MWh/year)
  - 70 percent annual capacity factor for 2020 through IRP planning period end (1,953,042 MWh/year)

# Flow Modeling

## Models

Idaho Power uses two primary models for forecasting future flows for the IRP. The Snake River Planning Model (SRPM) is used to forecast surface water flows and the Enhanced Snake Plain Aquifer Model (ESPAM) is used to forecast the impact of various aquifer management practices implemented on the Eastern Snake Plain Aquifer (ESPA). The SRPM was updated in late 2012 to include hydrologic conditions for years 1928 through 2009. ESPAM was also updated with the release of ESPAM 2.1 in late 2012. Beginning with the 2009 IRP, Idaho Power began running the SRPM and ESPAM as a combined modeling system. The combined model seeks to maximize diversions for aquifer recharge and system conversions without creating additional model irrigation shortages over a modeled reference condition.

## Model Inputs

The model inputs used in this effort are similar to the inputs used in the 2011 and 2013 IRP but those inputs continued to be refined to reflect future system conditions and management policies. The general inputs to the model are reach declines, weather modification, aquifer recharge, system conversions, and retirement of land from irrigation.

Future reach declines were determined using a variety of statistical analysis. Trend data indicate reach gains into American Falls Reservoir and from Milner Dam to Lower Salmon Falls Dam demonstrated a statistically significant decline for the period of 1980 to 2013. Reach gains into American Falls Reservoir declined on average 23 cubic feet per second per month (cfs/month) with declines ranging from 12 to 34 cfs/month. Reach gains from Milner Dam to Lower Salmon Falls Dam for American declined on average 34 cubic feet per second per month (cfs/month) with declines ranging from 22 to 53 cfs/month. Declines in these two reaches met strict, predefined criteria and were therefore included as inputs into the model.

Weather modification was added to the model at different levels of development. For IRP years 2015 through 2019, weather modification was increased to reflect projected levels of fully built-out programs in Eastern Idaho, the Wood River Valley, and the Boise Basin. Beyond IRP year 2019, weather modification levels in these three basins were held constant through the rest of the IRP forecast period. The level of weather modification was held constant at the current level in the Payette River Basin throughout the IRP forecast period. The amount of weather modification added to each year is

based on the total runoff for each year from 1928 through 2009. At full build out the Payette basin increase total discharge by an average of 271,567 acre-ft/year. The Upper Snake, Wood River, and Boise Basins, respectively, add an average of 453,130 acre-ft/year; 108,900 acre-ft/year; and 218,249 acre-ft/year by IRP year 2019.

Aquifer recharge was added to the model at levels reflected in the 2014 Idaho Water Resource Board Preliminary Draft—Managed Recharge Plan. In the 2015 IRP, recharge expanded to include wintertime recharge from winter time diversions at Milner Dam. Recharge peaks in IRP year 2021 at approximately 209,839 acre-ft and then slowly declines as diminishing reach gains limit the amount of water available for aquifer recharge.

System conversion projects involve the conversion of ground water supplied irrigated land to surface supplied irrigated land. The number of acres modeled and potential water savings was based on data provided by the Idaho Department of Water Resources (IDWR). The current model assumes a total of 14,767 acres of converted land on the ESPA with a total water savings of 2.0 acre-ft or water per acre of irrigated land (acre-ft/ac). Additional conversion projects are added to the model and from 2020 to 2034 they are held constant at 16,687 acres. Diversions for conversion projects are limited by water availability to meet the demand. Diversions for conversion projects peak in 2020 at 32,440 acre-ft. Diversions for conversion project generally declines after 2020 at declines in reach gains reduces water availability for diversion.

The model accounts for approximately 15,140 acres that are currently in the Conservation Reserve Enhancement Program (CREP). These acres are idled under a 15-year contract with the U.S. Department of Agriculture. Each idled acre is credited in the ESPAM model for reducing irrigation withdrawal from the ESPA by 2.0 acre-ft/year. Many of the CREP contracts were initiated in 2006 and are set to retire beginning in 2020. The current model phases out CREP acres over a four-year period and includes no idled acres by IRP year 2024. The reduction in CREP acres further results in reducing the amount of water available for other management activities such as aquifer recharge and system conversions. Also included in this model run are 750 acres of short-term projects to reduce water use by ground water appropriators. The projects may include the elimination of end gun on center pivots or drying pivot corners. These short-term projects run from 2015 to 2023.

## Model Results

The combined model allows for the ability to include future management activities, and the resulting reach gains from those management activities into Idaho Power's 2015 IRP. Management activities, such as recharge and system conversions, do not significantly change the total annual volume of water expected to flow through the Hells Canyon Complex, but instead change the timing and location of reach gains within the system. Other future management activities, such as weather modification and CREP do directly impact the annual volume of water expected through the Hells Canyon Complex as well as the timing and location of gains within the system.

Overall flow through the Hells Canyon Complex increases from IRP year 2015 through 2019 in response to increased weather modification in the Upper Snake, Wood and Boise River Basins. Flows peak in 2019 with the 50 percent exceedance flows into Brownlee Reservoir as just over 11.9 million acre-ft/year. In 2034, those flows have declined to approximately 11.3 million acre-ft/year,

with most of the declines attributable to declining flows into American Falls and the Milner to Lower Salmon Falls reach.

## 2015 Model Parameters

| IRP Year | Managed Recharge (acft/yr) | | | Weather Modification (acft/yr) | System Conversions (Ac) | CREP (Ac) | Reach Declines (acft/yr) | |
|---|---|---|---|---|---|---|---|---|
| | Above American Falls | Below American Falls | Total | | | | American Falls Inflows | Below Milner Inflows |
| 2015 | 34,060 | 29,793 | 63,852 | 715,209 | 14,767 | 15,890 | 102,644 | 152,147 |
| 2016 | 33,896 | 29,772 | 63,668 | 840,784 | 14,767 | 15,890 | 119,751 | 177,504 |
| 2017 | 34,339 | 69,965 | 104,304 | 960,948 | 14,767 | 15,890 | 136,858 | 202,862 |
| 2018 | 35,417 | 94,061 | 129,478 | 1,017,289 | 15,407 | 15,890 | 153,966 | 228,220 |
| 2019 | 43,433 | 168,533 | 211,966 | 1,051,936 | 16,047 | 15,890 | 171,073 | 253,578 |
| 2020 | 42,926 | 167,127 | 210,052 | 1,051,936 | 16,687 | 12,033 | 188,180 | 278,936 |
| 2021 | 42,989 | 166,850 | 209,839 | 1,051,936 | 16,687 | 8,312 | 205,287 | 304,293 |

[1] The sales and load forecast considers and reflects the impact of existing energy efficiency programs on average load and peak demand. The new energy efficiency programs, proposed as part of the 2015 IRP, are accounted for in the load and resource balance. The peak load forecast does not include the impact of existing or new demand response programs, which are both accounted for in the load and resource balance.

[1] The sales and load forecast considers and reflects the impact of existing energy efficiency programs on average load and peak demand. The new energy efficiency programs, proposed as part of the 2015 IRP, are accounted for in the load and resource balance. The peak load forecast does not include the impact of existing or new demand response programs, which are both accounted for in the load and resource balance.

[1] The sales and load forecast considers and reflects the impact of existing energy efficiency programs on average load and peak demand. The new energy efficiency programs, proposed as part of the 2015 IRP, are accounted for in the load and resource balance. The peak load forecast does not include the impact of existing or new demand response programs, which are both accounted for in the load and resource balance.

[1] The sales and load forecast considers and reflects the impact of existing energy efficiency programs on average load and peak demand. The new energy efficiency programs, proposed as part of the 2015 IRP, are accounted for in the load and resource balance. The peak load forecast does not include the impact of existing or new demand response programs, which are both accounted for in the load and resource balance.

[1] The sales and load forecast considers and reflects the impact of existing energy efficiency programs on average load and peak demand. The new energy efficiency programs, proposed as part of the 2015 IRP, are accounted for in the load and resource balance. The peak load forecast does not include the impact of existing or new demand response programs, which are both accounted for in the load and resource balance.

[1] The sales and load forecast considers and reflects the impact of existing energy efficiency programs on average load and peak demand. The new energy efficiency programs, proposed as part of the 2015 IRP, are accounted for in the load and resource balance. The peak load forecast does not include the impact of existing or new demand response programs, which are both accounted for in the load and resource balance.

[1] The sales and load forecast considers and reflects the impact of existing energy efficiency programs on average load and peak demand. The new energy efficiency programs, proposed as part of the 2015 IRP, are accounted for in the load and resource balance. The peak load forecast does not include the impact of existing or new demand response programs, which are both accounted for in the load and resource balance.

# DEMAND-SIDE RESOURCE DATA

## Cost Effectiveness

Idaho Power considers cost-effectiveness to be the primary screening tool prior to demand-side management (DSM) program implementation. Idaho Power uses the total resource cost (TRC) test and the utility cost (UC) test to develop benefit cost (B/C) ratios to determine the cost-effectiveness of DSM programs for inclusion in resource planning. The two tests insure that the program benefits will exceed costs from both the perspective of Idaho Power (UC) and its customers (TRC). For ongoing programs, tests are also run to look at cost-effectiveness from the point of view of the program participant. Each energy efficiency and demand response program and individual program measures are reviewed annually as part of preparation of an annual report that is submitted to both the Idaho and Oregon public utility commissions. More information on Idaho Power's programs and cost-effectiveness are included in the *Demand-Side Management 2012 Annual Report* and its *Supplement 1: Cost-Effectiveness,* (idahopower.com/EnergyEfficiency/reports.cfm).

Incorporated into the cost-effectiveness analysis are inputs from various sources that represent the most current and reliable information available. Measure savings, measure life, and participant cost assumptions for prescriptive programs are usually sourced from the Regional Technical Forum (RTF), which is the regional advisory group and technical arm of the Northwest Power and Conservation Council (NPCC). For custom and non-prescriptive programs, annual energy savings can be derived from program evaluations, engineering estimates, or regionally deemed values. Participant costs for non-prescriptive programs are often actual costs from customer-submitted information. Other inputs used in the cost-effectiveness models are obtained from the IRP process, including the financial assumptions along with the forecasted value of DSM alternative costs.

Idaho Power determines cost-effectiveness on both a program basis and also on a measure-by-measure basis. In all cases, when cost-effectiveness is calculated for one measure or for an entire program, to be considered cost-effective, the B/C ratios must be greater than one for both the TRC and UC tests.

For the 2015 IRP, non-energy related benefits (NEB) were included in the cost-effectiveness analysis of the program forecasts. NEB include savings from the customer's perspective, including water savings, deferred maintenance and operational costs, health and safety benefits, avoided supplemental fuels, and other quantifiable benefits apart from avoided energy production. NEB were applied to the energy efficiency forecast at the sector level based on cost-effectiveness analysis of the 2014 portfolio of programs. For a complete list of NEB and sources that Idaho Power currently uses for its program cost-effectiveness, see *Demand-Side Management 2014 Annual Report* and its *Supplement 1: Cost-Effectiveness,* (idahopower.com/EnergyEfficiency/reports.cfm).

The cost-effective analysis methods used at Idaho Power are consistent with published methods and standard practices. Idaho Power relies on the *Electric Power Research Institute End Use Technical Assessment Guide* (TAG) *Understanding Cost-Effectiveness of Energy Efficiency Programs,* and the *California Standard Practice Manual* for the cost-effectiveness methodology. As defined in the TAG and *California Standard Practice Manual*, the TRC and UC tests are most similar to supply-side cost analysis and provide a useful basis to compare demand-side and supply-side resources.

## Resource Development and Evaluation

When developing energy efficiency programs, Idaho Power uses actual data and experiences from other companies in the region, or throughout the country, where applicable, to help identify specific program

parameters. The regional program review is typically accomplished through discussions with other utilities' program managers and research staff. Other program development resources include; E Source, Edison Electrical Institute (EEI), Consortium for Energy Efficiency (CEE), American Council for an Energy Efficient Economy (ACEEE), Advanced Load Control Alliance (ALCA). For other assumptions, including estimated cost, savings, Idaho Power relies on sources, such as the NPCC, the RTF, NEEA, the Database for Energy Efficiency Resources (DEER), third-party consultants, and other regional utilities.

Sometimes Idaho Power launches pilot programs or limited-scale programs; to evaluate estimates or assumptions in the cost-effectiveness model. Pilot programs are designed to measure actual program experiences, including program expenses, savings, and participation. Following implementation of a program, the cost-effectiveness models are reviewed as data from actual program activity becomes available. The program design may be re-examined after program implementation.

All programs are included in an ongoing evaluation schedule where a third-party consultant verifies the claimed savings from the program. Programs are also evaluated to review the program processes to review the effectiveness of the program delivery. If an evaluation determines that savings are less than claimed or that there is potential for improvement in delivery of the program then changes can be made based on the recommendations. Recent evaluations from the 2014 program year can be reviewed in the *Demand-Side Management 2014 Annual Report* and its *Supplement 2: Evaluations*, (idahopower.com/EnergyEfficiency/reports.cfm).

## Planning Assumptions and Alternate Costs

The financial assumptions used in the analysis for the 2015 IRP are consistent with the financial assumptions made for supply-side resources, including the discount rate and cost escalation rates. Table DSM-1 lists the financial assumptions The IRP is also the source of the DSM alternative costs, which is the basis for estimating the value of energy savings and demand reduction resulting from the DSM programs. The DSM alternative costs vary by season and time-of-day. The DSM alternative energy costs are based on either projected fuel costs of a natural gas peaking unit for peak summer hours or forward marginal prices as determined by the AURORAxmp® Electric Market Model. The avoided capacity resource for peak summer hours and for demand response programs is based on a 170 MW natural gas-fired, simple-cycle combustion turbine (SCCT).

The prices of avoided energy throughout the 20-year planning period were simulated using 2015 IRP Portfolio 6b. Portfolio 6b was run assuming 111d sensitivity #5 within the AURORA model. The AURORA model is a production cost tool that simulates hourly economic dispatch and commitment of supply-side, demand-side, and transmission resources. Idaho Power's setup of the AURORA model forecasts electric market prices throughout the Western Electricity Coordinating Council (WECC) region. AURORA also forecasts marginal electricity costs for Idaho Power. Marginal electricity costs are set by the highest variable cost resource that is dispatched in any given forecasted hour. Variable costs include variable O&M and variable fuel costs. Idaho Power modeled hourly, marginal electricity costs for the years 2015 through 2034 to estimate the potential system benefit of avoiding production of the next unit of energy. An initial run of marginal costs are run during the preliminary analysis phase of the IRP process. The preliminary runs will combine updated planning assumptions including load and natural gas price forecasts run against the current preferred resource portfolio from the previous IRP. After the selection of the preferred portfolio which for the 2015 IRP is portfolio 6b, a final run of marginal prices are run which become the avoided energy prices for DSM energy valuation until the next IRP cycle.

The forward prices are placed into five homogenous pricing categories for the convenience of cost-effectiveness calculation the categories follow the pattern of heavy and light load pricing throughout each year of the planning period. The resulting categories include the following:

- Summer On-Peak (SONP)—Average of Idaho Power variable energy and operating costs of a 170 MW SCCT, which is the marginal resource for peak hour load deficits during summertime heavy load hours
- Summer Mid-Peak (SMP)—Average of heavy load prices from June to August (excluding the SONP hours)
- Summer Off-Peak (SOFP)—Average of light load prices from June to August
- Non-Summer Mid-Peak (NSMP)—Average of heavy load prices in January through May and September through December
- Non-Summer Off-Peak (NSOFP)—Average of light load prices in January through May and September through December

The SONP is treated differently than the other four pricing periods when valuing energy efficiency. The estimated levelized capacity cost of a new SCCT is approximately $119 per kW over a 30-year period. The avoided capacity value is spread across the annual SONP hours to estimate the value of energy efficiency savings occurring during the hours. The total SONP hours vary between 512 to 528 hours depending on the year. When the levelized capacity cost of a new SCCT ($119/kW) is multiplied by the Effective Load Carry Capacity (ELCC) of 89 percent which is the estimated percent of top 100 peak load hours that demand response can cover, the annual avoided capacity cost is $106/kW. For demand response or direct load control DSM programs $106 per kW becomes the cost threshold for program cost-effectiveness on an annual per kW basis.

Annual benefits for demand response are also established as part of the IRP process once the value of the 170 MW SCCT is determined. The method for determining cost-effectiveness for demand response programs was updated in 2014 as part of a series of public workshop supporting IPUC Case No. IP-E-13-14 resulting in orders from both the IPUPC (No. 32980) and Oregon (No.13-482). The orders established that through the IRP process IPC will establish an annual operating cost ceiling tied to the levelized annual benefit of a 170-MW SCCT. The updated established annual value for the 2015 IRP is $18.5 million which is an increase from 16.7 million from the 2013 IRP. While the intent of the benefit calculation provides guidance for annual cost limit to operating demand response in years with no anticipated peak deficits, actual 2014 operating costs of demand response programs were considerable less at 10.6 million.

## Forecast and Cost-Effectiveness Data

Table DSM-1 lists the financial assumptions used for the cost-effectiveness analysis and new program screening.

Table DSM-2 shows the results of averaging forward marginal energy prices over the 20-year planning period that were determined as a result of the IRP planning process and selection of the preferred portfolio. The alternate cost prices for energy efficiency measures that have a life longer than the 20-year planning horizon, which is typical for weatherization and building shell measures, are escalated at 2.2 percent annually beyond the planning period.

Tables DSM-3 and DSM-4 show the distribution of the three summer and two non-summer pricing periods across the hours and days of the week and for holidays.

Tables DSM-5 and DSM-6 lists the 20-year cumulative forecasted impact of average energy (aMW) and on-peak reduction (MW) by customer class.

Table DSM-7 details the 20-year estimated utility or program administrator costs to support the achievable potential forecast by customer class.

Table DSM-8 details the 20-year estimated TRC that accounts for both program administration costs and incremental costs to acquire efficient measures and equipments by customers listed by customer class.

Table DSM-9 outlines the 20-year flow of total benefits attributed to energy efficiency programs including NEB associated with the forecast.

Table DSM-10 summarizes the cost-effectiveness analysis for energy efficiency programs through the 20-year IRP planning period.

**Table DSM-1. IRP financial assumptions**

| DSM Analysis Assumptions | |
|---|---|
| **Avoided 30-Year Levelized Capacity Costs** | |
| SCCT | $119/kW |
| **Financial Assumptions** | |
| Weighted average cost of capital (2014 year ending after tax) | 6.74% |
| Financial escalation factor | 2.20% |
| **Transmission Losses** | |
| Non-summer secondary losses | 9.60% |
| Summer peak loss | 9.70% |

# SUPPLY-SIDE RESOURCE DATA

## Key Financial and Forecast Assumptions

| Financing Cap Structure and Cost | |
|---|---|
| **Composition** | |
| Debt | 50.04% |
| Preferred | 0.00% |
| Common | 49.96% |
| **Total** | **100.00%** |
| **Cost** | |
| Debt | 5.73% |
| Preferred | 0.00% |
| Common | 10.00% |
| Average Weighted Cost | 7.86% |

| Financial Assumptions and Factors | |
|---|---|
| Plant operating (book) life | Expected Life of the Asset |
| Discount rate (weighted average cost of capital[1]) | 6.74% |
| Composite tax rate | 39.10% |
| Deferred rate | 35.00% |
| General O&M escalation rate | 2.20% |
| Annual property tax rate (% of investment) | 0.29% |
| Property tax escalation rate | 3.00% |
| Annual insurance premiums (% of investment) | 0.31% |
| Insurance escalation rate | 2.00% |
| AFUDC rate (annual) | 7.75% |

[1] Incorporates tax effects.

| Emission Intensity Rate (lbs per MWh by technology) | |
|---|---|
| | $CO_2$ |
| Small aeroderivative SCCT | 1,115 |
| Large aeroderivative SCCT | 1,047 |
| Large frame SCCT | 1,413 |
| CCCT 1x1 | 809 |
| CCCT 2x1 | 809 |
| Combined heat and power (CHP) | 1,115 |
| Distributed generation–gas fired | 1,115 |
| Pulverized coal | 1,901 |
| IGCC | 2,279 |
| IGCC w/carbon sequestration | 421 |

| Fuel Forecast Base Case (Nominal, $ per MMBtu) | | | |
|---|---|---|---|
| **Year** | **Natural Gas** | **Generic Coal** | **Nuclear** |
| 2015 | $5.10 | $1.47 | $0.51 |
| 2016 | $4.70 | $1.52 | $0.52 |
| 2017 | $4.76 | $1.55 | $0.53 |
| 2018 | $5.25 | $1.58 | $0.54 |
| 2019 | $5.69 | $1.61 | $0.56 |
| 2020 | $5.91 | $1.64 | $0.57 |
| 2021 | $6.14 | $1.69 | $0.58 |
| 2022 | $6.30 | $1.74 | $0.59 |
| 2023 | $6.58 | $1.78 | $0.61 |
| 2024 | $6.82 | $1.83 | $0.62 |
| 2025 | $7.04 | $1.87 | $0.63 |
| 2026 | $6.99 | $1.91 | $0.65 |
| 2027 | $7.09 | $1.98 | $0.66 |
| 2028 | $7.35 | $2.00 | $0.68 |
| 2029 | $7.69 | $2.07 | $0.69 |
| 2030 | $8.18 | $2.12 | $0.71 |
| 2031 | $8.62 | $2.16 | $0.72 |
| 2032 | $8.85 | $2.21 | $0.74 |

| SCCT—Frame F Class (170 MW) | 170 | 800 | 194 | $994 | $1,059 | 5 | 5 | 0 | 10,300 | 35 |
| Shoshone Falls Upgrade (49.5 MW) | 50 | 2,255 | 269 | $2,524 | $2,825 | 2 | 0 | 0 | NA | 75 |
| Small Modular Nuclear (250 MW) | 600 | 5,000 | 520 | $5,520 | $8,371 | 0 | 23 | 0 | 11,493 | 40 |
| Solar Power Tower (110 MW) | 110 | 6,250 | 330 | $6,580 | $7,710 | 82 | 3 | 6 | NA | 20 |
| Solar PV—Distr Residential Fixed S (10 MW) | 10 | 3,500 | 0 | $3,500 | $3,639 | 25 | 0 | 6 | NA | 20 |
| Solar PV—Distr C&I Fixed S (10 MW) | 10 | 2,500 | 0 | $2,500 | $2,599 | 13 | 0 | 6 | NA | 20 |
| Solar PV—Distr C&I Fixed SW (10 MW) | 10 | 2,500 | 0 | $2,500 | $2,599 | 13 | 0 | 6 | NA | 20 |
| Solar PV—Utility Scale Fixed S (10 MW) | 10 | 1,500 | 305 | $1,805 | $1,877 | 13 | 0 | 6 | NA | 20 |
| Solar PV—Utility Scale Fixed SW (10 MW) | 10 | 1,500 | 305 | $1,805 | $1,877 | 13 | 0 | 6 | NA | 20 |
| Solar PV—Utility Scale 1-Axis Tracking (10 MW) | 10 | 1,750 | 305 | $2,055 | $2,136 | 20 | 0 | 6 | NA | 20 |
| Solar PV—Utility Scale 2-Axis Tracking (10 MW) | 10 | 1,860 | 305 | $2,165 | $2,251 | 24 | 0 | 6 | NA | 20 |
| TurboPhase (23.6 MW) | 24 | 400 | 0 | $400 | $403 | 0 | 4 | 0 | 7,824 | 35 |
| Wind (100 MW) | 100 | 1,800 | 330 | $2,130 | $2,276 | 40 | 0 | 15 | NA | 25 |

[1] Plant costs include engineering development costs, generating and ancillary equipment purchase, and installation costs, as well as balance of plant construction.

[2] Total Investment includes capital costs and AFUDC.

[3] Fixed O&M excludes property taxes and insurance (separately calculated within the levelized resource cost analysis)

# Transmission Cost Assumptions

## *Cost Assumptions by Supply-Side Resource Type*

| Capacity (MW Rating) | Overnight Transmission Capital Cost/kW[1] | Cost Assumptions Notes | Local Interconnection Assumptions | Backbone Transmission Assumptions |
|---|---|---|---|---|
| Battery Storage | | | | |
| 6 | $0 | Assume location in or near existing substation. | No transmission upgrades required. | No backbone upgrades required. |
| Biomass Direct—Woody Residue | | | | |
| 35 | $357 | Assume a 20-mile, 138-kV line to existing Idaho Power 138-kV substation. Add 3 new 138-kV terminals. Assume $250k in communications upgrades. | Assume a 20-mile, 138-kV line interconnection to existing Idaho Power 138-kV substation. Add 3 new 138-kV terminals. Assume $250k in communications upgrades. | No backbone upgrades required. |
| Biomass Indirect—Anaerobic Digester | | | | |
| 3 | $133 | Assume distribution feeder location with no backbone transmission upgrades required. | Assume $300k of distribution feeder upgrades and $100k in substation upgrades. | No backbone upgrades required. |
| Coal—Integrated Gasification Combined Cycle (IGCC) | | | | |
| 580 | $745 | Assume resource is located close to future 500-kV Aeolus substation. Pro-rated share of 3000 MW Gateway West project, with estimated toal cost of $2.19 billion. | Assume resource is located close to future 500-kV Aeolus substation. Assume 2 new terminals at 500-kV substation. | Pro-rata share of Gateway. |
| Coal—IGCC with Carbon Capture and Sequestration | | | | |
| 600 | $744 | Assume resource is located close to future 500-kV Aeolus substation. Pro-rated share of 3000 MW Gateway West project, with estimated toal cost of $2.19 billion . | Assume resource is located close to future 500-kV Aeolus substation. Assume 2 new terminals at 500-kV substation. | Pro-rata share of Gateway. |
| Geothermal (binary-cycle)—Idaho | | | | |
| 30 | $850 | Assume Raft River area. Requires 45-mile, 138-kV line to existing Minidoka substation. Assume capacity fits on existing backbone. | New 45-mile, 138-kV line to Minidoka substation with new 138-kV substation line terminal bay. | No backbone upgrades required. |
| Hydro—Canal Drop (Seasonal) | | | | |
| 10 | $70 | Assume 46-kV sub-transmission or local feeder interconnection. Feeder rebuild or 46-kV upgrade would likely be required. | Assume 4 miles of distribution rebuild at $150k per mile plus $100k in substation upgrades. | No backbone upgrades required. |
| Hydro—Shoshone Falls Expansion | | | | |
| 50 | $269 | Line and station modifications required. New substation above existing power plant. | Assume $2 million for transmission line modifications, $7 million for station upgrades, and $4.3 million for Cliff substation modifications. | Part of Generation Interconnect Cluster Study. No further backbone upgrades required. |
| Hydro—Hydrokinetic (In stream) | | | | |
| 1 | $100 | Assume minor upgrades required to distribution feeder or substation. | Assume $100k in substation upgrades. | No backbone upgrades required. |
| ICE Thermal Storage | | | | |
| 10 | $0 | No transmission upgrades required. | No transmission upgrades required. | No backbone upgrades required. |
| Natural Gas—Simple Cycle Combustion Turbine (SCCT) Aeroderivative | | | | |
| 47 | $46 | Assume plant located at or near existing Bennett Mountain plant. Capacity would fit within existing transmission system between Bennett Mountain and Boise. | New 230-kV substation terminal and station modifications. | No backbone upgrades required. |

| Capacity (MW Rating) | Overnight Transmission Capital Cost/kW[1] | Cost Assumptions Notes | Local Interconnection Assumptions | Backbone Transmission Assumptions |
|---|---|---|---|---|
| Natural Gas—SCCT Frame F Class (Idaho Power's peaker plants use this technology) | | | | |
| 170 | $194 | Build new facility south of Boise (assume Simco Road area) with new 230-kV switching station; 22-mile, 230-kV line to Boise Bench Substation, and 230-kV double circuit in/out of Danskin–Hubbard 230-kV line. | New 230-kV switching station with a 22-mile, 230-kV line to Boise Bench Substation and 1 mile, 23-kV double circuit in/out of Danksin–Hubbard 230-kV line. | No backbone upgrades required. |
| Natural Gas—Reciprocating Gas Engine Wartsila 34SG | | | | |
| 4.1 | $73 | Assume distribution feeder location with no backbone transmission upgrades required. | Assume $300k of distribution feeder upgrades. | No backbone upgrades required. |
| Natural Gas—CCCT (1x1) F Class with Duct Firing | | | | |
| 270 | $122 | Build new facility south of Boise (assume Simco Road area) with new 230-kV switching station; 22-mile, 230-kV line to Boise Bench Substation, and 230-kV double circuit in/out of Danskin–Hubbard 230-kV line. | New 230-kV switching station with a 22-mile, 230-kV line to Boise Bench Substation and 1 mile, 23-kV double circuit in/out of Danksin–Hubbard 230-kV line. | No backbone upgrades required. |
| Natural Gas—CCCT (2x1) F Class | | | | |
| 580 | $101 | Build new facility south of Boise (assume Simco Road area) with new 230-kV switching station; 22-mile, 230-kV line to Boise Bench Substation, and 230-kV double circuit in/out of Danskin–Hubbard 230-kV line. | New 230-kV switching station with a 22-mile; 230-kV line to Boise Bench Substation and 28-mile, 230-kV line to Hubbard Substation. | No backbone upgrades required. Entire project assumed as backbone upgrade. |
| Natural Gas—Combined Heat and Power (CHP) | | | | |
| 45 | $57 | Assume 0.5 mile tap to existing 138-kV line and new 138-kV source substation (or large upgrade to existing substation). | Assume 0.5 mile tap to existing 138-kV line and new 138-kV source substation. | No backbone upgrades required. |
| Nuclear—Small Modular Reactor (SMR) | | | | |
| 45 | $358 | Tie into nearby 230-kV transmission substation. Backbone transmission uprgrades required. | Assume 2 mile, 138-kV interconnection to existing Antelope substation and one new 138-kV terminal. | Pro rata share of Gateway West upgrade from Populus to Cedar Hill to Hemingway. Assume 2.5% ownership of the 280-mile Gateway West segments from Populus to Cedar Hill and Cedar Hill to Hemingway. |
| Nuclear—SMR | | | | |
| 250 | $520 | Tie into nearby 230-kV transmission substation. Build new 55 mile, 230-kV line. Backbone transmission uprgrades required. | Two 2-mile, 138-kV lines to interconnect to Antelope Substation. New 230-kV transformer terminal. New parallel 55-mile, 230-kV line from Antelope to Brady Substation. New 230-kV terminal at Brady Substation. | Pro rata share of Gateway West upgrade from Populus to Cedar hill to Hemingway. Assume 12.5% ownership of the 280-mile Gateway West segments from Populus to Cedar Hill and Cedar Hill to Hemingway. |
| Nuclear—Advanced Nuclear | | | | |
| 1,100 | $441 | Two new 345kV transmission lines required. One 55 mile line from site to Borah Substation. One 85 mile line from site to Kinport Substation via Goshen Substation. | New 345 kV station. New 55 mile 345kV transmission line to existing Borah substation and new 345kV line terminal. New 85 mile transmission line to existing Kinport Substation through existing Goshen Substation and three new 345 kV line terminals. | Pro rata share of Gateway West upgrade from Populus to Cedar hill to Hemingway. Assume 50% ownership of the 280 mile Gateway West segments from Populus to Cedar Hill and Cedar Hill to Hemingway. |
| Pumped Storage—new upper reservoir and new generation/pumping plant (pumping water from an existing lower reservoir to a new upper reservoir then running the water through a new power plant) | | | | |
| 100 | $1,095 | Tie into existing Oxbow 230-/ 138-kV switchyard. New 230-kV transmission line required from Oxbow to Treasure Valley (no existing backbone capacity). | Assume 0.5 mile tap off of Oxbow 138-kV line. | New 110 mile, 230-kV line from Oxbow to Treasure Valley. |

| Capacity (MW Rating) | Overnight Transmission Capital Cost/kW[1] | Cost Assumptions Notes | Local Interconnection Assumptions | Backbone Transmission Assumptions |
|---|---|---|---|---|
| Solar Thermal—Solar Power Tower with storage | | | | |
| 100 | $330 | Assume Mountain Home desert area with 20-mile, 138-kV line to new substation intersecting existing Danskin—Hubbard 230-kV line. | New 230-kV switching station with a 22-mile, 230-kV line to Boise Bench Substation and 1-mile, 230-kV double circuit in/out of Danskin–Hubbard 230-kV line. | No backbone upgrades required. |
| Solar PV—Distributed Residential Fixed-Tilt (S Orientation) | | | | |
| 10 | $0 | Assume that no upgrades are required for small residential installations. | Assume that no upgrades are required for small residential installations. | No backbone upgrades required. |
| Solar PV—Distributed C&I Fixed-Tilt (S Orientation) | | | | |
| 10 | $0 | Assume that no upgrades are required for small C&I installations. | Assume that no upgrades are required for small C&I installations. | No backbone upgrades required. |
| Solar PV—Distributed C&I Fixed-Tilt (SW Orientation) | | | | |
| 10 | $0 | Assume that no upgrades are required for small C&I installations. | Assume that no upgrades are required for small C&I installations. | No backbone upgrades required. |
| Solar PV—Utility Scale Fixed-Tilt (S Orientation) | | | | |
| 10 | $305 | Assume 1 mile, 138-kV interconnection to existing 138-kV transmission line. One 138-kV line terminal. Assume $250k communication infrastructure upgrades. | Assume 1 mile, 138-kV interconnection to existing 138-kV transmission line. One 138-kV line terminal. Assume $250 communication infrastructure upgrades. | Assume that no backbone upgrades are required for 10 MW (depending on point in time, assumption may not be valid if PURPA projects are constructed in the same geographic area). |
| Solar PV—Utility Scale Fixed-Tilt (SW Orientation) | | | | |
| 10 | $305 | Assume 1 mile, 138-kV interconnection to existing 138-kV transmission line. One 138-kV line terminal. Assume $250k communication infrastructure upgrades. | Assume 1 mile, 138-kV interconnection to existing 138-kV transmission line. One 138-kV line terminal. Assume $250 communication infrastructure upgrades. | Assume that no backbone upgrades are required for 10 MW (depending on point in time, assumption may not be valid if PURPA projects are constructed in the same geographic area). |
| Solar PV—Utility Scale 1-Axis Tracking | | | | |
| 10 | $305 | Assume 1 mile, 138-kV interconnection to existing 138-kV transmission line. One 138-kV line terminal. Assume $250k communication infrastructure upgrades. | Assume 1 mile, 138-kV interconnection to existing 138-kV transmission line. One 138-kV line terminal. Assume $250 communication infrastructure upgrades. | Assume that no backbone upgrades are required for 10 MW (depending on point in time, assumption may not be valid if PURPA projects are constructed in the same geographic area). |
| Solar PV—Utility Scale 2-Axis Tracking | | | | |
| 10 | $305 | Assume 1 mile, 138-kV interconnection to existing 138-kV transmission line. One 138-kV line terminal. Assume $250k communication infrastructure upgrades. | Assume 1 mile, 138-kV interconnection to existing 138-kV transmission line. One 138-kV line terminal. Assume $250 communication infrastructure upgrades. | Assume that no backbone upgrades are required for 10 MW (depending on point in time, assumption may not be valid if PURPA projects are constructed in the same geographic area). |
| Transmission—Boardman to Hemingway | | | | |
| Inbound<br>350—Average<br>500—Summer<br>350—Winter | $711 | Per the B2H Funding Agreement, Idaho Power's share of the project is roughly 21.2% of total project cost. Assume approximately $16 million in B2H 230-kV integration costs. | New 230-kV transmission circuit from Hemingway Substation to Bowmont Substation. New 230-kV line from Bowmont Substation to Hubbard Substation and 138-kV line re-configuration. | Pro-rata share of B2H project. |
| Wind—Idaho | | | | |
| 100 | $330 | Assume location near Midpoint Substation or Justice Substation. Estimated $1.5 million for upgrades at Midpoint or Justice Substation plus 100 MW pro-rata share of 2,000-MW Gateway West 500-kV project from Midpoint/Cedar Hill Substation to Hemingway Substation. | Assume 10 miles of 138-kV local transmission to project site with 138-kV substation and 138-/ 230-kV transformer. | Assume $1.5 million for upgrades at Midpoint Substation or Justice Substation. Assume 5% share of estimated $425 million Gateway West 500kV project from Midpoint/Cedar Hill Substation to Hemingway Substation. |

# Levelized Cost of Production

**30-Year Levelized Cost of Production (at stated capacity factors)**

| Supply-Side Resources | Cost of Capital | Non-Fuel O&M[1] | Fuel | Wholesale Energy | Net of Tax Credit/Steam sales/Integration | Total Cost per MWh | Capacity Factor |
|---|---|---|---|---|---|---|---|
| Advanced Nuclear (250 MW) | $88 | $25 | $7 | $0 | $0 | $119 | 90% |
| Battery Storage (6 MW) | $216 | $24 | $0 | $46 | $0 | $285 | 25% |
| Biomass Direct—Woody Residue (35 MW) | $44 | $40 | $19 | $0 | $0 | $102 | 85% |
| Biomass Indirect— Anaerobic Digester (3 MW) | $87 | $33 | $0 | $0 | $0 | $119 | 75% |
| Boardman to Hemingway (350 MW) | $21 | $2 | $0 | $54 | $0 | $78 | 33% |
| Canal Drop Hydro (1.28 MW) | $135 | $24 | $0 | $0 | $0 | $159 | 33% |
| CCCT (1x1) F Class with Duct Firing (270 MW) | $25 | $6 | $49 | $0 | $0 | $79 | 70% |
| CCCT (2x1) F Class (580 MW) | $20 | $7 | $48 | $0 | $0 | $75 | 70% |
| CHP (45 MW) | $32 | $19 | $46 | $0 | -$16 | $81 | 80% |
| IGCC (580 MW) | $71 | $28 | $17 | $0 | $0 | $116 | 75% |
| IGCC with Carbon Capture (580 MW) | $127 | $37 | $21 | $0 | $0 | $184 | 75% |
| Geothermal (30 MW) | $64 | $43 | $0 | $0 | -$6 | $101 | 90% |
| ICE Thermal Storage (10 MW) | $171 | $53 | $0 | $0 | $0 | $224 | 10% |
| Pumped Storage (150 MW) | $304 | $42 | $0 | $57 | $0 | $403 | 25% |
| Reciprocating Gas Engine (18.8 MW) | $66 | $14 | $55 | $0 | $0 | $136 | 10% |

## Peak-Hour Capacity Credit (Contribution to Peak)—Solar and Wind Resources

Peak hour capacity credit (contribution to peak) for new IRP intermittent generation resources:

| New IRP intermittent generation—Peak hour capacity credit | |
|---|---|
| **Resource** | **Peak Hour Capacity Credit** |
| PV solar south orientation | 28.4% |
| PV solar southwest orientation | 45.4% |
| PV solar single-axis tracking | 51.3% |
| Wind | 5.0% |

# Energy Shape—Solar

## *2015 IRP Assumed Solar Capacity Factors*

| Month | Utility Scale, Single Axis Tracking | Residential, Fixed Tilt |
|---|---|---|
| January | 12% | 7% |
| February | 19% | 11% |
| March | 26% | 16% |
| April | 32% | 20% |
| May | 37% | 23% |
| June | 41% | 25% |
| July | 42% | 26% |
| August | 39% | 24% |
| September | 33% | 20% |
| October | 25% | 16% |
| November | 14% | 9% |
| December | 11% | 7% |
| **Annual Capacity Factor** | **27.5%** | **17.0%** |

# PURPA Reference Data

The following information is provided for PURPA reference purposes.

1. Preferred portfolio: Portfolio P6(b)

## *Resource portfolio P6(b)*

| Date | Resource | Installed Capacity | Peak-Hour Capacity |
|---|---|---|---|
| 2025 | B2H | 500 MW transfer capacity April–Sep<br>200 MW transfer capacity Oct–Mar | 500 MW |
| 2025 | Retire North Valmy (both units) | (262 MW) | (262 MW) |
| 2030 | Demand response | 60 MW | 60 MW |
| 2030 | Ice-based TES | 20 MW | 20 MW |
| 2031 | CCCT | 300 MW | 300 MW |
| | | Total retired capacity | (262 MW) |
| | | Total added capacity | 880 MW |
| | | Net peak-hour capacity | 618 MW |

2. Deficiency period under preferred portfolio

   1st capacity deficit = (14) MW July 2025
   1st energy deficit = (34) MW July 2026

   Note—Above deficits are based on 461 MW of installed PV solar capacity under contract at the time of portfolio design, and do not reflect the April 2015 cancellation of 141 MW of PV solar PURPA contracts. With removal of the 141 MW of PV solar PURPA contracts, the first deficits for capacity and energy are respectively (47) MW in July 2024 and (76) MW in July 2026.

3. Intermittent generation integration costs

   See integration cost schedule included in *Appendix C—Technical Appendix*, section *Schedule 87—Integration Costs for Solar and Wind Resources*.

# Renewable Energy Certificate Price Forecast

| 2034 | $10.38 |

# JIM BRIDGER UNITS 3 AND 4 SELECTIVE CATALYTIC REDUCTION ANALYSIS

The 2015 Jim Bridger Plant units 3 and 4 Selective Catalytic Reduction (SCR) Analysis (2015 SCR Analysis) is intended to satisfy the conditions set forth by the Idaho Public Utilities Commission (IPUC) in Order No. 32929 approving the Certificate of Public Convenience and Necessity (CPCN) for the investment in SCR controls on Jim Bridger units 3 and 4. Commission Order No. 32929 directs Idaho Power to be "continuously analyzing the impact of changing environmental regulations on its upgrade project." (Order No. 32929, p. 11). In addition to the above requirement, the company files quarterly reports in Docket No. IPC-E-13-16 providing updates as to the current status of environmental policies that are relevant to the construction of the SCR controls at Jim Bridger units 3 and 4, construction progress updates, and any other pertinent updates related to the SCRs.

The company's 2015 SCR Analysis evaluates the impacts of new environmental regulations proposed since the company filed its Coal Unit Environmental Analysis in 2013 (2013 Coal Study) as well as the cost-effectiveness of continuing the installation of the SCRs compared to shutting down units 3 and 4 and replacing that generation with an alternate generation resource.

## Background

The Jim Bridger coal-fired power plant (Jim Bridger Plant) consists of four units and is located near Rock Springs, Wyoming. Idaho Power owns one-third of the Jim Bridger Plant with the other two-thirds owned by PacifiCorp. The plant is maintained and operated by PacifiCorp. Units 3 and 4 have nominal net generation capacities of 523 and 530 megawatts (MW) respectively, and Idaho Power's share of the generation capacity is approximately 351 MW from both units.

Currently, the Jim Bridger Plant is required to meet SCR-based emission limits of 0.07 lb/MMBtu for nitrogen oxides (NOx) for all four units to comply with the U.S. Environmental Protection Agency (EPA) Regional Haze (RH) rules and the resulting Wyoming State Implementation Plan (SIP). SCRs are used to facilitate a chemical reaction between NOx (created during combustion) and ammonia to create nitrogen and water.

In 2013, as part of the 2011 IRP Update, the company filed its 2013 Coal Study which examined future investments required for environmental compliance in existing coal units and compared those investments to the costs of alternative replacement resources. The results of the 2013 Coal Study analysis for Jim Bridger identified additional investments in environmental controls on all four Jim Bridger units as prudent decisions that represented the lowest cost and least-risk option when compared to the other investment alternatives. The company used the results of the 2013 Coal Study to support its Application for approval of a CPCN for the investment in SCRs on units 3 and 4. Subsequently, the IPUC issued its approval of the CPCN in December 2013 and construction of the SCRs began shortly after.

## SCR Construction Progress Update

The major components of an SCR upgrade consist of: large particle ash collection, ammonia injection grid, the SCR reactor vessel (which contains the catalyst modules), and all added flue gas path ductwork. In addition to the SCR, Unit 4 will require larger induced draft fans to compensate for the flow restriction of the SCR reactor.

Construction of the SCRs is ongoing; as of May 2015, 99 percent of the 2,588 tons of the Unit 3 structural steel and 83 percent of the 7,570 linear feet of the SCR reactor piping has been completed. For Unit 4, 63 percent of the 3,031 tons of structural steel has been completed.

The Unit 3 SCR is scheduled to be completed by November 5, 2015, with a Wyoming SIP compliance deadline of December 31, 2015. Unit 4 is scheduled for completion by November 3, 2016, with a Wyoming SIP compliance date of December 31, 2016.

## 2015 Jim Bridger Units 3 and 4 SCR Analysis

The 2015 SCR Analysis re-examines the previous conclusion that installation of the SCRs on units 3 and 4 is the least-cost and least-risk means of ensuring that units 3 and 4 comply with state and federal emissions regulations. The 2015 SCR Analysis had two objectives:

1. Evaluate changes in environmental requirements since the 2013 Coal Study that may have an impact on the cost-effectiveness and/or viability of the SCRs on units 3 and 4, and

2. Determine the cost-effectiveness of installing the SCRs compared to the fixed costs of replacing the coal-fired generation from units 3 and 4 with a combined-cycle combustion turbine (CCCT) generation resource alternative.

### *Changes in Environmental Regulations*

On June 2, 2014, the EPA released its draft proposal to regulate carbon dioxide ($CO_2$) emissions from existing power plants. In the rule, the EPA proposes enforceable $CO_2$ performance goals that are based on a bottom-up, multi-factor analysis that reflects a system-wide approach of four building blocks, including increasing efficiency of the existing coal-fired generation, natural gas re-dispatch, renewable energy deployment, and demand-side energy efficiency. The goals take the form of state-wide carbon intensity rates for the state's electric power sector. Each state's goal reflects an emissions target (stated as lbs of $CO_2$/MWh of generation) that EPA has determined to be reasonable based upon the theoretical application of the "best system of emission reduction" for fossil-fueled power plants.

The proposal directs states to submit plans for meeting their goals. States may also work together to submit a single, coordinated multi-state plan. States and multi-state groups have a June 2016 deadline for submitting their plans, with the possibility of a 1- or 2-year extension depending on the plan type. Under the proposed rule, each state's plan must be approved by the EPA, based on modeling projections by the state that demonstrate, to the agency's satisfaction, that the plan will be adequate to meet EPA's determination of the state's interim and final goals. State plans do not need to rely upon the four building block measures EPA used to construct each state's goal. Rather, each state has relatively broad discretion to determine the policy measures on which it will rely to meet its goal.

There are several alternative approaches to 111(d) compliance. The individual states where the generators are physically located will determine the final impact to each of the affected units. Idaho Power has reviewed the Wyoming intensity targets and alternative approaches to compliance, and the company believes that there will be minimal impact on the normal operation of Jim Bridger units 3 and 4.

### *SCR Cost-Effectiveness*

To determine if the SCRs on units 3 and 4 continue to be the least-cost and least-risk option for compliance, the 2015 SCR Analysis compared the costs of two compliance options:

**Option 1**—Continue to install SCRs for compliance with state and federal environmental regulations

**Option 2**—Stop installation of SCRs and replace the coal-fired generation from units 3 and 4 with a CCCT.

## Overall Analysis Methodology

The study approach examined the costs and benefits of each option. The company's share of the nominal generation capacity at units 3 and 4 of 351 MW was assumed to be replaced with a CCCT with the same capacity. Incremental capital investment and fixed operations and maintenance (O&M) were included in the analysis. In addition, the fuel and variable O&M were forecasted for the duration of the study period to forecast the total cost of generation, both fixed and variable, for each compliance option.

The 2015 SCR Analysis utilized a 20-year study period over which the costs of both options are calculated. One difference between the 2015 SCR Analysis and the 2013 Coal Study is the inclusion of the return on investment in the net present value (NPV) calculations. In the 2013 Coal Study, the Science Applications International Corporation (SAIC) capital evaluation approach evaluated the capital costs of construction *without* the associated return on investment that is included in the company's regulatory revenue requirement determinations.

## Option 1 NPV Methodology

The company determined the cost of Option 1 by calculating the revenue requirement of the existing investment in units 3 and 4, incremental capital additions over the study period, the SCR capital costs (total SCR construction costs and fixed O&M) over the study period, and decommissioning costs. The additional costs of fuel and O&M related to operating the units over the study period were added to the revenue requirement of the capital investments.

The revenue requirement associated with the existing investment in units 3 and 4 includes the return on the existing investment for units 3 and 4, O&M, and fuel costs over the study period. The O&M information used in the analysis comes from the company's 10-year budget information from the Jim Bridger Plant forecast through the end of the study period. The company used data from its coal price forecast over the study period to determine the annual fuel expense including transportation costs. The company's coal price forecast is based on long-term contracts for supplying coal to the Jim Bridger Plant. The incremental capital additions include the cost of the SCRs as well as routine capital expenditures for maintenance and repairs throughout the study period. Also included as part of the costs of Option 1 are the decommissioning costs for units 3 and 4 that will be required when the units are retired. The company took the present value of the annual cost stream over the study period to determine the cost of Option 1. The cost of continuing to install the SCRs for compliance is $1.42 billion over the study period.

## Option 2 NPV Methodology

The costs of Option 2 is the combination of the costs to shutdown units 3 and 4 and build a CCCT to replace the generation from those shuttered units. The shutdown costs of units 3 and 4 include the accelerated recovery of the existing investment at units 3 and 4, accelerated recovery of the costs-to-date of the SCRs (dollars committed including cancelation penalties as of December 31, 2014), and decommissioning costs. By shutting down units 3 and 4 early, future ongoing capital costs on units 3 and 4 are avoided. The revenue requirement of the CCCT includes construction costs, fixed O&M, and return on investment over a 20-year period. The cost of the CCCT was based on the costs identified in the 2015 IRP for this type of resource. The assumption is that the CCCT would be sized to exactly replace the MW capacity of units 3 and 4. The CCCT in the analysis has an 85 percent capacity factor with an assumed heat rate of 6,714 Btu/kWh. The natural gas price forecast used in the analysis is an Idaho Citygate price forecast based on the 2015 IRP. The Idaho Citygate price is a Henry hub gas price with a Sumas hub differential applied plus transportation costs. It is assumed the CCCT would be sited in a region with access to the Sumas hub natural gas pricing, with additional gas transportation charges and capacity to a generic Idaho Citygate. The costs of shuttering units 3 and 4 and replacing that capacity with a CCCT are $2.496 billion over the study period.

## Analysis Results

Over the study period, the NPV of Option 1 is $1.420 billion and the NPV of Option 2 is $2.496 billion. Option 1, continuing to install the SCRs for compliance, is $1.076 billion less than compliance alternative Option 2.

The company performed additional analyses on the results to determine the main drivers of the $1.076 billion difference. As shown in the table below, $793 million was due to higher fuel costs in Option 2, $186 million was due to a higher return on capital investment in Option 2 due to the higher capital costs, O&M costs were $35 million less than Option 1 as a CCCT would be less O&M intensive than the Jim Bridger Plant, and capital costs for Option 2 were $132 million higher.

### *Option 2 Impact of Various Cost Drivers*

| | |
|---|---|
| Impact from fuel costs: | $793,308,007 |
| Impact from ROI: | 185,890,627 |
| Impact from difference in O&M: | (35,319,989) |
| Impact due to difference in capital costs: | 132,407,174 |
| **Total** | **$1,076,285,819** |

## Conclusions and Recommendations

Based on the 2015 SCR Analysis, continuing with the installation of the SCRs on units 3 and 4 represents a cost savings of $1.076 billion compared to shuttering units 3 and 4 and replacing that generation with a CCCT resource. The company evaluated the changes in environmental regulations proposed since the 2013 Coal Study and believes there will be little impact to the normal operation of units 3 and 4. The SCRs remain the least-cost and least risk option for compliance and the company will continue the installation of the SCRs on units 3 and 4.

# Revenue Requirement Comparison between Jim Bridger Units 3 and 4 SCR Completion and CCCT Replacement

## *Revenue Requirement on Existing Investments*

| Year | Existing Investments |
|---|---|
| 2015 | $101,017,077 |
| 2016 | $101,191,683 |
| 2017 | $102,260,140 |
| 2018 | $102,958,825 |
| 2019 | $103,167,948 |
| 2020 | $94,039,451 |
| 2021 | $91,247,597 |
| 2022 | $91,513,087 |
| 2023 | $94,069,370 |
| 2024 | $107,116,956 |
| 2025 | $108,120,849 |
| 2026 | $109,746,974 |
| 2027 | $111,413,380 |
| 2028 | $113,148,724 |
| 2029 | $114,824,751 |
| 2030 | $116,577,779 |
| 2031 | $118,486,952 |
| 2032 | $120,459,297 |
| 2033 | $122,496,977 |
| 2034 | $124,607,408 |
| **Total** | **$2,148,465,226** |

| **Total IPC Generation** | **3,965,229** | **3,594,398** | | | |

1 A power factor rating of 0.8 is assumed on four units (Clear Lake, Shoshone Falls unit 2, and Thousand Springs units 1 and 2) with a total kVA rating of 6,127 kVA where there is no nameplate kW rating.

2 The two smaller units, 1 and 2, have nameplate ratings of 1.25 MVA and 1 MW and are not in service due to reduced flows from the springs and penstock integrity.

3 The Swan Falls units have been limited to 24,170 kW as a result of vibration issues.

4 Normal Rating is the normal kW output of the facility with all units on-line. This rating includes all equipment limitations and may be lower than the nameplate rating. To operate at the Normal Rating, appropriate water conditions must exist and the FERC license requirements permit.

5 Emergency Rating is the maximum kW output of the facility with all units on-line. The Emergency Rating is based on manufacturer guidelines, ANSI standards, and limited by auxiliary equipment ratings. To operate at the Emergency Rating, appropriate water conditions must exist and the FERC license requirements permit.

6 Ratings for coal-fired generators are provided by Idaho Power's thermal partners who operate these plants.

7 NDC is defined in the NERC Generating Availability Data System (GADS) as Gross Dependable Capacity (GDC) less the unit capacity utilized for that unit's station service or auxiliaries. GDC is the Gross Maximum Capacity (GMC) modified for seasonal limitations over a specified period of time. The GDC and Maximum Dependable Capacity (MDC) used in previous GADS reports are the same in intent and purpose. GMC is the maximum capacity a unit can sustain over a specified period of time when not restricted by seasonal or other de-ratings.

| **Total Wind Nameplate Rating 626.92 MW** | | | | | | | |
| **Total Nameplate Rating 1,161.80 MW** | | | | | | | |

The above is a summary of the Nameplate rating for the CSPP projects under contract with Idaho Power as of May 26, 2015. In the case of CSPP projects, Nameplate rating of the actual generation units is not an accurate or reasonable estimate of the actual energy these projects will deliver to Idaho Power. Historical generation information, resource specific industry standard capacity factors, and other known and measurable operating characteristics are accounted for in determining a reasonable estimate of the energy these projects will produce.

# Power Purchase Agreement Data

**Idaho Power Company Power Purchase Agreements Status as of April 1, 2015**

| Project | MW | Contract On-Line Date | Contract End Date |
|---|---|---|---|
| **Wind projects** | | | |
| Elkhorn Wind Project | 101 | December 2007 | December 2027 |
| **Total wind nameplate MW rating** | 101 | | |
| **Geothermal Projects** | | | |
| Raft River Unit 1 | 13 | April 2008 | April 2033 |
| Neal Hot Springs | 22 | November 2012 | November 2037 |
| **Total geothermal nameplate MW rating** | 35 | | |
| **Total nameplate MW rating** | 136 | | |

1. Above is a summary of the nameplate ratings for the Power Purchase Agreements under contract with Idaho Power. Nameplate ratings of the actual generation units are not an accurate or reasonable estimate of the actual energy these projects will deliver to Idaho Power. Historical generation information, resource-specific industry standard capacity factors, and other known and measurable operating characteristics are accounted for in determining a reasonable estimate of the energy the projects will produce.
2. Not included in the above table is the energy exchange agreement between Idaho Power and the Clatskanie PUD. Under the exchange, Idaho Power receives energy from the 18-MW power plant at Arrowrock Dam on the Boise River and returns to Clatskanie PUD energy of an equivalent value delivered seasonally. The agreement began in January 2010 and extends through 2015. Idaho Power retains the right to renew the agreement through 2025.

# STATE OF OREGON IRP GUIDELINES

ORDER NO. 07-047

ENTERED 02/09/07

**BEFORE THE PUBLIC UTILITY COMMISSION**

**OF OREGON**

UM 1056

| | | |
|---|---|---|
| In the Matter of<br><br>PUBLIC UTILITY COMMISSION OF OREGON<br><br>Investigation Into Integrated Resource Planning. | )<br>)<br>)<br>)<br>)<br>)<br>) | ERRATA ORDER |

DISPOSITION: APPENDIX TO ORDER NO. 07-002 CORRECTED

In Order No. 07-002, we adopted guidelines to govern the Integrated Resource Planning (IRP) process. In setting forth those guidelines in an appendix, we inadvertently omitted Guideline 1(d), which we discussed and adopted in the body of the order on pages 7 and 8. Accordingly, Appendix A to Order No. 07-002 is replaced with the attached appendix to this order, which includes all the adopted guidelines. The remainder of the order is unchanged.

IT IS SO ORDERED.

Made, entered, and effective FEB 0 9 2007.

**Lee Beyer**
Chairman

**John Savage**
Commissioner

**Ray Baum**
Commissioner

A party may request rehearing or reconsideration of this order pursuant to ORS 756.561. A request for rehearing or reconsideration must be filed with the Commission within 60 days of the date of service of this order. The request must comply with the requirements in OAR 860-014-0095. A copy of any such request must also be served on each party to the proceeding as provided by OAR 860-013-0070(2). A party may appeal this order by filing a petition for review with the Court of Appeals in compliance with ORS 183.480-183.484.

**Adopted IRP Guidelines**

**Guideline 1: Substantive Requirements**

*a. All resources must be evaluated on a consistent and comparable basis.*

- *All known resources for meeting the utility's load should be considered, including supply-side options which focus on the generation, purchase and transmission of power – or gas purchases, transportation, and storage – and demand-side options which focus on conservation and demand response.*
- *Utilities should compare different resource fuel types, technologies, lead times, in-service dates, durations and locations in portfolio risk modeling.*
- *Consistent assumptions and methods should be used for evaluation of all resources.*
- *The after-tax marginal weighted-average cost of capital (WACC) should be used to discount all future resource costs.*

*b. Risk and uncertainty must be considered.*

- *At a minimum, utilities should address the following sources of risk and uncertainty:*
  1. *Electric utilities: load requirements, hydroelectric generation, plant forced outages, fuel prices, electricity prices, and costs to comply with any regulation of greenhouse gas emissions.*
  2. *Natural gas utilities: demand (peak, swing and base-load), commodity supply and price, transportation availability and price, and costs to comply with any regulation of greenhouse gas emissions.*
- *Utilities should identify in their plans any additional sources of risk and uncertainty.*

*c. The primary goal must be the selection of a portfolio of resources with the best combination of expected costs and*

*associated risks and uncertainties for the utility and its customers.*[1]

- *The planning horizon for analyzing resource choices should be at least 20 years and account for end effects. Utilities should consider all costs with a reasonable likelihood of being included in rates over the long term, which extends beyond the planning horizon and the life of the resource.*

- *Utilities should use present value of revenue requirement (PVRR) as the key cost metric. The plan should include analysis of current and estimated future costs for all long-lived resources such as power plants, gas storage facilities, and pipelines, as well as all short-lived resources such as gas supply and short-term power purchases.*

- *To address risk, the plan should include, at a minimum:*

  1. *Two measures of PVRR risk: one that measures the variability of costs and one that measures the severity of bad outcomes.*

  2. *Discussion of the proposed use and impact on costs and risks of physical and financial hedging.*

- *The utility should explain in its plan how its resource choices appropriately balance cost and risk.*

d. *The plan must be consistent with the long-run public interest as expressed in Oregon and federal energy policies.*

**Guideline 2: Procedural Requirements.**

a. *The public, which includes other utilities, should be allowed significant involvement in the preparation of the IRP. Involvement includes opportunities to contribute information and ideas, as well as to receive information. Parties must have an opportunity to make relevant inquiries of the utility formulating the plan. Disputes about whether information requests are relevant or unreasonably burdensome, or whether a utility is being properly responsive, may be submitted to the Commission for resolution.*

[1] We sometimes refer to this portfolio as the "best cost/risk portfolio."

*b. While confidential information must be protected, the utility should make public, in its plan, any non-confidential information that is relevant to its resource evaluation and action plan. Confidential information may be protected through use of a protective order, through aggregation or shielding of data, or through any other mechanism approved by the Commission.*

*c. The utility must provide a draft IRP for public review and comment prior to filing a final plan with the Commission.*

**Guideline 3: Plan Filing, Review, and Updates.**

*a. A utility must file an IRP within two years of its previous IRP acknowledgment order. If the utility does not intend to take any significant resource action for at least two years after its next IRP is due, the utility may request an extension of its filing date from the Commission.*

*b. The utility must present the results of its filed plan to the Commission at a public meeting prior to the deadline for written public comment.*

*c. Commission staff and parties should complete their comments and recommendations within six months of IRP filing.*

*d. The Commission will consider comments and recommendations on a utility's plan at a public meeting before issuing an order on acknowledgment. The Commission may provide the utility an opportunity to revise the plan before issuing an acknowledgment order.*

*e. The Commission may provide direction to a utility regarding any additional analyses or actions that the utility should undertake in its next IRP.*

*f. Each utility must submit an annual update on its most recently acknowledged plan. The update is due on or before the acknowledgment order anniversary date. Once a utility anticipates a significant deviation from its acknowledged IRP, it must file an update with the Commission, unless the utility is within six months of filing its next IRP. The utility must summarize the update at a Commission public meeting. The utility may request acknowledgment of changes in proposed actions identified in an update.*

g. *Unless the utility requests acknowledgement of changes in proposed actions, the annual update is an informational filing that:*

- *Describes what actions the utility has taken to implement the plan;*
- *Provides an assessment of what has changed since the acknowledgment order that affects the action plan, including changes in such factors as load, expiration of resource contracts, supply-side and demand-side resource acquisitions, resource costs, and transmission availability; and*
- *Justifies any deviations from the acknowledged action plan.*

**Guideline 4: Plan Components.**

*At a minimum, the plan must include the following elements:*

a. *An explanation of how the utility met each of the substantive and procedural requirements;*

b. *Analysis of high and low load growth scenarios in addition to stochastic load risk analysis with an explanation of major assumptions;*

c. *For electric utilities, a determination of the levels of peaking capacity and energy capability expected for each year of the plan, given existing resources; identification of capacity and energy needed to bridge the gap between expected loads and resources; modeling of all existing transmission rights, as well as future transmission additions associated with the resource portfolios tested;*

d. *For natural gas utilities, a determination of the peaking, swing and base-load gas supply and associated transportation and storage expected for each year of the plan, given existing resources; and identification of gas supplies (peak, swing and base-load), transportation and storage needed to bridge the gap between expected loads and resources;*

e. *Identification and estimated costs of all supply-side and demand-side resource options, taking into account anticipated advances in technology;*

*f. Analysis of measures the utility intends to take to provide reliable service, including cost-risk tradeoffs;*

*g. Identification of key assumptions about the future( e.g., fuel prices and environmental compliance costs) and alternative scenarios considered;*

*h. Construction of a representative set of resource portfolios to test various operating characteristics, resource types, fuels and sources, technologies, lead times, in-service dates, durations and general locations – system-wide or delivered to a specific portion of the system;*

*i. Evaluation of the performance of the candidate portfolios over the range of identified risks and uncertainties;*

*j. Results of testing and rank ordering of the portfolios by cost and risk metric, and interpretation of those results;*

*k. Analysis of the uncertainties associated with each portfolio evaluated;*

*l. Selection of a portfolio that represents the best combination of cost and risk for the utility and its customers;*

*m. Identification and explanation of any inconsistencies of the selected portfolio with any state and federal energy policies that may affect a utility's plan and any barriers to implementation; and*

*n. An action plan with resource activities the utility intends to undertake over the next two to four years to acquire the identified resources, regardless of whether the activity was acknowledged in a previous IRP, with the key attributes of each resource specified as in portfolio testing.*

**Guideline 5: Transmission.**

*Portfolio analysis should include costs to the utility for the fuel transportation and electric transmission required for each resource being considered. In addition, utilities should consider fuel transportation and electric transmission facilities as resource options, taking into account their value for making additional purchases and sales, accessing less costly resources in remote*

*locations, acquiring alternative fuel supplies, and improving reliability.*

**Guideline 6: Conservation.**

a. *Each utility should ensure that a conservation potential study is conducted periodically for its entire service territory.*

b. *To the extent that a utility controls the level of funding for conservation programs in its service territory, the utility should include in its action plan all best cost/risk portfolio conservation resources for meeting projected resource needs, specifying annual savings targets.*

c. *To the extent that an outside party administers conservation programs in a utility's service territory at a level of funding that is beyond the utility's control, the utility should:*

   - *Determine the amount of conservation resources in the best cost/risk portfolio without regard to any limits on funding of conservation programs; and*

   - *Identify the preferred portfolio and action plan consistent with the outside party's projection of conservation acquisition.*

**Guideline 7: Demand Response.**

*Plans should evaluate demand response resources, including voluntary rate programs, on par with other options for meeting energy, capacity, and transmission needs (for electric utilities) or gas supply and transportation needs (for natural gas utilities).*

**Guideline 8: Environmental Costs.**

*Utilities should include, in their base-case analyses, the regulatory compliance costs they expect for carbon dioxide ($CO_2$), nitrogen oxides, sulfur oxides, and mercury emissions. Utilities should analyze the range of potential $CO_2$ regulatory costs in Order No. 93-695, from zero to $40 (1990$). In addition, utilities should perform sensitivity analysis on a range of reasonably possible cost adders for nitrogen oxides, sulfur oxides, and mercury, if applicable.*

**Guideline 9: Direct Access Loads.**

*An electric utility's load-resource balance should exclude customer loads that are effectively committed to service by an alternative electricity supplier.*

**Guideline 10: Multi-state Utilities.**

*Multi-state utilities should plan their generation and transmission systems, or gas supply and delivery, on an integrated-system basis that achieves a best cost/risk portfolio for all their retail customers.*

**Guideline 11: Reliability.**

*Electric utilities should analyze reliability within the risk modeling of the actual portfolios being considered. Loss of load probability, expected planning reserve margin, and expected and worst-case unserved energy should be determined by year for top-performing portfolios. Natural gas utilities should analyze, on an integrated basis, gas supply, transportation, and storage, along with demand-side resources, to reliably meet peak, swing, and base-load system requirements. Electric and natural gas utility plans should demonstrate that the utility's chosen portfolio achieves its stated reliability, cost and risk objectives.*

**Guideline 12: Distributed Generation.**

*Electric utilities should evaluate distributed generation technologies on par with other supply-side resources and should consider, and quantify where possible, the additional benefits of distributed generation.*

**Guideline 13: Resource Acquisition.**

a. *An electric utility should, in its IRP:*

   - *Identify its proposed acquisition strategy for each resource in its action plan.*
   - *Assess the advantages and disadvantages of owning a resource instead of purchasing power from another party.*
   - *Identify any Benchmark Resources it plans to consider in competitive bidding.*

b. *Natural gas utilities should either describe in the IRP their bidding practices for gas supply and transportation, or provide a description of those practices following IRP acknowledgment.*

# Compliance with State of Oregon IRP Guidelines

| Oregon Order 07-047 Action Items | 2015 IRP |
|---|---|
| **Guideline 1: Substantive Requirements**<br>a. All resources must be evaluated on a consistent and comparable basis.<br>• All known resources for meeting the utility's load should be considered, including supply-side options which focus on the generation, purchase and transmission of power – or gas purchases, transportation, and storage – and demand side options which focus on conservation and demand response.<br>• Utilities should compare different resource fuel types, technologies, lead times, in-service dates, durations and locations in portfolio risk modeling.<br>• Consistent assumptions and methods should be used for evaluation of all resources.<br>• The after-tax marginal weighted-average cost of capital (WACC) should be used to discount all future resource costs.<br>b. Risk and uncertainty must be considered.<br>• At a minimum, utilities should address the following sources of risk and uncertainty:<br>1. Electric utilities: load requirements, hydroelectric generation, plant forced outages, fuel prices, electricity prices, and costs to comply with any regulation of greenhouse gas emissions.<br>2. Natural gas utilities: demand (peak, swing and baseload), commodity supply and price, transportation availability and price, and costs to comply with any regulation of greenhouse gas emissions.<br>• Utilities should identify in their plans any additional sources of risk and uncertainty.<br>c. The primary goal must be the selection of a portfolio of resources with the best combination of expected costs and associated risks and uncertainties for the utility and its customers.<br>• The planning horizon for analyzing resource choices should be at least 20 years and account for end effects. Utilities should consider all costs with a reasonable likelihood of being included in rates over the long term, which extends beyond the planning horizon and the life of the resource.<br>• Utilities should use present value of revenue requirement (PVRR) as the key cost metric. The plan should include analysis of current and estimated future costs for all longlived resources such as power plants, gas storage facilities, and pipelines, as well as all short-lived resources such as gas supply and short-term power purchases.<br>• To address risk, the plan should include, at a minimum:<br>1. Two measures of PVRR risk: one that measures the variability of costs and one that measures the severity of bad outcomes.<br>2. Discussion of the proposed use and impact on costs and risks of physical and financial hedging.<br>• The utility should explain in its plan how its resource choices appropriately balance cost and risk.<br>d. The plan must be consistent with the long-run public interest as expressed in Oregon and federal energy policies. | a-1) Supply-side and purchased resources for meeting the utility's load are discussed in Chapter 3 (Idaho Power Today), section *Existing Supply-Side Resources*, pages 27–38. Demand-side options for meeting the utility's load are discussed in Chapter 4 (Demand-Side Resources). Chapter 6 (Transmission Planning) discusses transmission resources for meeting the utility's load.<br>a-2) New resource options are described in Chapters 4 through 7. Chapter 4 (Demand-Side Resources) describes demand-side resource options for IRP resource portfolios. Chapter 5 (Supply-Side Generation and Storage Resources) describes generating resources and energy storage resources to be considered for IRP resource portfolios. Chapter 6 (Transmission Planning) describes transmission resources considered for IRP resource portfolios. Chapter 7 (Planning Period Forecasts) provides resource cost information.<br>a-3) The consistent modeling method for evaluating new resource options is described in Chapter 7 (Planning Period Forecasts), sections *Resource Cost Analysis*, *Resource Cost Analysis II—Resource Stack*, and *Supply-Side Resource Costs*. The consistent modeling method for evaluating all resource portfolios is explained in Chapter 9 (Modeling Analysis and Results), pages 113–114.<br>a-4) The WACC rate used to discount all future resource costs is stated in Chapter 9 (Modeling Analysis and Results), in Table 9.1 Financial Assumptions, on page 114.<br>b-1) Electric utility risk and uncertainty factors (load, NG and water conditions) for resource portfolios are considered in Chapter 9 (Modeling Analysis and Results), section *Stochastic Risk Analysis*, pages 121–124. (For electricity prices, AURORA forecasts electric market prices; therefore AURORA variables are changed to create different electric market price scenarios). Sensitivity analysis for CAA Section 111(d) performed to address costs to comply with greenhouse gas regulations is discussed in Chapter 9 (Modeling Analysis and Results), section *CAA Section 111(d) Sensitivity Analysis*, beginning on page 114.<br>Note: Plant forced outages for resource options and resource portfolios are not discussed in the IRP document or *2015 IRP Technical Appendix*. Plant forced outages are modeled in AURORA on a unit basis.<br>b-1-other) Additional sources of risk and uncertainty are identified in Chapter 2 (Political, Regulatory, and Operational Issues) in the following sections: *FERC Relicensing*, page 14; *Idaho Water Issues*, page 15; *Northwest Power Pool Energy Imbalance Market*, page 19; and *Federal Energy Legislation CAA Section 111(d)*, page 21.<br>Further discussion of risks is included in Chapter 9 (Modeling Analysis and Results), in section *Qualitative Risk Analysis*, beginning on page 125. Uncertainty factoring into the selection of the preferred portfolio is expressed in Chapter 1 (Summary) on pages 8-10.<br>c-1) The IRP methodology and the planning horizon of 20 years are discussed in Chapter 1 (Summary), section *IRP Methodology,* page 3.<br>c-2) Idaho Power uses the company's internal P-Worth model to calculate the PVRR for the capital component of the various portfolios. AURORA is used to model the variable (operating) component of the various portfolios. All costs are then discounted using the company's WACC. The summary of the NPV accounting for total portfolio costs is provided in Chapter 9 (Modeling Analysis and Results), pages 113-114. |

| Oregon Order 07-047 Action Items | 2015 IRP |
|---|---|
| | c-1.) Measures of the variability of costs and the severity of bad outcomes are considered in Chapter 9 (Modeling Analysis and Results), section *Stochastic Risk Analysis,* pages 121–124. A discussion of extreme outcomes, including extreme bad outcomes, is provided in the *Stochastic Risk Analysis* section in the third paragraph of page 123.<br>c-2.) The risks of physical and financial hedging are referenced to Idaho Power's *Energy Risk Management Policy* discussed in Chapter 1 (Summary), in the last paragraph of section *Introduction*, on page 2. Idaho Power explains how its preferred portfolio appropriately balances cost and risk in Chapter 9 (Modeling Analysis and Results), section *Preferred Portfolio*, page 130. The accounting for qualitative risks and uncertainty in the preferred portfolio selection is discussed in Chapter 1 (Summary), section *Portfolio Analysis Summary*, beginning on page 8. Further discussion of the preferred portfolio's appropriate balancing of cost and risk is included in Chapter 10 (Preferred Portfolio and Action Plan), section *Preferred Portfolio (2015-2034)*, page 141.<br>d-1) The plan is consistent with long-run public interests and is discussed in Chapter 2 (Political, Regulatory, and Operational Issues). Additional discussion relevant to this requirement is in Chapter 1 (Summary), section *Public Advisory Process*, pages 2–3. |
| **Guideline 2: Procedural Requirements.**<br>a. The public, which includes other utilities, should be allowed significant involvement in the preparation of the IRP. Involvement includes opportunities to contribute information and ideas, as well as to receive information. Parties must have an opportunity to make relevant inquiries of the utility formulating the plan. Disputes about whether information requests are relevant or unreasonably burdensome, or whether a utility is being properly responsive, may be submitted to the Commission for resolution.<br>b. While confidential information must be protected, the utility should make public, in its plan, any non-confidential information that is relevant to its resource evaluation and action plan. Confidential information may be protected through use of a protective order, through aggregation or shielding of data, or through any other mechanism approved by the Commission.<br>c. The utility must provide a draft IRP for public review and comment prior to filing a final plan with the Commission. | As set forth in Guideline 2, part a., Idaho Power solicits public involvement in the planning process. The company convenes a public forum as part of the resource planning process. For the 2004, 2006, 2009, 2011, 2013, and 2015 plans, Idaho Power assembled an IRP Advisory Council composed of customer representatives, representatives from both the Idaho and Oregon public utility commission staffs, and representatives from special interest groups. A roster of the IRP Advisory Council members is provided in the technical appendices of the IRPs. The IRP Advisory Council meetings are open to the public. IRP Advisory Council meetings are attended by members of the public and Idaho Power has involved the public participants in the IRP Advisory Council's discussions. These meetings allow parties to make relevant inquiries of Idaho Power formulating the plan.<br>As set forth in Guideline 2, part b., Idaho Power makes public extensive information relevant to its resource evaluation and action plan in its plan. This information is found throughout the 2015 IRP, the 2015 Load and Sales Forecast and in the 2015 Technical Appendix.<br>As set forth in Guideline 2, part c., Idaho Power posted online a draft 2015 IRP for public review on Thursday, June 4, 2015. The company requested for comments to be provided no later than Friday, June 12, 2015. |

| Oregon Order 07-047 Action Items | 2015 IRP |
|---|---|
| **Guideline 3: Plan Filing, Review, and Updates.**<br>a. A utility must file an IRP within two years of its previous IRP acknowledgment order. If the utility does not intend to take any significant resource action for at least two years after its next IRP is due, the utility may request an extension of its filing date from the Commission.<br>b. The utility must present the results of its filed plan to the Commission at a public meeting prior to the deadline for written public comment.<br>c. Commission staff and parties should complete their comments and recommendations within six months of IRP filing.<br>d. The Commission will consider comments and recommendations on a utility's plan at a public meeting before issuing an order on acknowledgment. The Commission may provide the utility an opportunity to revise the plan before issuing an acknowledgment order.<br>e. The Commission may provide direction to a utility regarding any additional analyses or actions that the utility should undertake in its next IRP.<br>f. Each utility must submit an annual update on its most recently acknowledged plan. The update is due on or before the acknowledgment order anniversary date. Once a utility anticipates a significant deviation from its acknowledged IRP, it must file an update with the Commission, unless the utility is within six months of filing its next IRP. The utility must summarize the update at a Commission public meeting. The utility may request acknowledgment of changes in proposed actions identified in an update.<br>g. Unless the utility requests acknowledgement of changes in proposed actions, the annual update is an informational filing that:<br>• Describes what actions the utility has taken to implement the plan;<br>• Provides an assessment of what has changed since the acknowledgment order that affects the action plan, including changes in such factors as load, expiration of resource contracts, supply-side and demand-side resource acquisitions, resource costs, and transmission availability; and<br>• Justifies any deviations from the acknowledged action plan. | a. The OPUC acknowledged Idaho Power's 2013 IRP on July 8, 2014 in Order 14-253. Idaho Power plans to file the 2015 IRP by June 30, 2015.<br>b. Idaho Power will schedule a public meeting at the OPUC after the 2015 IRP has been filed.<br>c. No action needed.<br>d. No action needed unless the OPUC provides Idaho Power an opportunity to revise the plan.<br>e. In Order No. 12-013, the OPUC provided direction on IRP flexible resource guidelines. In Order No. 14-253, the OPUC provided its resolution of fourteen components of the 2013 IRP. Idaho Power has addressed these action items in the 2015 IRP.<br>f. In Order No. 14-253, the OPUC waived for Idaho Power the requirement to file an annual update to the 2013 IRP, the most recently acknowledged IRP.<br>g. No action needed. |

| Oregon Order 07-047 Action Items | 2015 IRP |
|---|---|
| **Guideline 4: Plan Components.**<br>At a minimum, the plan must include the following elements:<br>a. An explanation of how the utility met each of the substantive and procedural requirements;<br>b. Analysis of high and low load growth scenarios in addition to stochastic load risk analysis with an explanation of major assumptions;<br>c. For electric utilities, a determination of the levels of peaking capacity and energy capability expected for each year of the plan, given existing resources; identification of capacity and energy needed to bridge the gap between expected loads and resources; modeling of all existing transmission rights, as well as future transmission additions associated with the resource portfolios tested;<br>d. For natural gas utilities, a determination of the peaking, swing and base-load gas supply and associated transportation and storage expected for each year of the plan, given existing resources; and identification of gas supplies (peak, swing and base-load), transportation and storage needed to bridge the gap between expected loads and resources;<br>e. Identification and estimated costs of all supply-side and demand-side resource options, taking into account anticipated advances in technology;<br>f. Analysis of measures the utility intends to take to provide reliable service, including cost-risk tradeoffs;<br>g. Identification of key assumptions about the future (e.g., fuel prices and environmental compliance costs) and alternative scenarios considered;<br>h. Construction of a representative set of resource portfolios to test various operating characteristics, resource types, fuels and sources, technologies, lead times, in-service dates, durations and general locations – system-wide or delivered to a specific portion of the system;<br>i. Evaluation of the performance of the candidate portfolios over the range of identified risks and uncertainties;<br>j. Results of testing and rank ordering of the portfolios by cost and risk metric, and interpretation of those results;<br>k. Analysis of the uncertainties associated with each portfolio evaluated;<br>l. Selection of a portfolio that represents the best combination of cost and risk for the utility and its customers;<br>m. Identification and explanation of any inconsistencies of the selected portfolio with any state and federal energy policies that may affect a utility's plan and any barriers to implementation; and<br>n. An action plan with resource activities the utility intends to undertake over the next two to four years to acquire the identified resources, regardless of whether the activity was acknowledged in a previous IRP, with the key attributes of each resource specified as in portfolio testing. | a. Idaho Power anticipates delivering this table in an informal letter to the OPUC staff.<br>b. Idaho Power revises the sales and load forecast each year and Idaho Power included the most recent sales and load forecast assumptions in Chapter 7 (Planning Period Forecasts), section *Load Forecast,* beginning on page 73.. High-growth scenarios at the 90th and 95th percentile levels for peak hour, and at the 70th and 90th percentile levels for energy are provided in Chapter 7, Figures 7.1 and 7.2 and Tables 7.1 and 7.2. High- and low-growth scenarios analyzed for the stochastic load risk analysis are discussed in Chapter 9 (Modeling Analysis and Results), section *Stochastic Risk Analysis,* pages 121-124.<br>c. Peaking capacity and energy capability for each year of the plan for existing resources are discussed in Chapter 7 (Planning Period Forecasts), section *Generation Forecast for Existing Resources,* beginning on page 80. Idaho Power uses AURORA in the modeling of all existing transmission. Future transmission additions associated with the resource portfolios tested are discussed in Chapter 6 (Transmission Planning), section *Transmission Assumptions in the IRP Portfolios,* beginning on page 71.<br>d. Not applicable.<br>e. Supply-side resources considered are identified and described in Chapter 5 (Supply-Side Generation and Storage Resources). Resource costs are discussed and provided in Chapter 7 (Planning Period Forecasts), sections *Resource Cost Analysis*, *Resource Cost Analysis II—Resource Stack*, and *Supply-Side Resource Costs*. Demand-side resources and their levelized costs and technologies are covered in Chapter 4 (Demand-Side Resources).<br>f. Resource reliability is covered in Chapter 9 (Modeling Analysis and Results), section *Loss of Load Expectation (LOLE),* beginning on page 139.<br>g. Natural gas price forecasts are discussed in Chapter 7 (Planning Period Forecasts), section *Natural Gas Price Forecast*, page 84-85. Chapter 7 also includes key assumptions about future load in section *Load Forecast* and generation in section *Generation Forecast for Existing Resources*. Costs for environmental compliance with proposed $CO_2$ regulations are addressed in Chapter 9 (Modeling Analysis and Results), section *CAA Section 111(d) Sensitivity Analysis*, beginning on page 114. Compliance alternatives to SCR installation at Jim Bridger Units 1 and 2 are addressed by portfolios considering early retirement of Jim Bridger Units 1 and 2. Environmental compliance costs for SCR installation at Jim Bridger units 3 and 4 are addressed in the *Appendix C—Technical Appendix* in the section *Jim Bridger Units 3 and 4 Selective Catalytic Reduction Analysis*.<br>h. Resource portfolios considered for the 2015 IRP are described in Chapter 8 (Portfolio Selection). Resource portfolios were developed using resources from the resource stack provided in Chapter 7 (Planning Period Forecasts), sections *Resource Cost Analysis*, *Resource Cost Analysis II—Resource Stack*, and *Supply-Side Resource Costs*. Resource portfolios were developed with consult from the IRP Advisory Council and public participants.<br>i. The resource portfolios are evaluated against various risks in Chapter 9, Modeling Analysis and Results, section *Stochastic Risk Analysis,* pages 121–124.<br>j. Portfolio cost and risk results, with interpretations, are provided in Chapter 9 (Modeling Analysis and Results).<br>k. The uncertainties associated with each portfolio are evaluated in Chapter 9 (Modeling Analysis and Results), sections *Stochastic Risk Analysis* and *Qualitative Risk Analysis*.<br>l. The selection reasoning for the preferred resource portfolio is identified in Chapter 9 (Modeling Analysis and Results), section *Preferred Portfolio*, page 130.<br>m. No inconsistencies were identified.<br>n. An action plan is provided in Chapter 1 (Summary), section *Action Plan*, page 10. |

| Oregon Order 07-047 Action Items | 2015 IRP |
|---|---|
| **Guideline 5: Transmission.**<br>Portfolio analysis should include costs to the utility for the fuel transportation and electric transmission required for each resource being considered. In addition, utilities should consider fuel transportation and electric transmission facilities as resource options, taking into account their value for making additional purchases and sales, accessing less costly resources in remote locations, acquiring alternative fuel supplies, and improving reliability. | The transmission required for each resource being considered is described in the 2015 IRP *Technical Appendix*, section *Transmission Cost Assumptions*. Transmission assumptions for supply-side resources considered are included in Chapter 6 (Transmission Planning), section *Transmission Assumptions in the IRP Portfolios*, pages 71–72. AURORA accounts for the cost of wheeling when selling and purchasing power from the market. For natural gas-fired resources, the Idaho Citygate price reflects the cost of transport to a power plant. The Idaho Citygate price is described in Chapter 7 (Planning Period Forecasts), section Natural Gas Price Forecast, pages 84-85. Forecasts for Idaho Citygate price are provided in the 2015 IRP *Technical Appendix*, section *Fuel Price Forecasts*. |
| **Guideline 6: Conservation.**<br>a. Each utility should ensure that a conservation potential study is conducted periodically for its entire service territory.<br>b. To the extent that a utility controls the level of funding for conservation programs in its service territory, the utility should include in its action plan all best cost/risk portfolio conservation resources for meeting projected resource needs, specifying annual savings targets.<br>c. To the extent that an outside party administers conservation programs in a utility's service territory at a level of funding that is beyond the utility's control, the utility should:<br>• Determine the amount of conservation resources in the best cost/risk portfolio without regard to any limits on funding of conservation programs; and<br>• Identify the preferred portfolio and action plan consistent with the outside party's projection of conservation acquisition. | a. The potential study conducted by Applied Energy Group (AEG) for the 2015 IRP is described in Chapter 4 (Demand-Side Resources), section *Committed Energy Efficiency Forecast*, beginning on page 43.<br>b. The 2015 IRP action plan expresses Idaho Power's intent to continue pursuit of cost-effective energy efficiency. A forecast for energy efficiency effects in five-year blocks is provided in Chapter 4 (Demand-Side Resources), section *Committed Energy Efficiency Forecast*, Table 4.2. Detailed year-by-year forecast values are included in the 2015 IRP *Technical Appendix,* section *Monthly average energy load and resource balance*.<br>c. Treatment of third party market transformation savings provided by the Northwest Energy Efficiency Alliance (NEEA) in the 2015 IRP is discussed in Chapter 4 (Demand-Side Resource), pages 40-41. Idaho Power has changed how market transformation savings provided by NEEA are treated in the IRP. NEEA savings are now included as savings to meet targets because of the overlap of NEEA initiatives and IPC's most recent potential study. |
| **Guideline 7: Demand Response.**<br>Plans should evaluate demand response resources, including voluntary rate programs, on par with other options for meeting energy, capacity, and transmission needs (for electric utilities) or gas supply and transportation needs (for natural gas utilities). | Demand response resources are detailed in Chapter 4 (Demand-Side Resources), section *Demand Response Performance,* page 42. Additional demand response above baseline levels is considered in select portfolios, including the preferred portfolio. The additional demand response is discussed in Chapter 4 (Demand-Side Resources), section *Additional Demand Response*, page 47. |
| **Guideline 8: Environmental Costs.**<br>Utilities should include, in their base-case analyses, the regulatory compliance costs they expect for carbon dioxide ($CO_2$), nitrogen oxides, sulfur oxides, and mercury emissions. Utilities should analyze the range of potential $CO^2$ regulatory costs in Order No. 93-695, from zero to $40 (1990$). In addition, utilities should perform sensitivity analysis on a range of reasonably possible cost adders for nitrogen oxides, sulfur oxides, and mercury, if applicable. | It is noted in Chapter 9 (Modeling Analysis and Results), section *Portfolio Emissions*, page 125, that with the exception of portfolios retiring Jim Bridger Units 1 and 2 without installation of NOx-controlling retrofits, all portfolios are designed to comply with environmental regulations. CAA Section 111(d) is modeled to reflect future carbon dioxide regulations. Portfolio costs provided for the considered CAA Section 111(d) sensitivities as provided in Chapter 9 (Modeling Analysis and Results), section *CAA Section 111(d) sensitivity analysis – results*, Table 9.4, page 119. |
| **Guideline 9: Direct Access Loads.**<br>An electric utility's load-resource balance should exclude customer loads that are effectively committed to service by an alternative electricity supplier. | At present, Idaho Power does not have any customers served by alternative electricity suppliers and Idaho Power has no direct access loads. Guideline 9 is not expected to apply to Idaho Power during the 2015 IRP 20-year planning period. |
| **Guideline 10: Multi-state Utilities.**<br>Multi-state utilities should plan their generation and transmission systems, or gas supply and delivery, on an integrated-system basis that achieves a best cost/risk portfolio for all their retail customers. | Idaho Power intends to file the 2015 IRP in both the Idaho and Oregon jurisdictions. |
| **Guideline 11: Reliability.**<br>Electric utilities should analyze reliability within the risk modeling of the actual portfolios being considered. Loss of load probability, expected planning reserve margin, and expected and worst-case unserved energy should be determined by year for top-performing portfolios. Natural gas utilities should analyze, on an integrated basis, gas supply, transportation, and storage, along with demandside resources, to reliably meet peak, swing, and base-load system requirements. Electric and natural gas utility plans should demonstrate that the utility's chosen portfolio achieves its stated reliability, cost and risk objectives. | Idaho Power discussed the capacity planning margin in Chapter 9 (Modeling Analysis and Results), section *Capacity Planning Margin*, beginning on page 131, and the loss of load probability in Chapter 9 (Modeling Analysis and Results), section *Loss of Load Expectation,* beginning on page 139. |

| Oregon Order 07-047 Action Items | 2015 IRP |
|---|---|
| **Guideline 12: Distributed Generation.**<br>Electric utilities should evaluate distributed generation technologies on par with other supply-side resources and should consider, and quantify where possible, the additional benefits of distributed generation. | Idaho Power evaluated distributed solar PV as a resource option in portfolio 18. Portfolio 18 is described in Chapter 8 (Portfolio Selection), page 110. Distributed storage (ice-based thermal and V redox flow battery) resources were evaluated in multiple portfolios. Portfolios are described in Chapter 8 (Portfolio Selection), beginning on page 97. Distributed resources, generating and storage, were credited to account for avoided transmission line losses. |
| **Guideline 13: Resource Acquisition.**<br>a. An electric utility should, in its IRP:<br>• Identify its proposed acquisition strategy for each resource in its action plan.<br>• Assess the advantages and disadvantages of owning a resource instead of purchasing power from another party.<br>• Identify any Benchmark Resources it plans to consider in competitive bidding.<br>b. Natural gas utilities should either describe in the IRP their bidding practices for gas supply and transportation, or provide a description of those practices following IRP acknowledgment. | Idaho Power continues to evaluate resource ownership along with other supply options. Idaho Power conducts its resource acquisition and competitive bidding processes consistent with the guidelines established by Oregon in Order No. 14-149 issued on April 30, 2014.<br>Idaho Power discusses asset ownership in Chapter 10 (Action Plan), section *Action Plan (2015–2018)*, page 143.<br>Idaho Power's action plan includes ongoing permitting, planning studies, and regulatory filings associated with the Boardman to Hemingway transmission line. Construction of the Boardman to Hemingway transmission line will be managed to be consistent with resource acquisition and competitive bidding processes provided in guidelines established by Oregon in Order No. 14-149. |

# STATE OF OREGON IRP ELECTRIC VEHICLES (EV) GUIDELINES

ORDER NO. 12 013

ENTERED JAN 19 2012

**BEFORE THE PUBLIC UTILITY COMMISSION**

**OF OREGON**

UM 1461

| | |
|---|---|
| In the Matter of<br><br>PUBLIC UTILITY COMMISSION OF OREGON<br><br>Investigation of matters related to Electric Vehicle Charging. | ORDER |

DISPOSITION: GUIDELINES ADOPTED; UTILITIES ORDERED TO MAKE REVISED TARIFF FILINGS

## I. PROCEDURAL HISTORY

At our December 8, 2009, Public Meeting, we opened this docket at our Staff's request to investigate matters related to the charging infrastructure for plug-in hybrid vehicles and electric vehicles (collectively referred to as EVs).[1] Specifically, we intended this docket to address general matters related to the emergence and development of the EV charging market and industry, including the role of electric utilities with regard to owning and operating EV service equipment (EVSE) and acting as EV service providers (EVSP). The Citizens' Utility Board of Oregon (CUB) noticed its intervention in the investigation, and the following parties were authorized over the course of the docket to intervene as parties: the Oregon Department of Energy (ODOE); ECOtality, Inc.; Smart Grid of Oregon (SGO); Grid Mobility LLC; Mitsubishi Motors R&D of America; the Oregon Department of Environmental Quality (DEQ); Nissan North America, Inc.; CleanFuture; the Northwest Energy Coalition (NWEC); Portland General Electric Company (PGE); PacifiCorp, dba Pacific Power (Pacific Power); and Idaho Power Company (Idaho Power).

On June 22, 2010, Staff and interested parties participated in a public workshop to discuss the scope of the investigation. Staff subsequently prepared a "straw proposal," published on July 22, 2010, that was intended to facilitate and focus further discussion in the docket. On August 6, 2010, a second public workshop was held. Staff and parties submitted opening comments on August 27, 2010.

[1] *See* Staff Report for December 8, 2009 Public Meeting, Item No. 4.

*2. Resolution*

We agree with Staff and all of the other parties in this docket that there is no discernible reason, at least at this time, to treat EV charging load differently than any other load with regard to distribution system upgrades. Moreover, we acknowledge that EV charging load may not necessitate system upgrades at any time should the load be effectively managed. Consequently, we adopt Staff's recommendation that utilities' existing line extension policies continue to apply, without modification, to all loads, including plug-in EV load.

**D. Integrated Resource Planning Flexible Resources Guidelines**

The current Integrated Resource Planning (IRP) guidelines are silent regarding flexible capacity. In opening comments, Staff proposed an IRP guideline to fill this need.

*1. Parties' Positions*

Staff's proposed IRP guideline has three parts, as follows:

1. Forecast the Demand for Flexible Capacity: The electric utilities shall forecast the balancing reserves needed at different time intervals (e.g. ramping needed within 5 minutes) to respond to variation in load and intermittent renewable generation over the 20-year planning period;

2. Forecast the Supply of Flexible Capacity: The electric utilities shall forecast the balancing reserves available at different time intervals (e.g. ramping available within 5 minutes) from existing generating resources over the 20-year planning period; and

3. Evaluate Flexible Resources on a Consistent and Comparable Basis: In planning to fill any gap between the demand and supply of flexible capacity, the electric utilities shall evaluate all resource options, including the use of EVs, on a consistent and comparable basis.

Staff asserts that the proposed IRP guideline is consistent with the language and content of the existing IRP guidelines, and addresses an issue that is relevant for resource and planning both now and in the future. Staff states, "[f]lexibility is an increasingly important consideration in the integration of higher percentages of variable renewable generation resources."[31] Staff further comments that "EVs, as the first 'smart appliance', represent an opportunity to capture the power of demand response flexibility as a compliment to other flexibility strategies coming from generation and storage technologies."[32] Although Staff realizes that EVs will not be ready to provide flexible

[31] Staff Response to Bench Request, p. 25.
[32] *Id.*

capacity any time soon due to measured market penetration and technical challenges, Staff argues that it appropriate to begin planning for the future and that a 20-year planning horizon is consistent with current IRP practice.

ECOtality, Inc., agrees, observing that as IRPs involve long-range planning, they should include developing technologies, or events may eclipse planning. ODOE recommends supports Staff's proposed IRP guideline. Neither NWEC nor CUB object to Staff's proposed IRP guideline, although CUB notes a possible practical limitation to EVs functioning as a flexible capacity resource should the manufacturers of EVs or EV batteries be reluctant to allow third parties access to EV battery storage capacity, thereby limiting flexible capacity availability from EVs.

All three utilities oppose adoption of Staff's proposed IRP guideline, arguing that the guideline is prematurely too prescriptive about planning for a resource that is still unknown and uncertain. Pacific Power complains about the administrative burden on a utility versus the analytical value of studies that would be undertaken pursuant to Staff's proposed guideline. Similarly, Idaho Power argues that given the significant uncertainties about whether and when EVs might provide flexible capacity, the Commission should direct utilities to consider, but not model such resources. PGE takes the position that adoption of Staff's proposed guideline is premature, and would impose long range speculative assumptions and create significant administrative burden.

All three utilities recommend further discussion and study in some other forum before adopting an IRP guideline related to flexible resource planning. Pacific Power urges the Commission to further study flexible capacity resources in a manner that accounts for each utility's planning and modeling framework, whether as part of an evolving investigation or through the public IRP processes. Pacific Power also notes that to the extent that these new guidelines are intended to inform the development of demand response programs more generally, the Commission should open an investigation to reevaluate all IRP guidelines related to demand response programs, rather than adopting certain new guidelines in an EV-specific proceeding. As already discussed, PGE suggests the Commission develop a pilot program to collect information to be used to late guide policy. PGE observes, however, that the company is increasing non-controllable variable generation in the form of wind and losing access to controllable flexible generation in the form of hydro. PGE acknowledges, therefore, that this situation makes the assessment of flexible generation an important component of PGE's IRP planning on a going forward basis. Consequently, PGE indicates that the first two parts of Staff's proposed guideline may have value. PGE argues, however, that it is unreasonable to link flexible capacity to EVs at this time, since EVs may be at least a decade away from commercial viability.

### 2. *Resolution*

At the outset, we conclude there is no need for further discussion on this issue. All three utilities submitted several rounds of comments regarding Staff's proposed guideline, including responses to our bench request. Although all three

ORDER NO. 12 013

2. We direct each electric utility to fully address the new Integrated Resource Planning guideline adopted herein in the utility's next Integrated Resource Planning proceeding.

A party may request rehearing or reconsideration of this order under ORS 756.561. A request for rehearing or reconsideration must be filed with the Commission within 60 days of the date of service of this order. The request must comply with the requirements in OAR 860-001-0720. A copy of the request must also be served on each party to the proceedings as provided in OAR 860-001-0180(2). A party may appeal this order by filing a petition for review with the Court of Appeals in compliance with ORS 183.480 through 183.484.

# STATE OF OREGON ACTION ITEMS REGARDING IDAHO POWER'S 2013 IRP

ORDER NO. 12 253

ENTERED JUL 0 8 2014

**BEFORE THE PUBLIC UTILITY COMMISSION**

**OF OREGON**

LC 58

| | |
|---|---|
| In the Matter of<br>IDAHO POWER COMPANY,<br>2013 Integrated Resource Plan | ORDER |

DISPOSITION: PLAN ACKNOWLEDGED IN PART AND AS REVISED

## I. INTRODUCTION

Idaho Power Company is a public utility operating in Oregon and is subject to the Commission's jurisdiction and requirements regarding integrated resource planning. Idaho Power's 2011 Integrated Resource Plan (IRP) was acknowledged with exceptions and guidance for its next IRP in Order No. 12-177. Idaho Power now seeks acknowledgment of its 2013 IRP.

We require each regulated energy utility to prepare and file an IRP within two years of acknowledgment of the utility's last plan. In the IRP, an energy utility must: (1) evaluate resources on a consistent and comparable basis; (2) consider risk and uncertainty; (3) aim to select a portfolio of resources with the best combination of expected costs and associated risks and uncertainties for the utility and its customers; and (4) create a plan that is consistent with the long-run public interest as expressed in Oregon and federal energy policies.[1]

Once a utility completes a plan, we review for adherence to the procedural and substantive requirements outlined in Order No. 89-507. We generally acknowledge the plan—that is, find it reasonable based on the information available at that time—or return it to the utility with comments.[2] We may also decline to acknowledge specific action items if we question whether the utility's proposed resource decision presents the least cost and risk option for its customers.

We reaffirm our long-standing view that decisions made in IRP proceedings do not constitute ratemaking. Decisions whether to allow a utility to recover from its customers the costs associated with new resources may only be made in a rate proceeding. Acknowledgment of an IRP, however, is relevant to subsequent examination of whether a

[1] Order No. 07-002.
[2] *Id.* at 2.

utility's resource investment is prudent and should be recovered from ratepayers. As we have previously stated:

> Consistency of resource investments with least-cost planning principles will be an additional factor that the Commission will consider in judging prudence. When a plan is acknowledged by the Commission, it will become a working document for use by the utility, the Commission, and any other interested party in a rate case or other proceeding before the Commission[.] Consistency with the plan may be evidence in support of favorable rate-making treatment of the action, although it is not a guarantee of favorable treatment.[3]

Just as acknowledgment does not guarantee favorable ratemaking, a decision to not acknowledge an action item does not constitute a preliminary determination of imprudence. The purpose of the IRP process is to provide the utility with the information and opinion of stakeholders and the Commission based on information presented by the utility. The question of whether a specific investment made by a utility in its planning process was prudent will be fairly examined in a subsequent rate case proceeding.

## II. DISCUSSION

We conclude Idaho Power satisfies all the procedural guidelines and all but one of the substantive guidelines for IRP planning. Idaho Power did not comply with the IRP Guideline regarding flexible capacity adopted in Order No 12-013.

We acknowledge the short-term action items in Idaho Power's Action Plan, except for the investment in selective catalytic reduction emissions technology at Jim Bridger Units 3 and 4.[4] In addition, we acknowledge two additional action items recommended by Staff that relate to energy efficiency. We do not acknowledge the remaining action items, which are for the most part outside the two-to-four year action plan period.[5]

## III. IDAHO POWER'S IRP

During the 20-year planning period, Idaho Power expects that the number of its customers will increase by about 8,400 each year, from approximately 500,000 in 2012 to 670,000 in 2032. Idaho Power's expected-case load forecast predicts that summer-peaking hour load requirements will grow at about 55 MW per year, and that the average-energy requirements will grow at 21 aMW per year. Idaho Power's load and resource balance analysis, which accounts for forecast load growth and generation from all of the company's existing resources and planned purchases, shows no energy deficits through the planning period. Idaho Power's analysis shows a capacity deficit starting in 2016 and monthly peak-hour deficit positions growing steadily in magnitude and the number of months affected. By July 2032, the capacity deficits are approximately 870 MW.

---

[3] *Id.* at 24, *quoting* Order No. 89-507 at 7.
[4] *See* Appendix A.
[5] *See* Guideline 4(n).

Idaho Power identifies as its major resource addition the Boardman to Hemingway transmission line (B2H) with market purchases. The company's preferred portfolio also includes demand response, continued operations at the Jim Bridger and North Valmy coal facilities after investment in emission-control technology, and the continued operation of Idaho Power's other existing supply-side resources.

Guideline 4(n) requires the utility to include an action plan with resource activities the utility intends to undertake over the next two to four years. Idaho Power includes the following activities in its Action Plan:

| Year | Resource – Action |
|---|---|
| 2013-2018 | Boardman to Hemingway – Ongoing permitting, planning studies, and regulatory filings |
| 2013 | Gateway West – Ongoing permitting, planning studies, and regulatory filings |
| 2013 | North Valmy Unit 1 – Commit to the installation of dry sorbent injection emission-control technology |
| 2013 | Jim Bridger Units 3&4 – Commit to the installation of selective catalytic reduction emission-control technology |
| 2016-2017 | Demand response – Have demand response capacity available to satisfy deficiencies up to approximately 150 MW |
| 2018 | Boardman to Hemingway – Transmission line complete and in service |
| 2019 | Shoshone Falls – Upgrade complete and in service |
| 2019 | Jim Bridger Unit 2 – Commit to the installation of selective catalytic reduction emission-control technology |
| 2020 | Jim Bridger Unit 1 – Commit to the installation of selective catalytic reduction emission-control technology |
| 2020 | Boardman – Coal-fired operations at the Boardman plant are scheduled to end by year-end 2020 |
| 2024-2032 | Demand response – Have demand response capacity available to satisfy deficiencies in 50 MW increments up to approximately 370 MW |

## IV. DISCUSSION

In this order, we first address Idaho Power's Action Plan, discussing the comments filed by participants[6] and specific IRP Guidelines as appropriate. We then address issues raised by the participants or that we identify related to Idaho Power's compliance with the IRP Guidelines and our order regarding Idaho Power's 2011 IRP that are not discussed in connection with our review of the Action Plan.

[6] Renewable Northwest (RNW), the Citizens' Utility Board of Oregon (CUB), the Oregon Department of Energy (ODOE), and Staff of the Public Utility Commission (Staff) filed opening and reply comments regarding Idaho Power's IRP, and Idaho Power filed two rounds of comments in response. In addition, a resident of Idaho, John Weber, forwarded comments to Staff, which Staff forwarded to the Administrative Hearings Division for inclusion in the record.

ORDER NO. 14 253

## A. Transmission

### *1. Boardman to Hemingway*

Currently, the Boardman to Hemingway transmission project (B2H) is envisioned as a single-circuit 500 kV transmission line approximately 300 miles long between northeast Oregon and southwest Idaho. Idaho Power states that it has entered into a joint funding agreement with PacifiCorp and the Bonneville Power Administration to pursue permitting the project, under which Idaho Power is the permitting project manager.

Idaho Power proposes the following actions for the Boardman to Hemingway transmission project:

| | |
|---|---|
| *2013-2018* | *Boardman to Hemingway – Ongoing permitting, planning studies, and regulatory filings* |
| *2018* | *Boardman to Hemingway – Transmission line complete and in service* |

#### *a. Participants' Comments*

RNW supports investment in B2H because it would provide Idaho Power not only with transmission to a liquid market, enabling the company to access low-cost resources to meet capacity and energy needs, but to also generate revenue by selling energy to other regional utilities. RNW also contends B2H will provide environmental benefits by enabling Idaho Power to reach renewable energy resource zones, thereby facilitating renewable energy resources.

Staff recommends acknowledgement of ongoing permitting, planning studies, and regulatory filings for B2H. Staff notes that B2H is included in five of the nine portfolios modeled in the 2013 IRP. The preferred portfolio and the next lowest "total costs portfolios" include B2H. Staff finds that the IRP analysis regarding B2H supports acknowledgment of ongoing permitting, planning studies, and regulatory filings.

Staff recommends, however, that we decline to acknowledge B2H "Transmission line complete and in-service" in 2018. Staff reports that the estimated in-service date for B2H has moved from 2018 (the year noted in Idaho Power's IRP) to 2020 (the year reported in the company's reply comments). Staff concludes this action item is now well beyond the two-to-four year period prescribed in the IRP Guidelines.

With respect to Idaho Power's activities that occur between the our order in this docket and Idaho Power's 2015 IRP, Staff asks to be apprised of any (1) updated project plan incorporating changes related to Bureau of Land Management delays and Energy Facilities Siting Council developments; (2) final agreement regarding allocation of construction costs between project participants; and (3) significant regulatory decisions that impact the project schedule or costs. Staff also asks that the company to further explore whether B2H would significantly impact wind generation curtailment during

periods of low demand as well as the impact of B2H on resource integration costs in general.

In its first round of comments, Idaho Power asserts that Staff's recommendation to acknowledge only the permitting activities of B2H and not the construction phase of the project is inconsistent with the our past acknowledgment of B2H and is unnecessary to ensure continued analysis of this project. In its final comments, Idaho Power states that it is only requesting acknowledgment of specific action items scheduled to occur within the next four years (which excludes the construction of B2H), but does ask that we acknowledge the 2013 IRP in its entirety, which includes B2H in its preferred portfolio.

*b. Commission Resolution*

We acknowledge ongoing permitting, planning studies, and regulatory filings for B2H. As Staff notes, the analysis in the IRP supports these planned near-term activities. We anticipate additional analysis regarding B2H in Idaho Power's 2015 IRP before acknowledging other actions related to B2H.

We decline to acknowledge completion of B2H because it is well beyond the two-to-four year period for action items specified by the IRP Guidelines. Further, we disagree with any suggestion that declining to acknowledge the construction of B2H is inconsistent with our previous acknowledgment of certain activities (*e.g.*, permitting) related to this resource or inconsistent with previous orders acknowledging IRPs based on a preferred portfolio that includes B2H. Our acknowledgment of an IRP is based on our conclusion that it complies with our guidelines and that the plan seems reasonable based on information known at the time.

***2. Gateway West***

Gateway West is a multi-segment, multi-year, joint transmission project of Idaho Power and PacifiCorp/Rocky Mountain Power to build and operate approximately 1000 miles of new transmission lines from Wyoming to the Hemingway Substation near Melba, Idaho. The project timeline indicates line segments in service between 2019 and 2023. Idaho Power has a one-third interest in some, but not all, of the segments to be located in Idaho and sole interest in one segment.

Idaho Power asks for acknowledgment of the following action item related to Gateway West:

*2013* *Gateway West – Ongoing permitting, planning studies, and regulatory filings*

Idaho Power reports that the Gateway West and B2H projects are complementary and will provide an upgraded transmission path from the Pacific Northwest across Idaho and into eastern Wyoming with an additional transmission connection to a population center in Utah. Idaho Power states that Gateway West will benefit customers by (1) relieving transmission constraints on certain transmission paths allowing Idaho Power to move additional energy between the east and west sides of the system; (2) providing the option

to locate future generation resources east of the Treasure Valley load center; and (3) providing future load service to the Magic Valley from the Cedar Hill Substation. Idaho Power does not request acknowledgment of Gateway West as a supply side resource. Instead, the company asserts that Gateway West is reasonable to address transmission system constraints and provide for future least cost resource development.

*a. Participants' Comments*

RNW supports investment in Gateway West because it will provide the same benefits that B2H will provide—that is, access to low-cost resources, access to regions where renewable resources could be sited, and reliability.

CUB recommends that we not acknowledge Gateway West as presented. CUB notes that Gateway West is a large project composed of a number of segments that can be analyzed individually. CUB asserts that Idaho Power should narrow its request and seek acknowledgment only of the segments of Gateway West that it can demonstrate are cost effective for Idaho Power's customers.

Staff concludes that, although there is insufficient information to support acknowledgment of the construction of Gateway West, we should acknowledge the permitting-related activities that must occur prior to construction. For purposes of Idaho Power's next IRP, however, Staff recommends that the company include an analysis of the historical and projected power flows for the portions of the Gateway West project in which Idaho Power has an interest in order to demonstrate the need and specific constraint-related benefits.

*b. Commission Resolution*

We acknowledge ongoing permitting, planning studies, and regulatory filings for Gateway West. However, as CUB notes, the project is composed of multiple segments that can and should be analyzed individually. Moreover, Idaho Power has an ownership interest in relatively few of the segments and must demonstrate the need and specific constraint-related benefits for each segment in which it holds an interest before we will consider acknowledgment of the project's construction.

**B. Pollution Control Investments in Coal Resources**

***1. Idaho Power's Analysis***

IRP Guideline 8, as modified by Order No. 08-339, contains four requirements related to environmental costs. Under this guideline, the utility must model a base case scenario to reflect what it considers to be the most likely regulatory compliance future for carbon dioxide ($CO_2$), nitrogen oxides, sulfur oxides, and mercury emissions. The utility must also develop several compliance scenarios ranging from the present $CO_2$ level to the upper reaches of credible proposals by governing entities. Then, the utility must estimate, under each of the compliance scenarios, the present value of revenue requirement (PVRR) cost and risk measures in its preferred portfolio and alternate portfolios. Guideline 8 directs the utility to identify the $CO_2$ emission cost adder level

that triggers the selection of a portfolio that is substantially different from the preferred portfolio. In addition, Guideline 8 requires utilities develop a portfolio to achieve voluntary carbon emission reduction targets set forth in Oregon law.

*a. Participants' Comments*

RNW asserts that Idaho Power's analysis of its coal resources failed to meet IRP Guideline 8 because the company did not (1) model natural gas conversions of the Jim Bridger Units 3 and 4 boilers; (2) model a range of pollution control costs; and (3) account for recent direction from President Obama's Administration that may reduce the cost competitiveness of existing coal resources. RNW asserts that investing in coal units is generally not reasonable under scenarios with low natural gas costs or stringent $CO_2$ regulation or both.

CUB also criticizes Idaho Power's analysis, and contends the company failed to consider all possible scenarios. CUB proposes a four-part, Boardman-style analysis that (1) allows potential pollution controls under different scenarios; (2) compares the broader range of pollution control scenarios to alternative investments, such as repowering with natural gas, building a CCCT, or relying on front office transactions; (3) investigates whether there is a plausible scenario for a phase-out that is at a lower cost than either of the two options; and (4) analyzes whether committing to close a plant at the end of its depreciable life would reduce pollution control costs.

Staff voices a concern similar to CUB's regarding Idaho Power's failure to consider a range of early shutdown scenarios. Staff notes that Idaho Power compared the cost of early shutdown and no controls against other alternatives, but did not model a range of early shut-down scenarios, *e.g.*, smaller pollution control investment in exchange for shutdowns at different points in time, which Staff expected would be done. Like CUB, Staff recommends that future coal analysis consider alternative dates for pollution control equipment, shut down, or other alternatives such as gas conversion.

Staff concludes that Idaho Power's analysis is sufficient to comply with the IRP Guidelines, as well as our direction, provided in 2012, to evaluate whether there is flexibility in the emerging environmental regulations that would allow the company to avoid early compliance costs by offering to shut down individual units prior to the end of their useful lives.

Idaho Power responds that its modeling complies with Guideline 8. Idaho Power notes that it modeled three levels of carbon adders to evaluate the potential impact of carbon emissions regulations in its coal study and in the IRP. In addition, Idaho Power explains it created an alternate portfolio in which the North Valmy units are converted to a gas-fired plant and Jim Bridger Units 3 and 4 are replaced with combined cycle combustion turbines (CCCTs). Idaho Power points out that President Obama's announcement regarding $CO_2$ regulation was issued the same month Idaho Power filed its IRP and that Idaho Power could not account for the announcement without delaying the filing of the 2013 IRP. And, Idaho Power asserts the June 2013 Presidential Memorandum concerned regulations for new power plants and none are included in the company's IRP.

*b. Commission Resolution*

We conclude that Idaho Power's IRP complies with IRP Guideline 8, but as discussed below, is not sufficient to provide a basis to support acknowledgment of selective catalytic reduction emission-control technology (SCR) at Jim Bridger Units 3 and 4. Guideline 8 does not require Idaho Power to model every feasible alternative scenario, but requires the company to determine the PVRR costs and risk measures of a "set of reasonable alternative portfolios" assuming a range of different compliance scenarios. Although Idaho Power did not model a scenario in which both North Valmy units and Bridger Units 3 and 4 were converted to natural gas facilities, as RNW believes should have been done, Idaho Power did model a scenario in which North Valmy is converted to natural gas and Bridger Units 3 and 4 are replaced with CCCTs (portfolio 6). In addition, although Idaho Power did not build a compliance scenario that specifically accounts for the June 2013 Presidential Memorandum, Idaho Power did test its portfolios against a range of carbon compliance futures including a carbon adder in the planning case of $14.64 per ton beginning in 2018 and escalating three percent annually, and a carbon adder in the high case of $35 per ton beginning in 2018 and escalating nine percent annually.

The carbon adder was modeled at three levels: low ($0), planning, and high. Idaho Power did not model a distribution of values, as was done with gas prices, load, and hydro in the stochastic analysis. Instead, one-third of the simulations were drawn from each carbon adder level. The company's analysis showed the preferred portfolio 2 and the non-coal portfolio 6 would switch places at a carbon adder of $45 in 2018. We find the alternative portfolios selected by Idaho Power and the range of compliance futures sufficient to satisfy the requirements of Guideline 8.

We share CUB's and Staff's concern regarding the limited nature of Idaho Power's early retirement scenarios analysis. Even though Idaho Power may have technically complied with the action item from Order No. 12-177, we expected that Idaho Power would model a broader range of early shutdown scenarios. We expect Idaho Power to engage fully with Staff and stakeholders in a timely manner to design coal investment analyses for future IRPs to ensure more robust consideration of early shutdown as a compliance option.

Also, we direct Idaho Power to work with stakeholders to explore options for how it plans to model and perform analysis in the 2015 IRP in order to comply with the applicable emissions requirements of §111(d) of the Clean Air Act.

***2. North Valmy Unit 1***

North Valmy is a coal-fired plant consisting of two generating units located in Nevada. Idaho Power is a 50 percent owner of North Valmy. After adjusting for routine scheduled maintenance and estimated forced outages, the annual energy generating capability of Idaho Power's share of the plant is approximately 220 aMW. Idaho Power plans on the continued operation of North Valmy Unit 1 throughout the 20-year planning period of the 2013 IRP and both units of North Valmy are included in Idaho Power's preferred portfolio.

Idaho Power proposes the following action for North Valmy Unit 1 to comply with federal Mercury Air Toxics Standards (MATS):

*2013* *North Valmy Unit 1 – Commit to the installation of dry sorbent injection emission-control technology*

*a. Participants' Comments*

CUB is concerned because Idaho Power's preferred portfolio includes North Valmy with an end-of-life date that CUB fears is too far in the future. CUB notes that the end-of-life date for North Valmy is at or beyond the end of the 20-year planning period in Idaho Power's preferred portfolio but that the co-owner of North Valmy, Nevada Energy, has announced plans to close the plant in 2025.

Idaho Power responds that it modeled North Valmy consistently with its current expectation of the end-of-life date. Idaho Power asserts that Nevada Energy cannot close the plant early without Idaho Power's consent, which it has not given. Also, Idaho Power modeled two portfolios that included a shortened end-of-life date for North Valmy and replacement of lost energy with other resources. These portfolios were higher cost than the preferred portfolio.

Staff recommends acknowledgment of DSI installation. Staff finds that because the cost of the investment is so small, there is no tipping point in the modeled scenarios at which it is more cost-effective to shut down North Valmy rather than invest in DSI.

*b. Commission Resolution*

We acknowledge installation of DSI at North Valmy Unit 1. We find as Staff did that the relatively low cost of the investment leads to the conclusion that the DSI investment and continued operation of North Valmy is the least cost/least risk alternative given the information that is currently available.

We do not share CUB's concern regarding how Idaho Power included North Valmy in its preferred portfolio. First, shortening the life of North Valmy would not change the result of Idaho Power's analysis; installing DSI would still be the least cost/least risk alternative. Second, future events may lead to a shortened operating life for North Valmy, but whether they will is not certain. Idaho Power reasonably relied on the results of modeling based on the assumption North Valmy will operate as Idaho Power currently expects, rather than an assumption based on events that may, or may not, transpire.

***3. Jim Bridger Units 3 and 4***

Jim Bridger is a coal-fired plant consisting of four generating units located in Wyoming. Idaho Power owns one-third of the plant, or 771 MW. The Environmental Protection Agency (EPA) submitted a final rule on January 10, 2014, requiring the installation of selective catalytic reduction emission-control technology (SCR) at Bridger Units 3 and 4 by December 31, 2015 and December 31, 2016, respectively. Idaho Power's application to the Idaho Public Utilities Commission (IPUC) for a Certificate of Public Convenience

and Necessity states that Idaho Power's cost before AFUDC is estimated to be approximately $118 million.

Idaho Power proposes the following action for Jim Bridger Units 3 and 4:

*2013* *Jim Bridger Units 3 and 4 – Commit to the installation of selective catalytic reduction emission-control technology*

*a. Participants' Comments*

CUB and RNW recommend that we not acknowledge pollution control investments at Jim Bridger Units 3 and 4, contending additional analysis is needed. Specifically, CUB asserts that Idaho Power should analyze the effect that different early retirement dates would have on the need for pollution controls at Bridger Units 3 and 4 to inform whether the currently planned investment is cost-effective. CUB notes that a shorter life may reduce the controls needed (and therefore costs), making early retirement of coal plants more cost-effective than other options. RNW adds that Idaho Power did not adequately analyze conversion to natural gas or a sufficient range of future $CO_2$ compliance costs. Also, RNW believes that investing in coal units is generally not reasonable under scenarios with low natural gas costs or stringent $CO_2$ regulation or both.

Idaho Power disagrees with RNW's and CUB's conclusions regarding its analysis for Bridger Units 3 and 4, noting that it examined a range of options including early shutdown and conversion to natural gas, and that its analysis shows that installation of SCR at Bridger Units 3 and 4 is the least cost option for the majority of the alternate carbon and natural gas scenarios it modeled.

Staff recommends we acknowledge installation of SCR at Bridger Units 3 and 4. Staff concludes that Idaho Power's coal study demonstrates that the SCR investments are the lowest cost compared to the alternatives analyzed under planning case assumptions and in the majority of the carbon and gas sensitivities. In addition to reviewing the coal study, Staff constructed an independent spreadsheet analysis of the impact of a range of gas and carbon prices on the economics of the SCR investments, which confirmed the coal study results.

*b. Commission Resolution*

Based on the information we have at this time, we decline to acknowledge Idaho Power's action item related to Bridger Units 3 and 4. Our decision regarding these investments is inextricably tied to our decision regarding the same investments in the docket opened to address PacifiCorp's IRP, docket LC 57. In that docket, we did not acknowledge the investments for Bridger Units 3 and 4 for four interrelated reasons.

First, some of the alternatives modeled by PacifiCorp suggest that the installation of SCR at Bridger Units 3 and 4 is not the lowest cost resource option. Second, there were gaps in the analyses conducted by PacifiCorp. Third, some of the questions raised by Staff and other participants on the merit of retaining or retiring the units were not fully fleshed out, while others are more appropriately addressed in a rate proceeding. Finally, PacifiCorp,

the managing utility, is proceeding with the investments, which calls into question the appropriateness of addressing the investments in a planning docket.

We recognize that Idaho Power conducted its own analysis of whether installing SCR at Bridger Units 3 and 4 is the least cost and least risk option. However, Idaho Power's analysis does not persuade us to reach a resolution in this docket that differs from that in docket LC 57, at least in part because of deficiencies in Idaho Power's analysis. More specifically, Idaho Power did not (1) analyze a full range of reasonable scenarios; (2) consider a wider range of resource replacement options as PacifiCorp; or (3) evaluate an adequate range of natural gas price sensitivities.

Idaho Power is proceeding with the investments. We will undertake a fair and thorough investigation of the prudence of the SCR investments when Idaho Power seeks rate recovery. Our decision to not acknowledge them in this docket does not prejudge the prudence of the investments for purposes of rate recovery.

**C. Demand Response**

Idaho Power proposes the following near-term action related to demand response:

*2016-2017* *Have demand response capacity available to satisfy deficiencies up to approximately 150 MW*

*a. Participants' Comments*

Staff notes that both the Oregon and Idaho commissions recently issued orders approving stipulations regarding the redesign of Idaho Power's demand response programs for 2014 and beyond. Those stipulations provide that the annual value of demand response is equal to the levelized annual cost of the minimum size deferred resource, or 170 MW. Therefore, Staff recommends changing this action item to read: "Have demand response capacity available to satisfy deficiencies up to approximately ~~150 MW~~ 170 MW beginning in 2014, and increasing as needed through 2017."

Staff also recommends that the company update its assessment of demand response availability based on summer 2014 program participation and other relevant factors by the end of 2014. In addition, Staff recommends that the Energy Efficiency Advisory Group review any revisions to the resource assessment, along with other relevant factors.

RNW supports Idaho Power's continuation of its demand response program to meet the company's capacity needs.

*b. Commission Resolution*

We agree that revising the near-term demand response action item as recommended by Staff is appropriate in light of recently concluded dockets in Oregon and Idaho regarding demand response. We acknowledge the action item as revised by Staff. We also expect that Idaho Power will follow Staff's recommendation regarding updating its assessment of demand response availability in 2014.

ORDER NO. 14 253

**D. Long-term Action Items**

Idaho Power's Action Plan includes the following long-term activities:

| | |
|---|---|
| *2019* | *Shoshone Falls – Upgrade complete and in service* |
| *2019* | *Jim Bridger Unit 2 – Commit to the installation of selective catalytic reduction emission-control technology* |
| *2020* | *Jim Bridger Unit 1 – Commit to the installation of selective catalytic reduction emission-control technology* |
| *2020* | *Boardman – Coal-fired operations at the Boardman plant are scheduled to end by year-end* |
| *2024-2032* | *Demand Response – Have demand response capacity available to satisfy deficiencies in 50 MW increments up to approximately 370 MW* |

*a. Participants' Comments*

Both Staff and CUB note, and Idaho Power acknowledges, that Idaho Power's Action Plan includes long-term action items in addition to the short-term action items typically presented in an IRP action plan. Staff and CUB recommend that we not acknowledge action items occurring beyond a two-to-four year period. In response, Idaho Power states that it does not seek acknowledgment of the long-term items.

*b. Commission Resolution*

Although Idaho Power states it does not seek acknowledgment of these long-term action items, they remain part of the company's IRP. For this reason, we believe it is necessary to address them. We do not acknowledge these action items because, as Staff and CUB note, the purpose of an action plan is to identify specific near-term actions that the company plans to take to meet its resource needs.[7] We generally do not acknowledge action items planned to occur more than four years in the future.[8]

**D. Analysis of IRP**

***1. Wind Resources***

*a. Participants' Comments*

Several participants raise concerns related to wind resources. RNW asserts that Idaho Power's IRP underestimates the capacity factor of modern wind turbines and includes an unsupported and unreasonably high wind integration rate.

Staff and RNW raise concerns about Idaho Power's wind integration study (WIS), and the company's use of the technical review committee (TRC) we recommended the

[7] *See* Order No. 12-177.
[8] *Id.*

company form to improve such studies.[9] Staff notes that it anticipated more involvement of the TRC and recommends that Idaho Power engage with the TRC for future IRPs. RNW adds that Idaho Power's WIS based the size of the required balancing reserve on the difference between the day-ahead forecast and actual generation, which increased the assumed balancing reserves and costs. RNW notes that the TRC we required in Order No. 12-177 flagged this methodological assumption as a significant concern. Staff shares RNW's concern, and has reservations about using the study results in future filings.

In response to RNW's concern regarding overstated costs, Idaho Power notes the cost difference between the National Renewable Energy Laboratory (NREL) report and its costs comes from the conversion of 2009 dollars to 2013 dollars, the common base for the IRP's comparison of resource costs. In response to RNW's concern regarding the size of the balancing reserves, Idaho Power states that it chose to base the assumption on the day-ahead forecast because balancing reserves based on the hour-ahead forecast "would too often translate to a risky reliance on the wholesale energy market."

In response to RNW's concern regarding the average capacity factor, Idaho Power asserts that the NREL reports that Class 3 resources have an average capacity factor of 33 percent—a percentage Idaho Power adjusted downward to account for lower capacity factors of Class 2 resources. Idaho Power also asserts that its actual observations support the 26 percent average capacity factor used in the WIS and IRP.

In response to Staff's and RNW's concern regarding the role of the TRC, Idaho Power notes that we directed the company to form the committee in February 2012, nearly a year after the company had begun work on the WIS. Idaho Power announced the formation of the committee at an April 2012 workshop, but by this time the study was complete and the company was presenting preliminary study results.

*b. Commission Resolution*

We appreciate that Idaho Power responded quickly to our recommendation but are disappointed the TRC did not prove to be an effective mechanism for stakeholders to engage with Idaho Power regarding the analytical methodology of the WIS. Using the TRC to review and provide comments on the analytical methodology and results is not what we envisioned when making our 2012 recommendation. But, we recognize that our recommendation came late in Idaho Power's process, limiting the opportunity for TRC input.

We continue to recommend use of a TRC in connection with wind integration studies. The TRC could be an effective mechanism for stakeholders to engage with the company regarding the analytical methodology underlying the study and expect Idaho Power to engage with the TRC at the outset of any future study.

Regarding RNW's specific complaints regarding the WIS, we note that RNW does not urge us to disregard the WIS for the purpose of judging the reasonableness of Idaho Power's IRP, but cautions against using the WIS to determine avoided cost prices in a

[9] *Id.* at Appendix A at 3.

future proceeding. Our acknowledgment of Idaho Power's IRP has no effect on the validity of the WIS during any proceeding to establish avoided cost prices for variable wind resources. We do note, however, that effective engagement between stakeholders and utilities regarding the study methodology and inputs would likely lessen disagreements in any proceeding in which the accuracy of the study is at issue.

***2. Capacity Contribution of Solar and Other Resources***

*a. Participants' Comments*

ODOE recommends certain changes to how Idaho Power examines capacity credits for solar, wind, and hydro resources, and how the company models orientation of flat-plate solar PV systems.

Idaho Power disagrees with ODOE's specific recommendation regarding the capacity contribution, but recognizes that solar resources are unique and that its analysis must address numerous considerations such as tracking systems, resource orientation, and materials. Idaho Power states it seeks to attribute the proper capacity credit to distributed solar PV and has initiated an IRP Advisory Council distributed solar PV workgroup to address the cost and capacity credit of distributed solar PV in the 2015 IRP. Idaho Power states that it anticipates the workgroup will address topics such as panel orientation and tracking systems. Idaho Power also states that it is analyzing integration of large-scale solar PV projects and working on this topic with members of its Solar Integration Study Technical Review Committee.

*b. Commission Resolution*

We appreciate Idaho Power's willingness to work on the issues identified by ODOE for its next IRP. We hope Idaho Power will work directly with ODOE. In any event, we expect to see results of Idaho Power's work in its 2015 IRP.

***3. Gas Price Forecasts***

*a. Participants' Comments*

Staff comments on three aspects of Idaho Power's natural gas price forecasts used in the IRP. Staff expresses concerns regarding the symmetric adjustments to the base case forecast, the escalation of the Energy Information Administration (EIA) reference case gas price forecast, and the high correlation between natural gas prices and wholesale electricity prices in the company's modeling. Staff identifies gas price forecasts as an issue to be analyzed during the development of the 2015 IRP. The company responds that its stochastic inputs are reasonable and that it will consider alternatives to deriving high and low gas price scenarios for future IRPs.

*b. Commission Resolution*

We anticipate that these analytical issues will be raised by Staff and addressed during the planning process for the 2015 IRP.

ORDER NO. 14 253

### 4. *Flexibility Guideline*

In our investigation of matters related to electric vehicle charging, we adopted our Staff's recommendation to add an IRP guideline to require utilities to incorporate planning for flexible capacity in IRPs.[10] Utilities must forecast the balancing reserves needed at different time intervals to respond to variation in load and intermittent renewable generation over the 20-year planning period and to forecast the availability of balancing reserves at different time intervals. In planning to fill any gap between the demand and supply of flexible capacity, utilities must also evaluate all resource options on a consistent and comparable basis.

#### *a. Participants' Comments*

RNP asserts that Idaho Power's IRP does not comply with the IRP Guidelines because it does not forecast the demand for and supply of flexible capacity, or evaluate flexible resources on a consistent and comparable basis. RNW suggests that future IRPs should quantify the existing supply of flexible resources across multiple time scales, quantify the amount of reserves associated with each supply-side resource, and expand types of demand for flexible resources, *e.g.*, need to meet hourly ramps of load and other variable resources.

Idaho Power responds that its 2013 IRP did, in fact, include much of the flexibility analysis that RNW asserts is lacking. Idaho Power notes that a pumped storage hydro project was modeled as a resource alternative and as a tool to assist in the integration of wind resources. Idaho Power asserts that this modeling captured the flexibility and peaking capacity of the pumped storage hydro project and helped to integrate the variable wind generation into the system, and captured market arbitrage opportunities.

Staff recognizes that the company provided qualitative analysis that shows it is unlikely Idaho Power will need additional flexible capacity over the 20-year planning horizon, but agrees with RNW that the guideline asks for quantitative analysis of the size and timing of the flexible capacity resource balance. Staff recommends that Idaho Power substantially expand its analysis in the 2015 IRP. Staff is willing to work with Idaho Power and other stakeholders to help develop the quantitative analysis.

#### *b. Commission Resolution*

We find that Idaho Power's IRP does not comply with the Flexible Resources Guideline. Idaho Power did not submit the required analysis of demand and supply of balancing reserves disaggregated across multiple timescales. We expect the company to use the recommendations of both RNW and Staff to provide a compliant and more robust analysis regarding flexible resources in its 2015 IRP.

---

[10] Order No. 12-013 at16-18.

ORDER NO. 14 255

### 5. *Conservation Voltage Reduction*

Staff states that Idaho Power failed to include the required assessment of the available cost effective conservation voltage reduction (CVR) in its service area. Staff explains that we directed the assessment in our review of Idaho Power's 2012 IRP:

> The next IRP filed by Idaho Power will include an assessment of the available cost-effective conservation voltage reduction (CVR) resource potential in its service area. The company will propose an action item in its 2013 IRP related to this resource. The planned energy savings and reduced peak demand will be incorporated into Idaho Power's load-resource balance forecasts.[11]

We agree that Idaho Power's 2013 IRP failed to include this assessment, and direct the company to provide this assessment in its 2015 IRP.

In the interim, we direct our Staff to conduct the independent CVR and Volt/Var Ampere Reactive control programs we ordered in Idaho Power's 2013 Annual Smart Grid Report.[12] Staff should conduct the analysis within the next six months and report the results of the analysis to us at a public meeting.

### 6. *Energy Efficiency*

Although Idaho Power's IRP contains specific energy efficiency targets as part of its plan, the company does not include those amounts in the Action Plan. Staff proposes two action items to address energy efficiency:

| | | |
|---|---|---|
| *2013-2017* | *Energy Efficiency* | *The forecast reduction for 2013 to 2017 programs will be 69 aMW* |
| *2013-2017* | *Energy Efficiency* | *The incremental energy efficiency savings for 2013 to 2017 will reduce energy loads by 38 aMW* |

We adopt Staff's proposed additions to the Action Plan.

### 7. *NEEA*

Idaho Power plans to curtail funding to the Northwest Energy Efficiency Alliance (NEEA) in the next five-year funding cycle. Idaho Power explains that it has asked NEEA to operate under an alternative funding model that would allow Idaho Power's funds to be directed toward the costs of activities that Idaho Power believes are most valuable to its customers. Idaho Power supports the concept of optional programs in NEEA's 2015-2019 Business Plan in which funders could choose to participate and fund certain programs or opt out of them altogether.

---

[11] Order No. 12-177 at 5.
[12] Order No. 13-481 at 1-2.

ORDER NO. 14 257

*a. Participants' Comments*

CUB and Staff are concerned with Idaho Power's proposal to curtail funding to NEAA. Staff believes that NEAA is one of Idaho Power's most cost effective energy investments. Staff notes that NEEA is a compact between over 100 Northwest utilities and efficiency organizations that creates value for its supporters by broad market intervention and energy efficiency market development. NEEA's activities have resulted in the development of an energy efficiency products and practices pipeline to the region that benefits Idaho Power's and the region's ratepayers.

*b. Commission Resolution:*

We do not know Idaho Power's final decision about continued participation in NEEA. However, we are dismayed by the possibility that Idaho Power's approach could undermine support for regional market transformation. We agree with Staff's observations of the importance of NEEA. We believe that market transformation is an integral part of an effective energy efficiency strategy to lower cost and risk to ratepayers. Based on our analysis and our continued oversight of funding to NEEA from Oregon ratepayers, we believe that NEEA is capturing cost-effective energy efficiency over the long run and expanding opportunities for cost-effective energy efficiency in the future. For those programs Idaho Power opts out of, we expect Idaho Power will acquire commensurate savings from equivalent services at a cost equal to or less than what NEEA could provide.

**D. Recommendations For Idaho Power's 2015 IRP**

In Order No. 12-177, we reminded Idaho Power that IRP Guideline 4(n) requires utilities to include in an IRP action plan the resource activities the utility plans to undertake over the next two to four years to acquire the identified resources. We also recommended that Idaho Power's future IRPs include a "concise listing of action items for all resources and resource related activities, with each action item numbered."[13]

Idaho Power did include an action plan with resource activities it plans to take in the next two to four years, but the plan also includes longer-term actions. We clarify that, in future IRPs, Idaho Power should limit its Action Plan to activities it plans to undertake in the next two to four years. Idaho Power may compile other lists of activities planned for an extended period, as it has done in this IRP, but we recommend the company create and identify the action plan activities for which it requests specific acknowledgment. Again, we recommend that the company number each of these action items to facilitate our review.

**E. IRP Update**

Staff sought delays in these proceedings to facilitate our review of resource action items presented for acknowledgment in both PacifiCorp's IRP and Idaho Power's IRP.

[13] Order No. 12-177 at 8.

ORDER NO. 14 255

As a result of this delay, Idaho Power's annual update to its 2013 IRP, which is due no later than 12 months after acknowledgment. However, Idaho Power must file its 2015 IRP with the Idaho Public Utilities Commission no later than June 2015. Idaho Power intends to file an IRP in Oregon at the same time it files in Idaho.

Given that Idaho Power will file its next IRP with the Idaho commission by June 2015, we waive the requirement that Idaho Power file an annual update to this IRP. This waiver addresses only a routine IRP update, and we expect Idaho Power to file an IRP update if it anticipates a significant deviation from its acknowledged 2013 IRP in the manner required by IRP Guideline 3(f).

## V. ORDER

IT IS ORDERED that the 2013 Integrated Resource Plan filed by Idaho Power Company is acknowledged in part consistent with the terms of this order.

Made, entered, and effective JUL 08 2014.

**Susan K. Ackerman**
Chair

**John Savage**
Commissioner

**Stephen M. Bloom**
Commissioner

ORDER NO. 14 253

# Appendix A

**Acknowledged Action Plan Items**

| Year | Resource - Action |
|---|---|
| 2013- 2018 | Boardman to Hemingway – Ongoing permitting, planning studies, and regulatory filings |
| 2013 | Gateway West – Ongoing permitting, planning studies, and regulatory filings |
| 2013 | North Valmy Unit 1 – Commit to the installation of dry sorbent injection emission-control technology |
| 2016-2017 | Have demand response capacity available to satisfy deficiencies up to approximately 170 MW beginning in 2014, and increasing as needed through 2017 |
| 2013-2017 | Energy efficiency – The forecast reduction for 2013 to 2017 programs will be 69 aMW |
| 2013-2017 | The incremental energy efficiency savings for 2013-2017 will reduce energy loads by 38 aMW |
| 2013-2015 | CVR – Include an assessment of the available cost-effective conservation voltage reduction (CVR) resource potential in service area and an action item related to this resource in the next IRP. Incorporate the planned energy savings and reduced peak demand into load-resource balance forecasts. |

APPENDIX A
Page 1 of 1

# Compliance with State of Oregon IRP Guidelines

## A. Transmission

### 1. Boardman to Hemingway

***Commission Resolution (Order No. 14-253):***

We acknowledge ongoing permitting, planning studies, and regulatory filings for B2H. As Staff notes, the analysis in the IRP supports these planned near-term activities. We anticipate additional analysis regarding B2H in Idaho Power's 2015 IRP before acknowledging other actions related to B2H. We decline to acknowledge completion of B2H because it is well beyond the two-to-four year period for action items specified by the IRP Guidelines. Further, we disagree with any suggestion that declining to acknowledge the construction of B2H is inconsistent with our previous acknowledgment of certain activities (e.g., permitting) related to this resource or inconsistent with previous orders acknowledging IRPs based on a preferred portfolio that includes B2H. Our acknowledgment of an IRP is based on our conclusion that it complies with our guidelines and that the plan seems reasonable based on information known at the time.

***Idaho Power Response (2015 IRP):***

Discussion specific to B2H is found in Chapter 6 (Transmission Planning), section Boardman to Hemingway, pages 71-72. Portfolio design for the 2015 IRP provides a comparison of portfolios having B2H as a resource to portfolios not having B2H. A tabulation of resource portfolios with respect to B2H inclusion is provided in Chapter 8 (Portfolio Selection), section *Portfolio Design Summary*, page 111.

### 2. Gateway West

***Commission Resolution (Order No. 14-253):***

We acknowledge ongoing permitting, planning studies, and regulatory filings for Gateway West. However, as CUB notes, the project is composed of multiple segments that can and should be analyzed individually. Moreover, Idaho Power has an ownership interest in relatively few of the segments and must demonstrate the need and specific constraint-related benefits for each segment in which it holds an interest before we will consider acknowledgment of the project's construction.

***Idaho Power Response (2015 IRP):***

Discussion specific to Gateway West is found in Chapter 6 (Transmission Planning), pages 69–71. The results of a "need" analysis are provided in the section Gateway West Need Analysis, pages 70–71.

## B. Pollution Control Investments in Coal Resources

### 1. Idaho Power's Analysis

Commission Resolution (Order No. 14-253):

We conclude that Idaho Power's IRP complies with IRP Guideline 8, but as discussed below, is not sufficient to provide a basis to support acknowledgment of selective catalytic reduction emission-control technology (SCR) at Jim Bridger units 3 and 4. Guideline 8 does not require Idaho Power to model every feasible alternative scenario, but requires the company to determine the PVRR costs and risk measures of a "set of reasonable alternative portfolios" assuming a range of different compliance scenarios. Although Idaho Power did not model a scenario in which both North Valmy units and Bridger units 3 and 4 were converted to natural gas facilities, as RNW believes should have been done, Idaho Power did model a scenario in which North Valmy is converted to natural gas and Bridger units 3 and 4

are replaced with CCCTs (portfolio 6). In addition, although Idaho Power did not build a compliance scenario that specifically accounts for the June 2013 Presidential Memorandum, Idaho Power did test its portfolios against a range of carbon compliance futures including a carbon adder in the planning case of $14.64 per ton beginning in 2018 and escalating three percent annually, and a carbon adder in the high case of $35 per ton beginning in 2018 and escalating nine percent annually.

The carbon adder was modeled at three levels: low ($0), planning, and high. Idaho Power did not model a distribution of values, as was done with gas prices, load, and hydro in the stochastic analysis. Instead, one-third of the simulations were drawn from each carbon adder level. The company's analysis showed the preferred portfolio 2 and the non-coal portfolio 6 would switch places at a carbon adder of $45 in 2018. We find the alternative portfolios selected by Idaho Power and the range of compliance futures sufficient to satisfy the requirements of Guideline 8.

We share CUB's and Staff's concern regarding the limited nature of Idaho Power's early retirement scenario analysis. Even though Idaho Power may have technically complied with the action item from Order No. 12-177, we expected that Idaho Power would model a broader range of early shutdown scenarios. We expect Idaho Power to engage fully with Staff and stakeholders in a timely manner to design coal investment analyses for future IRPs to ensure more robust consideration of early shutdown as a compliance option.

Also, we direct Idaho Power to work with stakeholders to explore options for how it plans to model and perform analysis in the 2015 IRP in order to comply with the applicable emissions requirements of Section 111(d) of the Clean Air Act.

***Idaho Power Response (2015 IRP):***

The 2015 IRP considers multiple early retirement scenarios as described in Chapter 8 (Portfolio Selection), pages 97–111. These early retirement scenarios were developed with input from the IRP Advisory Council and public participants of the IRP process, including input received at a portfolio design workshop held on January 28, 2015.

CAA Section 111(d) was discussed frequently during IRP Advisory Council meetings. A discussion led by IRP Advisory Council member John Chatburn (Idaho Office of Energy Resources) was held as part of the December 4, 2014 IRP Advisory Council meeting. Multiple sensitivities for CAA Section 111(d) were analyzed for the IRP. These sensitivities are described in Chapter 9 (Modeling Analysis and Results), section *CAA Section 111(d) Sensitivity Analysis*, pages 114–120.

## 2. North Valmy Unit 1

***Commission Resolution (Order No. 14-253):***

We acknowledge installation of DSI at North Valmy Unit 1. We find as Staff did that the relatively low cost of the investment leads to the conclusion that the DSI investment and continued operation of North Valmy is the least cost/least risk alternative given the information that is currently available.

We do not share CUB's concern regarding how Idaho Power included North Valmy in its preferred portfolio. First, shortening the life of North Valmy would not change the result of Idaho Power's analysis; installing DSI would still be the least cost/least risk alternative. Second, future events may lead to a shortened operating life for North Valmy, but whether they will is not certain. Idaho Power reasonably relied on the results of modeling based on the assumption North Valmy will operate as Idaho Power currently expects, rather than an assumption based on events that may, or may not, transpire.

***Idaho Power Response (2015 IRP):***

No action required.

### 3. Jim Bridger Units 3 and 4

***Commission Resolution (Order No. 14-253):***

Based on the information we have at this time, we decline to acknowledge Idaho Power's action item related to Bridger units 3 and 4. Our decision regarding these investments is inextricably tied to our decision regarding the same investments in the docket opened to address PacifiCorp's IRP, docket LC 57. In that docket, we did not acknowledge the investments for Bridger units 3 and 4 for four interrelated reasons.

First, some of the alternatives modeled by PacifiCorp suggest that the installation of SCR at Bridger units 3 and 4 is not the lowest cost resource option. Second, there were gaps in the analyses conducted by PacifiCorp. Third, some of the questions raised by Staff and other participants on the merit of retaining or retiring the units were not fully fleshed out, while others are more appropriately addressed in a rate proceeding. Finally, PacifiCorp, the managing utility, is proceeding with the investments, which calls into question the appropriateness of addressing the investments in a planning docket.

We recognize that Idaho Power conducted its own analysis of whether installing SCR at Bridger units 3 and 4 is the least cost and least risk option. However, Idaho Power's analysis does not persuade us to reach a resolution in this docket that differs from that in docket LC 57, at least in part because of deficiencies in Idaho Power's analysis. More specifically, Idaho Power did not (1) analyze a full range of reasonable scenarios; (2) consider a wider range of resource replacement options as PacifiCorp; or (3) evaluate an adequate range of natural gas price sensitivities.

Idaho Power is proceeding with the investments. We will undertake a fair and thorough investigation of the prudence of the SCR investments when Idaho Power seeks rate recovery. Our decision to not acknowledge them in this docket does not prejudge the prudence of the investments for purposes of rate recovery.

***Idaho Power Response (2015 IRP):***

A section titled Jim Bridger units 3 and 4 SCR Analysis is included in *Appendix C—Technical Appendix*.

## *C. Demand Response*

### Commission Resolution (Order No. 14-253):

We agree that revising the near-term demand response action item as recommended by Staff is appropriate in light of recently concluded dockets in Oregon and Idaho regarding demand response. We acknowledge the action item as revised by Staff. We also expect that Idaho Power will follow Staff's recommendation regarding updating its assessment of demand response availability in 2014.

### Idaho Power Response (2015 IRP):

The performance of demand response programs in 2014 is provided in Chapter 4 (Demand-Side Resources), section *Demand Response Performance*, pages 42–43. Chapter 4 also notes that demand response is forecast to provide 390 MW of peak reduction during July throughout the planning period (section *Committed Demand Response*, page 46).

## D. Long-Term Action Items

### Commission Resolution (Order No. 14-253):

Although Idaho Power states it does not seek acknowledgment of these long-term action items, they remain part of the company's IRP. For this reason, we believe it is necessary to address them. We do not acknowledge these action items because, as Staff and CUB note, the purpose of an action plan is to identify specific near-term actions that the company plans to take to meet its resource needs. We generally do not acknowledge action items planned to occur more than four years in the future.

### Idaho Power Response (2015 IRP):

The action plan provided in the 2015 IRP is focused on resource actions for the four-year period 2015-2018. The action plan is provided in Chapter 1 (Summary), section *Action Plan*, page 10–11. The action plan is also provided in Chapter 10 (Action Plan), section *Action Plan (2015–2018)*, pages 141–143.

## E. Analysis of IRP

### 1. Wind Resources

#### *Commission Resolution (Order No. 14-253):*

We appreciate that Idaho Power responded quickly to our recommendation but are disappointed the TRC did not prove to be an effective mechanism for stakeholders to engage with Idaho Power regarding the analytical methodology of the WIS. Using the TRC to review and provide comments on the analytical methodology and results is not what we envisioned when making our 2012 recommendation. But, we recognize that our recommendation came late in Idaho Power's process, limiting the opportunity for TRC input.

We continue to recommend use of a TRC in connection with wind integration studies. The TRC could be an effective mechanism for stakeholders to engage with the company regarding the analytical methodology underlying the study and expect Idaho Power to engage with the TRC at the outset of any future study.

Regarding RNW's specific complaints regarding the WIS, we note that RNW does not urge us to disregard the WIS for the purpose of judging the reasonableness of Idaho Power's IRP, but cautions against using the WIS to determine avoided cost prices in a future proceeding. Our acknowledgment of Idaho Power's IRP has no effect on the validity of the WIS during any proceeding to establish avoided cost prices for variable wind resources. We do note, however, that effective engagement between stakeholders and utilities regarding the study methodology and inputs would likely lessen disagreements in any proceeding in which the accuracy of the study is at issue.

#### *Idaho Power Response (2015 IRP):*

No action required.While no IRP-related action is required, Idaho Power notes the use of a technical review committee from the outset of its first solar integration study, completed in June 2014. A technical review committee has also been in place since the January 2015 start of Idaho Power's second solar integration study.

## 2. Capacity Contribution of Solar and Other Resources

***Commission Resolution (Order No. 14-253):***

We appreciate Idaho Power's willingness to work on the issues identified by ODOE for its next IRP. We hope Idaho Power will work directly with ODOE. In any event, we expect to see results of Idaho Power's work in its 2015 IRP.

***Idaho Power Response (2015 IRP):***

Idaho Power convened public working group meetings to address solar-related issues, including capacity contribution, on August 6, 2014 and September 3, 2014. The results of the solar capacity contribution analysis conducted as part of the working group meetings are provided in Chapter 5 (Supply-Side Generation and Storage Resources), section *Solar Capacity Credit*, pages 50–51.

## 3. Gas Price Forecasts

***Commission Resolution (Order No. 14-253):***

We anticipate these analytical issues will be raised by Staff and addressed during the planning process for the 2015 IRP.

***Idaho Power Response (2015 IRP):***

The natural gas price forecast is provided in Chapter 7 (Planning Period Forecasts), section *Natural Gas Price Forecast*, pages 84–85. As noted in this section, Idaho Power uses EIA published nominal forecast prices. Also noted is the use of the EIA high resource case for the low case natural gas price forecast, and similarly use of the EIA low resource case for the high case natural gas price forecast. Finally, part of AURORA model calibration conducted for the IRP is verification that future power market (i.e., Mid-C) prices derived by the AURORA model maintain their historic relationship to natural gas market prices. The ratio of these prices, power market and natural gas market, is called the implied market heat rate. Idaho Power verified that future implied market heat rate values (ratio of AURORA-derived power market price to input natural gas market price) reasonably approximate historic values for this ratio. The implied market heat rate analysis was presented to the IRP Advisory Council and public participants at the February 5, 2015 IRP Advisory Council meeting.

## 4. Flexibility Guideline

***Commission Resolution (Order No. 14-253):***

We find that Idaho Power's IRP does not comply with the Flexible Resources Guideline. Idaho Power did not submit the required analysis of demand and supply of balancing reserves disaggregated across multiple timescales. We expect the company to use the recommendations of both RNW and Staff to provide a compliant and more robust analysis regarding flexible resources in its 2015 IRP.

***Idaho Power Response (2015 IRP):***

A discussion of the 2015 IRP's analysis for the flexibility guideline is provided in Chapter 9 (Modeling Analysis and Results), section *Flexible Resource Needs Assessment*, pages 135–139. Figure 9.4 on page 143 presents a projection for flexibility need across multiple timescales. Simulations of the system capability to provide flexibility are illustrated in Figures 9.5 through 9.9 on pages 136-138.

## 5. Conservation Voltage Reduction

***Commission Resolution (Order No. 14-253):***

Staff states that Idaho Power failed to include the required assessment of the available cost effective conservation voltage reduction (CVR) in its service area. Staff explains that we directed the assessment in our review of Idaho Power's 2012 IRP:

> The next IRP filed by Idaho Power will include an assessment of the available cost-effective conservation voltage reduction (CVR) resource potential in its service area. The company will propose an action item in its 2013 IRP related to this resource. The planned energy savings and reduced peak demand will be incorporated into Idaho Power's load-resource balance forecasts.

We agree that Idaho Power's 2013 IRP failed to include this assessment, and direct the company to provide this assessment in its 2015 IRP. In the interim, we direct our Staff to conduct the independent CVR and Volt/Var Ampere Reactive control programs we ordered in Idaho Power's 2013 Annual Smart Grid Report. Staff should conduct the analysis within the next six months and report the results of the analysis to us at a public meeting.

***Idaho Power Response (2015 IRP):***

CVR is discussed in Chapter 4 (Demand-Side Resources), section *Conservation Voltage Reduction*, page 48. The 2015 IRP's treatment of CVR was communicated to OPUC staff in a conference call on August 22, 2014.

## 6. Energy Efficiency

***Commission Resolution (Order No. 14-253):***

We adopt Staff's proposed additions to the Action Plan. [Staff proposed the addition of action plan items specifying IRP energy efficiency targets.]

***Idaho Power Response (2015 IRP):***

The action plan provided in the 2015 IRP includes an action item related to the pursuit of cost-effective energy efficiency, and expresses energy efficiency targets in a manner similar to that proposed by Staff. The action plan is provided in Chapter 1 (Summary), section *Action Plan*, pages 10–11. The action plan is also provided in Chapter 10 (Action Plan), section *Action Plan (2015–2018)*, pages 141–143.

## 7. NEEA

***Commission Resolution (Order No. 14-253):***

We do not know Idaho Power's final decision about continued participation in NEEA. However, we are dismayed by the possibility that Idaho Power's approach could undermine support for regional market transformation. We agree with Staff's observations of the importance of NEEA. We believe that market transformation is an integral part of an effective energy efficiency strategy to lower cost and risk to ratepayers. Based on our analysis and our continued oversight of funding to NEEA from Oregon ratepayers, we believe that NEEA is capturing cost-effective energy efficiency over the long run and expanding opportunities for cost-effective energy efficiency in the future. For those programs Idaho Power opts out of, we expect Idaho Power will acquire commensurate savings from equivalent services at a cost equal to or less than what NEEA could provide.

***Idaho Power Response (2015 IRP):***

Idaho Power continues its commitment to NEEA as a participant in NEEA's 2015-2019 funding cycle. On September 30, 2014 Idaho Power and NEEA executed a contract to participate in the 2015-2019 funding cycle. For complete details on Idaho Power's involvement in NEEA activities please see pages 9, 141-145 of the Company's Demand-Side Management 2014 Annual Report – Appendix B.

# 2017 IRP

LOOKING FORWARD

## ACKNOWLEDGEMENT

Resource planning is an ongoing process at Idaho Power. Idaho Power prepares, files, and publishes an Integrated Resource Plan (IRP) every two years. Idaho Power expects that the experience gained over the next few years will likely modify the 20-year resource plan presented in this document.

Idaho Power invited outside participation to help develop the 2017 IRP. Idaho Power values the knowledgeable input, comments, and discussion provided by the Integrated Resource Plan Advisory Council and other concerned citizens and customers.

It takes approximately one year for a dedicated team of individuals at Idaho Power to prepare the IRP. The Idaho Power team is comprised of individuals that represent many departments within the company. The IRP team members are responsible for preparing forecasts, working with the advisory council and the public, and performing all the analyses necessary to prepare the resource plan.

Idaho Power looks forward to continuing the resource planning process with customers, public-interest groups, regulatory agencies, and other interested parties. You can learn more about the Idaho Power resource planning process at idahopower.com.

# 1. SUMMARY

## Introduction

The *2017 Integrated Resource Plan* (IRP) is Idaho Power's 13th resource plan prepared to fulfill the regulatory requirements and guidelines established by the Idaho Public Utilities Commission (IPUC) and the Public Utility Commission of Oregon (OPUC). Idaho Power's resource planning process has four primary goals:

1. Identify sufficient resources to reliably serve the growing demand for energy within Idaho Power's service area throughout the 20-year planning period.

2. Ensure the selected resource portfolio balances cost, risk, and environmental concerns.

3. Give equal and balanced treatment to supply-side resources, demand-side measures, and transmission resources.

4. Involve the public in the planning process in a meaningful way.

The 2017 IRP evaluates the 20-year planning period from 2017 through 2036. During this period, load is forecasted to grow by 0.9 percent per year for average energy demand and 1.4 percent per year for peak-hour demand. Total customers are expected to increase to 756,000 by 2036 from 534,000 in 2016. Additional company-owned resources will be needed to meet these increased demands.[1]

Idaho Power owns and operates 17 hydroelectric projects, 3 natural gas-fired plants, 1 diesel-powered plant, and shares ownership in 3 coal-fired facilities. Hydroelectric generation is a large part of Idaho Power's generation fleet; however, hydroelectric plants are subject to variable water and weather conditions. Public and regulatory input encouraged Idaho Power to adopt more conservative planning criteria beginning with the 2002 IRP. In response to this input, Idaho Power continues to develop more conservative streamflow projections and planning criteria for use in resource adequacy planning. Idaho Power has an obligation to serve customer loads regardless of water and weather conditions. Further discussion of Idaho Power's IRP planning criteria can be found in Chapter 7.

[1] Recent company disclosures forecast load growth during the 2016 to 2035 planning period at 1 percent for average energy demand and 1.4 percent for peak-hour demand.

Other resources relied on for planning include demand-side management (DSM) and transmission resources. The goal of DSM programs is to achieve prudent, cost-effective energy efficiency savings and provide an optimal amount of peak reduction from demand response programs. Idaho Power also strives to provide customers with tools and information to help them manage their own energy usage. The company achieves these objectives through the implementation and careful management of incentive programs and through outreach and education.

Idaho Power's resource planning process also includes evaluating additional transmission capacity as a resource alternative to serve retail customers. Transmission projects are often regional resources, and their planning is conducted by regional industry groups, such as the Western Electricity Coordinating Council (WECC) and the Northern Tier Transmission Group (NTTG). Idaho Power coordinates local transmission planning with regional forums, as well as the Federal Energy Regulatory Commission (FERC). Idaho Power is obligated under FERC regulations to plan and expand its local transmission system to provide requested firm transmission service to third parties and to construct and place in service sufficient transmission capacity to reliably deliver energy and capacity to network customers[2] and Idaho Power retail customers.[3] The timing of new transmission projects is subject to complex permitting, siting, and regulatory requirements and coordination with co-participants.

IRPs address Idaho Power's long-term resource needs. Idaho Power plans for near-term energy and capacity needs in accordance with the *Energy Risk Management Policy* and *Energy Risk Management Standards*. The risk management standards were collaboratively developed in 2002 between Idaho Power, IPUC staff, and interested customers (IPUC Case No. IPC-E-01-16). The *Energy Risk Management Policy* and *Energy Risk Management Standards* specifies an 18-month load and resource review period, and Idaho Power assesses the resulting operations plan monthly.

[2] Idaho Power has a regulatory obligation to construct and provide transmission service to network or wholesale customers pursuant to a FERC tariff.

[3] Idaho Power has a regulatory obligation to construct and operate its system to reliably meet the needs of native load or retail customers.

## Public Advisory Process

IRPAC meeting, May 2017

Idaho Power has involved representatives of the public in the resource planning process since the early 1990s. The public forum is known as the IRP Advisory Council (IRPAC). The IRPAC meets most months during the development of the resource plan, and the meetings are open to the public. Members of the council include regulatory, political, environmental, and customer representatives, as well as representatives of other public-interest groups. Many members of the public also participate even though they are not members of the IRPAC. Some individuals have participated in Idaho Power's resource planning process for over 20 years. A list of the 2017 IRPAC members can be found in *Appendix C—Technical Appendix*.

For the 2017 IRP, Idaho Power conducted eight IRPAC meetings, including a workshop designed to explore the potential for distributed energy resources to defer grid investment.

Idaho Power believes working with members of the IRPAC and the public improves the IRP. Idaho Power and the members of the IRPAC recognize that final decisions on the resource plan are made by Idaho Power. However, Idaho Power encourages IRPAC members and members of the public to submit comments expressing their views regarding the 2017 IRP and the resource planning process in general.

## IRP Methodology

A primary goal of the IRP is to ensure Idaho Power's system has sufficient resources to reliably serve customer demand over the 20-year planning period. A tool critical to assessing resource sufficiency is the load and resource balance, which compares projected customer demand with system resources available for meeting demand. An effective IRP methodology identifies deficiencies in the 20-year load and resource balance and analyzes options for satisfying the identified resource deficiencies. The practical implication of successful integrated resource planning is that system operators of the future are equipped with a system having sufficient resources to maintain reliable electrical service to Idaho Power's customers.

Resource sufficiency is assessed for energy and capacity. Existing supply-side resources include generation resources and transmission import capacity from regional wholesale electric markets. Existing demand response resources are included in the capacity resource sufficiency assessment

as well. Idaho Power then includes the IRP target amount of cost-effective and achievable energy efficiency, which reflects expansion of existing energy-savings potential.

Based on identified resource deficiencies over the planning period, Idaho Power conducts a financial analysis of various resources and all portfolios to quantitatively evaluate the individual resources and resulting portfolios designed to remediate any energy or capacity deficiency over the planning period. Within the financial analysis, Idaho Power evaluates the costs and benefits of each resource type. The financial costs include construction, fuel, operation and maintenance (O&M), transmission upgrades associated with interconnecting new resource options, and anticipated environmental controls. The financial benefits include economic resource operations, projected market sales, and the market value of renewable energy certificates (REC) for REC-eligible resources.

The Idaho Power balancing area is part of the larger western interconnect. Idaho Power must balance loads and generation per North American Electric Reliability Corporation (NERC) system reliability standards. During times of acute oversupply, Idaho Power must rely on available system resources to regain intra-hour balance and must sometimes curtail intermittent resources like wind and solar. Power markets are available via transmission lines to purchase or sell power inter-hour to balance the system.

An additional transmission connection to the Pacific Northwest has been part of Idaho Power's preferred resource portfolio since the 2006 IRP. By the 2009 IRP, Idaho Power determined the approximate configuration and capacity of the transmission line, and since 2009 the addition has been called the Boardman to Hemingway (B2H) Transmission Line Project. Idaho Power again evaluated the B2H transmission line in the 2017 IRP to ensure the transmission addition remains a prudent resource acquisition.

## Greenhouse Gas Emissions

Idaho Power's carbon dioxide ($CO_2$) emission levels have historically been well below the national average for the 100 largest electric utilities in the United States (US), both in terms of $CO_2$ emissions intensity (pounds per megawatt-hour [MWh] generation) and total $CO_2$ emissions (tons) (Figure 1.1 and Figure 1.2).

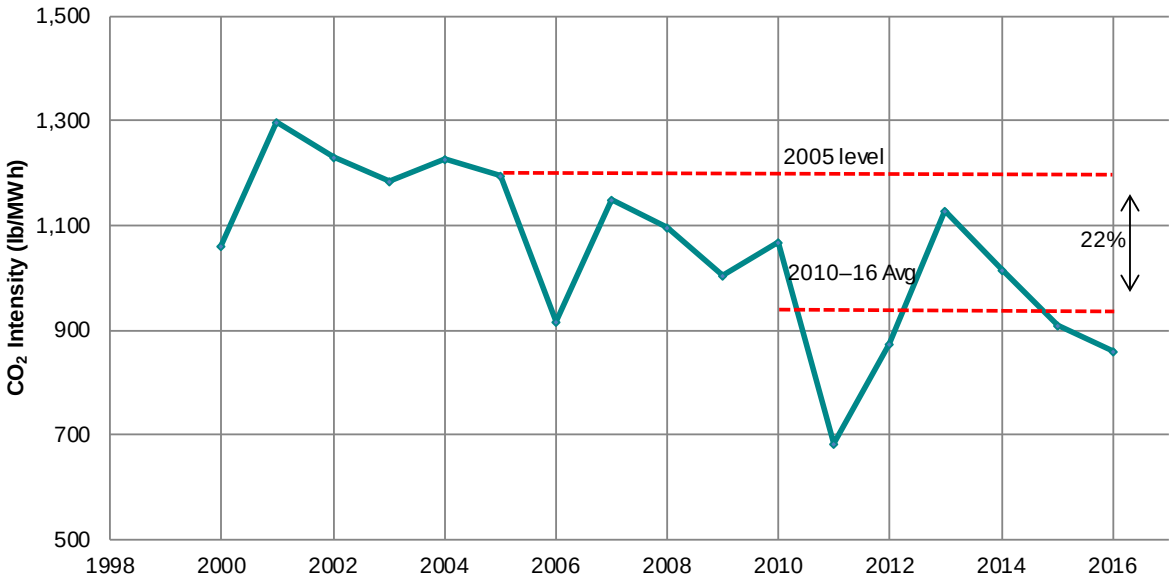

**Figure 1.1 Estimated Idaho Power $CO_2$ emissions intensity**

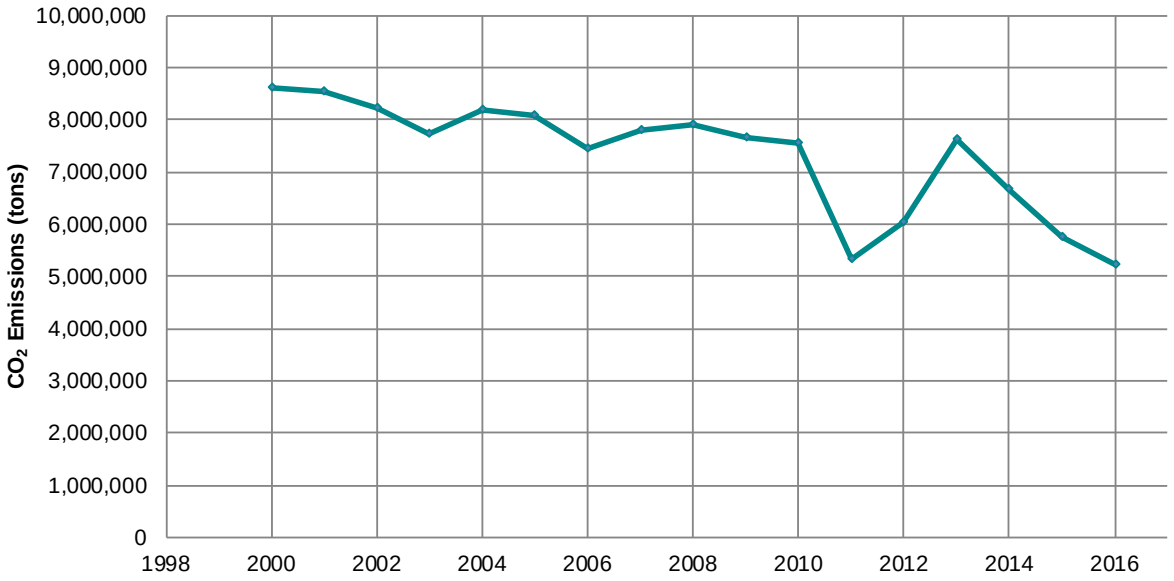

**Figure 1.2 Estimated Idaho Power $CO_2$ emissions**

In September 2009, Idaho Power's Board of Directors approved guidelines to reduce Idaho Power's resource portfolio average $CO_2$ emissions intensity from 2010 through 2013 to 10 to 15 percent below the company's 2005 $CO_2$ emissions intensity of 1,194 pounds per MWh. Because Idaho Power's $CO_2$ emissions intensity fluctuates with streamflows and production levels of existing and anticipated renewable resources, the company has adopted an average intensity reduction goal to be achieved over several years.

Generation and emissions from company-owned resources are included in the $CO_2$ emissions intensity calculation. The company's progress toward achieving this intensity reduction goal and additional information on Idaho Power's $CO_2$ emissions are reported on the company's website.[4] Information related to Idaho Power's $CO_2$ emissions, voluntarily reported annually, is also available through the Carbon Disclosure Project at cdp.net.

In November 2012, the Board of Directors approved an extension of the company's 2010 to 2013 goal for reducing $CO_2$ emissions intensity. The goal as restated in 2012 was to achieve a $CO_2$ emissions intensity 10 to 15 percent below the 2005 $CO_2$ emissions intensity from 2010 to 2015. That goal was met.

In May 2017, the Board of Directors approved the current $CO_2$ emissions intensity goal, which extends the target $CO_2$ emissions intensity of 15 to 20 percent below the 2005 $CO_2$ emissions intensity through 2020. As of the end of 2016, the company's $CO_2$ emissions intensity was 858 pounds per MWh, 28 percent below the 2005 $CO_2$ emissions intensity.

The portfolio analysis performed for the 2017 IRP assumes all resource portfolios comply with state-by-state mass-based emission limits detailed in the Clean Power Plan Final Rule filed in the Federal Register in October 2015. Further discussion of these $CO_2$ emission constraints is provided in Chapter 9. Projected $CO_2$ emissions for each analyzed resource portfolio are provided in *Appendix C—Technical Appendix*.

## Portfolio Analysis Summary

Idaho Power designed the portfolio analysis for the 2017 IRP to inform the IRP's action plan with respect to two key resource actions: 1) selective catalytic reduction (SCR) investments required for Jim Bridger units 1 and 2 by 2022 and 2021, respectively, and 2) the B2H transmission line. To achieve this objective, portfolios were formulated such that the effects of these two resource actions, or factors, could be isolated. This portfolio design approximates a controlled experiment using a factorial experimental design. This design is an effective statistical technique for studying differences between two (or more) factors, each factor having more than one possible level. An outline of the factorial design specifically in the context of the 2017 IRP is as follows:

- **Factor 1:** Treatment of Jim Bridger units 1 and 2
  - Level 1: Invest in SCRs and operate through 2036
  - Level 2: Retire Unit 1 in 2028 and Unit 2 in 2024 (without investing in SCRs)
  - Level 3: Retire Unit 1 in 2032 and Unit 2 in 2028 (without investing in SCRs)
  - Level 4: Retire Unit 1 in 2022 and Unit 2 in 2021 (without investing in SCRs)

[4] idahopower.com/AboutUs/Sustainability/CO2Emissions/co2Intensity.cfm

- **Factor 2:** Primary portfolio element(s)
  - Level 1: B2H
  - Level 2: Solar PV/natural gas-fired generation
  - Level 3: Natural gas-fired generation

Table 1.1 provides a matrix of the factorial design with the portfolios corresponding to each factorial combination.

**Table 1.1 Factorial design applied to portfolios**

| | Primary Portfolio Element(s) | | |
|---|---|---|---|
| **Treatment of Jim Bridger Units 1 and 2** | **B2H** | **Solar PV/Natural Gas** | **Natural Gas** |
| Invest in SCR | P1 | P2 | P3 |
| Retire Unit 1 in 2028 and Unit 2 in 2024 | P4 | P5 | P6 |
| Retire Unit 1 in 2032 and Unit 2 in 2028 | P7 | P8 | P9 |
| Retire Unit 1 in 2022 and Unit 2 in 2021 | P10 | P11 | P12 |

The IRP emphasizes that the validity of the factorial design relies on by-column and by-row uniformity; that is, all portfolios within a given row in the above table must uniformly reflect the same SCR investment scenario, and similarly all portfolios within a given column must uniformly reflect the same primary portfolio element(s). This uniformity is critical to yielding meaningful inferences from the factorial design.

The 12 resource portfolios formulated were analyzed under planning-case conditions for natural gas price, hydroelectric production, and system load. The analysis also included a range of eight natural gas sensitivities and a stochastic risk analysis. The stochastic risk analysis modeled 100 iterations (or futures) on the selected stochastic risk variables: natural gas price, hydroelectric production, and system load. These analyses are described in more detail in Chapter 9. The top performing portfolio from the quantitative portfolio analysis is portfolio 7 (P7). Table 1.1 demonstrates P7 is a portfolio with B2H as the primary element and assumes retirement of Jim Bridger units 1 and 2 in 2032 and 2028, respectively. The resource additions with dates for P7 are provided in Table 1.2.

**Table 1.2 P7 resource additions**

| Date | Resource | Installed Capacity |
|---|---|---|
| 2026 | B2H | 500 megawatts (MW) transfer capacity Apr–Sep, 200 MW transfer capacity Oct–Mar |
| 2031 | Reciprocating engines | 36 MW |
| 2032 | Reciprocating engines | 36 MW |
| 2033 | Combined-cycle combustion turbine (1x1) | 300 MW |
| 2035 | Reciprocating engines | 54 MW |
| 2036 | Reciprocating engines | 54 MW |

The qualitative risk analysis supports the selection of P7, finding that P7 does not carry greater exposure to qualitative risk factors than other portfolios. In fact, P7 has unique qualitative benefits associated with Idaho Power's participation in an energy imbalance market (EIM) and with expanded penetrations of intermittent renewable energy sources. P7 is also consistent with Idaho Power's goals related to responsibly transitioning away from coal-fired generating capacity.

## Action Plan

Table 1.3 provides the schedule of action items Idaho Power anticipates over the next four years. Further discussion surrounding the action plan is provided in Chapter 10.

**Table 1.3 Action plan[5]**

| Year | Resource | Action | Action Number |
|---|---|---|---|
| 2017–2018 | EIM | Continue planning for western EIM participation beginning in April 2018. | 1 |
| 2017–2018 | Loss-of-load and solar contribution to peak | Investigate solar PV contribution to peak and loss-of-load probability analysis. | 2 |
| 2017–2019 | North Valmy Unit 1 | Plan and coordinate with NV Energy Idaho Power's exit from coal-fired operations by year-end 2019. Assess import dependability from northern Nevada. | 3 |
| 2017–2021 | Jim Bridger units 1 and 2 | Plan and negotiate with PacifiCorp and regulators to achieve early retirement dates of year-end 2028 for Unit 2 and year-end 2032 for Unit 1. | 4 |
| 2017–2020 | B2H | Conduct ongoing permitting, planning studies, and regulatory filings. | 5 |
| 2018–2026[6] | B2H | Conduct preliminary construction activities, acquire long-lead materials, and construct the B2H project. | 6 |
| 2017–2021 | Boardman | Continue to coordinate with PGE to achieve cessation of coal-fired operations by year-end 2020 and the subsequent decommission and demolition of the unit. | 7 |
| 2017–2021 | Gateway West | Conduct ongoing permitting, planning studies, and regulatory filings. | 8 |
| 2017–2021 | Energy efficiency | Continue the pursuit of cost-effective energy efficiency. | 9 |
| 2017–2021 | Carbon emission regulations | Continue stakeholder involvement in CAA Section 111(d) proceedings, or alternative regulations affecting carbon emissions. | 10 |
| 2017–2021 | North Valmy Unit 2 | Plan and coordinate with NV Energy Idaho Power's exit from coal-fired operations by year-end 2025. | 11 |

[5] The B2H short-term action plan is 2017 to 2026. All other action plan items are for 2017 to 2021.

[6] B2H in-service date of 2024 or later, subject to coordination of activities with project co-participants.

# 2. POLITICAL, REGULATORY, AND OPERATIONAL ISSUES

## Idaho Strategic Energy Alliance

Under the umbrella of the Idaho Governor's Office of Energy and Mineral Resources (OEMR), the Idaho Strategic Energy Alliance allows various stakeholders to represent and participate in developing energy plans and strategies for Idaho's energy future. The Idaho Strategic Energy Alliance is Idaho's primary mechanism for advancing energy production, energy efficiency, and energy business in Idaho.

The purpose of the Idaho Strategic Energy Alliance is to develop a sound energy portfolio for Idaho that includes diverse energy resources and production methods; the highest value to the citizens of Idaho; quality stewardship of environmental resources; and an effective, secure, and stable energy system.

Idaho Power representatives serve on both the Idaho Strategic Energy Alliance Board of Directors and several volunteer task forces on the following topics:

- Energy efficiency and conservation
- Wind
- Geothermal
- Hydropower
- Carbon issues
- Baseload resources
- Economic/financial development
- Forestry
- Biogas
- Biofuel
- Solar
- Transmission
- Communication and outreach
- Energy storage

## Idaho Energy Primer

In 2016, the Idaho Strategic Energy Alliance prepared the 2016 Idaho Energy Primer (Primer). The Primer is a resource to help citizens of Idaho better understand the contemporary energy landscape in the state and to make informed decisions about Idaho's energy future.

The Primer provides information about energy resources, production, distribution, and use in the state. Having reliable, affordable, and sustainable energy for individuals, families, and businesses while protecting the environment is critical to achieving sustainable economic growth and maintaining our quality of life.

The 2016 Idaho Energy Primer finds that, despite Idaho's reliance on imported energy, Idaho citizens and businesses continue to benefit from stable and secure access to affordable energy. In a year with average hydroelectric generation, about 65 percent of Idaho's electricity is generated in Idaho. The other 35 percent comes primarily from coal-fired power plants located in neighboring states. Idaho has the fifth lowest carbon dioxide output of any state because of its abundant hydropower, wind, biomass, and other renewable energy sources.

## State of Oregon Biennial Energy Plan: 2015–2017

The Oregon Department of Energy (ODOE) completes a Biennial Energy Plan every two years. The ODOE's Biennial Energy Plan provides information on Oregon's energy supply and consumption, shows how long-term energy costs have been reduced, and highlights current energy issues and trends.

The ODOE 2015–2017 Biennial Energy Plan highlights some of the current challenges and opportunities for Oregon, including the following:

- Accelerated demand for energy efficiency due to a growing population in Oregon that drives increases in demand and energy use
- Continued development of clean energy that can help reduce the environmental impact of energy use
- Reduction of carbon emissions
- Energy supply due to numerous market forces that affect the type, number, and geographic diversity of energy siting projects

The 2015–2017 Biennial Energy Plan showed Oregon's energy supply consisting of primarily hydroelectric power, followed by coal and natural gas. The most significant change in electricity consumption from 2005 to 2010 is the growth of natural gas, from 3.3 percent to 16.24 percent. Wind has also grown consistently, increasing from 0.25 percent to 4.31 percent. Oregon's generation mix includes power generated outside of the state and delivered to Oregon consumers.

## FERC Relicensing

Like other utilities that operate non-federal hydroelectric projects on qualified waterways, Idaho Power obtains licenses from FERC for its hydroelectric projects. The licenses last for 30 to 50 years, depending on the size, complexity, and cost of the project.

Bayha Island

Idaho Power's remaining and most significant ongoing relicensing effort is for the Hells Canyon Complex (HCC). The HCC provides approximately two-thirds of Idaho Power's hydroelectric generating capacity and 34 percent of the company's total generating capacity. The current license for the HCC expired in July 2005. Until the new, multi-year license is issued, Idaho Power continues to operate the project under annual licenses issued by FERC.

The HCC license application was filed in July 2003 and accepted by FERC for filing in December 2003. FERC has been processing the application consistent with the requirements of the *Federal Power Act of 1920*, as amended (FPA); the *National Environmental Policy Act of 1969*, as amended (NEPA); the *Endangered Species Act of 1973* (ESA); the *Clean Water Act of 1972* (CWA); and other applicable federal laws. FERC is currently waiting for Oregon and Idaho to issue Section 401 certifications under the CWA. The certifications are expected on or before April 13, 2018.

Efforts to obtain a new multi-year license for the HCC are expected to continue until a new license is issued, which Idaho Power estimates will occur no earlier than 2021. Considering the costs incurred and the considerable passage of time, in December 2016 Idaho Power filed an application with the IPUC requesting a determination that Idaho Power relicensing expenditures of $220.8 million through year-end 2015 were prudently incurred and therefore eligible for inclusion in retail rates. After a new multi-year license is issued, further costs will be incurred to comply with the terms of the new license. Because the new license for the HCC has not been issued and discussions on the protection, mitigation, and enhancement (PM&E) packages are still being conducted, it is not possible to estimate the final total cost.

Relicensing activities include the following:

1. Coordinating the relicensing process
2. Consulting with regulatory agencies, tribes, and interested parties on resource and legal matters

3. Preparing and conducting studies on fish, wildlife, recreation, archaeological resources, historical flow patterns, reservoir operation and load shaping, forebay and river sedimentation, and reservoir contours and volumes

4. Analyzing data and reporting study results

5. Preparing all necessary reports, exhibits, and filings to support ongoing regulatory processes related to the relicensing effort.

Failure to relicense any of the existing hydroelectric projects at a reasonable cost will create upward pressure on the electric rates of Idaho Power customers. The relicensing process also has the potential to decrease available capacity and increase the cost of a project's generation through additional operating constraints and requirements for environmental PM&E measures imposed as a condition of relicensing. Idaho Power's goal throughout the relicensing process is to maintain the low cost of generation at the hydroelectric facilities while implementing non-power measures designed to protect and enhance the river environment.

No reduction of the available capacity or operational flexibility of the hydroelectric plants to be relicensed has been assumed in the 2017 IRP. If capacity reductions or reductions in operational flexibility do occur as a result of the relicensing process, Idaho Power will adjust future resource plans to reflect the need for additional generation resources.

## Idaho Water Issues

Power generation at Idaho Power's hydroelectric projects on the Snake River and its tributaries is dependent on the State water rights held by the company for these projects. The long-term sustainability of the Snake River Basin streamflows, including tributary spring flows and the regional aquifer system, is crucial for Idaho Power to maintain generation from these projects. The company is dedicated to the vigorous defense of its water rights. Idaho Power's ongoing participation in water-right issues and ongoing studies are intended to guarantee sufficient water is available for use at the company's hydroelectric projects on the Snake River.

Idaho Power, along with other Snake River Basin water-right holders, was engaged in the Snake River Basin Adjudication (SRBA), a general streamflow adjudication process started in 1987 to define the nature and extent of water rights in the Snake River Basin. The initiation of the SRBA resulted from the Swan Falls Agreement entered into by Idaho Power and the governor and attorney general of the State of Idaho in October 1984. Idaho Power filed claims for all its hydroelectric water rights in the SRBA. As a result of the SRBA, the company's water rights were adjudicated, resulting in the issuance of partial water-right decrees. The Final Unified Decree for the SRBA was signed on August 25, 2014.

In 1984, the Swan Falls Agreement resolved a struggle between the State of Idaho and Idaho Power over the company's water rights at the Swan Falls Project. The agreement stated

Idaho Power's water rights at its hydroelectric facilities between Milner Dam and Swan Falls entitled the company to a minimum flow at Swan Falls of 3,900 cubic feet per second (cfs) during the irrigation season and 5,600 cfs during the non-irrigation season.

The Swan Falls Agreement placed the portion of the company's water rights beyond the minimum flows in a trust established by the Idaho Legislature for the benefit of Idaho Power and the citizens of the State of Idaho. Legislation establishing the trust granted the state authority to allocate trust water to future beneficial uses in accordance with state law. Idaho Power retained the right to use water in excess of the minimum flows at its facilities for hydroelectric generation until it was reallocated to other uses.

Idaho Power filed suit in the SRBA in 2007 as a result of disputes about the meaning and application of the Swan Falls Agreement. The company asked the court to resolve issues associated with Idaho Power's water rights and the application and effect of the trust provisions of the Swan Falls Agreement. In addition, Idaho Power asked the court to determine whether the agreement subordinated the company's hydroelectric water rights to aquifer recharge.

A settlement signed in 2009 reaffirmed the Swan Falls Agreement and resolved the litigation by clarifying the water rights held in trust by the State of Idaho are subject to subordination to future upstream beneficial uses, including aquifer recharge. The settlement also committed the State of Idaho and Idaho Power to further discussions on important water-management issues concerning the Swan Falls Agreement and the management of water in the Snake River Basin. Idaho Power and the State of Idaho are actively involved in those discussions. The settlement also recognizes water-management measures that enhance aquifer levels, springs, and river flows—such as aquifer-recharge projects—that benefit both agricultural development and hydroelectric generation.

Idaho Power initiated and pursued a successful weather modification program in the Snake River Basin. The company partnered with an existing program in the upper Snake River Basin and has cooperatively expanded the existing weather modification operational program, along with forecasting and meteorological data support. The company has a long-term plan to continue the expansion of this program. In 2014, Idaho Power expanded its cloud-seeding program to the Boise and Wood River basins, in collaboration with basin water users and the Idaho Water Resource Board (IWRB). Wood River cloud seeding, along with the upper Snake River activities, will benefit the Eastern Snake River Plain Aquifer (ESPA) Comprehensive Aquifer Management Plan (CAMP) implementation through additional water supply.

Water management activities for the ESPA are currently being driven by the recent agreement between the Surface Water Coalition and the Idaho Ground Water Appropriators. This agreement settled a call by the Surface Water Coalition against groundwater appropriators for delivery of water to its members at Minidoka Dam and Milner Dam. The agreement provides a plan for the management of groundwater resources on the ESPA with the goal of improving

aquifer levels and spring discharge upstream of Milner Dam. The plan provides short-term and long-term aquifer level goals that must be met to ensure a sufficient water supply for the Surface Water Coalition. The plan also references ongoing management activities, such as aquifer recharge. The plan provided the framework for modeling future management activities on the ESPA. These management activities were included in the modeling to develop the flow file for assessing hydropower production through the IRP planning horizon.

On November 4, 2016, Idaho Department of Water Resources (IDWR) Director Gary Spackman signed an order creating a Ground Water Management Area (GWMA) for the ESPA. Spackman told the Idaho Water Users Association at their November 2016 Water Law Seminar:

> By designating a groundwater management area in the Eastern Snake Plain Aquifer region, we bring all of the water users into the fold—cities, water districts and others—who may be affecting aquifer levels through their consumptive use. […] As we've continued to collect and analyze water data through the years, we don't see recovery happening in the ESPA. We're losing 200,000 acre-feet of water per year.

Spackman said creating a GWMA will embrace the terms of a historic water settlement between the Surface Water Coalition and groundwater users, but the GWMA for the ESPA will also seek to bring other water users under management who have not joined a groundwater district, including some cities.

## Renewable Integration Costs

Idaho Power has completed two wind integration studies and two solar integration studies since the mid-2000s. These studies increased the company's understanding of the impacts and costs associated with integrating variable and intermittent resources without compromising reliability. The variable and uncertain production from wind and solar resources requires Idaho Power to provide additional balancing reserves from existing dispatchable generating resources, which results in opportunity costs and corresponding increases in power-supply expenses. Idaho Power completed the most recent wind integration study in 2013 and the most recent solar integration study in 2016. The costs found by these studies are the basis for renewable integration costs as provided in Idaho Schedule 87 and Oregon Schedule 85.

The results of the integration studies show periods of low customer demand to be the most difficult to cost-effectively integrate intermittent resources. During low demand periods, other existing resources are often already running at minimum levels or may already be shut off. Under these conditions, curtailment of the variable resources may be necessary to keep generation balanced with customer load. The integration studies also demonstrate the frequency of curtailment events is expected to increase as additional variable resources are added to the system.

For the IRP, integration costs for existing wind and solar resources are common to all portfolios analyzed and are not included in the portfolio cost accounting. However, portfolios with new solar resources include costs consistent with schedules 87 (Idaho) and 85 (Oregon) for the new resources. The schedule of integration costs is provided in *Appendix C—Technical Appendix*.

## Community Solar Pilot Program

In the 2009 IRP, Idaho Power proposed a solar PV pilot project. Due to a few extenuating circumstances, as detailed in the 2015 IRP, the pilot project was not pursued. However, customer interest in distributed solar generation continued to grow and was the subject of many 2015 IRP discussions. Late in the 2015 IRP public process, Idaho Power was approached by several interested parties and asked to consider sponsoring a community solar project.

In response to customer interest, in June 2016 Idaho Power filed an application with the IPUC requesting an order authorizing Idaho Power to implement an optional Community Solar Pilot Program.

For the pilot program, the company proposed to build and own a 500-kilowatt (kW) single-axis tracking community solar array in southeast Boise that would allow a limited number of Idaho Power's Idaho customers to voluntarily subscribe to the generation output on a first-come basis. Participating customers would be required to pay a one-time, upfront subscription fee, and in return would receive a monthly bill credit for their designated share of the energy produced from the array. Because the company's 2015 IRP did not reflect a load-serving need for the proposed solar resource, the overall program design was intended to result in program participants covering the full cost of the project with nominal impact to non-participating customers.

The IPUC approved the pilot program on October 31, 2016, and marketing efforts for customer subscription began immediately. At the time of publishing, the Community Solar Pilot Program was not fully subscribed, with only 15.5 percent of the allotted subscriptions purchased. The company is currently evaluating the future of the Community Solar Pilot Program.

## Energy Imbalance Market

In November 2014, the California Independent System Operator (CAISO) and PacifiCorp created the western EIM to enhance real-time coordination of market trading activity. The western EIM is a five-minute market administered by a single market operator, CAISO, which uses an automatic economic dispatch model to find and determine the least-cost energy resources to serve real-time customer demand across a wide geographic area. The western EIM focuses solely on real-time imbalances and allows EIM participants to retain all balancing responsibilities and transmission provider duties. In addition, the western EIM uses generating resources from market participants to meet real-time load efficiently and cost-effectively across the entire western EIM footprint.

Idaho Power is scheduled to begin participating in the western EIM in April 2018, at which time the western EIM participants will include PacifiCorp, CAISO, NV Energy, Puget Sound Energy, Arizona Public Service Company, and PGE. Market participants voluntarily bid resources into the western EIM, and the market operator provides least-cost dispatch instructions and generates a locational marginal price to be used for energy imbalances, factoring in load, available generation, and existing transmission constraints. Benefits to joining the western EIM include the following:

- The economic efficiency of an automated dispatch model for both generation and transmission line congestion
- Savings due to diversity of loads and variability of resources within the expanded footprint
- Reduced operational risk due to enhanced system reliability
- The ability to better support the integration of renewable resources

Since its inception, the western EIM has resulted in significant cost savings for its participants. Idaho Power expects its participation in the western EIM will similarly result in net power-supply expense savings for customers.

## Renewable Energy Certificates

RECs, also known as green tags, represent the green or renewable attributes of energy produced by certified renewable resources. A REC represents the renewable attributes associated with the production of 1 MWh of electricity generated by a qualified renewable energy resource, such as a wind turbine, geothermal plant, or solar facility. The purchase of a REC buys the renewable attributes, or "greenness," of that energy.

A renewable or green energy provider (e.g., a wind farm) is credited with one REC for every 1 MWh of electricity produced. RECs and the electricity produced by a certified renewable resource can either be sold together (bundled), sold separately (unbundled), or be retired to comply with a state- or federal-level renewable portfolio standard (RPS). A RPS is a policy requiring a minimum amount (usually a percentage) of the electricity each utility delivers to customers comes from renewable energy. Retired RECs also enable the retiring entity to claim the renewable energy attributes of the corresponding amount of energy delivered to customers.

A certifying tracking system gives each REC a unique identification number to facilitate tracking purchases, sales, and retirements. The electricity produced by the renewable resource is fed into the electrical grid, and the associated REC can then be used (retired), held (banked), or traded (sold).

REC prices depend on many factors, including the following:

- The location of the facility producing the RECs
- REC supply/demand
- Whether the REC is certified for RPS compliance
- The generation type (e.g., wind, solar, geothermal)
- Whether the RECs are bundled with energy or unbundled

When Idaho Power sells RECs, the proceeds are returned to Idaho Power customers through the power cost adjustment (PCA) as directed by the IPUC in Order No. 32002 and by the OPUC in Order No. 11-086. Idaho Power cannot claim the renewable attributes associated with RECs that are sold. The new REC owner has purchased the rights to claim the renewable attributes of that energy.

Idaho Power customers who choose to purchase renewable energy can do so under Idaho Power's Green Power Program. Under this program, each dollar of green power purchased represents 100 kilowatt-hours (kWh) of renewable energy delivered to the regional power grid, providing the Green Power Program participant associated claims for the renewable energy. Most the participant funds are used to purchase green power from renewable projects in the Northwest and to support Solar 4R Schools, a program designed to educate students about renewable energy by placing solar installations on school property. A portion of the funds are used to market the program, with the prospect of increasing participation in the program. On behalf of program participants, Idaho Power obtains and retires RECs. In 2016, Idaho Power purchased and subsequently retired 15,360 RECs on behalf of Green Power participants. Green Power is sourced from renewable energy projects in Idaho, Oregon, and Washington.

## Renewable Portfolio Standard

As part of the *Oregon Renewable Energy Act of 2007* (Senate Bill 838), the State of Oregon established an RPS for electric utilities and retail electricity suppliers. Under the Oregon RPS, Idaho Power is classified as a smaller utility because the company's Oregon customers represent less than 3 percent of Oregon's total retail electric sales. In 2015, per Energy Information Administration (EIA) data, Idaho Power's Oregon customers represented 1.3 percent of Oregon's total electric sales. As a smaller utility, Idaho Power will have to meet a 5- or 10-percent RPS requirement beginning in 2025. In 2016, the Oregon RPS was updated by Senate Bill 1547 to raise the target from 25 percent by 2025 to 50 percent renewable energy by 2040; however, Idaho Power's obligation as a smaller utility does not change.

The State of Idaho does not currently have an RPS.

# Clean Power Plan

## Rule History

On June 2, 2014, the Environmental Protection Agency (EPA), under President Obama's Climate Action Plan, released a proposal to regulate $CO_2$ emissions from existing power plants under the CAA Section 111(d) (Clean Power Plan). EPA's proposed Clean Power Plan included ambitious, mandatory $CO_2$ reduction targets for each state designed to achieve nationwide 30-percent $CO_2$ emission reductions over 2005 levels by 2030. On October 23, 2015, the final Clean Power Plan was published in the Federal Register, and the EPA proposed a Federal Implementation Plan.

Due to ongoing litigation about the legality of the rule, on February 9, 2016, the U.S. Supreme Court issued orders staying the Clean Power Plan pending resolution of challenges to the rule. The U.S. Court of Appeals for the District of Columbia Circuit (D.C. Circuit Court) heard oral arguments en banc before a panel of 10 judges on September 27, 2016.

On March 28, 2017, President Donald Trump issued an Executive Order on Energy Independence that, among other things, directs the EPA to review and, if appropriate, suspend, revise, or rescind the Clean Power Plan. On March 31, 2017, Scott Pruitt, the Director of the EPA, notified each state's governor that if any deadlines under the Clean Power Plan become relevant in the future, the EPA will toll its requirement for states to comply with the regulation.

On April 28, 2017, the D.C. Circuit Court approved an EPA motion to hold the Clean Power Plan case in abeyance for 60 days, or until June 27, 2017. According to the EPA's motion, "EPA should be afforded the opportunity to fully review the Clean Power Plan and respond to the President's direction in a manner that is consistent with the terms of the Executive Order, the Clean Air Act, and the agency's inherent authority to reconsider past decisions."[7] In the order granting the abeyance, the EPA was directed to file status reports every 30 days. The court also ordered the parties to file supplemental briefs on or before May 15, 2017, addressing whether the challenge should be remanded to the EPA rather than held in abeyance.

## Clean Power Plan Final Rule

The final Clean Power Plan establishes interim and final $CO_2$ emission performance rates for two subcategories of fossil fuel-fired electric generating units (EGU):

- Fossil fuel-fired EGUs (coal- and oil-fired power plants)
- Natural gas-fired combined cycle generating units

[7] *West Virginia v. EPA*, No. 15-1363 (D.C. Cir. March 28, 2017).

To maximize the range of choices available to states in implementing the standards and to utilities meeting them, the EPA has established interim and final statewide goals in three forms:

1. A rate-based state goal measured in pounds per MWh
2. A mass-based state goal measured in total short tons of $CO_2$
3. A mass-based state goal with a new source complement measured in short tons of $CO_2$

States must develop and implement plans that ensure the power plants in their state—individually, collectively, or in combination with other measures—achieve the interim $CO_2$ emission performance rates from 2022 to 2029 and the final $CO_2$ emission performance rates for their state by 2030.

In the final Clean Power Plan, the EPA determined the best system of emissions reduction (BSER) to reduce $CO_2$ from fossil fuel-fired power plants consisted of three building blocks:

1. Building Block 1—Improve efficiency in existing coal-fired power plants.
2. Building Block 2—Re-dispatch generation from existing coal-fired power plants to natural gas combined-cycle plants.
3. Building Block 3—Increase generation from non-$CO_2$-emitting resources.

The EPA applied the building blocks to all coal and natural gas power plants in each region to produce a regional emission performance rate for each category. From the resulting regional coal and natural gas power plant rates, the EPA chose the most readily achievable rate for each category to arrive at equitable $CO_2$ emission performance rates that represent the BSER. The same $CO_2$ emission performance rates were then applied to all affected sources in each state to arrive at individual statewide rate- and mass-based goals. Each state has a different goal based on its own mix of affected sources.

The final rule also gives states the option to work with other states on multi-state approaches, including emissions trading.

While specific actions based on the EPA's review of the Clean Power Plan are forthcoming, each resource portfolio in the 2017 IRP is compliant with the final Clean Power Plan mass-based emission limits. Due to the executive order and the Pruitt letter, Idaho Power anticipates more stringent compliance measures will not be required under the Clean Power Plan.

Further discussion of these $CO_2$ emission constraints is provided in Chapter 9. Projected $CO_2$ emissions for each analyzed resource portfolio are provided in *Appendix C—Technical Appendix*.

# 3. IDAHO POWER TODAY

## Customer Load and Growth

In 1992, Idaho Power served approximately 306,000 general business customers. Today, Idaho Power serves nearly 534,000 general business customers in Idaho and Oregon. Firm peak-hour load has increased from 2,164 MW in 1992 to over 3,400 MW. On July 2, 2013, the peak-hour load reached 3,407 MW—the system peak-hour record, nearly matched in 2015 (3,402 MW).

Construction in downtown Boise.

Average firm load increased from 1,280 average MW (aMW) in 1992 to 1,750 aMW in 2016 (load calculations exclude the load from the former special-contract customer Astaris, or FMC). Additional details of Idaho Power's historical load and customer data are shown in Figure 3.1 and Table 3.1. The data in Table 3.1 suggests each new customer adds over 5.5 kW to the peak-hour load and over 2 average kW (akW) to the average load.

Since 1992, Idaho Power's total nameplate generation has increased from 2,694 MW to 3,594 MW. The 900-MW increase in capacity represents enough generation to serve nearly 161,000 customers at peak times. Table 3.1 shows Idaho Power's changes in reported nameplate capacity since 1992.

Idaho Power has added about 228,000 new customers since 1992. The peak-hour and average-energy calculations mentioned earlier suggest the additional 228,000 customers require about 1,250 to 1,300 MW of additional peak-hour capacity and about 450 to 500 aMW of energy.

Idaho Power anticipates adding approximately 11,100 customers each year throughout the 20-year planning period. The expected-case load forecast for the entire system predicts summer peak-hour load requirements will grow over 50 MW per year, and the average-energy requirement is forecast to grow over 15 aMW per year. More detailed customer and load forecast information is presented in Chapter 7 and in *Appendix A—Sales and Load Forecast*.

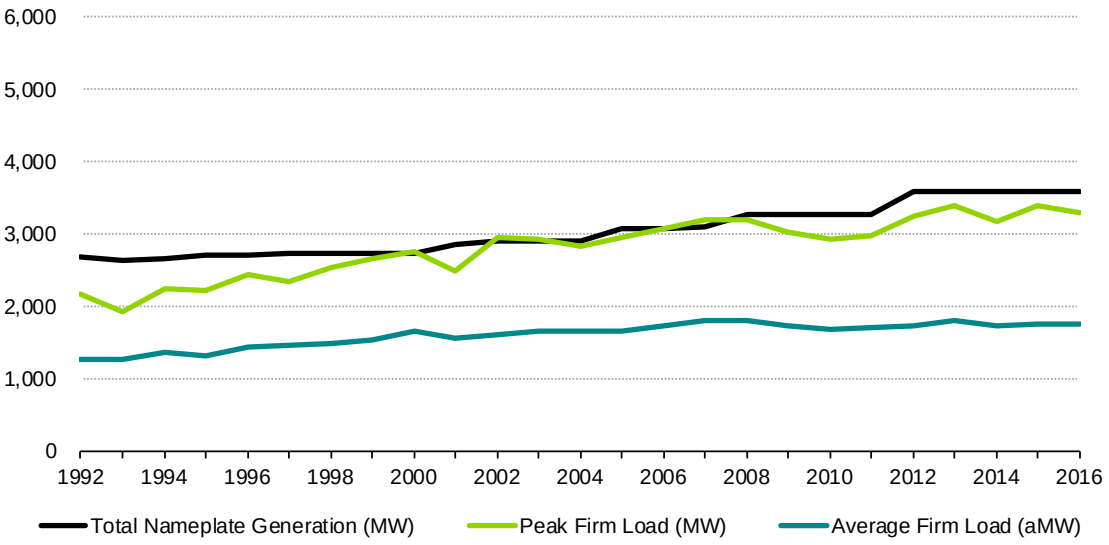

**Figure 3.1 Historical capacity, load, and customer data**

**Table 3.1 Historical capacity, load, and customer data**

| Year | Total Nameplate Generation (MW) | Peak Firm Load (MW) | Average Firm Load (aMW) | Customers[1] |
|---|---|---|---|---|
| 1992 | 2,694 | 2,164 | 1,281 | 306,292 |
| 1993 | 2,644 | 1,935 | 1,274 | 316,564 |
| 1994 | 2,661 | 2,245 | 1,375 | 329,094 |
| 1995 | 2,703 | 2,224 | 1,324 | 339,450 |
| 1996 | 2,703 | 2,437 | 1,438 | 351,261 |
| 1997 | 2,728 | 2,352 | 1,457 | 361,838 |
| 1998 | 2,738 | 2,535 | 1,491 | 372,464 |
| 1999 | 2,738 | 2,675 | 1,552 | 383,354 |
| 2000 | 2,738 | 2,765 | 1,654 | 393,095 |
| 2001 | 2,851 | 2,500 | 1,576 | 403,061 |
| 2002 | 2,912 | 2,963 | 1,623 | 414,062 |
| 2003 | 2,912 | 2,944 | 1,658 | 425,599 |
| 2004 | 2,912 | 2,843 | 1,671 | 438,912 |
| 2005 | 3,085 | 2,961 | 1,661 | 456,104 |
| 2006 | 3,085 | 3,084 | 1,747 | 470,950 |
| 2007 | 3,093 | 3,193 | 1,810 | 480,523 |
| 2008 | 3,276 | 3,214 | 1,816 | 486,048 |
| 2009 | 3,276 | 3,031 | 1,744 | 488,813 |
| 2010 | 3,276 | 2,930 | 1,680 | 491,368 |
| 2011 | 3,276 | 2,973 | 1,712 | 495,122 |
| 2012 | 3,594 | 3,245 | 1,746 | 500,731 |
| 2013 | 3,594 | 3,407 | 1,801 | 508,051 |
| 2014 | 3,594 | 3,184 | 1,739 | 515,262 |
| 2015 | 3,594 | 3,402 | 1,748 | 524,325 |
| 2016 | 3,594 | 3,299 | 1,750 | 534,528 |

[1] Year-end residential, commercial, and industrial customers plus the maximum number of active irrigation customers.

## 2016 Energy Sources

Idaho Power's energy sources for 2016 are shown in Figure 3.2. Idaho Power-owned generating capacity was the source for 73 percent of the energy delivered to customers. Hydroelectric production from company-owned projects was the largest single source of energy at 39 percent of the total. Coal contributed 24 percent, and natural gas- and diesel-fired generation contributed 10 percent. Purchased power comprised 27 percent of the total energy delivered to customers. Of the purchased power, about a third, or 9 percent of the total delivered energy, was from the wholesale electric market. The remaining purchased power was from long-term energy contracts (*Public Utility Regulatory Policies Act of 1978* [PURPA] and power purchase agreements [PPA]) primarily from wind, hydro, geothermal, biomass, and solar projects (in order of decreasing percentage). While Idaho Power enables production from PURPA and PPA projects, the company sells RECs associated with the production and does not represent the energy from these projects as energy delivered to customers.

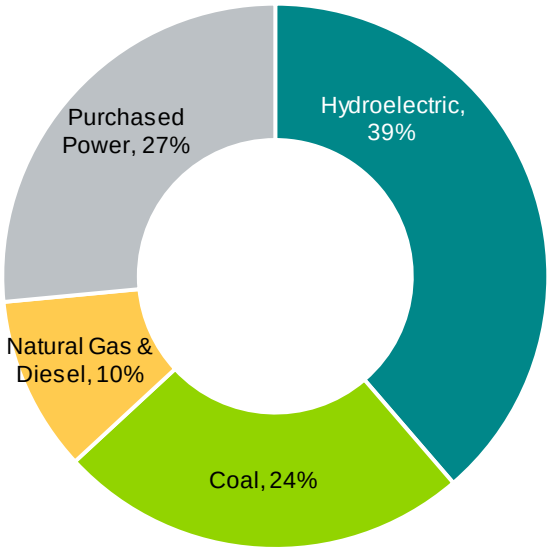

**Figure 3.2 2016 energy sources**

## Existing Supply-Side Resources

To identify the need and timing of future resources, Idaho Power prepares a load and resource balance that accounts for forecast load growth and generation from the company's existing resources and planned purchases. The load and resource balance worksheets showing Idaho Power's existing and committed resources for average-energy and peak-hour load are presented in *Appendix C—Technical Appendix*. Table 3.2 shows all of Idaho Power's existing company-owned resources, nameplate capacities, and general locations.

**Table 3.2 Existing resources**

| Resource | Type | Generator Nameplate Capacity (MW) | Location |
|---|---|---|---|
| American Falls | Hydroelectric | 92.3 | Upper Snake |
| Bliss | Hydroelectric | 75.0 | Mid-Snake |
| Brownlee | Hydroelectric | 585.4 | Hells Canyon |
| C. J. Strike | Hydroelectric | 82.8 | Mid-Snake |
| Cascade | Hydroelectric | 12.4 | North Fork Payette |
| Clear Lake | Hydroelectric | 2.5 | South Central Idaho |
| Hells Canyon | Hydroelectric | 391.5 | Hells Canyon |
| Lower Malad | Hydroelectric | 13.5 | South Central Idaho |
| Lower Salmon | Hydroelectric | 60.0 | Mid-Snake |
| Milner | Hydroelectric | 59.4 | Upper Snake |
| Oxbow | Hydroelectric | 190.0 | Hells Canyon |
| Shoshone Falls | Hydroelectric | 12.5 | Upper Snake |
| Swan Falls | Hydroelectric | 27.2 | Mid-Snake |
| Thousand Springs | Hydroelectric | 8.8 | South Central Idaho |
| Twin Falls | Hydroelectric | 52.9 | Mid-Snake |
| Upper Malad | Hydroelectric | 8.3 | South Central Idaho |
| Upper Salmon A | Hydroelectric | 18.0 | Mid-Snake |
| Upper Salmon B | Hydroelectric | 16.5 | Mid-Snake |
| Boardman | Coal | 64.2 | North Central Oregon |
| Jim Bridger | Coal | 770.5 | Southwest Wyoming |
| North Valmy | Coal | 283.5 | North Central Nevada |
| Langley Gulch | Natural Gas—CCCT* | 318.5 | Southwest Idaho |
| Bennett Mountain | Natural Gas—SCCT** | 172.8 | Southwest Idaho |
| Danskin | Natural Gas—SCCT** | 270.9 | Southwest Idaho |
| Salmon Diesel | Diesel | 5.0 | Eastern Idaho |
| **Total existing nameplate capacity** | | **3,594.4** | |

*Combined-cycle combustion turbine
**Simple-cycle combustion turbine

The following sections describe Idaho Power's existing supply-side generation resources and long-term power purchase contracts.

## Hydroelectric Facilities

Idaho Power operates 17 hydroelectric projects on the Snake River and its tributaries. Together, these hydroelectric facilities provide a total nameplate capacity of 1,709 MW and an annual generation equal to approximately 960 aMW, or 8.4 million MWh under median water conditions.

## Hells Canyon Complex

The backbone of Idaho Power's hydroelectric system is the HCC in the Hells Canyon reach of the Snake River. The HCC consists of Brownlee, Oxbow, and Hells Canyon dams and the associated generation facilities. In a normal water year, the three plants provide approximately 70 percent of Idaho Power's annual hydroelectric generation and enough energy to meet over 30 percent of the energy demand of retail customers. Water storage in Brownlee Reservoir also enables the HCC projects to provide the major portion of Idaho Power's peaking and load-following capability.

Idaho Power operates the HCC to comply with the existing annual FERC license, as well as voluntary arrangements to accommodate other interests, such as recreational use and environmental resources. Among the arrangements are the Fall Chinook Program, voluntarily adopted by Idaho Power in 1991 to protect the spawning and incubation of fall Chinook salmon below Hells Canyon Dam. The fall Chinook salmon is currently listed as threatened under the ESA.

Brownlee Reservoir is the main HCC reservoir and Idaho Power's only reservoir with significant active storage. Brownlee Reservoir has 101 vertical feet of active storage capacity, which equals approximately 1 million acre-feet of water. Both Oxbow and Hells Canyon reservoirs have significantly smaller active storage capacities—approximately 0.5 percent and 1 percent of Brownlee Reservoir's volume, respectively.

Brownlee Reservoir is a year-round, multiple-use resource for Idaho Power and the Pacific Northwest. Although its primary purpose is to provide a stable power source, Brownlee Reservoir is also used for system flood control, recreation, and the benefit of fish and wildlife resources.

Brownlee Dam is one of several Pacific Northwest dams coordinated to provide springtime flood control on the lower Columbia River. Idaho Power operates the reservoir in accordance with flood-control directions received from the US Army Corps of Engineers (COE) as outlined in Article 42 of the existing FERC license.

After flood-control requirements have been met in late spring, Idaho Power attempts to refill the reservoir to meet peak summer electricity demands and provide suitable habitat for spawning bass and crappie. The full reservoir also offers optimal recreational opportunities through the Fourth of July holiday.

The US Bureau of Reclamation (USBR) releases water from USBR storage reservoirs in the Snake River Basin above Brownlee Reservoir to augment flows in the lower Snake River to help anadromous fish migrate past the Federal Columbia River Power System (FCRPS) projects. The releases are part of the flow augmentation implemented by the 2008 FCRPS biological opinion. Much of the flow augmentation water travels through Idaho Power's middle

Snake River (mid-Snake) projects, with all the flow augmentation eventually passing through the HCC before reaching the FCRPS projects.

Brownlee Reservoir's releases are managed to maintain constant flows below Hells Canyon Dam in the fall as a result of the Fall Chinook Program adopted by Idaho Power in 1991. The constant flow is set at a level to protect fall Chinook spawning nests, or redds. During fall Chinook operations, Idaho Power attempts to refill Brownlee Reservoir by the first week of December to meet wintertime peak-hour loads. The fall Chinook plan spawning flows establish the minimum flow below Hells Canyon Dam throughout the winter until the fall Chinook fry emerge in the spring.

### Upper Snake and Mid-Snake Projects

Idaho Power's hydroelectric facilities upstream from the HCC include the Cascade, Swan Falls, C. J. Strike, Bliss, Lower Salmon, Upper Salmon, Upper and Lower Malad, Thousand Springs, Clear Lake, Shoshone Falls, Twin Falls, Milner, and American Falls projects. Although the upstream projects typically follow run-of-river (ROR) operations, a small amount of peaking and load-following capability exists at the Lower Salmon, Bliss, and C. J. Strike projects. These three projects are operated within the FERC license requirements to coincide with daily system peak demand when load-following capacity is available.

Idaho Power completed a study to identify the effects of load-following operations at the Lower Salmon and Bliss power plants on the Bliss Rapids snail, a threatened species under the ESA. The study was part of a 2004 settlement agreement with the US Fish and Wildlife Service (FWS) to relicense the Upper Salmon, Lower Salmon, Bliss, and C. J. Strike hydroelectric projects. During the study, Idaho Power annually alternated operating the Bliss and Lower Salmon facilities under ROR and load-following operations. Study results indicated that while load-following operations had the potential to harm individual snails, the operations were not a threat to the viability or long-term persistence of the species.

A *Bliss Rapids Snail Protection Plan* developed in consultation with the FWS was completed in March 2010. The plan identifies appropriate protection measures to be implemented by Idaho Power, including monitoring snail populations in the Snake River and associated springs. By implementing the protection and monitoring measures, the company has been able to operate the Lower Salmon and Bliss projects in load-following mode while protecting the stability and viability of the Bliss Rapids snail. Idaho Power has received a license amendment from FERC for both projects that allows load-following operations to resume.

### Water Lease Agreements

Idaho Power views the rental of water for delivery through its hydroelectric system as a potentially cost-effective power-supply alternative. Water leases that allow the company to request delivery when the hydroelectric production is needed are especially beneficial.

Acquiring water through the water bank also helps the company improve water-quality and temperature conditions in the Snake River as part of ongoing relicensing efforts associated with the HCC. The company does not currently have any water lease agreements but plans to continue to evaluate potential water-lease opportunities in the future.

## Cloud Seeding

In 2003, Idaho Power implemented a cloud-seeding program to increase snowpack in the south and middle forks of the Payette River watershed. In 2008, Idaho Power began expanding its program by enhancing an existing program operated by a coalition of counties and other stakeholders in the upper Snake River Basin above Milner Dam. Idaho Power has continued to work with the stakeholders in the upper Snake River to expand the program and has recently collaborated with irrigators in the Boise and Wood river basins to expand the target area to include those watersheds.

Idaho Power seeds clouds by introducing silver iodide (AgI) into winter storms. Cloud seeding increases precipitation from passing winter storm systems. If a storm has abundant supercooled liquid water vapor and appropriate temperatures and winds, conditions are optimal for cloud seeding to increase precipitation. Idaho Power uses two methods to seed clouds:

1. Remotely operated ground generators at high elevations
2. Modified aircraft burning flares containing AgI

Benefits of either method vary by storm, and the combination of both methods provides the most flexibility to successfully introduce AgI into passing storms. Minute water particles within the clouds freeze on contact with the AgI particles and eventually grow and fall to the ground as snow.

AgI is a very efficient ice nuclei, allowing it to be used in minute quantities. It has been used as a seeding agent in numerous western states for decades without any known harmful effects.[8] Analyses conducted by Idaho Power since 2003 indicate the annual snowpack in the Payette River Basin increased between 1 and 28 percent annually, with an annual average of 14 percent. Idaho Power estimates cloud seeding provides an additional 346,000 acre-feet from the upper Snake River and 272,000 acre-feet from the Payette River. At program build-out, Idaho Power estimates additional runoff from the Payette, Boise, Wood, and Upper Snake projects will total approximately 1,000,000 acre-feet. Studies conducted by the Desert Research Institute from 2003 to 2005 support the effectiveness of Idaho Power's program.

[8] weathermodification.org/images/AGI_toxicity.pdf

For the 2016 to 2017 winter season, Idaho Power continued to collaborate with the State of Idaho and water users to augment water supplies with cloud seeding. The program included 30 remote-controlled, ground-based generators and two aircraft for Idaho Power-operated cloud seeding in the west-central mountains of Idaho (Payette, Boise, and Wood River basins). The Upper Snake River Basin program included 25 remote-controlled, ground-based generators and one aircraft operated by Idaho Power targeting the Upper Snake, as well as 25 manual, ground-based generators operated by a coalition of stakeholders in the Upper Snake. The 2016 to 2017 season provided abundant storms and seeding opportunities. Suspension criteria were met in some areas in early February, and operations were suspended for the season for all target areas by early March.

## Coal Facilities

### Jim Bridger

Idaho Power owns one-third, or 771 MW (generator nameplate rating), of the Jim Bridger coal-fired power plant located near Rock Springs, Wyoming. The Jim Bridger plant consists of four generating units. PacifiCorp has two-thirds ownership and is the operator of the Jim Bridger facility.

The 2017 IRP considers a range of scenarios for Jim Bridger units 1 and 2. The scenarios relate to varying options for capital investments into environmental retrofits. The scenarios are described in Chapter 7.

### North Valmy

Idaho Power owns 50 percent, or 284 MW (generator nameplate rating), of the North Valmy coal-fired power plant located near Winnemucca, Nevada. The North Valmy plant consists of two generating units. NV Energy has 50 percent ownership and is the operator of the North Valmy facility.

A baseline assumption of the 2017 IRP has Idaho Power retiring its share of North Valmy Unit 1 at year-end 2019 and its share of North Valmy Unit 2 at year-end 2025. Further discussion surrounding this assumption is provided in Chapter 7.

### Boardman

Idaho Power owns 10 percent, or 64.2 MW (generator nameplate rating), of the Boardman coal-fired power plant located near Boardman, Oregon. The plant consists of a single generating unit. PGE has 90 percent ownership and is the operator of the Boardman facility.

The 2017 IRP assumes Idaho Power's share of the Boardman plant will not be available after December 31, 2020. The 2020 date is the result of an agreement reached between the Oregon Department of Environmental Quality (ODEQ), PGE, and the EPA related to compliance with

Regional Haze Best Available Retrofit Technology (RH BART) rules on particulate matter, sulfur dioxide ($SO_2$), and nitrogen oxide (NOx) emissions.

## Natural Gas Facilities

### Langley Gulch

Idaho Power owns and operates the Langley Gulch plant, a nominal 318-MW natural gas-fired CCCT. The plant consists of one 187-MW Siemens STG-5000F4 combustion turbine and one 131.5-MW Siemens SST-700/SST-900 reheat steam turbine. The Langley Gulch plant, located south of New Plymouth in Payette County, Idaho, became commercially available in June 2012.

Langley Gulch Power Plant

### Danskin

Idaho Power owns and operates the 271-MW Danskin natural gas-fired SCCT facility. The facility consists of one 179-MW Siemens 501F and two 46-MW Siemens–Westinghouse W251B12A combustion turbines. The Danskin facility is located northwest of Mountain Home, Idaho. The two smaller turbines were installed in 2001, and the larger turbine was installed in 2008. The Danskin units are dispatched when needed to support system load.

### Bennett Mountain

Idaho Power owns and operates the Bennett Mountain plant, which consists of a 173-MW Siemens–Westinghouse 501F natural gas-fired SCCT located east of the Danskin plant in Mountain Home, Idaho. The Bennett Mountain plant is also dispatched as needed to support system load.

### Salmon Diesel

Idaho Power owns and operates two diesel generation units in Salmon, Idaho. The Salmon units have a combined generator nameplate rating of 5 MW and are operated during emergency conditions, primarily for voltage and load support.

## Solar Facilities

In 1994, a 25-kW solar PV array with 90 panels was installed on the rooftop of Idaho Power's corporate headquarters (CHQ) in Boise, Idaho. The 25-kW solar array is still operational, and Idaho Power uses the hourly generation data from the solar array for resource planning.

In 2015, Idaho Power installed a 50-kW solar array at its new Twin Falls Operations Center. The array came on-line in October 2016.

Idaho Power also has solar lights in its parking lot and uses small PV panels in its daily operations to supply power to equipment used for monitoring water quality, measuring streamflows, and operating cloud-seeding equipment. In addition to these solar PV installations, Idaho Power participates in the Solar 4R Schools Program and owns a mobile solar trailer that can be used to supply power for concerts, radio remotes, and other events.

## Net Metering Service

Idaho Power's net metering service allows customers to generate power on their property and connect to Idaho Power's system. For net metering customers, the energy generated is first consumed on the property itself, while excess energy flows out to the company's grid. The majority of net metering customers use solar PV systems. As of March 1, 2017, there were 1,045 solar PV systems were interconnected through the company's net metering service with a total capacity of 8.079 MW. At that time, the company had received completed applications for an additional 110 net metered solar PV systems, representing an incremental capacity of 1.376 MW. For further details regarding customer-owned generation resources interconnected through the company's net metering service, see Table 3.3 and Table 3.4.

**Table 3.3 Net metering service customer count as of March 1, 2017**

| Resource Type | Active | Pending | Total |
|---|---|---|---|
| Solar PV | 1,045 | 110 | 1,155 |
| Wind | 62 | 2 | 64 |
| Other/hydroelectric | 10 | 1 | 11 |
| **Total** | **1,117** | **113** | **1,230** |

**Table 3.4 Net metering service generation capacity (MW) as of March 1, 2017**

| Resource Type | Active | Pending | Total |
|---|---|---|---|
| Solar PV | 8.079 | 1.3760 | 9.455 |
| Wind | 0.378 | 0.0016 | 0.380 |
| Other/hydroelectric | 0.147 | 0.0120 | 0.159 |
| **Total** | **8.604** | **1.3900** | **9.994** |

## Oregon Solar PV Pilot Program and Oregon Solar PV Capacity Standard

In 2009, the Oregon Legislature passed Oregon Revised Statute (ORS) 757.365 as amended by House Bill 3690, which mandated the development of pilot programs for electric utilities operating in Oregon to demonstrate the use and effectiveness of volumetric incentive rates for electricity produced by solar PV systems.

As required by the OPUC in Order Nos. 10-200 and 11-089, Idaho Power established the Oregon Solar Photovoltaic Pilot Program in 2010, offering volumetric incentive rates to customers in Oregon. Under the pilot program, Idaho Power acquired 400 kW of installed capacity from solar PV systems with a nameplate capacity of less than or equal to 10 kW. In July 2010, approximately 200 kW were allocated, and the remaining 200 kW were offered during an enrollment period in October 2011. However, because some PV systems were not completed from the 2011 enrollment, a subsequent offering was held on April 1, 2013, for approximately 80 kW.

In 2013, the Oregon Legislature passed House Bill 2893, which increased Idaho Power's required capacity amount by 55 kW. An enrollment period was held in April 2014, and all capacity was allocated, bringing Idaho Power's total capacity in the program to 455 kW.

Under the previously required Oregon Solar PV Capacity Standard, Idaho Power was required to either own or purchase the generation from a 500-kW utility-scale solar PV facility by 2020. This requirement was repealed, effective March 8, 2016, pursuant to Oregon Senate Bill 1547.

## *PURPA*

In 1978, the US congress passed PURPA, requiring investor-owned electric utilities to purchase energy from any qualifying facility (QF) that delivers energy to the utility. A QF is defined by FERC as a small renewable-generation project or small cogeneration project. The acronym CSPP (cogeneration and small power producers) is often used in association with PURPA. Individual states were tasked with establishing PPA terms and conditions, including price, that each state's utilities are required to pay as part of the PURPA agreements. Because Idaho Power operates in Idaho and Oregon, the company must adhere to IPUC rules and regulations for all PURPA facilities located in Idaho, and to OPUC rules and regulations for all PURPA facilities located in Oregon. The rules and regulations are similar but not identical for the two states.

Under PURPA, Idaho Power is required to pay for generation at the utility's avoided cost, which is defined by FERC as the incremental cost to an electric utility of electric energy or capacity which, but for the purchase from the QF, such utility would generate itself or purchase from another source. The process to request an Energy Sales Agreement for Idaho QFs is described in Schedule 73, and for Oregon QFs, Schedule 85. QFs also have the option to sell energy "as-available" under Schedule 86.

As of April 1, 2017, Idaho Power had 133 PURPA contracts with independent developers for approximately 1,135 MW of nameplate capacity. These PURPA contracts are for hydroelectric projects, cogeneration projects, wind projects, solar projects, anaerobic digesters, landfill gas, wood-burning facilities, and various other small, renewable-power generation facilities. Of the 133 contracts, 128 were on-line as of April 1, 2017, with a cumulative nameplate rating of approximately 1,115 MW. Figure 3.3 shows the percentage of the total PURPA nameplate capacity of each resource type under contract.

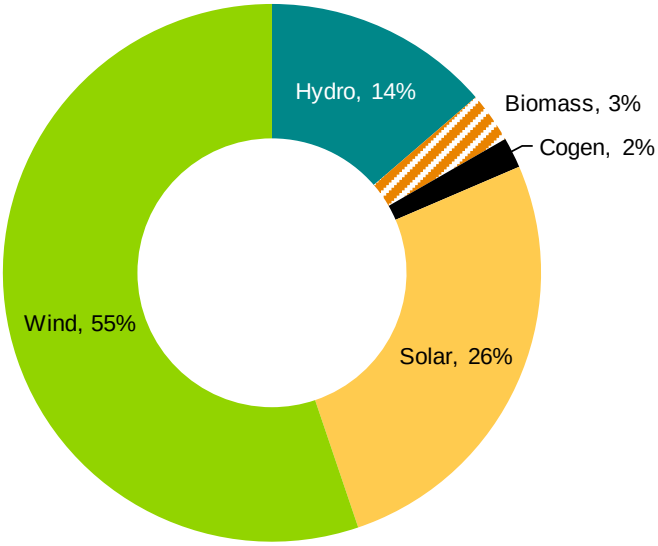

**Figure 3.3 PURPA contracts by resource type**

Idaho Power cannot predict the level of future PURPA development; therefore, only signed contracts are accounted for in Idaho Power's resource planning process. Generation from PURPA contracts is forecasted early in the IRP planning process to update the load and resource balance. The PURPA forecast used in the 2017 IRP was completed in December 2016.

## *Power Purchase Agreements*

### Elkhorn Valley Wind Project

In February 2007, the IPUC approved a PPA with Telocaset Wind Power Partners, LLC a subsidiary of Horizon Wind Energy, for 101 MW of nameplate wind generation from the Elkhorn Valley Wind Project located in northeastern Oregon. The Elkhorn Valley Wind Project was constructed during 2007 and began commercial operations in December 2007. Under the PPA, Idaho Power receives all the RECs from the project.

Elkhorn Valley Wind Project, Union County, Oregon

### Raft River Geothermal Project

In January 2008, the IPUC approved a PPA for 13 MW of nameplate generation from the Raft River Geothermal Power Plant (Unit 1) located in southern Idaho. The Raft River project began commercial operations in October 2007 under a PURPA contract with Idaho Power that was canceled when the new PPA was approved by the IPUC. For the first 10 years (2008–2017)

of the agreement, Idaho Power is entitled to 75 percent of the RECs from the project for generation that exceeds 10 aMW monthly. The Raft River geothermal project has rarely exceeded the monthly 10 aMW of generation since 2009, and Idaho Power is currently receiving negligible RECs from the project. For the second 10 years of the agreement (2018–2027), Idaho Power is entitled to 51 percent of all RECs generated by the project.

### Neal Hot Springs Geothermal Project

In May 2010, the IPUC approved a PPA for approximately 22 MW of nameplate generation from the Neal Hot Springs Geothermal Project located in eastern Oregon. The Neal Hot Springs project achieved commercial operation in November 2012. Under the PPA, Idaho Power receives all RECs from the project.

### Clatskanie Energy Exchange

In September 2009, Idaho Power and the Clatskanie People's Utility District (Clatskanie PUD) in Oregon entered into an energy exchange agreement. Under the agreement, Idaho Power receives the energy as it is generated from the 18-MW power plant at Arrowrock Dam on the Boise River; in exchange, Idaho Power provides the Clatskanie PUD energy of an equivalent value delivered seasonally, primarily during months when Idaho Power expects to have surplus energy. An energy bank account is maintained to ensure a balanced exchange between the parties where the energy value will be determined using the Mid-Columbia market price index. The Arrowrock project began generating in January 2010, with the initial exchange agreement with Idaho Power ending in 2015. At the end of the initial term, Idaho Power exercised its right to extend the agreement through 2020. Idaho Power holds one more option to extend through 2025, exercisable in 2020. The Arrowrock project is expected to produce approximately 81,000 MWh annually.

## *Wholesale Contracts*

Idaho Power currently has no long-term wholesale energy contracts (no long-term wholesale sales contracts and no long-term wholesale purchase contracts).

## *Power Market Purchases and Sales*

Idaho Power relies on regional power markets to supply a significant portion of energy and capacity needs during certain times of the year. Idaho Power is especially dependent on the regional power market purchases during peak-load periods. The existing transmission system is used to import the power purchases. A reliance on regional power markets has benefited Idaho Power customers during times of low prices through the import of low-cost energy. Customers also benefit from sales revenues associated with surplus energy from economically dispatched resources.

### Transmission MW Import Rights

Idaho Power's interconnected transmission system facilitates market purchases to access resources to serve load. Five transmission paths connect Idaho Power to neighboring utilities:

1. Idaho–Northwest (Path 14)
2. Idaho–Nevada (Path 16)
3. Idaho–Montana (Path 18)
4. Idaho–Wyoming (Path 19)
5. Idaho–Utah (Path 20).

However, Idaho Power does not own exclusive rights to all the transmission capacity available on each path. Idaho Power is either a partial owner of a path shared with other partners, or other entities have acquired long-term purchased capacity for a portion of a path. Idaho Power is allowed to set aside portions of its transmission capacity to import energy for load service. Beyond the existing set-aside capacity and contractual obligations, Idaho Power's import capacity on these paths is fully allocated, except for 86 MW of available capacity on Path 19.

# 4. FUTURE SUPPLY-SIDE GENERATION AND STORAGE RESOURCES

## Generation Resources

Supply-side resources are traditional generation resources. Early IRP utility commission orders directed Idaho Power and other utilities to give equal treatment to both supply-side and demand-side resources. As discussed in Chapter 5, demand-side programs are an essential component of Idaho Power's resource strategy. The following sections describe the supply-side resources and storage technologies considered when Idaho Power developed the resource portfolios for the 2017 IRP. While a variety of resource options was analyzed, the portfolio design for the IRP allowed the selection of a subset for inclusion in resource portfolios.

The primary source of cost information for the 2017 IRP is *Lazard's Levelized Cost of Energy Analysis*.[9] Lazard, a leading independent financial advisory and asset management firm, issued the levelized cost report in December 2016. Other information sources were relied on or considered on a case-by-case basis depending on the credibility of the source and the age of the information. Refer to Chapter 7 for a full list of all the resources considered and cost information. All cost information presented is in 2017 dollars.

## Renewable Resources

Renewable energy resources are the foundation of Idaho Power, and the company has a long history of renewable resource development and operation. Renewable resources are discussed in general terms in the following sections.

### *Solar*

The primary types of solar technology are utility-scale PV and distributed PV. In general, PV technology converts solar energy collected from sunlight shining on panels of solar cells into electricity. The solar cells have one or more electric fields that force electrons to flow in one direction as a direct current (DC). The DC energy passes through an inverter, converting it to alternating current (AC) that can be used on-site or sent to the grid. Even on cloudy days, a solar PV system can still provide 15 percent of the system's rated output.

Insolation is a measure of solar radiation reaching the earth's surface and is used to evaluate the solar potential of an area. Typically, insolation is measured in kWh per square meter ($m^2$)

[9] Lazard. 2016. Lazard's levelized cost of energy analysis 10.0 (LCOE 10.0). https://www.lazard.com/media/438038/levelized-cost-of-energy-v100.pdf.

per day (daily insolation average over a year). The higher the insolation number, the better the solar power potential for an area. National Renewable Energy Laboratory (NREL) insolation charts show the southwest desert has the highest solar potential in the US.

In designing resource portfolios that included solar resources, Idaho Power chose the utility-scale PV technology because of its compliance to EPA's proposed CAA Section 111(d) regulation, its flexibility, and its lower overall cost. Modern solar PV technology has existed for several years but has historically been cost prohibitive. Recent improvements in technology and manufacturing, combined with increased demand due to state RPSs, have made PV resources more cost competitive with other renewable and conventional generating technologies.

The capital-cost estimate used in the 2017 IRP for utility-scale PV resources is based on the Lazard report, which estimates a cost of $1,375 per kW for PV with a single-axis tracking system. The 25-year levelized cost of energy for PV with single-axis tracking is $74 per MWh with a 27-percent annual capacity factor.

Rooftop solar was considered in two forms as part of the 2017 IRP. The capital-cost estimate used in the 2017 IRP for residential rooftop solar PV resources is based on the Lazard report, which estimates a cost of $2,400 per kW for PV on residential rooftops. The 25-year levelized cost of energy for residential rooftop solar PV resources is $153 per MWh with a 21-percent annual capacity factor. The capital-cost estimate used for commercial and industrial rooftop solar PV resources is based on the Lazard report, which estimates a cost of $2,925 per kW for PV on commercial and industrial rooftops. The 25-year levelized cost of energy for commercial and industrial rooftop solar PV resources is $179 per MWh with a 21-percent annual capacity factor. The cost of rooftop solar PV resources is recognized to vary by region, and the Lazard-reported costs are not indicative of solar PV costs in Idaho Power's service area.[10] Rooftop solar PV cost estimates vary by source, and based on Idaho Power's review of sources, the Lazard-reported costs are toward the lower end of the cost range. For example, the Department of Energy (DOE) Tracking the Sun study indicates rooftop solar pricing of approximately $4,000 per kW for residential installations and $3,000 per kW for non-residential installations.[11]

Energy production from solar PV arrays declines over time. This is known as PV degradation. For the 2017 IRP, Idaho Power assumes a 0.5 percent annual degradation rate of energy production from solar PV arrays.

[11] DOE. August 2016. Tracking the sun IX, the installed price of residential and non-residential photovoltaic systems in the United States. https://emp.lbl.gov/sites/default/files/tracking_the_sun_ix_report.pdf.

### Solar Capacity Credit

Idaho Power applied the solar capacity credit calculations derived from the 2015 IRP. As part of the 2015 IRP process, Idaho Power, interested members of the IRPAC, and interested members of the public formed a study group separate from the IRPAC to evaluate solar peak-hour capacity factors. The group formally met and conducted meetings and conversations with members of the study group. Idaho Power updated the solar PV peak-hour capacity factors based on guidance from members of the solar work group.

The solar capacity credit is expressed as a percentage of installed AC nameplate capacity. The solar capacity credit is used to determine the amount of peak-hour capacity delivered to the Idaho Power system from a solar PV plant considered as a new IRP resource option. The solar capacity credit values used in the 2017 IRP are reported in Table 4.1.

**Table 4.1 Solar capacity credit values**

| PV System Description | Peak-Hour Capacity Credit |
|---|---|
| South orientation | 28.4% |
| Southwest orientation | 45.5% |
| Tracking | 51.3% |

## *Geothermal*

Potential for commercial geothermal generation in the Pacific Northwest includes both flashed-steam and binary-cycle technologies. Based on exploration in southern Idaho, binary-cycle geothermal development is more likely than flashed steam within Idaho Power's service area. The flashed-steam technology requires higher water temperatures. Most optimal locations for potential geothermal development are believed to be in the southeastern part of the state; however, the potential for geothermal generation in southern Idaho remains somewhat uncertain. The time required to discover and prove geothermal resource sites is highly variable and can take years or even decades.

The overall cost of a geothermal resource varies with resource temperature, development size, and water availability. Flashed-steam plants are applicable for geothermal resources where the fluid temperature is 300º Fahrenheit (F) or greater. Binary-cycle technology is used for lower-temperature geothermal resources. In a binary-cycle geothermal plant, geothermal water is pumped to the surface and passed through a heat exchanger where the geothermal energy is transferred to a low-boiling-point fluid (the secondary fluid). The secondary fluid is vaporized and used to drive a turbine/generator. After driving the generator, the secondary fluid is condensed and recycled through a heat exchanger. The secondary fluid is in a closed system and is reused continuously in a binary cycle plant. The primary fluid (the geothermal water) is returned to the geothermal reservoir through injection wells.

Cost estimates and operating parameters used for binary-cycle geothermal generation in the 2017 IRP are based on data from the Northwest Power and Conservation Council (NWPCC) Seventh Power Plan. The capital-cost estimate used in the 2017 IRP for geothermal resources is $4,675 per kW, and the 25-year levelized cost of energy is $111 per MWh based on an 88-percent annual capacity factor.

## Hydroelectric

Hydroelectric power is the foundation of Idaho Power's generation fleet. The existing generation is low cost and does not emit potentially harmful pollutants. Idaho Power believes the development of new, large hydroelectric projects is unlikely because few appropriate sites exist and because of environmental and permitting issues associated with new, large facilities. However, small hydroelectric sites have been extensively developed in southern Idaho on irrigation canals and other sites, many of which have PURPA contracts with Idaho Power.

### Small Hydroelectric

Small hydroelectric projects, such as ROR and projects requiring small or no impoundments, do not have the same level of environmental and permitting issues as large hydroelectric projects. The potential for new, small hydroelectric projects was studied by the Idaho Strategic Energy Alliance's Hydropower Task Force, and the results released in May 2009 indicate between 150 MW to 800 MW of new hydroelectric resources could be developed in Idaho. These figures are based on potential upgrades to existing facilities, undeveloped existing impoundments and water delivery systems, and in-stream flow opportunities. The capital-cost estimate used in the 2017 IRP for small hydroelectric resources is $3,753 per kW, and the 75-year levelized cost of energy is $165 per MWh.

## Wind

A typical wind project consists of an array of wind turbines ranging in size from 1 to 3 MW each. The majority of potential wind sites in southern Idaho lie between the south-central and the most southeastern part of the state. Areas that receive consistent, sustained winds greater than 15 miles per hour are prime locations for wind development.

When compared to other renewable options, wind resources are well suited for the Pacific Northwest and Intermountain regions, as evidenced by the number of existing projects. Wind resources present operational challenges for utilities due to the variable and intermittent nature of wind generation. Therefore, planning new wind resources requires estimates of the expected annual energy and peak-hour capacity. For the 2017 IRP, Idaho Power used an annual average capacity factor of 28 percent and an on-peak capacity factor of 5 percent for peak-hour planning. The capital-cost estimate used in the IRP for wind resources is $1,475 per kW, and the 25-year levelized cost of energy is $111 per MWh, which includes a wind integration cost of $16.33 per MWh.

### Biomass

Biomass resource types considered in the 2017 IRP include wood-burning resources and anaerobic digesters. Wood-burning resources typically rely on a steady supply of woody residue collected from forested areas. Fuel supply can be an issue for these types of plants as the radius of the area used to collect fuel is expanded. Several anaerobic digesters have been built in southern Idaho due to the size of the dairy industry and the quantity of fuel available. The 2017 IRP considered anaerobic digesters as a best fit for the service area.

The capital-cost estimate used in the 2017 IRP for an anaerobic digester project is $6,522 per kW for a 35-MW facility. The anaerobic digester is expected to have an annual capacity factor of 85 percent. Based on the annual capacity factors, the 30-year levelized cost of energy is $133 per MWh for the anaerobic digester.

## Conventional Resources

While much attention has been paid to renewable resources over the past few years, conventional generation resources are essential to provide dispatchable capacity, which is critical in maintaining the reliability of an electrical power system. These conventional generation technologies include natural gas-fired resources, nuclear, and coal.

### Natural Gas-Fired Resources

Natural gas-fired resources burn natural gas in a combustion turbine to generate electricity. CCCTs are typically used for baseload energy, while less-efficient SCCTs are used to generate electricity during peak-load periods. Additional details on the characteristics of both types of natural gas resources are presented in the following sections.

CCCT and SCCT resources are typically sited near existing gas pipelines, which is the case for Idaho Power's existing gas resources. However, the capacity of the existing gas pipeline system is almost fully allocated. The additional cost as necessary for expanded gas pipeline allocation is accounted for in portfolios containing new gas resources and not in the resource stack cost estimate for CCCTs or SCCTs.

#### Combined-Cycle Combustion Turbines

CCCT plants have been the preferred choice for new commercial, dispatchable power generation in the region. CCCT technology carries a low initial capital cost compared to other baseload resources, has high thermal efficiencies, is highly reliable, offers significant operating flexibility, and emits fewer emissions when compared to coal, therefore requiring fewer pollution controls. Modern CCCT facilities are highly efficient and can achieve efficiencies of approximately 60 percent (lower heating value).

A traditional CCCT plant consists of a gas turbine/generator equipped with a heat-recovery steam generator (HRSG) to capture waste heat from the turbine exhaust. The HRSG uses waste heat from the combustion turbine to drive a steam turbine generator to produce additional electricity. In a CCCT plant, heat that would otherwise be wasted is used to produce additional power beyond that typically produced by an SCCT. New CCCT plants can be built or existing SCCT plants can be converted to combined-cycle units by adding an HRSG.

Several CCCT plants, similar to Idaho Power's Langley Gulch project, are planned in the region due to a sustained depression in natural gas prices, the need for baseload energy, and additional operating reserves needed to integrate intermittent resources. While there is no current shortage of natural gas, fuel supply is a critical component of the long-term operation of a CCCT. The capital-cost estimate used in the IRP for a CCCT (1 x 1) resource is $1,246 per kW, and the 30-year levelized cost of energy at a 70-percent annual capacity factor is $64 per MWh.

### Simple-Cycle Combustion Turbines

Simple cycle, natural gas-turbine technology involves pressurizing air that is then heated by burning gas in fuel combustors. The hot, pressurized air expands through the blades of the turbine that connects by a shaft to the electric generator. Designs range from larger, industrial machines at 80 to 200 MW to smaller machines derived from aircraft technology. SCCTs have a lower thermal efficiency than CCCT resources and are not typically economical to operate other than to meet peak-hour load requirements.

Several natural gas-fired SCCTs have been brought on-line in the region in the past decade, primarily in response to the regional energy crisis of 2000 to 2001. High electricity prices combined with persistent drought conditions during 2000 to 2001, as well as continued summertime peak-load growth, created interest in generation resources with low capital costs and relatively short construction lead times.

Idaho Power has approximately 430 MW of SCCT capacity. As peak summertime electricity demand continues to grow within Idaho Power's service area, SCCT generating resources remain a viable option to meet peak load during critical high-demand times when the transmission system has reached full import capacity. The plants may also be dispatched for financial reasons during times when regional energy prices are at their highest.

The 2017 IRP evaluated a 170-MW industrial-frame (F class) SCCT unit. The capital-cost estimate used in the 2017 IRP is $878 per kW. The industrial-frame unit is expected to have an annual capacity factor of 10 percent.

Based on an annual capacity factor of 10 percent, the 35-year levelized cost of energy is $197 per MWh for the industrial-frame SCCT unit. If Idaho Power were to identify the need for a SCCT, it would evaluate SCCT technologies in greater detail prior to issuing a request for proposal (RFP) to determine which technology would provide the greatest benefit.

## Reciprocating Engines

Reciprocating engine generation sets are typically multi-fuel engines connected to a generator through a flywheel and coupling. They are typically capable of burning natural gas. Because they are mounted on a common baseframe, the entire unit can be assembled, tuned, and tested in the factory before being delivered to the power plant location, which minimizes capital costs. Operationally, reciprocating engines are typically installed in configurations with multiple, identical units, which allows each unit to run at its best efficiency point once started. As more generation is needed, additional units are started. This configuration also allows for relatively inexpensive future expansion of the plant capacity. Reciprocating engines provide unique benefits to the electrical grid. They are extremely flexible in the sense that they can provide ancillary services to the grid in a few minutes. Engines can go from a cold start to full-load in 10 minutes.

For the IRP, Idaho Power modeled a reciprocating engine similar to the 34SG model manufactured by Wärtsilä with a nameplate rating of approximately 18 MW. The capital-cost estimate used for a reciprocating engine resource is $775 per kW, and the 40-year levelized cost of energy at a 25-percent annual capacity factor is $94 per MWh.

## Combined Heat and Power

Combined heat and power (CHP), or cogeneration, typically refers to simultaneous production of both electricity and useful heat from a single plant. CHP plants are typically located at, or near, commercial or industrial facilities capable of using the heat generated in the process. These facilities are sometimes referred to as a steam host. Generation technologies frequently used in CHP projects are gas turbines or engines with a heat-recovery unit.

The main advantage of CHP is that higher overall efficiencies can be obtained because the steam host can use a large portion of the waste heat that would otherwise be lost in a typical generation process. Because CHP resources are typically located near load centers, investment in additional transmission capacity can also often be avoided. In addition, reduced costs for the steam host provide a competitive advantage that would ultimately benefit the local economy.

In the evaluation of CHP resources, it became evident that CHP could be a relatively high-cost addition to Idaho Power's resource portfolio if the steam host's need for steam forced the electrical portion of the project to run at times when electricity market prices were below the dispatch cost of the plant. To find ways to make CHP more economical, Idaho Power is committed to working with individual customers to design operating schemes that allow power to be produced when it is most valuable, while still meeting the needs of the steam host's production process. This would be difficult to model for the IRP because each potential CHP opportunity could be substantially different.

Recognizing the actual cost of a CHP resource varies depending on the specific facility being considered, the capital-cost estimate used in the 2017 IRP for CHP is $2,213 per kW, and the 40-year levelized cost of energy evaluated at an annual capacity factor of 80 percent is $71 per MWh.

## Nuclear Resources

The nuclear power industry has been working to develop and improve reactor technology for some time, and Idaho Power has continued to evaluate various technologies in the IRP. Due to the Idaho National Laboratory (INL) site in eastern Idaho, the IRP has typically assumed that an advanced-design or small modular reactor (SMR) could be built on the site. For the 2017 IRP, high capital costs coupled with a great amount of uncertainty in waste-disposal issues prevented a nuclear resource from being included in the portfolio analysis. Recent large-scale nuclear development in the US has proven to be fraught with project delays and projected construction cost overruns exceeding $1 billion. In addition, the 2011 earthquake and tsunami in Japan, and the impact on the Fukushima nuclear plant, created a global concern over the safety of nuclear power generation. While there have been new design and safety measures implemented, it is difficult to know the full impact this disaster will have on the future of nuclear power generation. While Idaho Power does not currently view traditional nuclear resources as a viable supply-side resource option for the company, it continues to monitor the advancement of SMR technology and will evaluate it in the future as the Nuclear Regulatory Commission reviews proposed SMR designs in the coming years.

For the 2017 IRP, a 50-MW small modular plant was analyzed. The capital-cost estimate used in the IRP for an advanced SMR nuclear resource is $6,126 per kW, and the 40-year levelized cost of energy, evaluated at an annual capacity factor of 90 percent, is $163 per MWh.

## Coal Resources

Conventional coal resources have been a part of Idaho Power's generation portfolio since the early 1970s. Growing concerns over global warming and climate change coupled with historic low natural gas prices have made it impractical to consider building new conventional coal resources.

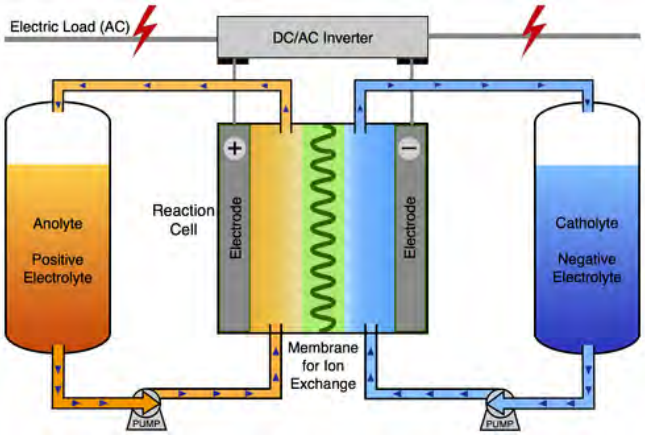
Integrated gasification combined cycle (IGCC) is an evolving coal-based technology designed to substantially reduce $CO_2$ emissions. As the regulation of $CO_2$ emissions eventually makes conventional coal resources obsolete, the commercialization of this technology may allow the continued use of the country's coal resources. IGCC technology is also dependent on the development of carbon capture and sequestration technology that would allow $CO_2$ to be stored underground for long periods.

Coal gasification is a relatively mature technology, but it has not been widely adopted as a resource to generate electricity. IGCC technology involves turning coal into a synthetic gas or

"syngas" that can be processed and cleaned to meet pipeline quality standards. To produce electricity, the syngas is burned in a conventional combustion turbine that drives a generator.

The addition of $CO_2$-capture equipment decreases the overall efficiency of an IGCC plant by as much as 15 percent. In addition, once the carbon is captured, it must either be used or stored for long periods of time. $CO_2$ has been injected into existing oil fields to enhance oil recovery; however, if IGCC technology were widely adopted by utilities for power production, the quantities of $CO_2$ produced would require the development of underground sequestration methods.

Carbon sequestration involves taking captured $CO_2$ and storing it away from the atmosphere by compressing and pumping it into underground geologic formations. If compression and pumping costs are charged to the plant, the overall efficiency of the plant is reduced by an additional 15 to 20 percent. Sequestration methods are currently being developed and tested; however, commercialization of the technology is not expected to happen for some time. No new coal-based energy resources were modeled as part of the 2017 IRP.



## Storage Resources

RPSs and PURPA have spurred the development of renewable resources in the Pacific Northwest, leading to periodic oversupply of energy in the region. Mid-Columbia wholesale market prices for electricity continue to remain relatively low. At the same time, retail rates for electricity continue to grow, as utilities must pass the cost of building these resources on to customers. The oversupply issue has grown to the point where at certain times of the year, such as in the spring, low customer demand coupled with large amounts of hydro and wind generation cause real-time and day-ahead wholesale market prices to decrease into negative values.

As more intermittent renewable resources like wind and solar continue to be built within the region, the need for energy storage is amplified. Many storage technologies are at various stages of development, such as hydrogen storage, compressed air, and flywheels. The 2017 IRP considered and evaluated multiple energy storage technologies, including battery storage, ice-based thermal energy storage (TES), and pumped hydro storage.

## Battery Storage

Just as there are many types of storage technologies being researched and developed, there are numerous types of battery storage technologies at various stages of development. The 2017 IRP analyzed the vanadium redox-flow battery (VRB), lithium-ion battery systems and zinc battery systems.

Basic illustration of a flow battery.[12]

Advantages of the VRB technology include its low cost, long life, and scalability to utility/grid applications. Most battery technologies are not a good fit for utility-scale applications because they cannot be easily or economically scaled to much larger sizes. The VRB overcomes much of this issue because the capacity of the battery can be increased by increasing the size of the tanks that contain the electrolytes, which also helps keep the cost relatively low.

VRB technology also has an advantage in maintenance and replacement costs, as only certain components need to be replaced about every 10 years, whereas other battery technologies require a complete and often more frequent replacement of the battery depending on the duty cycle. For the IRP, the capital-cost estimate for the VRB is $3,736 per kW, and the 10-year levelized cost of energy, evaluated at an annual capacity factor of 4 percent, is $2,010 per MWh. Idaho Power recognizes the continued technological development of VRB batteries used in utility-scale storage facilities. Idaho Power will continue to monitor price trends and the scalability of this technology in the coming years.

In recent months, lithium-ion battery systems have gone on-line commercially in the US on the west coast. Lithium-ion battery storage systems realize high charging and discharging efficiencies. Lithium-based energy storage devices present possible safety concerns due to overheating.

For the IRP, the capital-cost estimate for lithium-ion battery storage is $3,114 per kW, and the 10-year levelized cost of energy, evaluated at an annual capacity factor of 14 percent, is $476 per MWh. Idaho Power recognizes the continued technological development of lithium-ion batteries

[12] Source: http://wernerantweiler.ca/blog.php?item=2014-09-28

used in utility-scale storage facilities. Idaho Power will continue to monitor price trends and the scalability of this technology in the coming years.

A third type of battery storage system analyzed in the 2017 IRP was zinc battery storage. Zinc battery storage systems are capable of deep discharge cycles and are relatively low cost due to the abundance of the primary metals in a zinc battery. Zinc-based energy storage devices do present concerns due to their lack of proven utility-scale application. Zinc battery systems are typically less efficient than other types of battery storage technologies.

For the IRP, the capital-cost estimate for zinc battery storage is $2,010 per kW, and the 10-year levelized cost of energy, evaluated at an annual capacity factor of 7 percent, is $621 per MWh. Idaho Power recognizes the continued technological development of Zinc batteries and will continue to monitor price trends and the technical viability of this technology in the coming years.

## Ice-Based TES

Ice-based TES is a concept developed to take advantage of the air conditioning (A/C) needs of mid-sized to large commercial buildings. The general concept is to create ice during low-load/low-price times (light load hours), then to use the ice for A/C needs during the high-load/higher-price times (heavy-load hours). While this concept does not specifically store electricity, it does shift the time the energy is consumed, with the overall goal of reducing peak daytime demand.

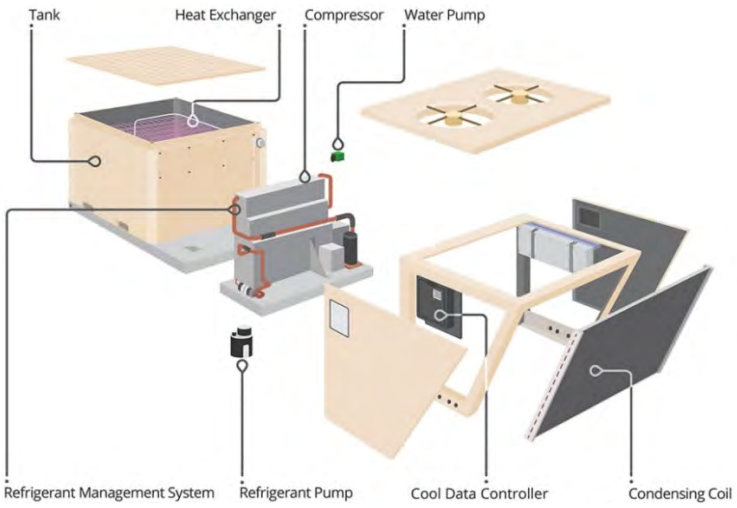


Illustration of an ice-based TES system.[13]

One company currently commercializing the ice-based TES technology is Ice Energy with their Ice Bear Energy Storage System. Requirements in California to develop energy storage have allowed several utilities to begin installing and testing this technology, with several installations of 5 MW to 15 MW in size. For the IRP, the capital-cost estimate used for this technology is

[13] Source: http://www.ice-energy.com/technology/ice-bear-energy-storage-system

$2,000 per kW, and the 20-year levelized cost of energy, evaluated at an annual capacity factor of 6 percent, is $508 per MWh.

## Pumped Hydro Storage

Pumped storage is a type of hydroelectric power generation used to change the "shape" or timing of when electricity is produced. The technology stores energy in the form of water, pumped from a lower-elevation reservoir to a higher elevation. Lower-cost, off-peak electricity is used to pump water from the lower reservoir to the upper reservoir. During higher-cost periods of high electrical demand, the water stored in the upper reservoir is used to produce electricity.

For pumped storage to be economical, there must be a significant differential (arbitrage) in the price of electricity between peak and off-peak times to overcome the costs incurred due to efficiency. Historically, the differential between peak and off-peak energy prices in the Pacific Northwest has not been sufficient to make pumped storage an economically viable resource; however, with the recent increase in the number of wind projects, the amount of intermittent generation provided, and the ancillary services required, Idaho Power continues to monitor the viability of pumped storage projects in the region. The capital-cost estimate used in the IRP for pumped storage is $2,352 per kW, and the 50-year levelized cost of energy, evaluated at an annual capacity factor of 20 percent, is $229 per MWh.

# 5. DEMAND-SIDE RESOURCES

## DSM Program Overview

Demand-side resources are the first selected resources in each IRP. No supply-side generation resource is considered as part of Idaho Power's plan until all future cost-effective, achievable potential energy efficiency and forecasted demand response is accounted for and credited against future loads. In the 2017 IRP, demand response provides 390 MW of committed peak summer capacity, while energy efficiency will reduce average annual loads by 273 aMW and 483 MW of peak reduction by the year 2036.

The Shade Tree Project provides free trees for residential customers in select counties to shade their homes. Shade trees, properly grown on the west side of a home, can help reduce energy needed for summer cooling by 15 percent or more. In 2016, Idaho Power distributed 2,070 trees.

## Changes from the 2015 IRP

Methods for incorporating and accounting for energy efficiency and demand response resources in the 2017 IRP were similar to methods used in the 2015 IRP. As in the 2013 and 2015 IRPs, the planning case for energy efficiency as a resource potential was determined by a third-party consultant. Notably, the company's 20-year load forecast for the 2017 IRP accounted for all accumulated potential energy efficiency savings. As a result, over the last seven years of the IRP planning period (2030–2036), no adjustments to forecast loads were required to reflect incremental energy efficiency savings potential determined by the third party but not included in the load forecast. The alignment of the energy efficiency savings potential forecasts is a result of sharing data and assumptions from the 2015 potential study and the early results of the 2017 potential study. Another highlight for the 2017 IRP is the continued improvement in estimating peak contribution from energy efficiency that was first estimated using hourly load shapes in the 2015 IRP. Prior to the 2015 IRP, peak contribution from energy efficiency was estimated using average monthly energy values.

## Program Screening

All DSM programs and measures included in Idaho Power's current programs and the forecast have been screened for cost-effectiveness. Cost-effectiveness analyses of DSM forecasts for the 2017 IRP are presented in more detail in *Appendix C—Technical Appendix*. *Appendix B—Demand-Side Management 2016 Annual Report* contains a detailed description of Idaho Power's 2016 energy efficiency programs, along with historical program performance. A complete review of Idaho Power's DSM programs, evaluations, and cost-effectiveness can be found in the

2016 annual report, *Demand-Side Management 2016 Annual Report*, *Supplement 1: Cost-Effectiveness*, and *Supplement 2: Evaluation*, which are available on Idaho Power's website at idahopower.com/EnergyEfficiency/reports.cfm.

# DSM Program Performance

While the IRP planning process primarily looks forward, recent DSM performance is a good predictor of near-term performance for the 2017 IRP. Accumulated annual savings from energy efficiency investments grow over time based on measure lives of the efficient equipment and measures adopted and installed by customers each year. Additionally, past performance of demand response programs has changed over time as the design and use of the programs have evolved.

## *Energy Efficiency Performance*

Energy efficiency investments since 2002 have resulted in a cumulative average annual load reduction of 209 aMW, or over 1.6 million MWh, of reduced supply-side energy production to customers through 2016. Figure 5.1 shows the cumulative annual growth in energy efficiency effects over the 13-year period from 2002 through 2016, along with the associated IRP targets developed as part of the IRP process since 2004.

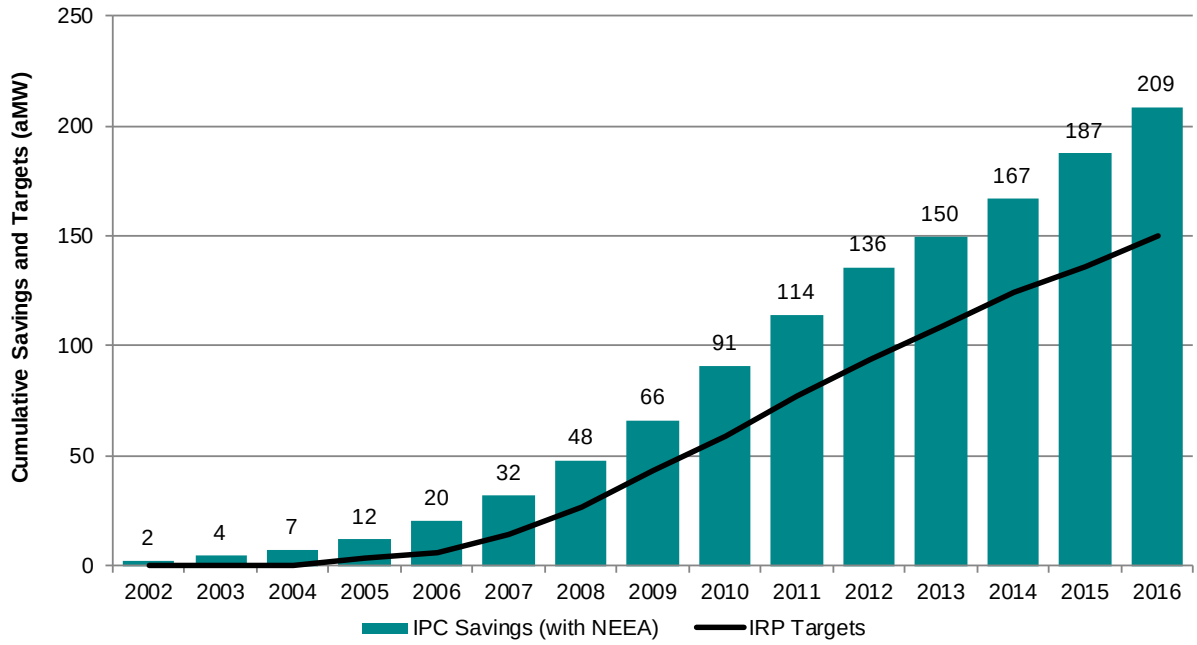

**Figure 5.1 Cumulative annual growth in energy efficiency**

## *Demand Response Performance*

Demand response resources have been part of the demand-side portfolio since the 2004 IRP. The current demand response portfolio is comprised of three programs that work together as one resource. Each program targets a different customer class. Table 5.1 lists the three programs that

make up the current demand response portfolio, along with the different program characteristics. The Irrigation Peak Rewards program represents the largest percent of potential demand reduction. During the 2016 summer season, Irrigation Peak Rewards participants contributed 81 percent of the total potential demand-reduction capacity, or 317 MW. More details on Idaho Power's demand response programs can be found in *Appendix B—Demand-Side Management 2016 Annual Report*.

**Table 5.1 Demand response programs**

| Program | Customer Class | Reduction Technology | 2016 Total Demand Response Capacity (MW) | Percent of Total 2016 Peak Performance* |
|---|---|---|---|---|
| A/C Cool Credit | Residential | Central A/C | 34 | 9% |
| Irrigation Peak Rewards | Irrigation | Pumps | 317 | 81% |
| Flex Peak Program | Commercial, industrial | Various | 42 | 11% |
| | | **Total** | **392** | |

*Values may not add to 100 percent due to rounding.

Figure 5.2 shows the historical annual demand response program capacity between 2004 and 2016 along with associated IRP targets between 2006 and 2012 and 2015 through 2016. There were no demand response targets for 2013 to 2014 in the 2013 IRP. The large jump in demand response capacity from 61 MW in 2008 to 218 MW in 2009 was a result of transitioning most the Irrigation Peak Rewards participants to a dispatchable program. The demand response capacity in 2011 and 2012 included 320 and 340 MW of capacity, respectively, from the Irrigation Peak Rewards program, which was not used based on the lack of need and the variable cost to dispatch the program. The reported demand response capacity value was lower in 2013 because of the one-year suspension of both the irrigation and residential programs.

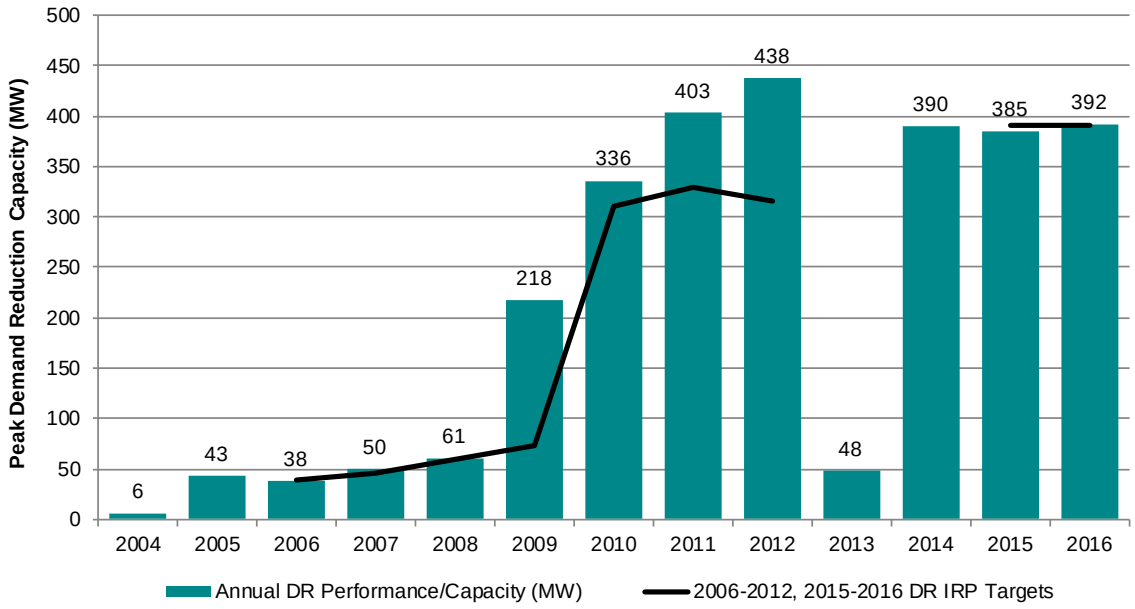

**Figure 5.2 Historical annual demand response programs**

## Committed Energy Efficiency Forecast

For the 2017 IRP, Applied Energy Group (AEG) was retained to update the previous study prepared for the 2015 IRP and provide an updated 20-year comprehensive view of Idaho Power's energy efficiency potential.

Typical irrigation pivots

AEG developed three levels of potential: technical, economic, and achievable. Technical and economic potential are both theoretical limits to efficiency savings, while achievable savings become the planning case forecast for energy efficiency in the 2017 IRP. Achievable potential embodies a set of assumptions about the decisions consumers make regarding the efficiency of the equipment they purchase, the maintenance activities they undertake, the controls they use for energy-consuming equipment, and the elements of building construction. The three levels of potential are described below.

- *Technical*—Technical potential is defined as the theoretical upper limit of energy efficiency potential. Technical potential assumes customers adopt all feasible measures regardless of cost. At the time of equipment replacement, customers are assumed to select the most efficient equipment available. In new construction, customers and developers are also assumed to choose the most efficient equipment available. Technical potential also assumes the adoption of every other applicable measure available. The retrofit measures are phased in over several years, which is increased for higher-cost measures.

- *Economic*—Economic potential represents the adoption of all cost-effective energy efficiency measures. In the potential study, AEG applies the total resource cost (TRC) test for cost-effectiveness, which compares lifetime energy and capacity benefits to the incremental cost of the measure. Economic potential assumes customers purchase the most cost-effective option at the time of equipment failure and adopt every other cost-effective and applicable measure.

- *Achievable*—Achievable potential considers market maturity, customer preferences for energy-efficient technologies, and expected program participation. Achievable potential establishes a realistic target for the energy efficiency savings a utility can achieve through its programs. It is determined by applying a series of annual market-adoption factors to the economic potential for each energy efficiency measure. These factors represent the ramp rates at which technologies will penetrate the market.

The market characterization study bundles industries and building types into homogenous groupings. Idaho Power's special-contract customers were treated outside of the potential study model. Forecasts for these unique customers, who tend to be very active in efficiency, were based on the combined customer group's history of participation along with the near-term projected projects.

AEG provides the annual savings potential forecast to Idaho Power in gigawatt-hours (GWh), where it is converted to hourly, then monthly, average energy reduction (aMW) to compare with supply-side resources for the IRP analysis. The savings are shaped by end-use load shapes that spread the forecasted savings across all hours of the year. The load shapes used to allocate savings by end use were provided by AEG as part of the study deliverables. All reported energy efficiency and demand response forecasts are expressed at generation level and therefore include line losses of 9.6 percent for energy and 9.7 percent for peak demand to account for energy that would have been lost as a result of transmitting energy from a supply-side generation resource to the meter level.

Table 5.2 shows the forecasted potential effect of the current portfolio of energy efficiency programs for 2017 to 2036 in five-year blocks in terms of cumulative average annual energy reduction (aMW) by customer class. Detailed annual forecast values can be found in *Appendix C—Technical Appendix*.

**Table 5.2 Total energy efficiency portfolio forecasted effects (2017–2036) (aMW)**

| Customer Class | 2017 | 2021 | 2026 | 2031 | 2036 |
|---|---|---|---|---|---|
| Industrial/commercial/special contracts | 9 | 51 | 105 | 140 | 175 |
| Residential | 2 | 14 | 27 | 46 | 66 |
| Irrigation | 2 | 8 | 16 | 23 | 31 |
| **Total*** | **13** | **73** | **147** | **208** | **273** |

*Totals may not add exactly due to rounding.

Table 5.3 shows the 20-year cost-effectiveness summary based on the AEG potential study and preliminary DSM alternative costs. TRCs account for both the costs to administer the programs and the customer's incremental cost to invest in efficient technologies and measures offered through the programs. The benefit of the programs is avoided energy, which is calculated by valuing energy savings with the DSM preliminary alternative costs.

**Table 5.3 Total energy efficiency portfolio cost-effectiveness summary**

| Customer Class | 2036 Load Reduction (aMW) | 2036 Peak-Load Reduction (MW)* | Resource Costs ($000s) 20-Year NPV) | Total Benefits ($000s) (20-Year NPV) | TRC: Benefit/ Cost Ratio | TRC Levelized Costs (cents/kWh) |
|---|---|---|---|---|---|---|
| Residential | 66 | – | $155,425 | $295,479 | 1.9 | 6.7 |
| Industrial/commercial/ special contract | 176 | – | $302,559 | $567,923 | 1.9 | 3.9 |
| Irrigation | 31 | – | $81,981 | $133,498 | 1.6 | 6.7 |
| **Total** | **273** | **483** | **$539,965** | **$996,900** | **1.8** | **4.8** |

*Final peak-reduction estimates were calculated only for the portfolio as a whole.

The completed energy efficiency forecast is included in the IRP planning horizon and the load and resource balance analysis after ensuring all future energy efficiency was properly accounted for and netted out of future loads prior to portfolio analysis. As noted earlier in this chapter, the company's IRP load forecast accounted for all of the accumulated 20-year potential energy efficiency savings, exceeding the AEG-determined potential over the last seven years of the IRP planning period (2030–2036). Portfolios for the IRP were developed based on the assumption that for 2030 to 2036, the amount of energy efficiency in the load and resource balance is the amount accounted for in the company's load forecast, rather than the smaller amount determined by AEG in the potential study. For the energy load and resource balance, the accumulated energy efficiency in the company's load forecast is 300 aMW, rather than the 273 aMW load reduction provided in Table 5.3 above. The accumulated peak-load reduction in the company's load forecast is 531 MW, rather than the 483 MW noted in Table 5.3.

The amount of energy efficiency determined by the DSM potential study to be cost-effective and achievable sets an appropriate and prudent target for energy efficiency for the 2017 IRP; this amount of energy efficiency is included in all analyzed portfolios before all other resources. Idaho Power recognizes that the amount of energy efficiency achieved in practice may ultimately exceed the 2017 IRP target amount as a result of implementation efforts of the company and the Energy Efficiency Advisory Group (EEAG). The achievable potential is in no way considered a ceiling for funding or the company's efforts.

Further, the company recognizes that alternative (or avoided) costs used for the cost-effectiveness evaluation are likely to change in the interim between the 2017 IRP and 2019 IRP as key drivers of these costs (e.g., natural gas price) vary. Thus, it is the company's view that the DSM potential study-determined cost-effective and achievable energy efficiency sets the target for the amount of energy efficiency available in this IRP. This target does not represent a ceiling or finite amount for actual energy efficiency activities. It is emphasized that neither the cost-effectiveness nor the achievability of this target is fixed; both attributes can change following completion of this IRP, and future analysis (e.g., the 2019 IRP) will reflect these changes.

### *Transmission and Distribution Deferral Benefits Associated with Energy Efficiency*

The transmission and distribution (T&D) deferral benefits associated with energy efficiency were determined using all growth projects from Idaho Power's officer-reviewed three-year budget for 2016. Transmission, substation, and distribution projects were represented. The limiting capacity (determined by feeder or transformer) was identified for each project along with the anticipated in-service date, projected cost, peak loading, and projected growth rate.

The forecast for the penetration of energy efficiency was incorporated into the formula. Independent energy efficiency demand reduction forecasts for different rate classes were applied at summer and winter peak. If the adjusted forecast was below the limiting capacity, it was assumed the project could be deferred. The financial savings of deferring the project were then calculated.

The total savings from all the deferrable projects were divided by the total annual energy efficiency reduction forecast over the service area. A sensitivity analysis was conducted with an energy efficiency forecast multiplier of 0 to 10 times the existing forecast. Based on the analysis, a value of $3.76 per kW per year will be used as the T&D deferral value.

## Committed Demand Response Forecast

Under the current program design and participation levels, demand response from all programs is forecast to provide 390 MW of peak capacity during July throughout the IRP planning period, with additional program potential available during June and August. The committed demand response included in the IRP has a capacity cost of $29 per kW per year.

## Additional Demand Response

As part of the IRP's expressed strategy to set the highest standard for evaluating B2H cost-effectiveness, B2H alternative portfolios include an additional 50 MW of demand response in 25 MW increments in 2021 and 2026. The achievement of this additional 50 MW is reasonable and consistent with the role of demand response as a cost-effective capacity resource available to shift peak loading for a finite number of hours. While the B2H-based portfolios did not include the added demand response for the purpose of focusing the costs and benefits of these portfolios on B2H, the company does not view B2H as precluding the continued evaluation and as-needed expansion of demand response resources.

This page left blank intentionally.

# 6. TRANSMISSION PLANNING

## Past and Present Transmission

500-kilovolt (kV) transmission line near Melba, Idaho

High-voltage transmission lines are vital to the development of energy resources to serve Idaho Power customers. Transmission lines have facilitated the development of southern Idaho's network of hydroelectric projects that serve southern Idaho and eastern Oregon. Regional transmission lines that stretch from the Pacific Northwest to the HCC and to the Treasure Valley were central to the development of the HCC projects in the 1950s and 1960s. In the 1970s and 1980s, transmission lines facilitated partnerships in the three coal-fired power plants located in neighboring states that deliver energy to Idaho Power customers. Finally, transmission lines allow Idaho Power to economically balance the variability of its intermittent resources with access to wholesale energy markets.

Idaho Power's transmission interconnections provide economic benefits and improve reliability through the flexibility to move electricity between utilities to serve load and to share operating reserves. Historically, Idaho Power has been a summer peaking utility, while most other utilities in the Pacific Northwest experience peak loads during the winter; as a result, Idaho Power can purchase energy from the Mid-Columbia energy trading market to meet peak summer load and sell excess energy to Pacific Northwest utilities during the winter and spring. Additional regional transmission connections to the Pacific Northwest will benefit the environment and Idaho Power customers in the following ways:

- The construction of additional resources to serve summer peak load is delayed or avoided.
- Revenue from off-system sales during the winter and spring is credited to customers through the PCA.
- Revenue from others' use of the transmission system is credited to Idaho Power customers.
- System reliability is increased.
- Increased capacity can help integrate intermittent resources, such as wind and solar.

- Improve the ability to more efficiently implement advanced market tools, such as the EIM.

## Transmission Planning Process

FERC mandates several aspects of the transmission planning process. FERC Order No. 1000 requires Idaho Power to participate in transmission planning on a local, regional, and interregional basis, as described in Attachment K of the Idaho Power Open-Access Transmission Tariff (OATT) and summarized in the following sections.

### *Local Transmission Planning*

The expansion planning of Idaho Power's transmission network occurs through the biennial local transmission planning (LTP) process which identifies the transmission required to interconnect load centers, integrate planned generation resources, and incorporate regional transmission plans. The LTP is a 20-year plan that incorporates the planned supply-side resources identified in the IRP process, the transmission upgrades identified in the local-area transmission advisory process, the forecasted network customer load (e.g., Bonneville Power Administration [BPA] customers in eastern Oregon and southern Idaho), Idaho Power's retail customer load, and third-party transmission customer requirements. By identifying potential resources, potential resource locations, and load-center growth, the required transmission system capacity expansions are identified to safely and reliably provide service to customers. The LTP is shared with the regional transmission planning process.

Idaho Power develops long-term, local-area transmission plans for various load centers within Idaho Power's service area by applying a local-area transmission advisory process. This process uses community advisory committees and is performed every 10 years for each area. The community advisory committees consist of jurisdictional planners; mayors; council members; commissioners; and large industry, commercial, residential, and environmental representatives. The plans identify the transmission and substation infrastructure required for the full development of the area. The plans account for land-use limits and other resources of the local area. The plans identify the approximate year a project will be placed in service. Local-area plans have been created for the following load centers in southern Idaho:

1. Eastern Idaho
2. Magic Valley
3. Wood River Valley
4. Eastern Treasure Valley
5. Western Treasure Valley
6. West Central Mountains

### *Regional Transmission Planning*

Idaho Power is active in regional transmission planning through the NTTG. The NTTG was formed in early 2007 to improve the operation and expansion of the high-voltage transmission system that delivers power to consumers in seven western states. In addition to Idaho Power, other members include Deseret Power Electric Cooperative, NorthWestern Energy, PGE, PacifiCorp (Rocky Mountain Power and Pacific Power), Montana–Alberta Tie Line (MATL), and the Utah Associated Municipal Power Systems (UAMPS). Biennially, the NTTG develops a regional transmission plan using a public stakeholder process to evaluate transmission needs resulting from members' load forecasts, LTPs, IRPs, generation interconnection queues, other proposed resource development, and forecast uses of the transmission system by wholesale transmission customers.

### *Interconnection-Wide Transmission Planning*

The WECC Transmission Expansion Planning Policy Committee (TEPPC) serves as the interconnection-wide transmission planning facilitator in the western US. Specifically, the TEPPC has three functions:

1. Oversee data management for the western interconnection.
2. Provide policy and management of the planning process.
3. Guide the analyses and modeling for Western Interconnection economic transmission expansion planning.

In addition to providing the means to model the transmission implications of various load and resource scenarios at an interconnection-wide level, the TEPPC coordinates planning between transmission owners, transmission operators, and regional planning entities.

The WECC Planning Coordination Committee manages additional transmission planning and reliability-related activities on behalf of electric-industry entities in the West. WECC activities include resource adequacy analyses and corresponding NERC reporting, transmission security studies, and the transmission line rating process.

## Existing Transmission System

Idaho Power's transmission system extends from eastern Oregon through southern Idaho to western Wyoming and is composed of 115-, 138-, 161-, 230-, 345-, and 500-kV transmission facilities. The sets of lines that transmit power from one geographic area to another are known as transmission paths. There are defined transmission paths to other states and between specific southern Idaho load centers. Idaho Power's transmission system and paths are shown in Figure 6.1.

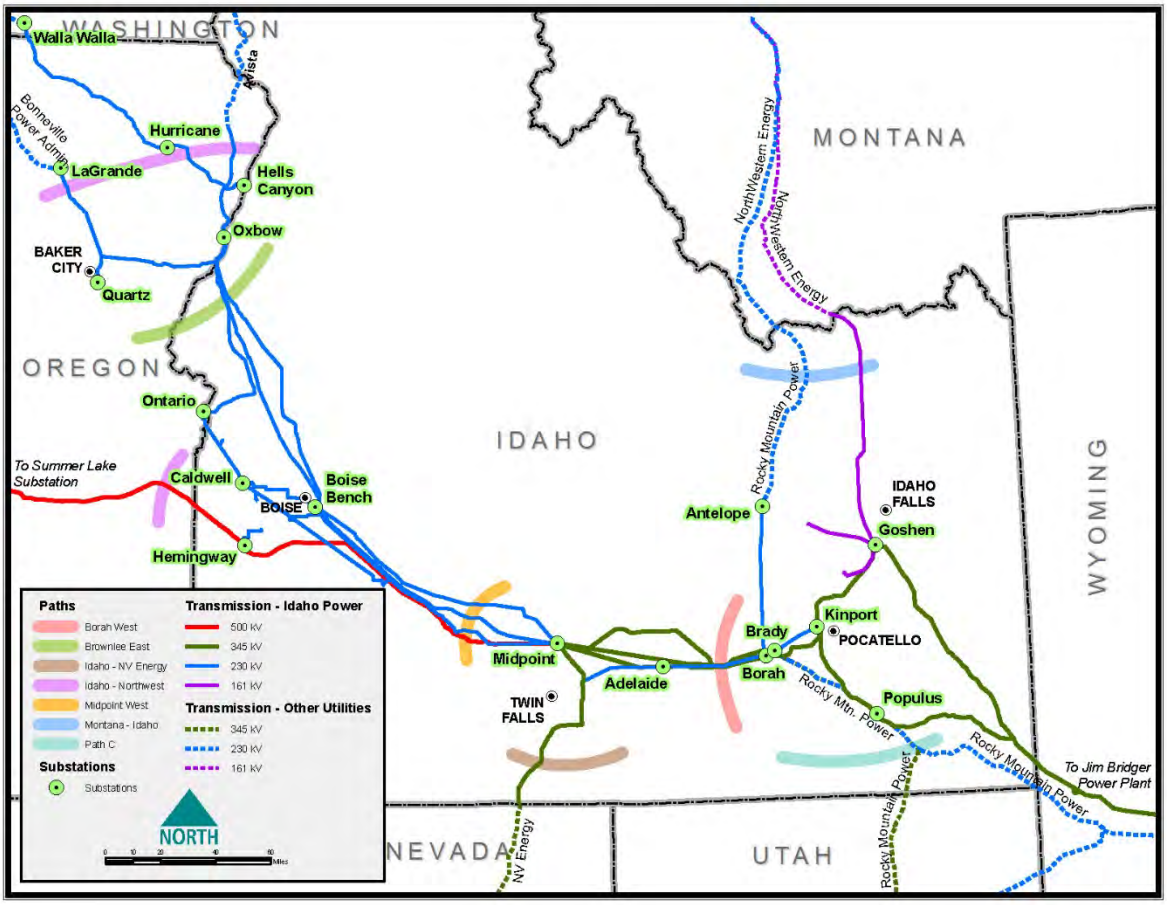

**Figure 6.1 Idaho Power transmission system map**

The transmission paths identified on the map are described in the following sections, along with the conditions that result in capacity limitations.

## Idaho–Northwest Path

The Idaho–Northwest transmission path consists of the 500-kV Hemingway–Summer Lake line, the three 230-kV lines between the HCC and the Pacific Northwest, and the 115-kV interconnection at Harney Substation near Burns, Oregon. The Idaho–Northwest path is capacity-limited during summer months due to energy imports from the Pacific Northwest to serve Idaho Power retail load and transmission-wheeling obligations for the BPA load in eastern Oregon and southern Idaho. To access new resources, including market purchases, located west of the path, additional transmission capacity will be required to deliver the energy to Idaho Power's service area.

## Brownlee East Path

The Brownlee East transmission path is on the east side of the Idaho–Northwest Interconnection shown in Figure 6.1. Brownlee East is comprised of the 230-kV and 138-kV lines east of the

HCC and Quartz Substation near Baker City, Oregon. When the Hemingway–Summer Lake 500-kV line is included with the Brownlee East path, the path is typically referred to as the Brownlee East Total path.

The Brownlee East path is capacity-limited during the summer months due to a combination of HCC hydroelectric generation flowing east into the Treasure Valley concurrent with transmission-wheeling obligations for BPA southern Idaho load and Idaho Power energy imports from the Pacific Northwest. Capacity limitations on the Brownlee East path limit the amount of energy Idaho Power can import from the HCC, as well as off-system purchases from the Pacific Northwest. If new resources, including market purchases, are located west of the path, additional transmission capacity will be required to deliver the energy to the Treasure Valley load center.

### Montana–Idaho Path

The Montana–Idaho transmission path consists of the Antelope–Anaconda 230-kV and Goshen–Dillon 161-kV transmission lines. The Montana–Idaho path is also capacity-limited during the summer months as Idaho Power, BPA, PacifiCorp, and others move energy south from Montana into Idaho.

### Borah West Path

The Borah West transmission path is internal to Idaho Power's system and is jointly owned between Idaho Power and PacifiCorp. Idaho Power owns 1,467 MW of the path, and PacifiCorp owns 1,090 MW of the path. The path is comprised of 345-kV, 230-kV, and 138-kV transmission lines west of the Borah Substation located near American Falls, Idaho. Idaho Power's one-third share of energy from the Jim Bridger plant flows over this path, as well as energy from east-side resources and imports from Montana, Wyoming, and Utah. Heavy path flows are also likely to exist during the light-load hours of the fall and winter months as high eastern thermal and wind production move east to west across the system to the Pacific Northwest. Additional transmission capacity will likely be required if new resources or market purchases are located east of the Borah West path.

### Midpoint West Path

The Midpoint West transmission path is internal to Idaho Power's system and is a jointly owned path between Idaho Power and PacifiCorp. Idaho Power owns 1,710 MW of the path and PacifiCorp owns 1,090 MW of the path (all on the Midpoint–Hemingway 500-kV line). The path is comprised of 500-kV, 230-kV, and 138-kV transmission lines west of Midpoint Substation located near Jerome, Idaho. Like the Borah West path, the heaviest path flows are likely to exist during the fall and winter when significant wind and thermal generation is present east of the path. Additional transmission capacity will likely be required if new resources or market purchases are located east of the Midpoint West path.

## Idaho–Nevada Path

The Idaho–Nevada transmission path is comprised of the 345-kV Midpoint–Humboldt line. Idaho Power and NV Energy are co-owners of the line, which was developed at the same time the North Valmy Power Plant was built in northern Nevada. Idaho Power is allocated 100 percent of the northbound capacity, while NV Energy is allocated 100 percent of the southbound capacity. The available import, or northbound, capacity on the transmission path is fully subscribed with Idaho Power's share of the North Valmy generation plant.

## Idaho–Wyoming Path

The Idaho–Wyoming path, referred to as Bridger West, is comprised of three 345-kV transmission lines between the Jim Bridger generation plant and southeastern Idaho. Idaho Power owns 774 MW of the 2,400-MW east-to-west capacity. PacifiCorp owns the remaining capacity. The Bridger West path effectively feeds into the Borah West path when power is moving east to west from Jim Bridger; consequently, the import capability of the Bridger West path is limited by Borah West path capacity constraints.

## Idaho–Utah Path

The Idaho–Utah path, referred to as Path C, is comprised of 345-, 230-, 161-, and 138-kV transmission lines between southeastern Idaho and northern Utah. PacifiCorp is the path owner and operator of all the transmission lines. The path effectively feeds into Idaho Power's Borah West path when power is moving from east to west; consequently, the import capability of Path C is limited by Borah West path capacity limitations.

Table 6.1 summarizes the import capability for paths impacting Idaho Power operations and lists their total capacity and available capacity; most of paths are completely allocated with no capacity remaining.

**Table 6.1 Transmission import capacity**

| Transmission Path | Import Direction | Capacity (MW) | ATC (MW)* |
|---|---|---|---|
| Idaho–Northwest | West to east | 1,200 | 0 |
| Idaho–Nevada | South to north | 262 | 0 |
| Idaho–Montana | North to south | 383 | 0 |
| Brownlee East | West to east | 1,915 | Internal Path |
| Midpoint West | East to west | 1,710 | Internal Path |
| Borah West | East to west | 2,557 | Internal Path |
| Idaho–Wyoming (Bridger West) | East to west | 2,400 | 86 (Idaho Power Share) |
| Idaho–Utah (Path C) | South to north | 1,250 | PacifiCorp Path |

* The available transmission capacity (ATC) of a specific path may change based on changes in the transmission service and generation interconnection request queue (i.e., the end of a transmission service, granting of transmission service, or cancelation of generation projects that have granted future transmission capacity).

## B2H

In the 2006 IRP process, Idaho Power identified the need for a transmission line to the Pacific Northwest electric market. At that time, a 230-kV line interconnecting at the McNary Substation to the greater Boise area was included in IRP portfolios. Since its initial identification, the project has been refined and developed, including evaluating upgrade options of existing transmission lines, evaluating terminus locations, and sizing the project to economically meet projected demand. The project identified in 2006 has evolved into what is currently the B2H project. The project involves permitting, constructing, operating, and maintaining a new, single-circuit 500-kV transmission line approximately 300 miles long between the proposed Longhorn Station near Boardman, Oregon, and the existing Hemingway Substation in southwest Idaho. The new line will provide many benefits, including the following:

- Greater access to the Pacific Northwest electric market to economically serve homes, farms, and businesses in Idaho Power's service area
- Improved system reliability and resiliency
- Reduced capacity limitations on the regional transmission system as demands on the system continue to grow
- Flexibility to integrate renewable resources and more efficiently implement advanced market tools, such as the EIM

The B2H project was identified as part of the preferred resource portfolio in Idaho Power's 2009, 2011, 2013, and 2015 IRPs.

The B2H project is a regionally significant project. The project has been identified as producing a more efficient or cost-effective plan in the NTTG's 2007, 2009, 2011, 2013, and 2015 biennial regional transmission plans.[14] NTTG regional transmission plans aim to produce a more efficient or cost-effective regional transmission plan that meets the transmission requirements associated with the load and resource needs of the NTTG footprint.

Additionally, the B2H project is a nationally recognized project. The project was selected by the Obama administration as one of seven nationally significant transmission projects that, when built, will help increase electric reliability, integrate new renewable energy into the grid, create jobs and save consumers money.[15]

## Project Participants

In January 2012, Idaho Power entered into a joint funding agreement with PacifiCorp and BPA to pursue permitting of the project. The agreement designates Idaho Power as the permitting project manager for the B2H project. Table 6.2 shows each party's B2H capacity and permitting cost allocation.

**Table 6.2 B2H capacity and permitting cost allocation**

| | Idaho Power | BPA | PacifiCorp |
|---|---|---|---|
| Capacity (MW) west to east | 350<br>200 winter/500 summer | 400<br>550 winter/250 summer | 300 |
| Capacity (MW) east to west | 85 | 97 | 818 |
| Permitting cost allocation | 21% | 24% | 55% |

Additionally, a Memorandum of Understanding (MOU) was executed between Idaho Power, BPA, and PacifiCorp to explore opportunities for BPA to serve eastern Idaho load from the Hemingway Substation. BPA identified six solutions—including two B2H options—to meet its load-service obligations in southeast Idaho. On October 2, 2012, BPA publicly announced the preferred solution to be the B2H project. The participation of three large utilities working toward the permitting of B2H further demonstrates the regional significance and regional benefits of the project.

## Permitting Update

The permitting phase of the B2H project is subject to review and approval by, among other government entities, the Bureau of Land Management (BLM), US Forest Service (USFS), Department of the Navy, and ODOE. The federal permitting process is dictated primarily by the *Federal Land Policy Management Act* and *National Forest Management Act* and is subject to NEPA review. The BLM is the lead agency in administering the NEPA process for the B2H project. On November 25, 2016, BLM published the Final Environmental Impact Statement (EIS). Figure 6.2 shows the proposed transmission line routes included in the Final EIS with the agency preferred route. Idaho Power expects the BLM to issue a Record of Decision (ROD) by summer 2017.

For the State of Oregon permitting process, Idaho Power submitted the preliminary Application for Site Certificate (pASC) to the ODOE in February 2013. Idaho Power plans to submit an amended pASC in summer 2017.

Given the ongoing permitting requirements, Idaho Power is unable to accurately determine an approximate in-service date for the line but expects the in-service date would be in 2024 or beyond.

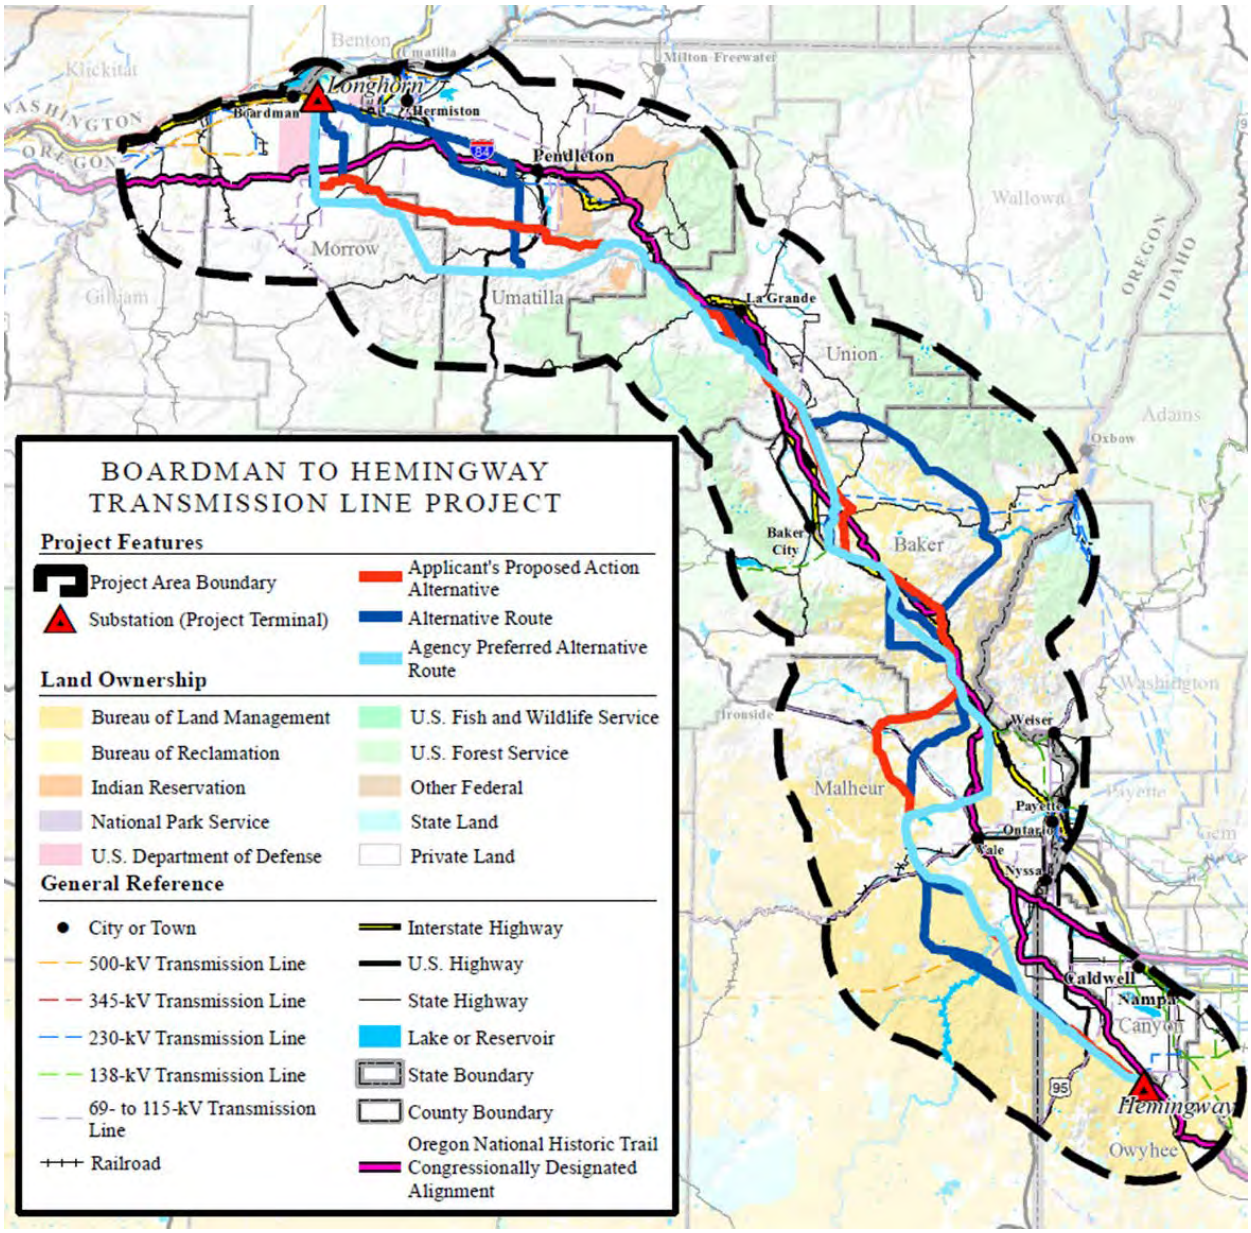

**Figure 6.2 B2H routes with the agency-preferred alternative**

## *Activities after BLM ROD*

After the BLM issues a ROD and the amended pASC has been submitted to the ODOE and deemed complete, sufficient route certainty will exist to begin preliminary construction activities. These activities include, but are not limited to, the following:

- Geotechnical surveys
- Detailed ground surveys (light detection and ranging [LiDAR] surveys)
- Sectional surveys

- Right-of-way (ROW) activities
- Detailed design
- Construction bid package development

After the Oregon permitting process concludes, construction activities would commence. Construction activities include, but are not limited to, the following:

- Long-lead material acquisition
- Transmission line construction
- Substation construction or upgrades

The specific timing of each of the preliminary construction and construction activities will be coordinated with the project co-participants. Additional project information is available at boardmantohemingway.com.

## B2H Cost Treatment in the IRP

The B2H transmission line project is modeled in AURORA as additional transmission capacity available for Idaho Power energy purchases from the Pacific Northwest. In general, for new supply-side resources modeled in the IRP process, surplus sales of generation are included as a cost offset in the AURORA portfolio modeling. However, historically, additional transmission wheeling revenue has not been quantified for a transmission capacity addition. For the 2017 IRP, Idaho Power modeled the additional transmission wheeling revenue for the B2H project. After the B2H line is in-service, the cost of Idaho Power's share of the transmission line will go into Idaho Power's transmission rate base as a transmission asset. Idaho Power's transmission assets are funded by native load customers, network customers, and transmission wheeling customers based on a ratio of each party's usage of the transmission system. In the IRP modeling, the estimated incremental transmission wheeling revenue from non-native load customers was modeled as an annual revenue credit for B2H portfolios.

## Northwest Seasonal Resource Availability Forecast

The assessment of regional resource adequacy is part of the regional transmission planning process, and the review of adequacy assessments is useful in understanding the liquidity of regional wholesale electric markets. For the 2017 IRP, Idaho Power has reviewed two recent assessments and their respective characterizations of regional resource adequacy in the Pacific Northwest: 1) the adequacy assessment conducted by the NWPCC Resource Adequacy Advisory Committee (RAAC) and 2) the adequacy assessment conducted by the BPA.

In July 2013, the NWPCC approved a charter for the RAAC, which provided that the RAAC's purpose is to assess power-supply adequacy in the Northwest. Idaho Power has participated in the RAAC since its inception, and also in the NWPCC's Resource Adequacy Forum, which preceded the RAAC.

The NWPCC adopted an adequacy standard used by the RAAC as a metric for assessing resource adequacy. The purpose of the resource adequacy standard is to provide an early warning should resource development fail to keep pace with demand growth. The analytical information generated with each resource adequacy assessment assists regional utilities when preparing their individual IRPs. The statistic used to assess compliance with the adequacy standard is the likelihood of supply shortage, which is commonly known as the loss-of-load probability (LOLP). Under the adequacy standard, the LOLP is held to a maximum level of 5 percent.

The RAAC issued a report in September 2016 on resource adequacy for the 2021 operating year.[16] The 2021 operating year follows the 2020 retirement of 1,330 MW of coal-fired generating capacity at Centralia (Washington) Unit 1 and the Boardman power plant. The RAAC adequacy assessment reports the LOLP for operating year 2021 is 10 percent, and that to maintain resource adequacy at the maximum level of 5 percent the Pacific Northwest needs to add slightly more than 1,000 MW of new capacity. The RAAC also reports that the retirement of approximately 600 MW of coal-fired generating capacity at Colstrip units 1 and 2, currently anticipated for summer 2022, would increase the LOLP to approximately 13 percent if the retirement of the Colstrip units was moved up to earlier than operating year 2021. The adequacy assessment demonstrates Pacific Northwest adequacy concerns in both winter and summer. Winter LOLP exceeds summer LOLP, except for the analysis assuming pre-2021 retirement of Colstrip units 1 and 2, wherein late summer LOLP exceeds winter LOLP. Under both assumptions for Colstrip units 1 and 2, the LOLP in June and July is zero. The RAAC is currently conducting an updated adequacy assessment for the 2022 operating year. Preliminary results of the updated assessment released by the RAAC indicate a lowered LOLP for operating year 2022 of just under 8 percent. A report on the updated adequacy assessment from the RAAC is anticipated in 2017.

BPA annually assesses regional resource adequacy in its Pacific Northwest load and resource study. The BPA assessment accounts for forecast load growth in the Pacific Northwest (including Idaho and Montana), existing generation, planned new generation considered as highly certain, and committed generation retirements. In their assessment, BPA considers regional load diversity (i.e., winter- or summer-peaking utilities) and expected monthly

[16] NWPCC. Pacific Northwest power supply adequacy assessment for 2021. 2016. Document 2016-10. https://www.nwcouncil.org/media/7150591/2016-10.pdf. Accessed on: April 25, 2017.

production from the Pacific Northwest hydroelectric system under the critical case water year for the region (1937).

The most recent BPA adequacy assessment report was released in December 2016 and evaluates resource adequacy from 2018 through 2027.[17] Monthly capacity adequacy is analyzed from the perspective of one-hour capacity and 120-hour sustained capacity. In the 2016 assessment, the Pacific Northwest region is projected in 2027 to have summer surpluses from the one-hour perspective in June through the first half of August, then a deficit of nearly 200 MW in the second half of August. From the 120-hour sustained capacity perspective, the Pacific Northwest region is projected in 2027 to have a surplus in June, then to be in deficit for July and August. However, the projected 120-hour deficits in July and the first half of August are less than half those predicted for the winter months, suggesting the addition of sustained capacity needed to address winter deficits would be available as surplus capacity to the summer wholesale market in the region.

The Pacific Northwest was historically characterized as an energy-constrained region, rather than capacity constrained. Load-serving entities could typically serve capacity needs, but during periodic low water conditions may encounter energy constraints. However, over time the region has trended toward becoming capacity constrained, as shown by the RAAC and BPA adequacy assessments. While the regional adequacy assessments suggest potential capacity inadequacies, these inadequacies for both assessments are shifted from the timing of Idaho Power's peak needs. Specifically, the adequacy assessments find summer inadequacies in the region occur in the late summer, by which time demand for energy from Idaho Power's irrigation customers has substantially declined from its late-June through early-July peak. Further, the RAAC adequacy assessment acknowledges that its assessment does not include generating capacity not yet sited or licensed, or generating capacity additions driven by RPS requirements. Known new generating capacity planned by 2021 of about 550 MW, along with RPS requirements in Washington, Oregon, and California, will drive resource expansion. The regional resource adequacy assessments are consistent with Idaho Power's view that expanded transmission interconnection to the Pacific Northwest (i.e., B2H) provides access to a market with capacity for meeting its summer load needs and abundant low-cost energy, and that expanded transmission is critical in a future with automated energy markets (i.e., western EIM) and high penetrations of renewable intermittent resources.

## Gateway West

The Gateway West transmission line project is a joint project between Idaho Power and PacifiCorp to build and operate approximately 1,000 miles of new transmission lines from the planned Windstar Substation near Glenrock, Wyoming, to the Hemingway Substation near Melba, Idaho. PacifiCorp has been designated the permitting project manager for Gateway West, with Idaho Power providing a supporting role.

Figure 6.3 shows a map of the project identifying the currently authorized routes in the federal permitting process based on the BLM's November 2013 ROD for segments 1 through 7 and 10. Segments 8 and 9 were further considered through a Supplemental EIS by the BLM. The BLM issued a ROD for segments 8 and 9 on January 20, 2017. In March 2017, this ROD was rescinded by the BLM for further consideration. On May 5, 2017, the *Morley Nelson Snake River Birds of Prey National Conservation Area Boundary Modification Act of 2017* (H.R. 2104) was enacted. H.R. 2104 authorized the Gateway West route through the Birds of Prey area that was proposed by Idaho Power and PacifiCorp and supported by the Idaho Governor's Office, Owyhee County and certain other constituents. Per this legislation, the Secretary of the Interior must issue a ROW for Idaho Power's proposed routes for segments 8 and 9 by early August 2017.

Idaho Power has a one-third interest in the segments between Midpoint and Hemingway, Cedar Hill and Hemingway, and Cedar Hill and Midpoint. Further, Idaho Power has sole interest in the segment between Borah and Midpoint (segment 6), which is an existing transmission line operated at 345 kV but constructed at 500 kV.

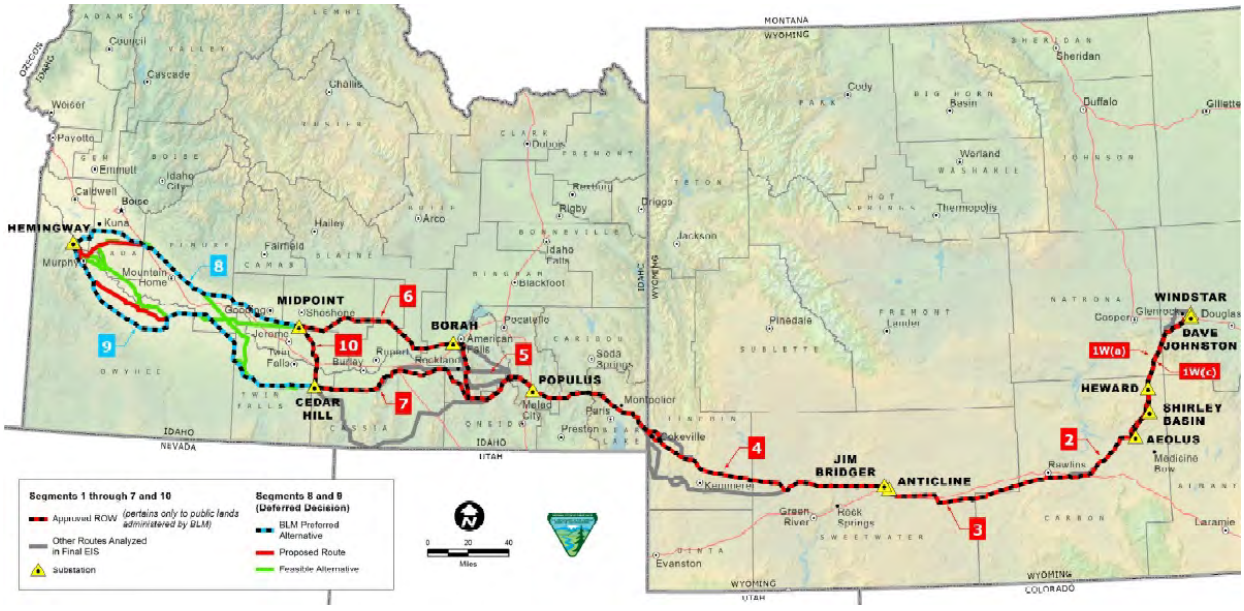

**Figure 6.3 Gateway West map**

The Gateway West project will provide many benefits to Idaho Power customers, including the following:

1. Relieve Idaho Power's constrained transmission system between the Magic Valley area (Midpoint) and the Treasure Valley area (Hemingway). Transmission connecting the Magic Valley and Treasure Valley is part of Idaho Power's core transmission system, connecting two major Idaho Power load centers.
2. Provide the option to locate future generation resources east of the Treasure Valley.
3. Provide future load-service capacity to the Magic Valley from the Cedar Hill Substation.
4. Help meet the transmission needs of the future, including transmission needs associated with intermittent resources.

Phase 1 of the Gateway West project is expected to provide up to 1,500 MW of additional transfer capacity between Midpoint and Hemingway. The fully completed project would provide a total of 3,000 MW of additional transfer capacity. Idaho Power has a one-third interest in these capacity additions.

The Gateway West and B2H projects are complementary and will provide upgraded transmission paths from the Pacific Northwest across Idaho and into eastern Wyoming.

More information about the Gateway West project can be found at gatewaywestproject.com.

## Nevada without North Valmy

The Idaho–Nevada transmission path is co-owned by Idaho Power and NV Energy, with Idaho Power having full allocation of northbound capacity and NV Energy having full allocation of southbound capacity. As noted earlier in this chapter, the northbound capacity of the path is fully subscribed with Idaho Power's share of the North Valmy generation plant.

In its evaluation of North Valmy retirement options, Idaho Power has reviewed the potential to import wholesale energy across the Idaho–Nevada transmission path following retirement of North Valmy generating capacity. Idaho Power has principally participated in the Mid-Columbia wholesale power market to the northwest and considers the availability of wholesale energy for import across the Idaho–Nevada path as less certain. In particular, the frequent import of wholesale energy from Nevada is likely to encounter scarcity and/or costly energy. Therefore, while Nevada is not considered a viable source for abundant wholesale energy, it may have potential to source seldom-needed capacity during peak-loading periods. For this reason, Idaho Power is assuming for the 2017 IRP that the retirement of North Valmy generating capacity can be adequately replaced with infrequent wholesale capacity imports across the Idaho–Nevada transmission path.

Idaho Power recognizes the uncertainty of assuming wholesale capacity imports from Nevada can replace North Valmy generating capacity. The viability of the Idaho–Nevada path can be evaluated as the company continues to transition away from coal in a measured and responsible manner. Idaho Power expects to develop greater understanding of the viability of the Idaho–Nevada path with participation in the western EIM beginning in spring 2018. As it continues its evaluation, Idaho Power recognizes the assumption that wholesale capacity imports from Nevada can replace North Valmy generating capacity may prove unfounded, and future IRPs may need to reflect such a change.

## Transmission Assumptions in the IRP Portfolios

Idaho Power makes resource location assumptions to determine transmission requirements as part of the IRP development process. Regardless of the location, supply-side resources included in the resource stack typically require local transmission improvements for integration into Idaho Power's system. Additional transmission improvement requirements depend on the location and size of the resource. The transmission assumptions and transmission upgrade requirements for incremental resources are summarized in Table 6.3. The assumptions about the geographic area where supply-side resources are developed determine the transmission upgrades required.

Transmission lines leading from Danskin Power Plant

**Table 6.3 Transmission assumptions and requirements**

| Resource | Capacity | Cost Assumption Notes | Local Interconnection Assumptions | Backbone Transmission Assumptions |
|---|---|---|---|---|
| Biomass indirect—Anaerobic digester | 35 | Assume distribution feeder locations in the Magic Valley; displaces equivalent MW of portfolio resources in same region. | Assume $3.5 million of distribution feeder upgrades and $1.2 million in substation upgrades. | Assigns pro-rata share for transmission upgrades identified for resources east of Boise. |
| Geothermal (binary-cycle)—Idaho | 35 | Assume Raft River area location; displaces equivalent MW of portfolio resources in same region. | Requires 5-mile 138-kV line to nearby station with new 138-kV substation line terminal bay. | Assigns pro-rata share for transmission upgrades identified for resources east of Boise. |
| Hydro—Canal drop (seasonal) | 1 | Assume Magic Valley location connecting to 46-kV sub-transmission or local feeder. | Assume 4 miles of distribution rebuild at $150,000 per mile plus $100,000 in substation upgrades. | No backbone upgrades required. |

| Resource | Capacity | Cost Assumption Notes | Local Interconnection Assumptions | Backbone Transmission Assumptions |
|---|---|---|---|---|
| Natural gas—SCCT frame F class (Idaho Power's peaker plants use this technology) | 170 | Assume Mountain Home location; displaces equivalent MW of portfolio resources in same region. | Assume 2-mile 230-kV line required to connect to nearby station. | Assigns pro-rata share for transmission upgrades identified for resources east of Boise. |
| Natural gas—Reciprocating gas engine Wärtsilä 34SG | 18 | Assume Mountain Home location; displaces equivalent MW of portfolio resources in same region. | Interconnecting at 230-kV Rattle Snake Substation. | Assigns pro-rata share for transmission upgrades identified for resources east of Boise. |
| Natural gas—CCCT (1x1) F class with duct firing | 300 | Assume Langley Gulch location; displaces equivalent MW of portfolio resources in same region. | New LGSY–GARNET 230-kV line w/ Garnet 230/138 transformer and Garnet 138-kV tap line. Bundle conductor on the LGSY–CDWL 230-kV line. Reconductor CDWL–LNDN. | No additional backbone upgrades required. |
| Natural gas—CCCT (1x1) F class with duct firing | 300 | Assume Mountain Home location; displaces equivalent MW of portfolio resources in same region. | Assume 2-mile 230-kV line required to connect to nearby station. | Assigns pro-rata share for transmission upgrades identified for resources east of Boise. |
| Natural gas—CCCT (2x1) F class | 550 | Build new facility south of Boise (assume Simco Road area). | New 230-kV switching station with a 22-mile 230-kV line to Boise Bench Substation and wrap 230-kV Danskin Power Plant to Hubbard line into new station. | Rebuild Rattle Snake to DRAM 230-kV line, rebuild Boise Bench to DRAM 230-kV line, rebuild Micron to Boise Bench 138-kV line. |
| Natural gas—CHP | 35 | Assume location in Treasure Valley. | Assume 1-mile tap to existing 138-kV line and new 138-kV source substation. | No backbone upgrades required. |
| Nuclear—SMR | 50 | Assume tie into ANTS 230-kV transmission substation; displaces equivalent MW of portfolio resources east of Boise. | Two 2-mile 138-kV lines to interconnect to Antelope Substation. New 138-kV terminal at Antelope Substation. | New parallel 55-mile 230-kV line from Antelope to Brady Substation. New 230-kV terminal at Brady Substation. Assigns pro-rata share for transmission upgrades identified for resources east of Boise. |
| Pumped storage—New upper reservoir and new generation/pumping plant | 100 | Assume Anderson Ranch location; displaces equivalent MW of portfolio resources in same region. | 18-mile 230-kV line to connect to Rattle Snake Substation. | Assigns pro-rata share for transmission upgrades identified for resources east of Boise. |
| Solar PV—Utility-scale 1-axis tracking | 30 | Assume Magic Valley location; displaces equivalent MW of portfolio resources in same region. | Assume 1-mile 230-kV line and associated stations equipment. | Assigns pro-rata share for transmission upgrades identified for resources east of Boise. |
| Wind—Idaho | 100 | Assume location within 5 miles of Midpoint Substation; displaces equivalent MW of portfolio resources in same region. | Assume 5-mile 230-kV transmission from Midpoint Substation to project site. | Assigns pro-rata share for transmission upgrades identified for resources east of Boise. |

# 7. PLANNING PERIOD FORECASTS

The IRP process requires Idaho Power to prepare numerous forecasts and estimates, which can be grouped into four main categories:

1. Load forecasts
2. Generation forecast for existing resources
3. Natural gas price forecast
4. Resource cost estimates

Pedestrians at the Drive Electric Week event in Boise.

The load and generation forecasts—including supply-side resources, DSM, and transmission import capability—are used to estimate surplus and deficit positions in the load and resource balance. The identified deficits are used to develop resource portfolios evaluated using financial tools and forecasts. The following sections provide details on the forecasts prepared as part of the 2017 IRP.

## Load Forecast

Each year, Idaho Power prepares a forecast of sales and demand of electricity using the company's electrical T&D network. This forecast is a product of historical system data and trends in electricity usage along with numerous external economic and demographic factors.

Idaho Power has its annual peak demand in the summer, with peak loads driven by irrigation pumps and A/C in June, July, and August. Historically, Idaho Power's growth rate of the summertime peak-hour load has exceeded the growth of the average monthly load. Both measures are important in planning future resources and are part of the load forecast prepared for the 2017 IRP.

The expected case (median) load forecasts for peak-hour and average energy (average load) represent Idaho Power's most probable outcome for load growth during the planning period. In addition, Idaho Power prepared two probabilistic load forecasts that address the load variability associated with abnormal weather trends. The 70$^{th}$-percentile and 90$^{th}$-percentile load forecasts were developed to assist Idaho Power in reviewing the resource requirements that would result from higher loads due to variable weather conditions.

The expected case forecast for system load growth is determined by summing the load forecasts for individual classes of service, as described in *Appendix A—Sales and Load Forecast*.

For example, the expected annual average system load growth of 0.9 percent (over the period 2017 through 2036) is comprised of a residential load growth of 1.2 percent, a commercial load growth of 0.7 percent, an irrigation load growth of 0.6 percent, an industrial load growth of 0.7 percent, and an additional firm load growth of 0.7 percent.

The number of residential customers in Idaho Power's service area is expected to increase 1.8 percent annually from 444,000 at the end of 2016 to nearly 632,000 by the end of the planning period in 2036. Growth in the number of customers within Idaho Power's service area, combined with an expected declining consumption per customer, results in a 1.2-percent average residential load-growth rate.

Significant factors and considerations that influenced the outcome of the 2017 IRP load forecast include the following:

- The load forecast used for the 2017 IRP reflects the continuing recovery of the service-area economy following a severe recession in 2008 and 2009. Customer growth was at a near standstill until 2012, but since then acceleration of net migration and business investment has resulted in renewed growth. By 2017, customer additions have approached sustainable growth rates experienced prior to the housing bubble (2000–2004) and are expected to continue.

- The electricity price forecast used to prepare the sales and load forecast in the 2017 IRP reflects the impact of additional plant investments and associated variable costs of integrating new resources identified in the 2015 IRP preferred portfolio, including the expected cost to comply with carbon-emission regulations. Compared to the electricity price forecast used to prepare the 2015 IRP sales and load forecast, the 2017 IRP price forecast yields lower future prices. The retail prices are most evident after the first two years of the planning period and can impact the sales forecast positively, a consequence of the inverse relationship between electricity prices and electricity demand.

- There continues to be significant uncertainty associated with the industrial and special-contract sales forecasts due to the number of parties that contact Idaho Power expressing interest in locating operations within Idaho Power's service area, typically with an unknown magnitude of the energy and peak-demand requirements. The expected load forecast reflects only those industrial customers that have made a sufficient and significant binding investment indicating a commitment of the highest probability of locating in the service area. The large numbers of prospective businesses that have indicated an interest in locating in Idaho Power's service area but have not made sufficient commitments are not included in the current sales and load forecast.

- Conservation impacts, including DSM energy efficiency programs and codes and standards, and other naturally occurring efficiencies are considered and integrated into the sales forecast. Impacts of demand response programs (on peak) are accounted for in the load and resource balance analysis within supply-side planning (i.e., are treated as a supply-side peaking resource). The amount of committed and implemented DSM programs for each month of the planning period is shown in the load and resource balance in *Appendix C—Technical Appendix*.

- The 2017 irrigation sales forecast is higher than the 2015 IRP forecast throughout the entire forecast period due to the significant trend toward more water-intensive crops, primarily alfalfa and corn, occurring as a result of growth in the dairy industry. The irrigation sales forecast is higher also as a consequence of renewed production from high-lift acreage. Additionally, load increases have come from the conversion of flood/furrow irrigation to sprinkler irrigation, primarily related to efforts to reduce labor costs.

## Weather Effects

The expected-case load forecast assumes median temperatures and median precipitation, which means there is a 50-percent chance loads will be higher or lower than the expected-case load forecast due to colder-than-median or hotter-than-median temperatures and wetter-than-median or drier-than-median precipitation. Since actual loads can vary significantly depending on weather conditions, two alternative scenarios were analyzed to address load variability due to weather—70$^{th}$-percentile and 90$^{th}$-percentile load forecasts. Seventieth-percentile weather means that in 7 out of 10 years, load is expected to be less than forecast, and in 3 out of 10 years, load is expected to exceed the forecast. Ninetieth-percentile load has a similar definition with a 1-in-10 likelihood the load will be greater than the forecast.

Weather conditions are the primary factor affecting the load forecast on a monthly or seasonal basis. Over the longer-term, economic conditions, demographic conditions, and changing technologies influence the load forecast.

## Economic Effects

Numerous external factors influence the sales and load forecast that are primarily economic and demographic in nature. Moody's Analytics serves as the primary provider for this data. The national, state, metropolitan statistical area (MSA) and county economic and demographic projections are tailored to Idaho Power's service area using an in-house economic database. Specific demographic projections are also developed for the service area from national and local census data. Additional data sources used to substantiate Moody's data include, but are not limited to, the US Census Bureau, the Bureau of Labor Statistics, the Idaho Department of Labor, Woods & Poole, Construction Monitor, and Federal Reserve Economic Databases.

The number of households in Idaho is projected to grow at an annual rate of 1.2 percent during the forecast period. The growth in the number of households within individual counties in Idaho Power's service area is projected to grow faster than the remainder of the state over the planning period. The number of households in the Boise City–Nampa MSA is projected to grow faster than the rest of Idaho, at an annual rate of 1.6 percent during the forecast period. The Boise MSA (or the Treasure Valley) is an area that encompasses Ada, Boise, Canyon, Gem, and Owyhee counties in southwestern Idaho. In addition, the number of households, incomes, employment, economic output, electricity prices, and customer consumption patterns are used to develop load projections.

The population in Idaho Power's service area, due to migration to Idaho from other states, is expected to increase throughout the planning period. This population increase is included in the load forecast models. Idaho Power also continues to receive requests from prospective large-load customers attracted to southern Idaho's positive business climate and relatively low electric rates. In addition, the economic conditions in surrounding states may encourage some manufacturers to consider moving operations to Idaho.

The 2017 IRP average annual system load forecast reflects continued improvement in the service-area economy. While economic conditions during the development of the 2015 IRP were positive, the resulting sales forecast was more optimistic than the actual performance experienced in the interim period leading up to the 2017 IRP. The improving economic and demographic variables driving the 2017 forecast are reflected by a positive sales outlook throughout the planning period. However, the 2017 IRP forecast is more moderate, and the growth path is less steep.

## Average-Energy Load Forecast

Potential monthly average-energy use by customers in Idaho Power's service area is defined by three load forecasts that reflect load uncertainty resulting from different weather-related assumptions. Figure 7.1 and Table 7.1 show the results of the three forecasts used in the 2017 IRP as annual system load growth over the planning period. There is an approximately 50-percent probability Idaho Power's load will exceed the expected-case forecast, a 30-percent probability of load exceeding the 70$^{th}$-percentile forecast, and a 10-percent probability of load exceeding the 90$^{th}$-percentile forecast. The projected 20-year average compound annual growth rate in each of the forecasts is 0.9 percent over the 2017 through 2036 period.

Idaho Power uses the 70$^{th}$-percentile forecast as the basis for monthly average-energy planning in the IRP. The 70$^{th}$-percentile forecast is based on 70$^{th}$-percentile weather to forecast average monthly load and 95$^{th}$-percentile average peak-day temperature to forecast monthly peak-hour load.

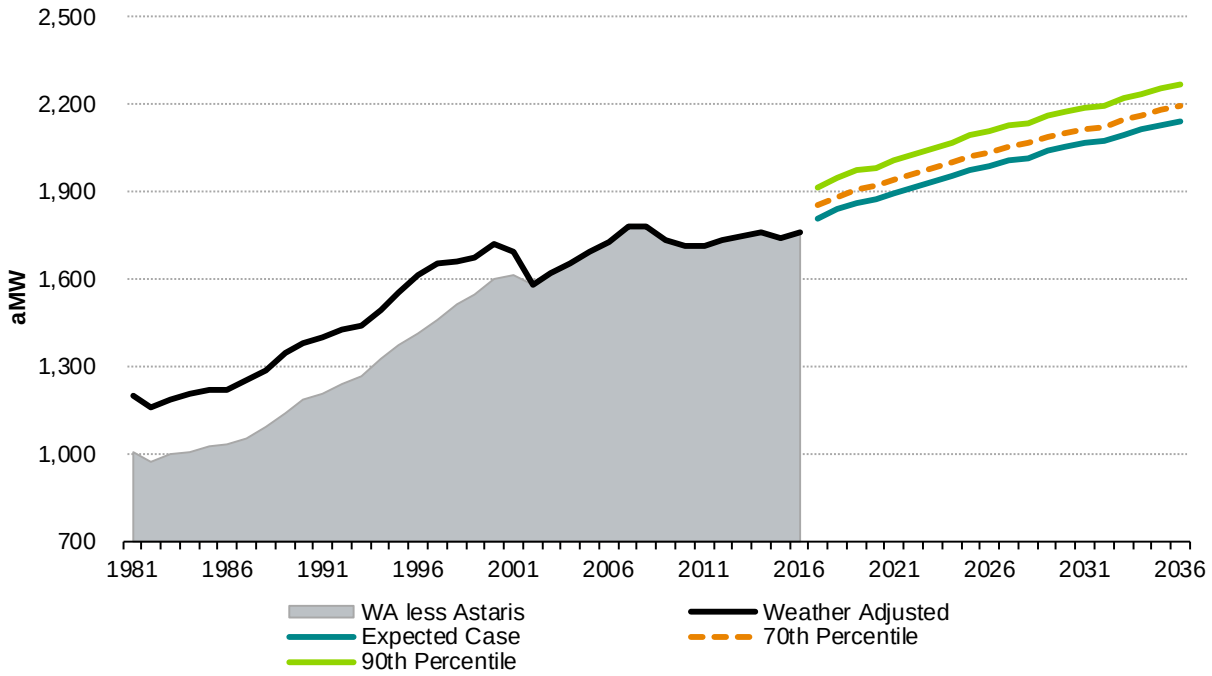

**Figure 7.1 Average monthly load-growth forecast**

**Table 7.1 Load forecast—average monthly energy (aMW)**

| Year | Median | 70th Percentile | 90th Percentile |
|---|---|---|---|
| 2017 | 1,810 | 1,853 | 1,917 |
| 2018 | 1,840 | 1,883 | 1,948 |
| 2019 | 1,864 | 1,907 | 1,973 |
| 2020 | 1,874 | 1,918 | 1,984 |
| 2021 | 1,894 | 1,939 | 2,006 |
| 2022 | 1,914 | 1,959 | 2,027 |
| 2023 | 1,935 | 1,981 | 2,049 |
| 2024 | 1,955 | 2,001 | 2,070 |
| 2025 | 1,975 | 2,022 | 2,092 |
| 2026 | 1,990 | 2,037 | 2,108 |
| 2027 | 2,007 | 2,054 | 2,126 |
| 2028 | 2,018 | 2,066 | 2,137 |

## Peak-Hour Load Forecast

As average demands as discussed in the preceding section are an integral component to the load forecast so is the impact of peak-hour demands on the system. Peak-hour forecasts are expressed as a function of the sales forecast, as well as the impact of peak-day temperatures.

The system peak-hour load forecast includes the sum of the individual coincident peak demands of residential, commercial, industrial, and irrigation customers, as well as special contracts. Idaho Power uses the 95$^{th}$-percentile forecast as the basis for peak-hour planning in the IRP. The 95$^{th}$-percentile forecast is based on the 95$^{th}$-percentile average peak-day temperature to forecast monthly peak-hour load.

Idaho Power's system peak-hour load record—3,407 MW—was recorded on July 2, 2013, at 4:00 p.m. The system peak-hour load record was nearly matched on June 30, 2015, at 4:00 p.m., when the system peak reached 3,402 MW. Summertime peak-hour load growth accelerated in the previous decade as A/C became standard in nearly all new residential home construction and new commercial buildings. System peak demand slowed considerably in 2009, 2010, and 2011—the consequences of a severe recession that brought new home and new business construction to a standstill. Demand response programs operating in the summer have also had a significant effect on reducing peak demand. The 2017 IRP load forecast projects peak-hour load to grow by over 50 MW per year throughout the planning period in the 95$^{th}$-percentile case. The peak-hour load forecast does not reflect the company's demand response programs, which are accounted for in the load and resource balance in a manner similar to a supply-side resource.

Idaho Power's winter peak-hour load record is 2,527 MW, recorded on January 6, 2017, at 9:00 a.m., matching the previous record peak dated December 10, 2009, at 8:00 a.m. Historical winter peak-hour load is much more variable than summer peak-hour load. The winter peak variability is due to peak-day temperature variability in winter months, which is far greater than the variability of peak-day temperatures in summer months.

Figure 7.2 and Table 7.2 summarize three forecast outcomes of Idaho Power's estimated annual system peak load—median, 90$^{th}$ percentile, and 95$^{th}$ percentile. The 95$^{th}$-percentile forecast uses the 95$^{th}$-percentile peak-day average temperature to determine monthly peak-hour demand and serves as the planning criteria for determining the need for peak-hour capacity. The alternative scenarios are based on their respective peak-day average temperature probabilities to determine forecast outcomes.

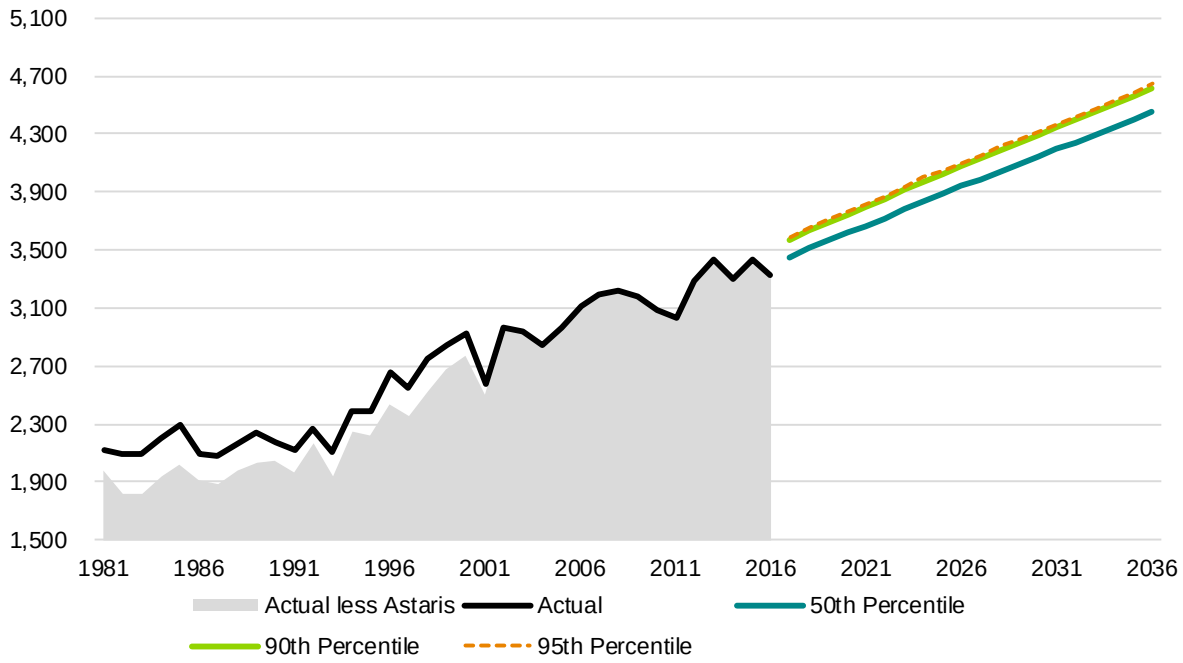

**Figure 7.2 Peak-hour load-growth forecast (MW)**

**Table 7.2 Load forecast—peak hour (MW)**

| Year | Median | 90th Percentile | 95th Percentile |
|---|---|---|---|
| 2016 (Actual) | 3,327 | 3,327 | 3,327 |
| 2017 | 3,446 | 3,566 | 3,586 |
| 2018 | 3,508 | 3,630 | 3,651 |
| 2019 | 3,567 | 3,692 | 3,713 |
| 2020 | 3,618 | 3,745 | 3,766 |
| 2021 | 3,668 | 3,797 | 3,819 |
| 2022 | 3,722 | 3,854 | 3,876 |
| 2023 | 3,778 | 3,912 | 3,934 |
| 2024 | 3,838 | 3,974 | 3,998 |
| 2025 | 3,888 | 4,026 | 4,050 |
| 2026 | 3,937 | 4,078 | 4,102 |
| 2027 | 3,989 | 4,132 | 4,157 |
| 2028 | 4,042 | 4,187 | 4,212 |
| 2029 | 4,092 | 4,240 | 4,265 |
| 2030 | 4,141 | 4,292 | 4,317 |
| 2031 | 4,192 | 4,344 | 4,370 |
| 2032 | 4,239 | 4,394 | 4,420 |
| 2033 | 4,289 | 4,447 | 4,474 |
| 2034 | 4,342 | 4,502 | 4,529 |
| 2035 | 4,395 | 4,557 | 4,584 |
| 2036 | 4,449 | 4,613 | 4,641 |
| **Growth Rate (2017–2036)** | **1.4%** | **1.4%** | **1.4%** |

The median or expected case peak-hour load forecast predicts that peak-hour load will grow from 3,446 MW in 2017 to 4,449 MW in 2036—an average annual compound growth rate of 1.4 percent. The projected average annual compound growth rate of the 95$^{th}$-percentile peak forecast is also 1.4 percent. In the 95$^{th}$-percentile forecast, summer peak-hour load is expected to increase from 3,586 MW in 2017 to 4,641 MW in 2036. Historical peak-hour loads, as well as the three forecast scenarios, are shown in Figure 7.2.

## Additional Firm Load

The additional firm-load category consists of Idaho Power's largest customers. Idaho Power's tariff requires the company to serve requests for electric service greater than 20 MW under a special-contract schedule negotiated between Idaho Power and each large-power customer. The contract and tariff schedule are approved by the appropriate commission. A special contract allows a customer-specific cost-of-service analysis and unique operating characteristics to be accounted for in the agreement.

Individual energy and peak-demand forecasts are developed for special-contract customers, including Micron Technology, Inc.; Simplot Fertilizer Company (Simplot Fertilizer); and the INL. These three special-contract customers comprise the entire forecast category labeled additional firm load.

### Micron Technology

Micron Technology represents Idaho Power's largest electric load for an individual customer and employs approximately 5,000 workers in the Boise MSA. The company operates its research and development fabrication facility in Boise and performs a variety of other activities, including product design and support; quality assurance (QA); systems integration; and related manufacturing, corporate, and general services. Micron Technology's electricity use is a function of the market demand for their products.

### Simplot Fertilizer

The Simplot Fertilizer plant is the largest producer of phosphate fertilizer in the western US. The future electricity usage at the plant is expected to grow slowly through 2017, then stay flat throughout the remainder of the planning period.

### INL

The INL is part of the DOE's complex of national laboratories. The INL is the nation's leading center for nuclear energy research and development. The DOE provided an energy-consumption and peak-demand forecast through 2036 for the INL. The forecast calls for loads to increase through 2024, then levelize through the remainder of the forecast period.

# Generation Forecast for Existing Resources

Hells Canyon Dam

To identify the need and timing of future resources, Idaho Power prepares a load and resource balance that accounts for forecast load growth and generation from the company's existing resources and planned purchases. Updated load and resource balance worksheets showing Idaho Power's existing and committed resources for average-energy and peak hour load are shown in *Appendix C—Technical Appendix*. The following sections provide a description of Idaho Power's hydroelectric, thermal, and transmission resources and how they are accounted for in the load and resource balance.

## *Hydroelectric Resources*

For the 2017 IRP, Idaho Power continues the practice of using 70$^{th}$-percentile future streamflow conditions for the Snake River Basin as the basis for the projections of monthly average hydroelectric generation. The 70$^{th}$ percentile means basin streamflows are expected to exceed the planning criteria 70 percent of the time and are expected to be worse than the planning criteria 30 percent of the time.

Likewise, for peak-hour resource adequacy, Idaho Power continues to assume 90$^{th}$-percentile streamflow conditions to project peak-hour hydroelectric generation. The 90$^{th}$ percentile means streamflows are expected to exceed the planning criteria 90 percent of the time and to be worse than the planning criteria only 10 percent of the time.

The practice of basing hydroelectric generation forecasts on worse-than-median streamflow conditions was initially adopted in the 2002 IRP in response to suggestions that Idaho Power use more conservative water planning criteria as a method of encouraging the acquisition of sufficient firm resources to reduce reliance on market purchases. However, Idaho Power continues to prepare hydroelectric generation forecasts for 50$^{th}$-percentile (median) streamflow conditions because the median streamflow condition is still used for rate-setting purposes and other analyses.

Idaho Power uses two primary models for forecasting future flows for the IRP. The Snake River Planning Model (SRPM) is used to determine surface-water flows, and the Enhanced Snake Plain Aquifer Model (ESPAM) is used to determine the effect of various aquifer management practices on Snake River reach gains. The two models are used in combination to produce a

normalized hydrologic record for the Snake River Basin from 1928 through 2009. The record is normalized to account for specified conditions relating to Snake River reach gains, water-management facilities, irrigation facilities, and operations. The 50th-, 70th-, and 90th-percentile streamflow forecasts are derived from the normalized hydrologic record. Further discussion of flow modeling for the 2017 IRP is included in *Appendix C—Technical Appendix.*

A review of Snake River Basin streamflow trends suggests that persistent decline documented in the ESPA is mirrored by downward trends in total surface-water outflow from the river basin. The current water-use practices driving the steady decline over recent years are expected to continue, resulting in declining basin outflows assumed to persist well into the 2030s. The declining basin outflows for this IRP are assumed to continue through the planning period.

A water-management practice affecting Snake River streamflows involves the release of water to augment flows during salmon outmigration. Various federal agencies involved in salmon migration studies have, in recent years, supported efforts to shift delivery of flow augmentation water from the Upper Snake River and Boise River basins from the traditional months of July and August to the spring months of April, May, and June. The objective of the streamflow augmentation is to more closely mimic the timing of naturally occurring flow conditions. Reported biological opinions indicate the shift in water delivery is most likely to take place during worse-than-median water years. Because worse-than-median water is assumed in the IRP, and because of the importance of July as a resource-constrained month, Idaho Power continues to incorporate the shifted delivery of flow augmentation water from the Upper Snake River and Boise River basins for the IRP. Augmentation water delivered from the Payette River Basin is assumed to remain in July and August. Additionally, yearly flow augmentation shortages from the upper Snake River Basin are filled from the Boise River Basin if adequate water is available.

Monthly average generation for Idaho Power's hydroelectric resources is calculated with a generation model developed internally by Idaho Power. The generation model treats the projects upstream of the HCC as ROR plants. The generation model mathematically manages reservoir storage in the HCC to meet the remaining system load while adhering to the operating constraints on the level of Brownlee Reservoir and outflows from the Hells Canyon project. For the peak-hour analysis, a review of historical (2001—2016) operations was performed to estimate the maximum HCC output achieved on an annual basis with 90-percent probability.

A representative measure of the streamflow condition for any given year is the volume of inflow to Brownlee Reservoir during the April through July runoff period. Figure 7.3 shows historical April through July Brownlee inflow, as well as forecast Brownlee inflow for the 50th, 70th, and 90th percentiles. The historical record demonstrates the variability of inflows to Brownlee Reservoir. The forecast inflows do not reflect the historical variability but do include reductions related to declining base flows in the Snake River. As noted previously in this section, these declines are assumed to continue through the planning period.

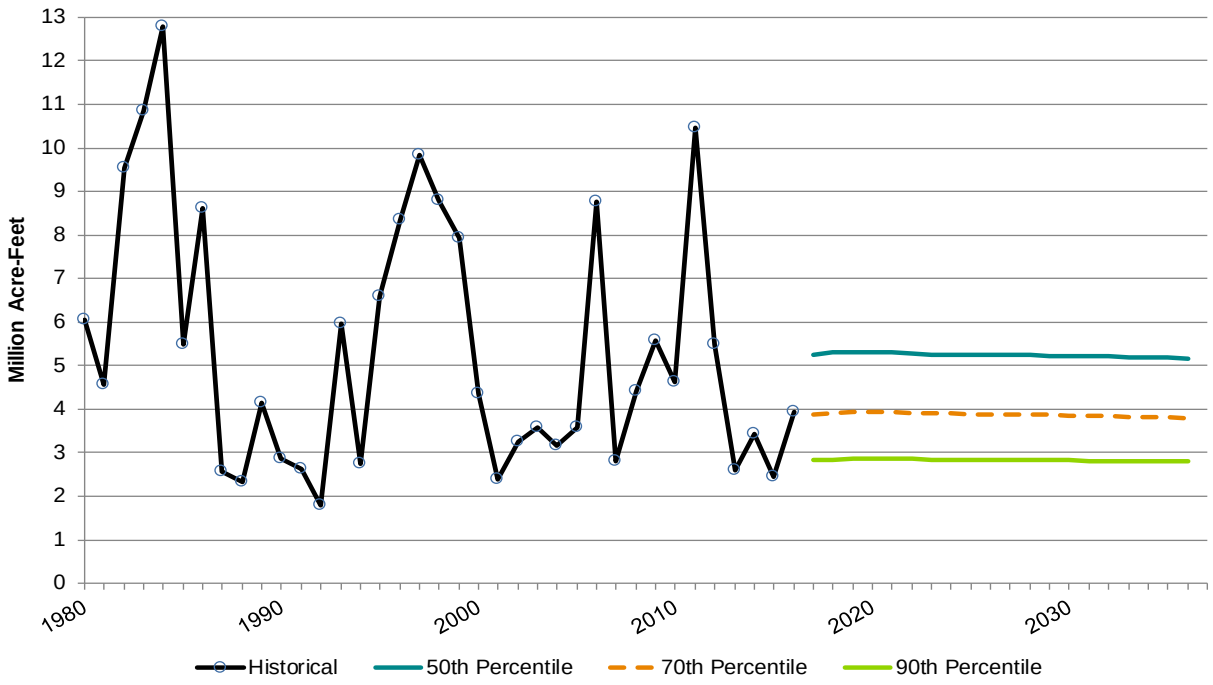

**Figure 7.3 Brownlee historical and forecast inflows, April through July**

Idaho Power recognizes the need to remain apprised of scientific advancements concerning climate change on the regional and global scale. Idaho Power believes too much uncertainty exists to predict the scale and timing of hydrologic effects due to climate change. Therefore, no adjustments related to climate change have been made in the 2017 IRP. Further discussion of climate change and expectations of possible effects on Snake River water supply is available starting on page 64 of the IDACORP Inc. 2016 Form 10-K.

## Coal Resources

Idaho Power's coal-fired power plants continue to deliver generating capacity during high-demand periods. However, production of baseload energy from the company's coal plants has declined over recent years, a trend mirrored by coal plants across the region and nation. The decline in baseload energy production is primarily viewed as driven by low natural gas prices and the expansion of renewable generating capacity; because of the low natural gas prices and expanded renewable generating capacity, wholesale electric market prices over recent years have frequently been too low to merit economic dispatch of coal generating capacity. The challenging economics posed by low wholesale electric market prices, particularly when coupled with the need for capital investments for environmental retrofits, have increasingly led owners of coal-fired power plants to evaluate the cost-effectiveness of continued capital expenditure and continued operation. For the 2017 IRP, Idaho Power makes such economic evaluations for the Jim Bridger and North Valmy coal-fired power plants, as described in the following sections.

While coal-fired power plants over recent years are less frequently dispatched for baseload energy production, the projected monthly average energy output from the coal plants in the load and resource balance continues to reflect typical baseload output levels. Because the load and resource balance is a tool for assessing resource adequacy, rather than a forecast of actual resource output, it is appropriate to include the amount of production a resource can produce. With respect to peak-hour output, the capacity load and resource balance includes the coal-fired power plants at their full-rated, maximum dependable capacity, minus 6 percent to account for forced outages. A summary of the expected coal price forecast is included in *Appendix C—Technical Appendix*.

### Boardman Retirement

The 2017 IRP assumes Idaho Power's share of the Boardman plant will not be available for coal-fired operations after December 31, 2020. This date is the result of an agreement reached between the ODEQ and PGE related to compliance with regional-haze regulations on particulate matter, $SO_2$, and NOx emissions.

### North Valmy

The preferred portfolio from the 2015 IRP included retirement of both North Valmy units year-end 2025. The baseline assumption for North Valmy for the 2017 IRP is updated to reflect retirement of Unit 1 year-end 2019 and Unit 2 year-end 2025. The selection of the preferred portfolio for the 2015 IRP, including the 2025 retirement of both North Valmy units, was consistent with strategies to manage exposure to qualitative risk factors. The qualitative risk factors considered in selecting the preferred portfolio for the 2015 IRP included PURPA contract uncertainty, cooperation with NV Energy on retirement planning, B2H execution, and the Clean Power Plan. For the 2017 IRP, these qualitative risks have diminished.

A review of a North Valmy Unit 1 shutdown year-end 2019 determined the likelihood of customer economic benefits associated with the 2019 retirement outweighs the diminished 2015 IRP qualitative risks. The 2017 IRP load and resource balance impact of retiring North Valmy units 1 and 2 in 2019 and 2025, respectively, is mitigated by the assumption that import capacity across the Idaho–Nevada transmission path will be available. For the 2017 IRP, Idaho Power assumed new resources will not be required to replace retiring North Valmy units, as the existing transmission path can satisfy hourly peak needs. Further discussion of the viability of wholesale capacity imports across the Idaho–Nevada transmission path is included in Chapter 6.

### Jim Bridger Units 1 and 2 Scenarios

Each of the four Jim Bridger units requires capital investment for retrofitting to comply with regional-haze regulations. The implementation of these regulations is stipulated in a state implementation plan (SIP). PacifiCorp and Idaho Power, as joint owners of the Jim Bridger plant, with the Wyoming Department of Environmental Quality (WDEQ), have developed a plan to implement the regional-haze regulation. The current SIP stipulates installation of SCR

retrofitting on Jim Bridger units 3 and 4 in 2015 and 2016, and on units 1 and 2 in 2022 and 2021, respectively. The installation of SCRs on Jim Bridger Units 3 and 4 is complete, and as a baseline assumption, units 3 and 4 are operating resources through the 20-year IRP planning period.

The 2017 IRP analyzes four scenarios related to SCR installation on Jim Bridger units 1 and 2. The scenarios include one in which the SCR investments are made by the required dates in 2021 and 2022, and three alternative scenarios in which units 1 and 2 are retired early at varying dates within the 20-year IRP planning period. The three early-retirement scenarios are analyzed to evaluate the economics of alternatives to SCR installation and to help guide future discussions with the WDEQ in developing a SIP for regional-haze compliance. The four scenarios are as follows:

1. Make the SCR investments and operate Jim Bridger units 1 and 2 through the end of the planning period.

2. Do not make SCR investments and retire Jim Bridger units 1 and 2 year-end 2028 and year-end 2024, respectively.

3. Do not make SCR investments and retire Jim Bridger units 1 and 2 year-end 2032 and year-end 2028, respectively.

4. Do not make SCR investments and retire Jim Bridger units 1 and 2 on their respective compliance dates of year-end 2022 and year-end 2021.

The four Jim Bridger scenarios are discussed further in Chapter 8.

## Natural Gas Resources

Idaho Power owns and operates four natural gas-fired SCCTs and one natural gas-fired CCCT. The SCCT units are typically operated during peak-load events in the summer and winter. The monthly average-energy forecast for the SCCTs is based on the assumption that the generators are operated at full capacity for heavy-load hours during January, June, July, August, and December and produce approximately 235 aMW of gas-fired generation for the five months. With respect to peak-hour output, the SCCTs are assumed capable of producing an on-demand peak capacity of 416 MW. While the peak dispatchable capacity is assumed achievable for all months, it is most critical to system reliability during summer and winter peak-load months.

Idaho Power's CCCT, Langley Gulch, became commercially available in June 2012. Because of its higher efficiency rating, Langley Gulch is expected to be dispatched more frequently and for longer runtimes than the existing SCCTs. Langley Gulch is forecast to contribute approximately 280 aMW, with an on-demand peaking capacity of 300 MW.

## Natural Gas Price Forecast

Future natural gas price assumptions significantly influence the financial results of the operational modeling used to evaluate and rank resource portfolios. For the 2017 IRP, Idaho Power is continuing to use the EIA as the source for the natural gas price forecast. Idaho Power reviewed two natural gas price forecast cases reported by the EIA in the 2016 Annual Energy Outlook (AEO): 1) the Reference Case and 2) the High Oil and Gas Resource and Technology Case. These forecasts are reported by the EIA at Henry Hub, which is an important natural gas distribution hub and pricing point in Louisiana. A graph of historical Henry Hub prices and the reviewed EIA forecasts is provided in Figure 7.4.

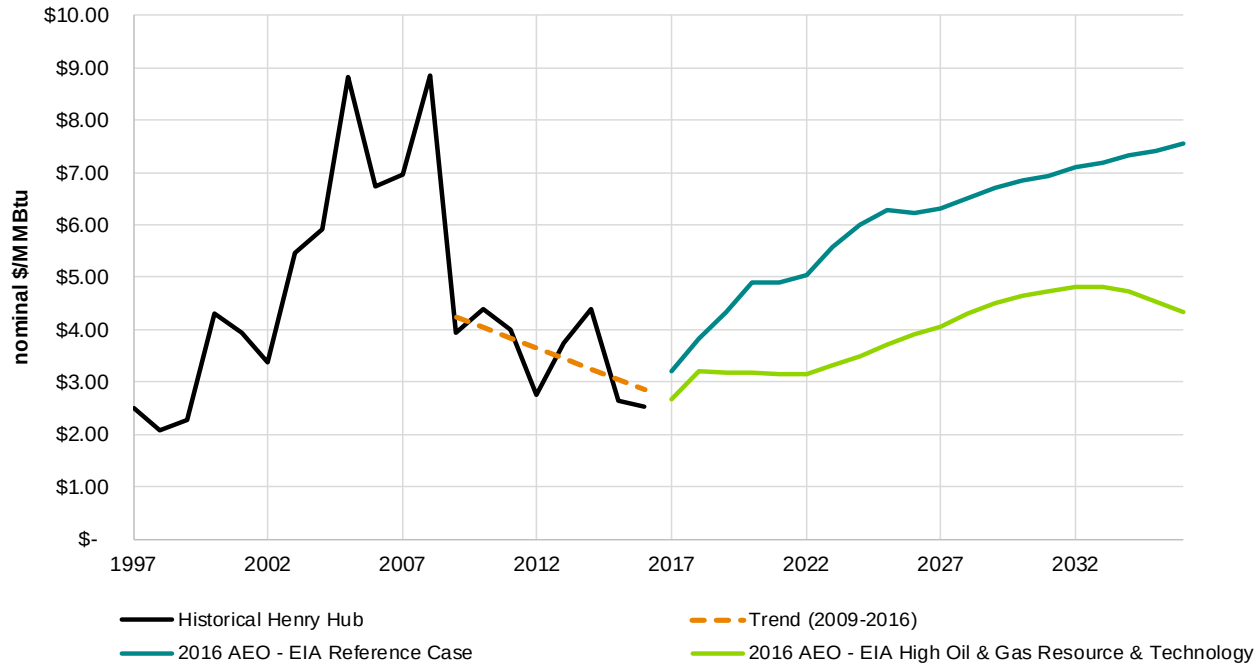

**Figure 7.4 Henry Hub natural gas spot price**

Importantly, historical Henry Hub prices beginning in 2009 have remained relatively stable and have even trended slightly downward; the illustrated trendline fit to the annual prices for 2009 through 2016 declines at a rate of $0.20 per year. The natural gas price trends since 2009 are highly related to marked expansion of natural gas production from shale. Based on natural gas price trends since 2009 and the coincident expansion of shale gas production, Idaho Power uses the High Oil and Gas Resource and Technology Case as the planning case natural gas price forecast for the 2017 IRP; this case is more consistent with recent price trends than the reference case.

A sensitivity analysis using alternative natural gas price forecasts is described in Chapter 9. The natural gas price is also included as a risk variable in the stochastic risk analysis performed on the IRP resource portfolios.

Idaho Power applies a Sumas basis adjustment and transportation cost to the Henry Hub price to derive an Idaho Citygate price. The Idaho Citygate price is representative of the gas price delivered to Idaho Power's natural gas plants. The Idaho Citygate price forecast is provided in *Appendix C—Technical Appendix.*

## Analysis of IRP Resources

The electrical energy sector has experienced considerable transformation during the past decade. Variable energy resources, such as wind and solar, have markedly expanded their market penetration during this period, and through this expansion they have affected the wholesale market for electrical energy. The expansion of variable energy resources has also highlighted the need for flexible capacity resources to provide balancing. A consequence of the expanded penetration of variable energy resources is periodic energy oversupply alternating with energy undersupply. Flexible capacity is provided by multiple resources. Dispatchable natural gas-fired generating capacity is commonly designated as cost-effectively providing flexible capacity, particularly during the recent era of low natural gas prices. Transmission resources can be used to provide balancing by the locational moving of energy from parts of the regional grid experiencing oversupply to parts experiencing undersupply. Storage resources can provide balancing by the temporal moving of energy from oversupply periods to undersupply periods. Demand response resources can also provide balancing by temporally moving the demand for energy from periods of undersupply to periods of oversupply.

For the 2017 IRP, Idaho Power continues to analyze resources on the basis of cost, specifically the cost of a resource to provide energy and capacity to the system. The IRP also qualitatively analyzes resources on the basis of their system attributes. In addition to the capability to provide flexible capacity, the system attributes analyzed include the capability to provide dispatchable capacity, non-dispatchable (i.e., coincidental) capacity, and energy. Importantly, energy in this qualitative analysis is considered to include not only baseload-type resources but also resources, such as wind and solar, that provide relatively predictable output when averaged over long periods (i.e., monthly or longer). The resource attribute analysis also designates those resources whose intermittent production gives rise to the need for flexible capacity.

### *Resource Costs—IRP Resources*

Resource costs are compared using two cost metrics: levelized cost of capacity (fixed) (LCOC) and levelized cost of energy (LCOE). These metrics are discussed later in this section. The resource cost analysis performed for the IRP assumes Idaho Power incurs all costs of ownership and operation, even for resources for which this ownership paradigm has historically not been typical, such as for geothermal, wind, and solar resources. The assumption that Idaho Power incurs the total resource costs of ownership and operation allows a like-versus-like comparison between resources.

In resource cost calculations, Idaho Power assumes potential IRP resources have varying economic lives. Financial analysis for the IRP assumes the annual depreciation expense of capital costs is based on an apportionment of the capital costs over the entire economic life of a given resource.

The levelized costs for the various resource alternatives analyzed include capital costs, O&M costs, fuel costs, and other applicable adders and credits. The initial capital investment and associated capital costs of resources include engineering development costs, generating and ancillary equipment purchase costs, installation costs, plant construction costs, and the costs for a transmission interconnection to Idaho Power's network system. The capital costs also include an allowance for funds used during construction (AFUDC) (capitalized interest). The O&M portion of each resource's levelized cost includes general estimates for property taxes and property insurance premiums. The value of RECs is not included in the levelized cost estimates but is accounted for when analyzing the total cost of each resource portfolio. The B2H resource includes an offsetting cost associated with estimated transmission tariff revenue.

The levelized costs for demand-side resource options include annual program administrative and marketing costs, an annual incentive, and annual participant costs. The demand-side resource costs do not reflect the financial effects resulting from the load-reduction programs.

Specific resource cost inputs, fuel forecasts, key financing assumptions, and other operating parameters are provided in *Appendix C—Technical Appendix*.

## LCOC—IRP Resources

The annual fixed revenue requirements in nominal dollars for each resource are summed and levelized over the assumed economic life and are presented in terms of dollars per kW of nameplate capacity per month. Included in these LCOCs are the initial resource investment and associated capital cost and fixed O&M estimates. As noted earlier, resources are considered to have varying economic lives, and the financial analysis to determine the annual depreciation of capital costs is based on an apportioning of the capital costs over the entire economic life. The LCOCs for the potential IRP resources are provided in Figure 7.5. B2H, after netting out transmission tariff revenue, is the lowest-cost resource in terms of LCOC. Other resources among those having a lower LCOC include demand response, reciprocating gas engines, and SCCTs.

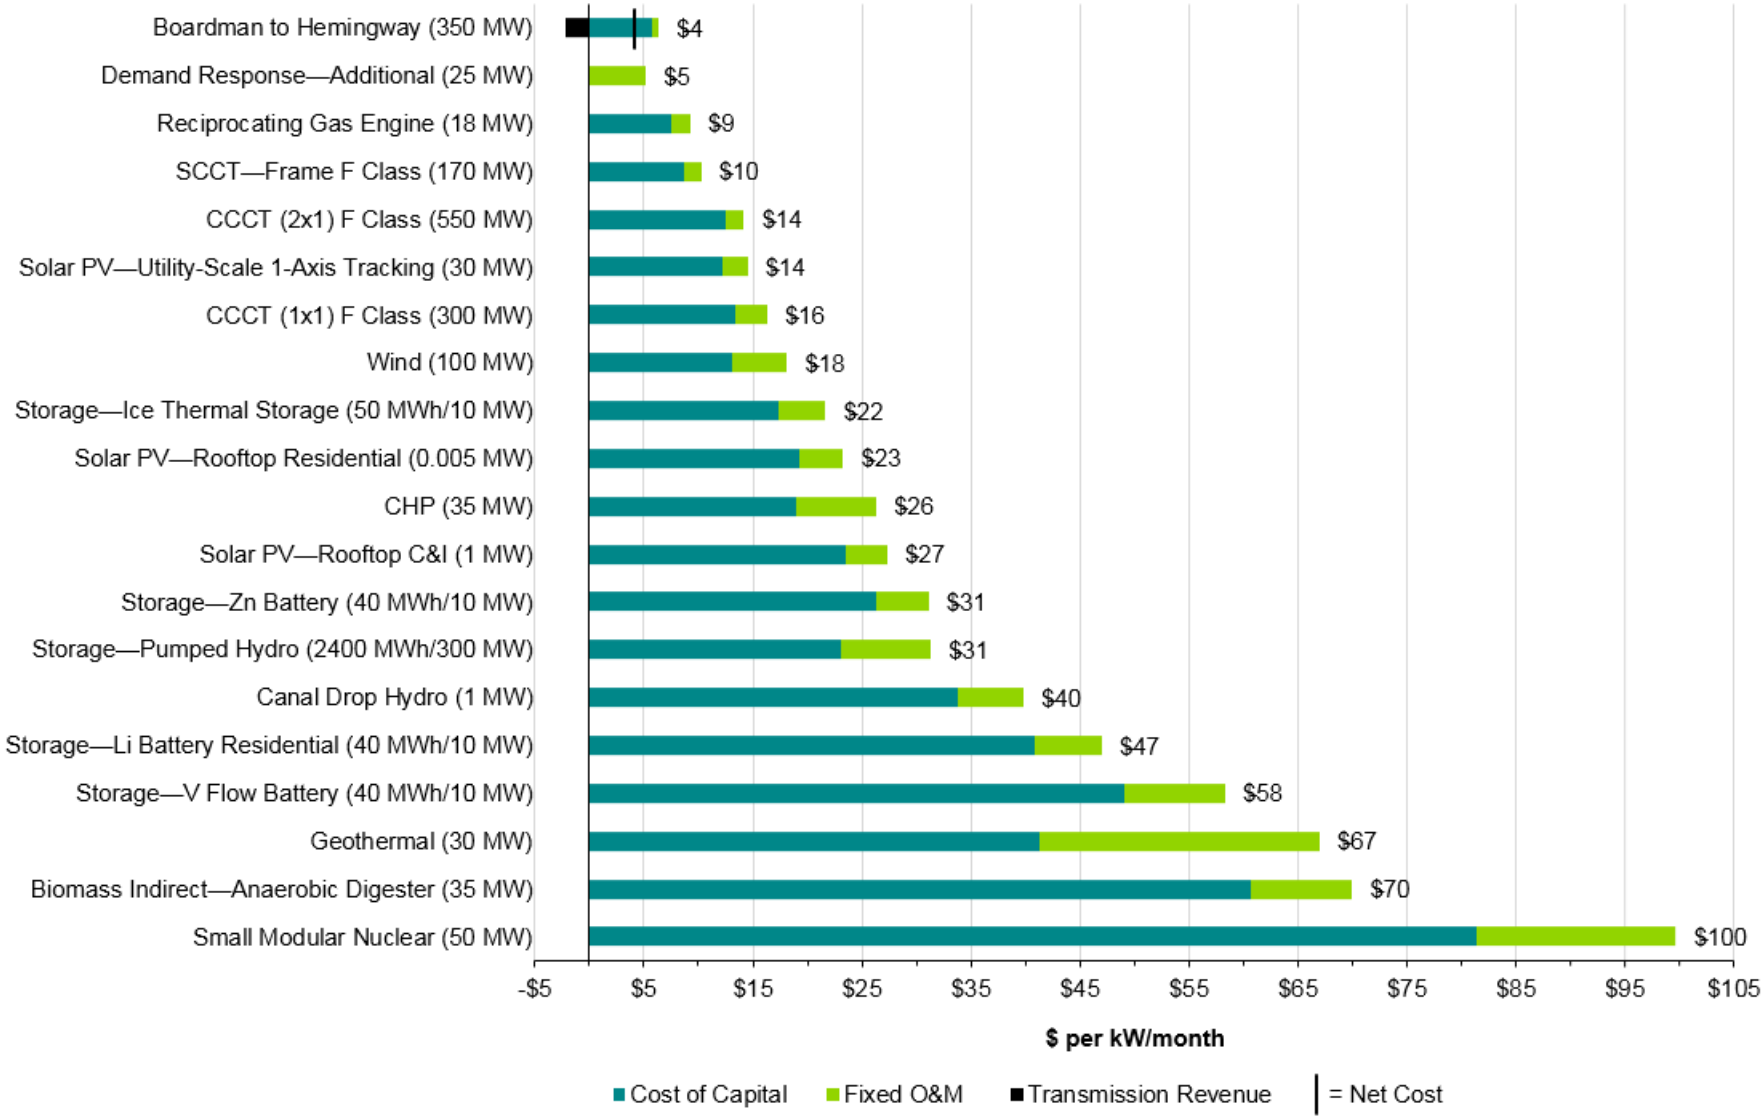

**Figure 7.5 Levelized capacity (fixed) costs**

## LCOE—IRP Resources

Certain resource alternatives carry low fixed costs and high variable operating costs, while other alternatives require significantly higher capital investment and fixed operating costs but have low (or zero) operating costs. The LCOE metric represents the estimated annual cost (revenue requirements) per MWh in nominal dollars for a resource based on an expected level of energy output (capacity factor) over the economic life of the resource. The nominal LCOE assuming the expected capacity factors for each resource is shown in Figure 7.6. Included in these costs are the capital cost, non-fuel O&M, fuel, integration costs, and wholesale energy for transmission and storage resources. Variable costs are offset by transmission tariff revenue for B2H, steam sales for CHP, and RECs for renewable-qualifying resources. B2H is the lowest-cost energy resource, followed by energy efficiency and natural gas-fired generation (CCCT).

When comparing LCOEs between resources, consistent assumptions for the computations must be used. The LCOE metric is the annual cost of energy over the life of a resource converted into an equivalent annual annuity. This is similar to the calculation used to determine a car payment; however, in this case the car payment would also include the cost of gasoline to operate the car and the cost of maintaining the car over its useful life.

An important input into the LCOE calculation is the assumed level of annual energy output over the life of the resource being analyzed. The energy output is commonly expressed as a capacity factor. At a higher capacity factor, the LCOE is reduced as a result of spreading resource fixed costs over more MWh. Conversely, lower capacity-factor assumptions reduce the MWh over which resource fixed costs are spread, resulting in a higher LCOE.

For the portfolio cost analysis, resource fixed costs are annualized over the assumed economic life for each resource and are applied only to the years of output within the IRP planning period, thereby accounting for end effects.

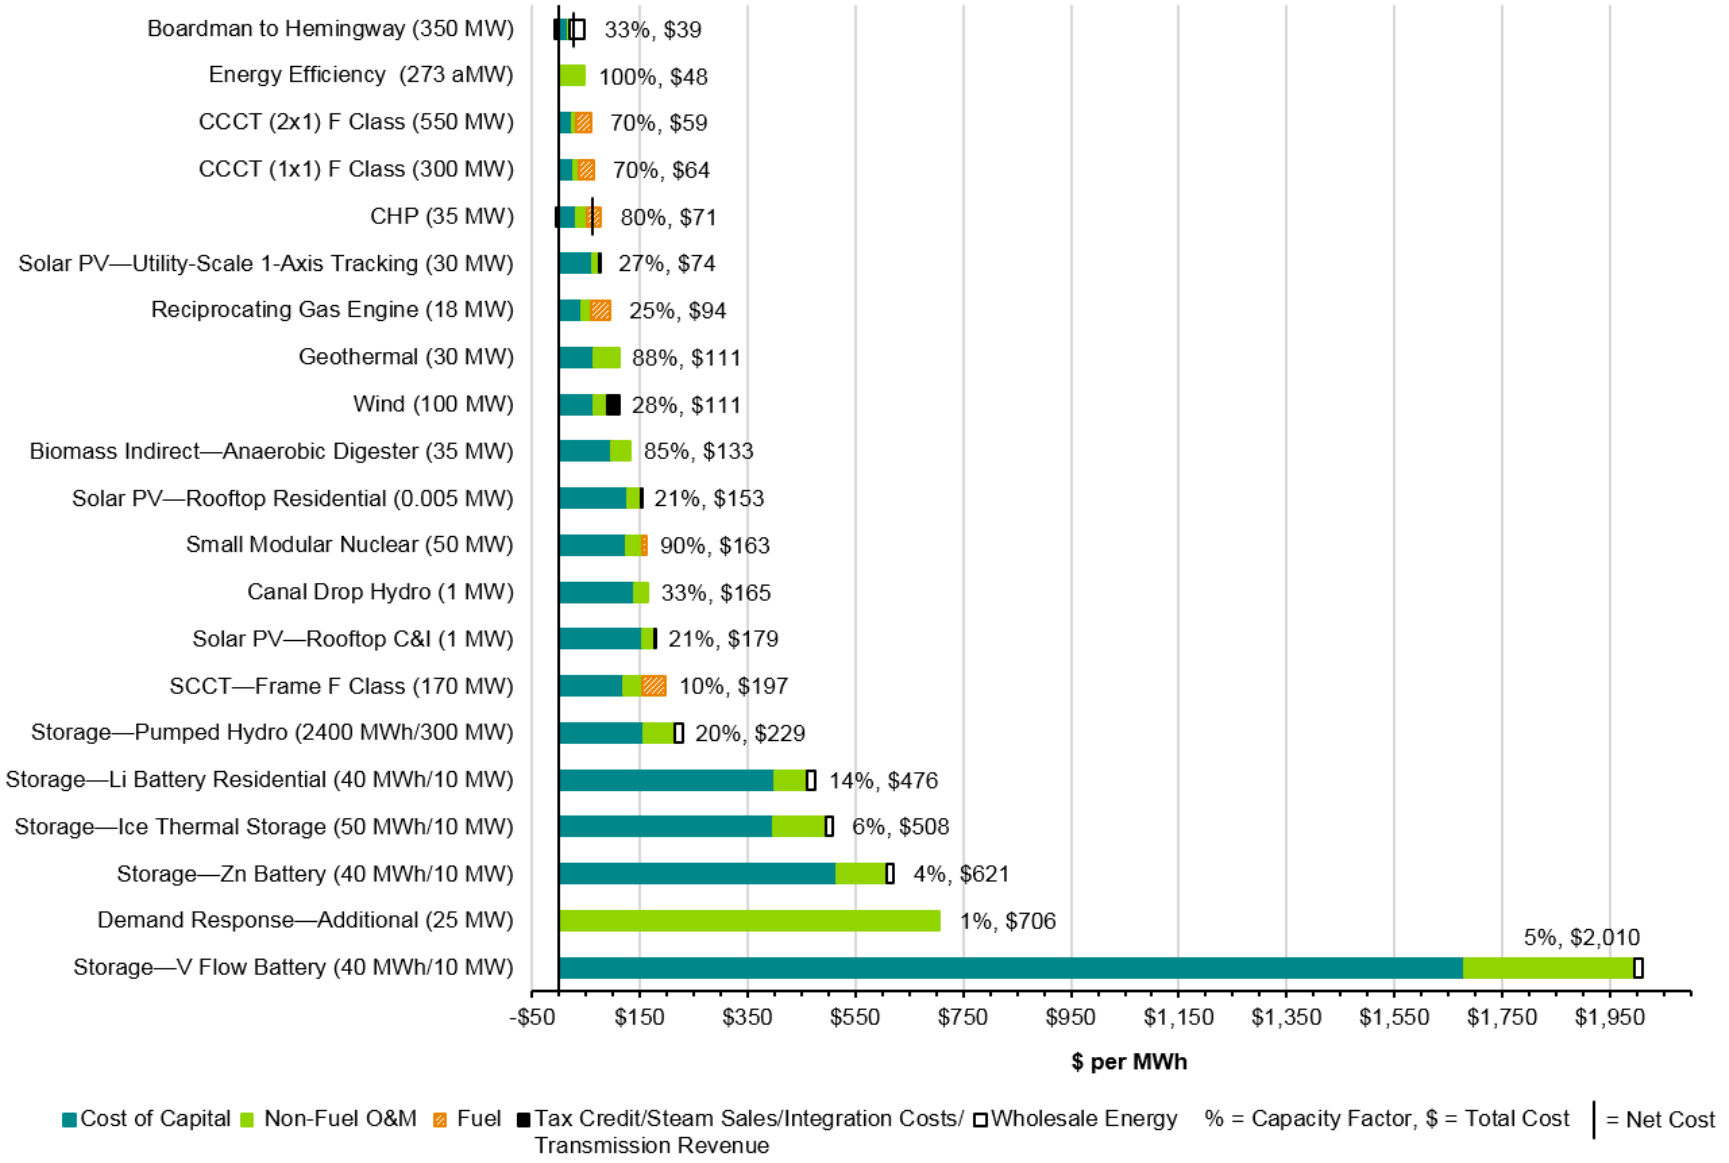

**Figure 7.6 LCOE (as stated capacity factors)**

## Resource Attributes—IRP Resources

While the cost metrics described in this section are informative, caution must be exercised when comparing costs for resources providing different attributes or qualities to the power system. For the LCOC metric, this critical distinction arises because of differences for some resources between *installed* capacity and *on-peak* capacity. Specifically, for intermittent renewable resources, an installed capacity of 1 kW equates to an on-peak capacity of less than 1 kW. For example, wind is estimated to have an LCOC of $18 per month per kW of installed capacity.[18] However, assuming wind delivers on-peak capacity equal to 5 percent of installed capacity, the LCOC ($18/month/kW) converts to $360 per month per kW of on-peak capacity.

For the LCOE metric, the critical distinction between resources arises because of differences for some resources with respect to the timing at which MWh are delivered. For example, wind and geothermal have effectively equivalent LCOEs. However, the energy output from geothermal generating facilities tends to be delivered in a steady and predictable manner, including relatively dependably during peak-loading periods. Conversely, wind tends to less dependably deliver during the high-value peak-loading periods; in effect, the energy delivered from wind tends to be of lesser value than that delivered from geothermal, and because of this difference caution should be exercised when comparing LCOEs for these resources.

In recognition of differences between resource attributes, potential IRP resources for the 2017 IRP are classified based on their attributes or qualities. The following resource attributes are considered in this analysis:

- *Intermittent renewable*—Renewable resources, such as wind and solar, characterized by intermittent output and causing an increased need for resources providing balancing or flexibility

- *Dispatchable capacity-providing*—Resources that can be dispatched as needed to provide capacity during periods of peak-hour loading or to provide output during generally high-value periods

- *Non-dispatchable (coincidental) capacity-providing*—Resources whose output tends to naturally occur with moderate likelihood during periods of peak-hour loading or during generally high-value periods

[18] The units of the denominator can be expressed in reverse order from the cost estimates provided in Figure 7.5 without mathematically changing the cost estimate.

- *Balancing/flexibility-providing*—Fast-ramping resources capable of balancing the variable output from intermittent renewable resources

- *Energy-providing*—Resources producing relatively predictable energy when averaged over long time periods (i.e., monthly or longer).

Table 7.3 provides classification of potential IRP resources with respect to the above attributes. The table also provides cost information as graphed previously and the estimated size potential and scalability for each resource.

**Table 7.3 Resource attributes**

| Resource | Intermittent Renewable | Dispatchable Capacity-Providing | Non-Dispatchable (Coincidental) Capacity-Providing | Balancing/ Flexibility-Providing | Energy-Providing | LCOE ($/MWh) | LCOC ($/kW/Month) | Size Potential |
|---|---|---|---|---|---|---|---|---|
| Biomass Indirect—Anaerobic Digester | | ✓ | | | ✓ | $133 | $70 | Scalable up to about 50 MW |
| B2H | | ✓ | | ✓ | ✓ | $39 | $4 | (200 Oct–March, 500 April–Sep) |
| Canal Drop Hydro | | ✓ | | | ✓ | $165 | $40 | Scalable up to about 50 MW |
| CCCT (1x1) | | ✓ | | ✓ | ✓ | $64 | $16 | 300-MW increments |
| CCCT (2x1) | | ✓ | | ✓ | ✓ | $59 | $14 | 550-MW increments |
| CHP | | ✓ | | | ✓ | $71 | $26 | Scalable up to about 50 MW |
| Demand Response—Additional | | ✓ | | | | $706 | $5 | Scalable up to achievable MW |
| Energy Efficiency | | | ✓ | | ✓ | $48 | N/A | Scalable up to achievable MWh |
| Geothermal | | ✓ | | | ✓ | $111 | $67 | Scalable up to about 50 MW |
| Reciprocating Gas Engine | | ✓ | | ✓ | ✓ | $94 | $9 | 18-MW increments |
| SCCT—Frame F Class | | ✓ | | ✓ | | $197 | $10 | 170-MW increments |

## IRP Resources and Portfolio Design

As described in the following chapter, the portfolio design for the 2017 IRP focuses on evaluating two key resource actions: the capital investment in environmental retrofits at Jim Bridger units 1 and 2, and the B2H transmission line. This portfolio design allows the 2017 IRP resource portfolios to be composed of resources that most cost competitively test the key resource actions while providing the necessary system attributes to ensure continued reliability. Based on Idaho Power's assessment of resource costs and resource attributes, the analysis of IRP resource portfolios containing natural gas-fired generating capacity (reciprocating engines and CCCTs), expanded demand response, and single-axis tracking solar PV is consistent with the portfolio design objectives of the 2017 IRP.

Idaho Power recognizes that resources attaining modest market penetration to date, particularly electrochemical energy storage technologies (i.e., battery technologies), may become increasingly cost competitive and in future IRPs outcompete natural gas-fired generating capacity. Idaho Power values the discussions held during IRPAC meetings related to emerging technologies and understands that the analysis of a variety of resource technologies, supply- and demand-side, is vital to long-term planning. The focused portfolio design of the 2017 IRP permits the development of portfolios containing resources demonstrated by today's analysis to be most cost competitive.

## T&D Deferral Benefit Associated with DERs

The T&D deferral benefits associated with solar distributed energy resources (DER) were discussed at the T&D Deferral Workshop on December 19, 2016. The main considerations in determining the potential for solar DERs to defer T&D investments were discussed. Idaho Power performed a preliminary analysis to determine locations where solar DERs could result in an asset replacement deferral opportunity.

Several criteria were considered to determine viable candidates for asset deferral:

- Summer-peaking assets
- Peak loads that occur before 4:00 p.m.
- Assets that have a use factor at peak greater than or equal to 90 percent
- Load growth rate
- Cost of alternatives

Only two substation transformers and two feeders in Idaho Power's service area fit the criteria, representing approximately 0.5 percent of the total transformers and feeders.

However, Idaho Power is aware that the rapid decrease in the cost of solar PV and energy storage may provide future opportunities for asset replacement deferral. Idaho Power will continue to look for opportunities where DERs may result in cost-effective asset replacement deferral opportunities in the next few years.

## Load and Resource Balance

Idaho Power assumes drier-than-median water conditions and higher-than-median load conditions in its resource planning process. Targeting a balanced position between load and resources while using the conservative water and load conditions is considered comparable to requiring a capacity margin in excess of load while using median load and water conditions. Both approaches are designed to result in a system having sufficient generating reserve capacity to meet daily operating reserve requirements.

To identify the need and timing of future resources, Idaho Power prepares a load and resource balance that accounts for generation from all the company's existing resources and planned purchases. For the 2017 IRP, load and resource balances were developed for each of the four scenarios for Jim Bridger units 1 and 2. A baseline assumption in the load and resource balances is the early retirement of Valmy units 1 and 2 in 2019 and 2025, respectively. North Valmy units are assumed to be replaced with market purchases imported across the Idaho–Nevada path. Each Jim Bridger scenario will include a load and resource balance using average monthly energy planning assumptions and peak-hour planning assumptions.

Average-energy surpluses and deficits are determined using 70$^{th}$-percentile water and 70$^{th}$-percentile average load conditions, coupled with Idaho Power's ability to import energy from firm market purchases using reserved network capacity.

Peak-hour load deficits are determined using 90$^{th}$-percentile water and 95$^{th}$-percentile peak-hour load conditions. The hydrologic and peak-hour load criteria are the major factors in determining peak-hour load deficits. Peak-hour load planning criteria are more stringent than average-energy criteria because Idaho Power's ability to import additional energy is typically limited during peak-hour load periods.

All load and resource balances include the following:

- Existing demand reduction due to the demand response programs and the forecast effect of existing energy efficiency programs.
- Expected generation from all Idaho Power-owned resources. The Boardman coal plant has a planned retirement date of 2020. Additionally, the 2017 IRP includes a baseline assumption for the early retirement of Valmy Unit 1 at the end of 2019 and Valmy Unit 2 at the end of 2025.

- Firm Pacific Northwest import capability, including import capacity over the Idaho–Nevada path. The northbound capacity of this line has historically been fully subscribed with Idaho Power's share of energy from the North Valmy generation plant. The load and resource balance scenarios do not include the import capacity from the B2H transmission line or the Gateway West transmission line.

- Existing PPAs with Elkhorn Valley Wind, Raft River Geothermal, and Neal Hot Springs. The agreement with Elkhorn Valley Wind expires at the end of 2027, and a replacement contract is not contemplated. The agreement with Raft River Geothermal expires at the end of 2033 and is expected to be replaced. The agreement with Neal Hot Springs does not expire within the planning period.

- Existing PURPA projects and contracts. The 2017 IRP forecast includes all contracts completed by December 9, 2016. Since that time, one biomass project with a nameplate of 5 MW has been added and is scheduled to come on-line in 2018. Idaho Power assumes all PURPA contracts, except for wind projects, will continue to deliver energy throughout the planning period, and the renewal of contracts will be consistent with PURPA rules and regulations existing at the time the replacement contracts are negotiated.
  Wind projects are not expected to be renewed. Currently, 627 MW of wind are under PURPA contract, and contract expirations begin in October 2025. By February 2033, the total wind under contract drops to 130 MW and remains at that level through the end of the planning period.

At times of peak summer load, Idaho Power is using all ATC from the Pacific Northwest. If Idaho Power encountered a significant outage at one of its main generation facilities or a transmission interruption on one of the main import paths, the company would fail to meet reserve requirement standards. If Idaho Power was unable to meet reserve requirements, the company would be required to shed load by initiating rolling blackouts. Although infrequent, Idaho Power has initiated rolling blackouts in the past during emergencies. Idaho Power has committed to a build program, including demand-side programs, generation, and transmission resources, to reliably meet customer demand and minimize the likelihood of events that would require the implementation of rolling blackouts.

Idaho Power's customers reach a maximum energy demand in the summer. From a resource adequacy perspective, July has historically been the month during which Idaho Power's system is most constrained. Based on projections for the 2017 IRP, July is likely to remain the most resource-constrained month. Table 7.4 provides the monthly average energy deficits, and Table 7.5 provides the monthly peak-hour deficits for July for each of the Jim Bridger futures considered in the 2017 IRP. Darker shading in the tables corresponds with larger deficits, which occur more in later years and begin earlier with the retirement of units 1 and 2 in 2021 and 2022, respectively. Surplus positions are not specified in the tables. Because no deficits exist prior to 2023, the tables include data only for the period 2023 to 2036.

**Table 7.4 July monthly average energy deficits (aMW) by Bridger coal future with existing and committed supply- and demand-side resources (70th-percentile water and 70th-percentile load)**

| Energy Deficits (aMW) | 2023 | 2024 | 2025 | 2026 | 2027 | 2028 | 2029 | 2030 | 2031 | 2032 | 2033 | 2034 | 2035 | 2036 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|

# 8. PORTFOLIOS

## Portfolio Design

Idaho Power designed the portfolio analysis for the 2017 IRP with the objective of informing the IRP's Action Plan with respect to two key resource actions: 1) SCR investments required for Jim Bridger units 1 and 2 by 2022 and 2021, respectively, and 2) the B2H transmission line. To achieve this objective, the portfolio design consisted of four Jim Bridger SCR investment scenarios, with three resource portfolios formulated within each scenario, resulting in 12 resource portfolios. The SCR investment scenarios study a range of early retirement scenarios at Jim Bridger units 1 and 2 versus a scenario in which the SCR investments are made. The three resource portfolios formulated within each SCR investment scenario include one B2H-focused portfolio and two B2H alternative portfolios. The portfolio design is considered to approximate a controlled experiment isolating two key factors: 1) the cost-effectiveness of making the SCR investments versus practicable early retirement alternatives and 2) the cost-effectiveness of B2H in meeting resource needs versus practicable resource alternatives. This type of portfolio design is also described as a factorial experimental design. Further discussion of the portfolio design is provided in Chapter 1 and at the end of this chapter.

To analyze the SCR investments for Jim Bridger, four scenarios were analyzed:

1. *Scenario* 1—Install SCRs and operate Jim Bridger units 1 and 2 through the end of the planning period.

2. *Scenario 2*—Do not make SCR investments and retire Jim Bridger units 1 and 2 at year-end 2028 and year-end 2024, respectively.

3. *Scenario 3*—Do not make SCR investments are retire Jim Bridger units 1 and 2 at year-end 2032 and year-end 2028, respectively.

4. *Scenario 4*—Do not make SCR investments and retire Jim Bridger units 1 and 2 on their respective compliance dates of year-end 2022 and year-end 2021.

The B2H alternative portfolios within each Jim Bridger SCR investment scenario have similar characteristics: an alternative portfolio containing a mix of solar- and natural gas-powered generating capacity, and a second alternative containing solely natural gas-powered generating capacity. Demand response capacity is also added to the B2H alternative portfolios in two steps in the early- to mid-2020s. The supply- and demand-side resources composing the B2H alternative portfolios set the highest standard for B2H economics based on current costs. The portfolio design objective is to determine whether a B2H-based portfolio can be outperformed based on current cost estimates of alternative resources. The resources judged to practicably set the highest standard for B2H cost-effectiveness included expanded demand response, flexible capacity-providing natural gas-fired reciprocating engines, single-axis solar

PV, and natural gas-fired CCCTs. Other potential IRP resources were analyzed and considered for inclusion in portfolios. However, the inclusion of less cost-effective resources would lower the standard for the evaluation of B2H.

Capacity needs require the addition of natural gas-powered generating capacity to the B2H-based portfolios; however, this added generating capacity is relatively small compared to B2H, and the costs and benefits of the B2H-based portfolios are considered primarily driven by B2H as a portfolio element. Detailed portfolio descriptions are provided later in this chapter.

The SCR compliance alternatives considered in this IRP are in recognition of past negotiations between owners of coal-powered generating units, regulators, and other stakeholders that yielded a resolution permitting extended operation in exchange for early unit retirement. Idaho Power views the analyzed compliance alternatives as placeholder assumptions representing negotiated resolutions permitting varying operation extensions. The company does not presuppose extensions will be necessarily negotiated, nor that specific alternatives analyzed in this IRP are more likely outcomes than other possible early retirement dates.

Energy savings achieved from implementing cost-effective energy efficiency programs and measures are included in all portfolios prior to the inclusion of supply-side resources. The forecasted energy savings are based on the assessment performed by AEG for Idaho Power. The AEG assessment and the projected energy savings are discussed in Chapter 5.

## Studied Portfolios

The following sections describe the portfolios analyzed for each Jim Bridger scenario. All portfolios are designed to balance forecast load with available or additional resources to eliminate energy and capacity deficits according to the IRP planning criteria described in Chapter 7. The energy and capacity deficits for the Jim Bridger scenarios are also provided in Chapter 7.

### *Jim Bridger Scenario 1*

Three portfolios were developed for the Jim Bridger scenario in which the SCR investments are made and Jim Bridger units 1 and 2 are operable through the end of the planning period. P1 is the B2H-based portfolio. P2 is the B2H alternative portfolio containing a blend of solar- and natural gas-powered generating capacity. The reciprocating engine generating capacity of P2 is considered to provide the flexible capacity necessary to reliably integrate the solar-powered capacity of the portfolio. The single-axis solar PV generating capacity is assumed to deliver peak-hour capacity equal to 51.3 percent of installed (AC) nameplate capacity. The analysis supporting the assumed peak-hour capacity for solar-powered PV generating capacity is discussed in Chapter 4. P3 is the B2H alternative portfolio composed of natural gas-powered generating capacity. In addition to supply-side capacity, P2 and P3 include added demand response capacity developed in two steps in 2021 and 2026.

## P1

**Table 8.1 P1 timeline**

| Date | Resource | Installed Capacity (MW) | Peak-Hour Capacity (MW) |
|---|---|---|---|
| 2026 | B2H | 500, 200 (Apr–Sep, Oct–Mar transfer capacity) | 500 |
| 2034 | Reciprocating engines | 36 | 36 |
| 2035 | Reciprocating engines | 54 | 54 |
| 2036 | Reciprocating engines | 54 | 54 |
| | **Total** | **644** | **644** |

**Table 8.2 P1 resource summary**

| Resource | Installed Capacity (MW) |
|---|---|
| B2H (Apr–Sep capacity) | 500 |
| Natural gas | 144 |

## P2

**Table 8.3 P2 timeline**

| Date | Resource | Installed Capacity | Peak-Hour Capacity |
|---|---|---|---|
| 2021 | Demand response | 25 | 25 |
| 2026 | Demand response | 25 | 25 |
| 2027 | Reciprocating engines | 36 | 36 |
| 2027 | Single-axis solar PV | 25 | 13 |
| 2028 | Reciprocating engines | 36 | 36 |
| 2028 | Single-axis solar PV | 50 | 26 |
| 2029 | Reciprocating engines | 36 | 36 |
| 2029 | Single-axis solar PV | 50 | 26 |
| 2030 | Reciprocating engines | 36 | 36 |
| 2030 | Single-axis solar PV | 50 | 26 |
| 2031 | Reciprocating engines | 36 | 36 |

| 2036 | Reciprocating engines | 54 | 54 |
| | **Total*** | **638** | **638** |

*Includes demand response

**Table 8.6 P3 resource summary**

| Resource | Installed Capacity (MW) |
|---|---|
| Demand response | 50 |
| Natural gas | 588 |

## *Jim Bridger Scenario 2*

Three portfolios were developed for the Jim Bridger scenario in which the SCR investments are not made and Jim Bridger units 1 and 2 are permitted to operate through 2028 and 2024, respectively. Within this scenario, P4 is the B2H-based portfolio. P5 is the B2H alternative portfolio containing a blend of solar- and natural gas-powered generating capacity, including a 300 MW CCCT. P6 is the B2H alternative portfolio composed of natural gas-powered generating capacity. In addition to supply-side capacity, P5 and P6 include added demand response capacity developed in two steps in 2021 and 2026.

## P4

## *Jim Bridger Scenario 3*

Three portfolios were developed for the Jim Bridger scenario in which the SCR investments are not made and Jim Bridger units 1 and 2 are permitted to operate through 2032 and 2028, respectively. Within this scenario, P7 is the B2H-based portfolio. P8 is the B2H alternative portfolio containing a blend of solar- and natural gas-powered generating capacity, including two 300-MW CCCTs. P9 is the B2H alternative portfolio composed of natural gas-powered generating capacity. In addition to supply-side capacity, P8 and P9 include added demand response capacity developed in two steps in 2021 and 2026.

### P7

**Table 8.13 P7 timeline**

| Date | Resource | Installed Capacity (MW) | Peak-Hour Capacity (MW) |

## *Jim Bridger Scenario 4*

Three portfolios were developed for the Jim Bridger scenario in which the SCR investments are not made and Jim Bridger units 1 and 2 are retired on their respective compliance dates of year 2022 and year-end 2021. Within this scenario, P10 is the B2H-based portfolio. P11 is the B2H alternative portfolio containing a blend of solar- and natural gas-powered generating capacity, including two 300-MW CCCTs. P12 is the B2H alternative portfolio composed of natural gas-powered generating capacity. In addition to supply-side capacity, P11 and P12 include added demand response capacity developed in two steps in 2021 and 2026.

### P10

**Table 8.19 P10 timeline**

| Date | Resource | Installed Capacity (MW) | Peak-Hour Capacity (MW) |
|---|---|---|---|
| 2023 | Reciprocating engines | 216 | 216 |
| 2024 | B2H | 500, 200 (Apr–Sep, Oct–Mar transfer capacity) | 500 |

## Portfolio Design with Two Factors

The portfolio analysis for the 2017 IRP is described as a factorial design. This type of experimental design allows an analysis isolating on two (or more) factors, each factor having more than one level describing it. The two factors studied in the portfolio analysis with their respective levels are as follows:

- **Factor 1:** Treatment of Jim Bridger units 1 and 2
  - Level 1: Invest in SCRs and operate through 2036
  - Level 2: Retire Unit 1 in 2028 and Unit 2 in 2024 (without investing in SCRs)
  - Level 3: Retire Unit 1 in 2032 and Unit 2 in 2028 (without investing in SCRs)
  - Level 4: Retire Unit 1 in 2022 and Unit 2 in 2021 (without investing in SCRs)

- **Factor 2:** Primary portfolio element(s)
  - Level 1: B2H
  - Level 2: Solar PV/natural gas-fired generation
  - Level 3: Natural gas-fired generation

Table 8.25 provides a matrix of the factorial design with the portfolios corresponding to each factorial combination.

**Table 8.25 Factorial design applied to portfolios**

| | Primary Portfolio Element(s) | | |
|---|---|---|---|
| **Treatment of Jim Bridger Units 1 and 2** | **B2H** | **Solar PV/Natural Gas** | **Natural Gas** |
| Invest in SCR | P1 | P2 | P3 |
| Retire Unit 1 in 2028 and Unit 2 in 2024 | P4 | P5 | P6 |
| Retire Unit 1 in 2032 and Unit 2 in 2028 | P7 | P8 | P9 |
| Retire Unit 1 in 2022 and Unit 2 in 2021 | P10 | P11 | P12 |

Importantly, to validate this design, portfolios must be devised so they can be categorized according to the studied factor levels. For example, P4, P5, and P6 must all include retirement of Jim Bridger units 1 and 2 in 2028 and 2024, respectively. Similarly, P2, P5, P8, and P11 must all be characterized as having solar PV and natural gas-fired generation as their primary portfolio elements. A tabulation of the portfolio analysis results in the form of the factorial design is provided in Chapter 9.

# 9. MODELING ANALYSIS AND RESULTS

## Planning Case Portfolio Analysis

Idaho Power evaluated the net present value (NPV) costs of each resource portfolio over the full 20-year planning horizon. The resource portfolio cost is the expected cost to serve customer load using all resources in the portfolio.

The IRP portfolio costs consist of fixed and variable components. The fixed component includes annualized capital costs for new portfolio resources, including transmission interconnection costs for new generating facilities, fixed O&M costs, and return on investment (ROI). Capital costs for new resources are annualized over the resource's estimated economic life. Annualized capital costs beyond the IRP planning window (2017–2036) are not included in portfolio costs.

Portfolios that consider early retirement of coal units include costs for the accelerated recovery of depreciation expenses and accelerated recovery of estimated decommissioning and demolition costs (net of salvage). The costs of coal-retirement portfolios are countered by savings from avoiding future coal plant capital upgrades and fixed operating expenses beyond the early retirement dates, including avoidance of environmental retrofit upgrades where applicable.

Idaho Power uses the AURORA electric market model as the primary tool for modeling resource operations and determining operating costs for the 20-year planning horizon. AURORA modeling results provide detailed estimates of wholesale market energy pricing and resource operation and emissions data.

The AURORA software applies economic principles and dispatch simulations to model the relationships between generation, transmission, and demand to forecast market prices. The operation of existing and future resources is based on forecasts of key fundamental elements, such as demand, fuel prices, hydroelectric conditions, and operating characteristics of new resources. Various mathematical algorithms are used in unit dispatch, unit commitment, and regional pool pricing logic. The algorithms simulate the regional electrical system to determine how utility generation and transmission resources operate to serve load.

Multiple electricity markets, zones, and hubs can be modeled using AURORA. Idaho Power models the entire WECC system when evaluating the various resource portfolios for the IRP. A database of WECC data is maintained and regularly updated by the software vendor EPIS Inc. Prior to starting the IRP analysis, Idaho Power updates the AURORA database based on available information on generation resources within the WECC and calibrates the model to ensure it provides realistic results.

Portfolio costs are calculated as the NPV of the 20-year stream of annualized costs, fixed and variable, for each portfolio. The full set of financial variables used in the analysis is shown in Table 9.1. Each resource portfolio was evaluated using the same set of financial variables.

**Table 9.1 Financial assumptions**

| Plant Operating (Book) Life | 30 Years |
|---|---|
| Discount rate (weighted average capital cost) | 6.74% |
| Composite tax rate | 39.10% |
| Deferred rate | 35.00% |
| General O&M escalation rate | 2.10% |
| Annual property tax escalation rate (% of investment) | 0.29% |
| Property tax escalation rate | 3.00% |
| Annual insurance premium (% of investment) | 0.31% |
| Insurance escalation rate | 2.00% |
| AFUDC rate (annual) | 7.72% |

Idaho Power is limiting the CAA Section 111(d) analysis to a state-by-state mass-based approach. Under state-by-state mass-based compliance, CAA Section 111(d) proposed state-specific target reductions are the basis for compliance. Langley Gulch is assumed to be unconstrained. The proposed target reductions are defined in Table 9.2.

**Table 9.2 Proposed target reductions for state-by-state mass-based compliance (Idaho Power share)**

| Affected Source | 2022–2024 Target MWh | 2025–2027 Target MWh | 2028–2029 Target MWh | 2030 and Beyond Target MWh |
|---|---|---|---|---|
| Jim Bridger Below 2012 | 3,499,795 (-23%) | 3,176,356 (-30%) | 2,986,317 (-34%) | 2,873,560 (-37%) |
| North Valmy Below 2012 | 790,247 (-3%) | 737,627 (-9%) | 715,611 (-12%) | 708,848 (-13%) |

The planning case natural gas price variable costs, the new resource fixed costs, and the Bridger units 1 and 2 fixed costs are shown in Table 9.3.

**Table 9.3 2017 IRP Portfolios, NPV years 2017–2036 ($ x 1,000)**

| Portfolio Details | | | | Variable Costs | | | New Resource Fixed Costs | | | Bridger | Summary | | |

| P11 | Bridger retire in 21 & 22, DR, recips, solar | | ✓ | $5,529,258 | 1 | – | $767,183 | 12 | $675,917 | $283,328 | $6,579,769 | 11 | $243,998 |
| P12 | Bridger retire in 21 & 22, DR, recips, CCCT | | ✓ | $5,689,172 | 5 | $159,914 | $699,009 | 11 | $607,743 | $283,328 | $6,671,510 | 12 | $335,739 |

Under the planning case natural gas price, P7 has a total fixed and variable 20-year NPV cost of $6,335,771,000 and a lowest cost rank of 1.

## Natural Gas Price Sensitivities

The planning case natural gas shown in Table 9.3 reflects a 2017 IRP lower bound of future gas prices. An additional eight natural gas price sensitivities described as 125, 150, 175, 200, 225, 250, 300, and 400 percent of the planning case price were modeled for each of the 12 portfolios. The natural gas price sensitivities represent a phasing-in of the named percentage over the years 2017 to 2026 and the full named percentage escalation for 2027 to 2036.

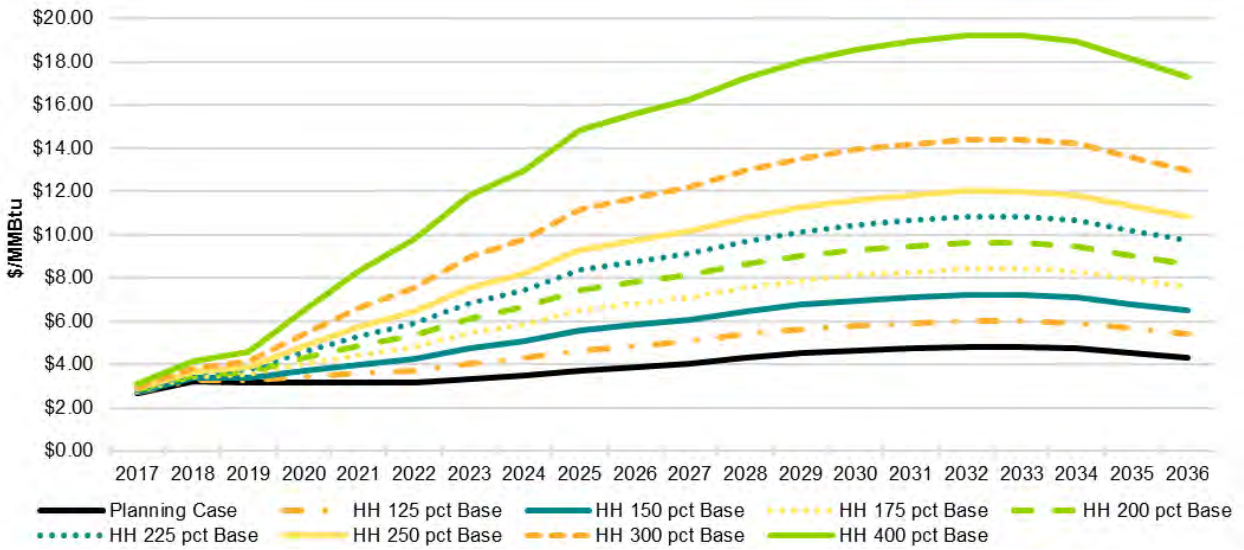

**Figure 9.1 Natural gas planning case and eight sensitivities (nominal $)**

The relative difference between the NPV of the lowest-cost portfolio under the natural gas price planning case and eight higher natural gas sensitivities, along with the rankings of the 12 portfolios under the nine Natural Gas Price forecasts, are shown in Table 9.4 and Table 9.5.

**Table 9.4 Portfolio relative costs under nine natural gas price forecasts, NPV years 2017–2036 ($ x 1,000)**

| Sensitivity | P1 | P2 | P3 | P4 | P5 | P6 | P7 | P8 | P9 | P10 | P11 | P12 |

**Note**: Darker shading indicates increasing values.

**Table 9.5 Portfolio rankings under nine natural gas price forecasts**

| Sensitivity | P1 | P2 | P3 | P4 | P5 | P6 | P7 | P8 | P9 | P10 | P11 | P12 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Planning Case | 4 | 6 | 9 | 2 | 10 | 8 | 1 | 7 | 5 | 3 | 11 | 12 |
| HH 125 Percent | 3 | 6 | 9 | 2 | 10 | 8 | 1 | 7 | 5 | 4 | 11 | 12 |
| HH 150 Percent | 3 | 5 | 10 | 2 | 9 | 8 | 1 | 7 | 6 | 4 | 11 | 12 |
| HH 175 Percent | 3 | 4 | 10 | 2 | 8 | 9 | 1 | 6 | 7 | 5 | 11 | 12 |
| HH 200 Percent | 3 | 4 | 11 | 2 | 7 | 9 | 1 | 5 | 6 | 8 | 10 | 12 |
| HH 225 Percent | 3 | 4 | 11 | 2 | 6 | 10 | 1 | 5 | 7 | 9 | 8 | 12 |
| HH 250 Percent | 3 | 4 | 10 | 2 | 5 | 9 | 1 | 6 | 7 | 11 | 8 | 12 |
| HH 300 Percent | 5 | 4 | 10 | 3 | 2 | 9 | 1 | 6 | 8 | 11 | 7 | 12 |
| HH 400 Percent | 6 | 2 | 9 | 7 | 1 | 10 | 4 | 5 | 8 | 11 | 3 | 12 |

**Note**: Darker shading indicates increasing values.

P7 ranks first under eight of the nine natural gas price escalation sensitivities. P5 ranks first under the highest natural gas price sensitivity.

## Stochastic Risk Analysis

The stochastic analysis assesses the effect on portfolio costs when select variables take on values different from their planning-case levels. Stochastic variables are selected based on the degree to which there is uncertainty regarding their forecasts and the degree to which they can affect the analysis results (i.e., portfolio costs).

Idaho Power identified the following three variables for the stochastic analysis:

1. *Natural gas price*—Natural gas prices follow a log-normal distribution adjusted upward from the planning case gas price forecast, which is shown as the dashed line in Figure 9.2. Natural gas prices are adjusted upward from the planning case to capture upward risk in natural gas prices. The correlation factor used for the year-to-year variability is 0.60, which is based on historic values from 1997 through 2015.

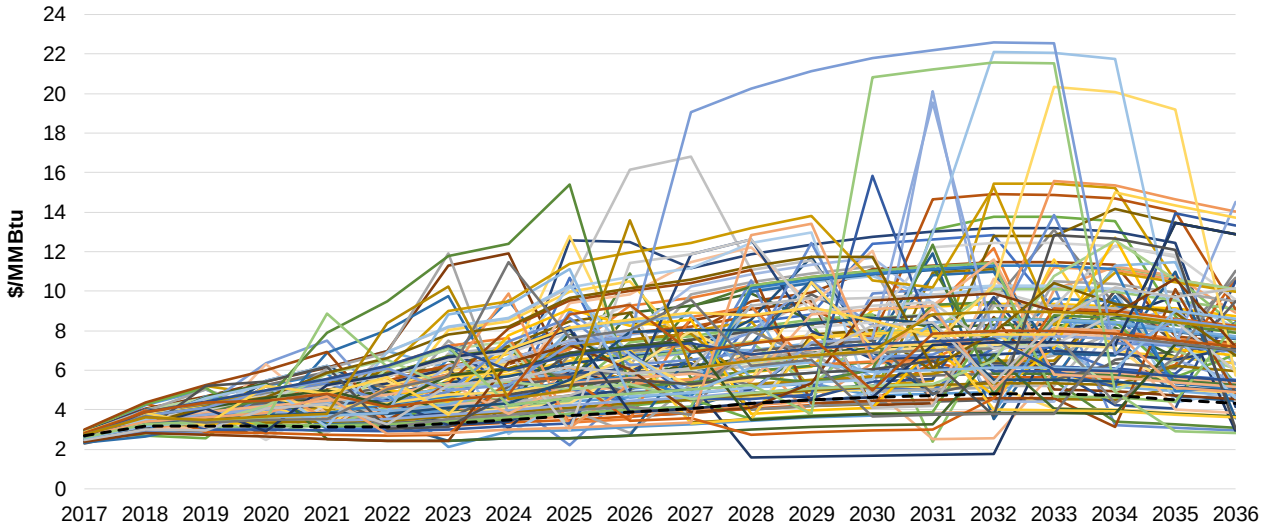

**Figure 9.2 Natural gas sampling (Nominal $/MMBtu)**

2. *Customer load*—Customer load follows a normal distribution and is adjusted around the planning case load forecast, which is shown as the dashed line in Figure 9.3.

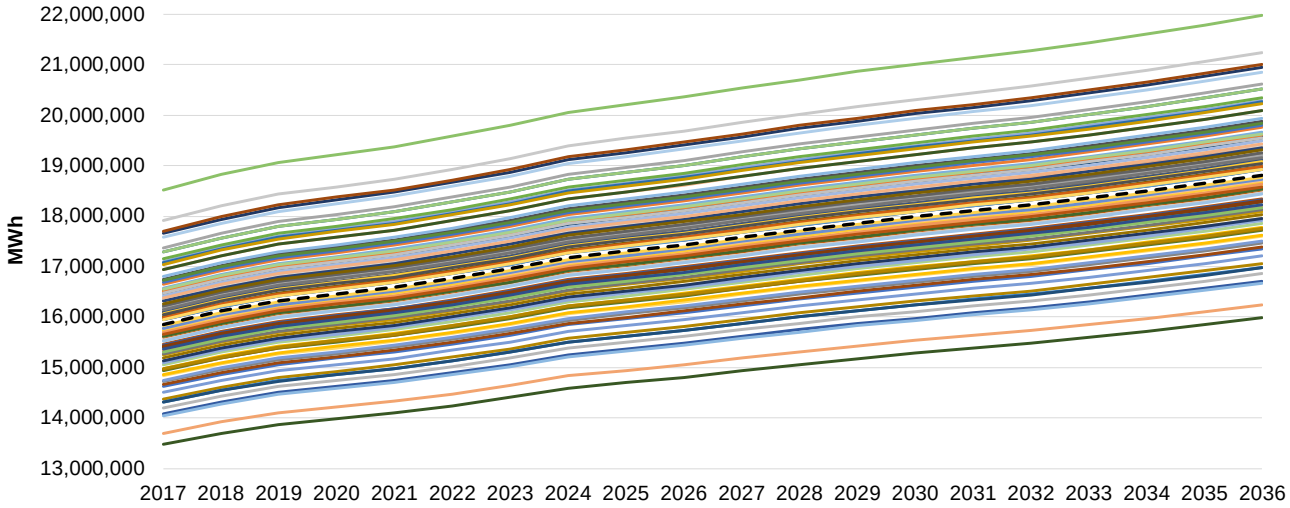

**Figure 9.3 Customer load sampling (annual MWh)**

3. *Hydroelectric variability*—Hydroelectric variability follows a log-normal distribution and is adjusted around the planning case hydroelectric generation forecast, which is shown as the black dashed line in Figure 9.4. The correlation factor used for the year-to-year variability is 0.50, which is based on historic values from 1975 through 2015.

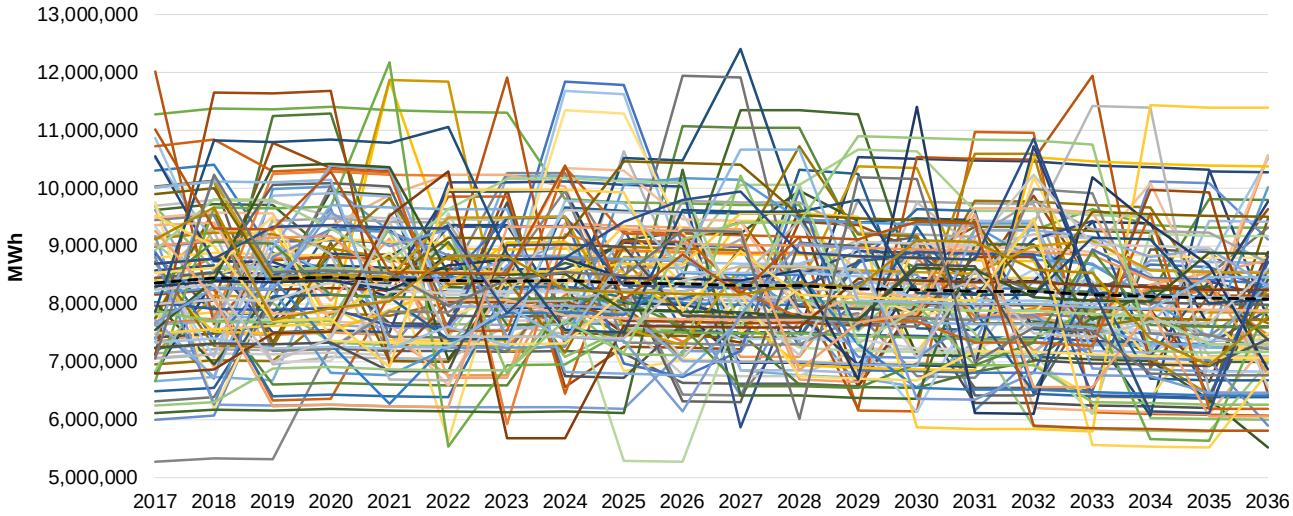

**Figure 9.4 Hydro generation sampling (annual MWh)**

The three selected stochastic variables are key drivers of variability in year-to-year power-supply costs and therefore provide suitable stochastic shocks to allow differentiated results for analysis.

The purpose of the analysis is to understand the range of portfolio costs across the full extent of stochastic shocks (i.e., across the full set of stochastic iterations) and how the ranges for portfolios differ.

Idaho Power created a set of 100 iterations based on the three stochastic variables (hydro condition, load, and natural gas price). Idaho Power then calculated the 20-year NPV portfolio cost for each of the 100 iterations for all 12 portfolios. The distribution of 20-year NPV portfolio costs for all 12 portfolios is shown in Figure 9.5.

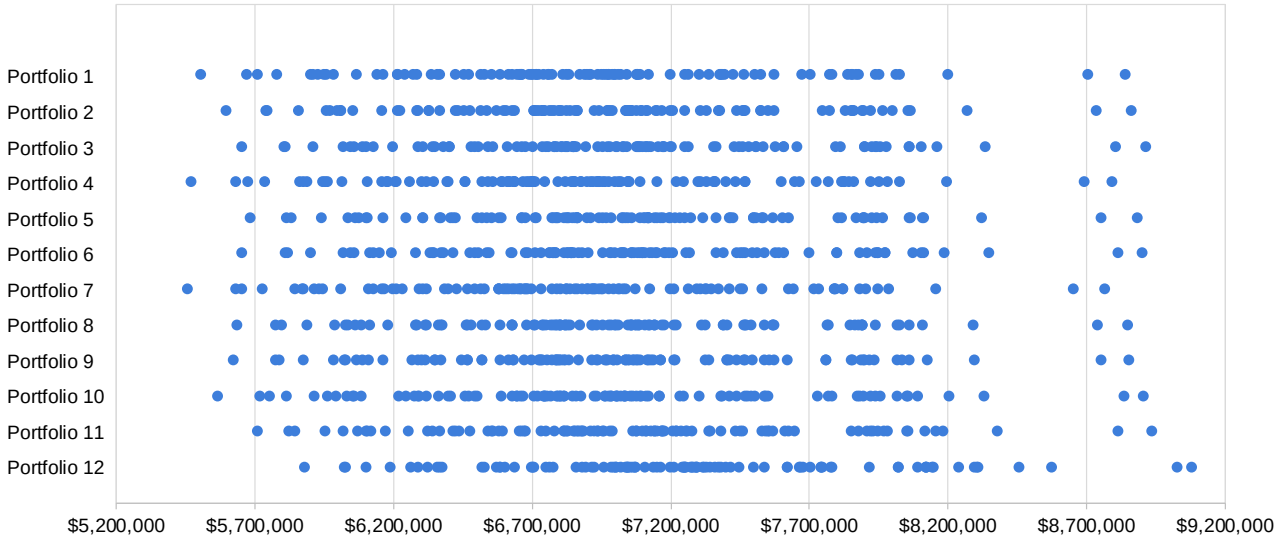

**Figure 9.5 Portfolio stochastic analysis, total portfolio cost, NPV years 2017–2036 ($ x 1,000)**

The horizontal axis on Figure 9.5 represents the portfolio cost (NPV) in millions of dollars, and the 12 portfolios are represented by their designation on the vertical axis. Each portfolio has 100 dots for the 100 different stochastic iterations scattered across different NPV ranges. P7 is the lowest-cost portfolio for 92 of the 100 stochastic iterations. P4 is the lowest-cost portfolio for the remaining eight stochastic iterations.

Table 9.6 is a descriptive statistical table for all 12 portfolios after the NPV is calculated for each of the 100 stochastic iterations. When calculated for the 100 iterations, P7 ranked the lowest in average, median, lowest minimum value, and lowest maximum value. P5 ranked the lowest in the standard deviation value. While P5, with 520 MW of installed solar PV capacity, has the lowest standard deviation, the approximately $20 million difference between its standard deviation and that for P7 is small when compared to the $175 million by which average portfolio costs for P7 are lower than those for P5. The difference in median portfolio costs between P7 and P5 is even greater at approximately $195 million.

**Table 9.6 AURORA variable + fixed costs, NPV years 2017–2036 ($ x 1,000)**

| Portfolio | Average | Rank | Median | Rank | Standard Deviation | Rank | Minimum | Rank | Maximum | Rank |
|---|---|---|---|---|---|---|---|---|---|---|
| P1 | $6,918,595 | 3 | $6,894,944 | 3 | $658,486 | 10 | $5,505,259 | 3 | $8,839,719 | 3 |
| P2 | $6,975,320 | 4 | $6,956,065 | 4 | $648,415 | 7 | $5,597,752 | 5 | $8,862,931 | 6 |
| P3 | $7,036,514 | 8 | $7,005,725 | 8 | $648,272 | 6 | $5,651,871 | 8 | $8,913,532 | 10 |
| P4 | $6,888,487 | 2 | $6,854,217 | 2 | $661,474 | 11 | $5,469,530 | 2 | $8,794,886 | 2 |
| P5 | $7,041,812 | 10 | $7,026,159 | 10 | $634,864 | 1 | $5,686,144 | 10 | $8,882,295 | 7 |
| P6 | $7,040,185 | 9 | $7,021,875 | 9 | $649,384 | 8 | $5,654,847 | 9 | $8,903,320 | 8 |
| P7 | $6,867,722 | 1 | $6,831,522 | 1 | $655,351 | 9 | $5,458,222 | 1 | $8,766,645 | 1 |
| P8 | $7,003,716 | 7 | $6,980,730 | 7 | $639,107 | 2 | $5,638,058 | 7 | $8,850,010 | 4 |

| P11 | $7,073,118 | 11 | $7,071,434 | 11 | $644,490 | 4 | $5,708,125 | 11 | $8,934,737 | 11 |
| P12 | $7,249,564 | 12 | $7,244,615 | 12 | $647,536 | 5 | $5,880,258 | 12 | $9,078,774 | 12 |

## Portfolio Analysis Results in Factorial Design Format

As discussed in Chapter 8, the portfolio analysis for the 2017 IRP uses a factorial design. Table 9.7 presents the results of the design.

**Table 9.7 2017 IRP portfolios, NPV years 2017–2036 ($ x 1,000)**

| | Primary Portfolio Element(s) | | | | |
|---|---|---|---|---|---|
| Treatment of Jim Bridger Units 1 and 2 | B2H | Solar PV/ Natural Gas | Natural Gas | Average | Rank |
| Invest in SCR | $6,400,696 | $6,497,505 | $6,530,856 | $6,476,352 | 3 |
| Retire Unit 1 in 2028 and Unit 2 in 2024 | $6,338,683 | $6,566,567 | $6,508,242 | $6,471,164 | 2 |
| Retire Unit 1 in 2032 and Unit 2 in 2028 | $6,335,771 | $6,503,524 | $6,483,000 | $6,440,765 | 1 |
| Retire Unit 1 in 2022 and Unit 2 in 2021 | $6,400,507 | $6,579,769 | $6,671,510 | $6,550,595 | 4 |
| **Average** | $6,368,915 | $6,536,842 | $6,548,402 | | |
| **Rank** | 1 | 2 | 3 | | |

A review of the row averages indicates the lowest-cost level of the factor related to the treatment of Jim Bridger units 1 and 2 is the 2032 (Unit 1) and 2028 (Unit 2) retirement scenario. Similarly, reviewing the column averages indicates the B2H-based portfolios are low cost. These findings support P7 as the low-cost portfolio, but they are also instrumental in allowing the IRP's portfolio analysis to inform the action plan with respect to the cost-effectiveness of the SCR investments and B2H.

## Solar Tipping-Point Analysis

At the direction of the IRPAC, a solar tipping-point analysis was performed to evaluate the sensitivity of the portfolio rankings to a reduction in solar cost. The solar tipping-point analysis reduces the capital cost of the solar PV included in P2, P5, P8, and P11 by 50 percent and 100 percent from the base-case capital cost of $1,375 per kW. The impact of the reduced solar capital costs on the NPV ranking of portfolios is shown in Table 9.8.

Assuming solar capital costs are reduced by 50 percent, P7 and P4 remain the two lowest-cost portfolios. P11, with 765 MW of installed solar capacity, is the third lowest in the 50-percent reduction case, moving up eight positions from its ranking under base-case capital costs. Assuming solar capital costs are reduced by 100 percent (i.e., free solar), P11, P5 (520 MW installed solar), and P2 (450 MW installed solar) are the lowest-ranked portfolios. P7 is the fourth lowest-cost portfolio in the 100-percent reduction case.

The conclusion is the economic performance of P7 under a reduction in solar costs is very robust.

**Table 9.8 2017 IRP portfolios, NPV years 2017–2036 ($ x 1,000)**

| Portfolio Details | | | | Planning Case | | 50% Reduction | | 100% Reduction | |
|---|---|---|---|---|---|---|---|---|---|
| Portfolio Index | Portfolio Description | B2H | Bridger Capacity Retirement | Rank | Lowest Cost Relative Difference | Rank | Lowest Cost Relative Difference | Rank | Lowest Cost Relative Difference |
| P1 | SCR invest, B2H, recips | ✓ | | 4 | $64,925 | 5 | $64,925 | 7 | $290,518 |
| P2 | SCR invest, DR, recips, solar | | | 6 | $161,733 | 6 | $85,878 | 3 | $219,766 |
| P3 | SCR invest, DR, recips, CCCT | | | 9 | $195,084 | 11 | $195,084 | 11 | $420,678 |
| P4 | Bridger retire in 24 & 28, B2H, recips | ✓ | ✓ | 2 | $2,912 | 2 | $2,912 | 5 | $228,505 |
| P5 | Bridger retire in 24 & 28, DR, recips, solar | | ✓ | 10 | $230,796 | 7 | $101,391 | 2 | $170,539 |
| P6 | Bridger retire in 24 & 28, DR, recips, CCCT | | ✓ | 8 | $172,470 | 10 | $172,470 | 10 | $398,064 |
| P7 | Bridger retire in 28 & 32, B2H, recips, CCCT | ✓ | ✓ | 1 | – | 1 | – | 4 | $225,593 |
| P8 | Bridger retire in 28 & 32, DR, recips, solar, CCCT | | ✓ | 7 | $167,753 | 8 | $125,487 | 8 | $299,982 |
| P9 | Bridger retire in 28 & 32, DR, recips, CCCT | | ✓ | 5 | $147,229 | 9 | $147,229 | 9 | $372,822 |
| P10 | Bridger retire in 21 & 22, B2H, recips | ✓ | ✓ | 3 | $64,736 | 4 | $64,736 | 6 | $290,329 |
| P11 | Bridger retire in 21 & 22, DR, recips, solar | | ✓ | 11 | $243,998 | 3 | $31,413 | 1 | – |
| P12 | Bridger retire in 21 & 22, DR, recips, CCCT | | ✓ | 12 | $335,739 | 12 | $335,739 | 12 | $561,332 |

# Qualitative Risk Analysis

The quantitative portfolio cost analysis indicates P7 as the lowest-cost portfolio. For the 2017 IRP, Idaho Power is assessing qualitative risk in terms of each portfolio's exposure to selected qualitative risk factors relative to P7's exposure to the same risk factors. This comparative analysis recognizes that differing exposure to qualitative risks can lead to the selection of a preferred portfolio different from the portfolio emerging as the lowest-cost portfolio from the quantitative analysis. Idaho Power has expanded the qualitative analysis to not only assess differing exposure to qualitative risks but also differing exposure to qualitative benefits. The considered qualitative risks and benefits are described in the following sections.

## *Qualitative Risks*

### Hydro—Water Supply Risk

The long-term sustainability of the Snake River Basin streamflows is important for Idaho Power to sustain hydro generation as a resource to meet future demand. Several assumptions related to the management of streamflows were made in developing the 20-year streamflow forecasts for the IRP. These assumptions include the following:

- The implementation of aquifer management practices on the ESPA, including aquifer recharge, system conversions, and the Conservation Reserve Enhancement Program (CREP)
- Future irrigation demand and return flows
- Declines in reach gains tributary to the Snake River
- Expansion of weather-modification efforts (i.e., cloud seeding).

The assumptions used in developing the 20-year streamflow forecast are carefully planned and based on the current knowledge of Idaho Power staff in consultation with other stakeholders. Those assumptions are also subject to the limitations of the current forecasting models.

Additional risks to future hydro generation not included in the development of the 20-year streamflow outlook consist of the following:

- Changes in the timing and demand for irrigation water due to climate variability
- Changes to the sources of flow augmentation water and the potential for overestimation of flow augmentation availability in low-water years
- Long-term changes in the timing of flood control releases at Brownlee Reservoir in response to earlier snowmelt

- The potential for underestimation of the decline in reach gains within the Snake River Basin

- Changes to funding or the ability to achieve forecasted levels of aquifer management on the ESPA.

### Relicensing Risk

Working within the constraints of the original FERC licenses, the HCC has historically provided operational flexibility that has benefited Idaho Power's customers. The operational flexibility of the HCC is increasingly critical to the successful integration of variable-energy resources. As a result of the FERC relicensing process, operational requirements, such as minimum reservoir elevations, minimum flows, and limitations on ramping rates, may become more stringent. The loss of operational flexibility will limit Idaho Power's ability to optimally manage the HCC, making the integration of variable-energy resources more challenging and ultimately increasing power-supply costs.

### Regulatory Risk

Idaho Power is a regulated utility with an obligation to serve customer load in its service area and is therefore subject to regulatory risk. Idaho Power expects future resource additions and removals will be approved for inclusion in the rate base and it will be allowed to earn a fair rate of ROIs related to resource actions of the IRP portfolios. Idaho Power includes public involvement in the IRP process through an IRPAC and by opening the IRPAC meetings to the public. The open public process allows a public discussion of the IRP and establishes a foundation of customer understanding and support for resource additions and removals when the plan is submitted for approval. The open public process reduces the regulatory risk associated with developing a resource plan.

### NOx Compliance Alternatives Risk

Six of the 12 portfolios, including P7, assume Jim Bridger units 1 and 2 will be permitted to operate beyond their regional-haze compliance dates without installation of SCRs. The remaining six portfolios either assume SCR installation or retirement of the units in 2021 (Unit 2) and 2022 (Unit 1) as stipulated by regional-haze requirements. While agreements permitting operating extensions have been reached in the past, uncertainty remains that such agreements can be reached for Jim Bridger units 1 and 2. An inability to successfully achieve permitting consistent with the assumptions of these compliance alternatives would likely have a significant effect on the costs and feasibility of portfolios with extended operations without SCR installation.

### Permitting/Siting Risk

Significant challenges are often encountered during permitting and siting for energy resources. While these challenges are not uniform for all resources or for all proposed resource locations,

it is nevertheless reasonable to assume all portfolios are exposed to permitting/siting risk, and no portfolio is markedly less exposed than P7; B2H planners have been collaborating with stakeholders for several years on resolving permitting/siting issues, and while challenges remain, much progress has been made.

### Regional Resource Adequacy

B2H-based portfolios have higher exposure to potential regional resource inadequacies. However, Idaho Power's review of regional resource adequacy assessments conducted by the NWPCC and BPA indicates B2H will provide access to a wholesale electric market with capacity for meeting summer load needs and abundant low-cost energy. Further discussion of the NWPCC and BPA adequacy assessments is in Chapter 6.

### DSM Implementation

While Idaho Power has considerable experience in DSM programs and has consistently achieved IRP energy efficiency targets, an implementation risk always exists with a new program. The actual energy savings and peak reductions may vary significantly from the estimated amounts if customer participation rates are not achieved.

### Technological Obsolescence

The energy industry is experiencing considerable technological innovation, a trend expected to continue well into the future. This innovation could lead to greater market penetration for emerging resources and correspondingly drive competing resources to obsolescence. The determination of competitive resources in the energy industry of the future is highly speculative. However, current trends support the critical role the electric grid is expected to continue to play well into the future, with a growing need to move intermittently produced energy from grid locations experiencing oversupply to those experiencing undersupply. Moreover, a grid resource such as B2H positions Idaho Power to participate in the Pacific Northwest wholesale electric market as the energy sources comprising that market evolve over the coming decades. Therefore, Idaho Power qualitatively views portfolios without B2H as having greater exposure to technological innovation than those with B2H.

## *Qualitative Benefits*

### Regional Resource Diversity

The Pacific Northwest wholesale electric market is a diverse mix of renewable and thermal resources. Renewable resources primarily consist of hydropower and wind generation, with lesser amounts of solar and geothermal. B2H provides expanded access to the Pacific Northwest wholesale market and its attendant diverse mix of low-cost energy resources and abundant zero-carbon energy.

### Regional Transmission Initiatives

Idaho Power has a long history of collaboration in regional transmission planning. B2H is a resource providing value to project co-participants, and also to the region as a whole, with the spread of automated energy markets, such as the western EIM. B2H positions Idaho Power and the region well in furthering the interconnectivity of the regional transmission system.

### Transmission Tariff Revenue

B2H is a critical interconnection to the Pacific Northwest providing Idaho Power access to low-cost energy, capacity, and balancing. B2H, uniquely among the potential IRP resources considered, provides revenue in the form of transmission tariffs when used by other entities during periods Idaho Power is not using it to transfer energy.

### Local Economic Effects

The scope of the IRP does not include an analysis of macroeconomic impacts associated with considered resource portfolios. Therefore, any evaluation of macroeconomic impacts is strictly qualitative in nature and highly conjectural. Locally sited resources, such as solar PV and natural gas-fired power plants, can be reasonably linked to localized job growth associated with plant construction and operation; however, long-term job opportunities associated with plant operation are expected to be more significant with natural gas power plants than solar PV power plants. Further, solar PV modules are substantially sourced from overseas markets, whereas fuel for natural gas power plants relies heavily on domestic production and consequently can be linked more closely to domestic macroeconomic growth. B2H can be expected to lead to construction-related job growth. Moreover, B2H, as a source for reliable and low-cost energy, is consistent with Idaho Power's mission to provide reliable and fair-priced energy services, qualities recognized as instrumental in promoting economic growth in Idaho Power's service area.

## *Summary of Qualitative Risks and Benefits*

Table 9.9 and Table 9.10 summarize the relative risks and benefits of the 12 portfolios analyzed. As noted earlier, the qualitative risk analysis is structured as an assessment of qualitative risks and benefits in relation to the lowest-cost P7, with the objective of assessing whether qualitative risk leads to the selection of a preferred portfolio different from P7. The findings of the qualitative risk analysis do not support the selection of a portfolio other than P7 as preferred.

**Table 9.9 Qualitative risk analysis**

| Risk | P1 | P2 | P3 | P4 | P5 | P6 | P7 | P8 | P9 | P10 | P11 | P12 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Hydro—Water Supply Risk | = | = | = | = | = | = | | = | = | = | = | = |
| Relicensing Risk | = | = | = | = | = | = | | = | = | = | = | = |

< Less benefit
= Equal benefit

## *CAA Section 111(d)*

All 12 portfolios in the 2017 IRP comply with the mass-based carbon-emission regulations as stipulated in the final rule for Section 111(d). While Idaho Power believes carbon-emission regulations in some form are likely during the next 20 years, the final regulations will likely not be as modeled in this IRP. Qualitatively, under a non-carbon-constrained future Idaho Power believes SCR investments that extend the time period of coal-fired generation at Jim Bridger units 1 and 2 would likely result in a better financial outcome for customers. Conversely, a carbon-constrained future would favor an earlier retirement of the Jim Bridger units and preclude investment in additional SCRs at Jim Bridger. While uncertainty exists regarding carbon-emission regulations, Idaho Power is not inclined to pursue a direction toward making the SCR investments. The additional SCR investments are counter to the findings of the portfolio analysis, in which portfolios without SCRs on Jim Bridger units 1 and 2 generally performed better. Finally, the company's expressed objectives related to transitioning away from coal-fired generating capacity weigh against making additional SCR investments at Jim Bridger.

## Capacity Planning Margin

Idaho Power discussed planning criteria with state utility commissions and the public in the early 2000s before adopting the present planning criteria. Idaho Power's future resource requirements are not based directly on the need to meet a specified reserve margin. The company's long-term resource planning is driven instead by an objective to develop resources sufficient to meet higher-than-expected load conditions under lower-than-expected water conditions, which effectively provides a reserve margin.

As part of preparing the 2017 IRP, Idaho Power calculated the capacity planning margin resulting from the resource development identified in P7, the preferred resource portfolio. When calculating the planning margin, the total resources available to meet demand consist of the additional resources available under the preferred portfolio plus the generation from existing and committed resources, assuming expected-case ($50^{th}$-percentile) water conditions. The generation from existing resources also includes expected firm purchases from regional markets. The resource total is then compared with the expected-case ($50^{th}$-percentile) peak-hour load, with the excess resource capacity designated as the planning margin. The calculated planning margin provides an alternative view of the adequacy of the preferred portfolio, which was formulated to meet more stringent load conditions under less favorable water conditions.

Idaho Power maintains 330 MW of transmission import capacity above the forecast peak load to cover the worst single planning contingency. The worst single planning contingency is defined as an unexpected loss equal to Idaho Power's share of two units at the Jim Bridger coal facility or the loss of Langley Gulch. The reserve level of 330 MW translates into a reserve margin of over 10 percent, and the reserved transmission capacity allows Idaho Power to import energy during an emergency via the Northwest Power Pool (NWPP). A 330-MW reserve margin also results in a loss of-load expectation (LOLE) of roughly 1 day in 10 years, a standard industry measurement. Capacity planning margin calculations for July of each year through the planning period are shown in Table 9.11.

**Table 9.11 Capacity planning margin**

| | July 2017 | July 2018 | July 2019 | July 2020 | July 2021 | July 2022 | July 2023 | July 2024 | July 2025 | July 2026 | July 2027 | July 2028 | July 2029 | July 2030 | July 2031 | July 2032 | July 2033 | July 2034 | July 2035 | July 2036 |

# Flexible Resource Needs Assessment

Idaho Power analysis for the 2017 IRP indicates Idaho Power customers and independent power producers will place increasing flexibility needs on the power system. Idaho Power analyzed historical data, then compared the historical data with a forecast of conditions in 2026. Flexibility needs increase in most months based on the analysis.

## *Historical Analysis*

Idaho Power analyzed hourly load and hourly energy production from intermittent wind generation resources during the historical time period 2012 through 2016. Idaho Power calculated hourly net load by subtracting hourly wind generation from hourly system load (there was very limited solar production on Idaho Power's system during the 2012 through 2016 time period).

$$Hourly\ net\ load = Hourly\ load - Hourly\ wind\ generation$$

Idaho Power then calculated the change in hourly net load over four time intervals:

$$\Delta\ Net\ Load_{0} = Net\ Load\ Hour_{0} - Net\ Load\ Hour_{-1}$$

$$\Delta\ Net\ Load_{-1} = Net\ Load\ Hour_{-1} - Net\ Load\ Hour_{-2}$$

$$\Delta\ Net\ Load_{-2} = Net\ Load\ Hour_{-2} - Net\ Load\ Hour_{-3}$$

$$\Delta\ Net\ Load_{-3} = Net\ Load\ Hour_{-3} - Net\ Load\ Hour_{-4}$$

Idaho Power calculated a flexibility score by averaging the four calculated absolute (ABS) changes in net load (a four-hour moving average of the hourly change in net load):

$$Flexibility\ Score = [ABS(\Delta\ Net\ Load_{0}) + ABS(\Delta\ Net\ Load_{-1})$$

$$+ ABS(\Delta\ Net\ Load_{-2}) + ABS(\Delta\ Net\ Load_{-3})] / 4$$

The absolute change was used so a significant positive change in one hour coupled with a significant negative change in an adjoining hour would not cancel the flexibility score calculation. Significant net load changes in adjoining hours are considered to represent a genuine need for system flexibility regardless of whether the net load changes are positive or negative.

The five years of historical data yielded approximately 44,000 hourly flexibility scores.

Idaho Power then specified a flexibility threshold:

$$Flexibility\ Score >= 100\ MW$$

AND

$$Flexibility\ Score/Hourly\ Net\ Load >= 0.12$$

The flexibility threshold is used to identify a specific number of flexibility events. The flexibility score must be equal to or exceed 100 MW, and the flexibility score must be equal to or greater than 12 percent of the net system load to be identified as a flexibility event; both criteria must be satisfied.

The flexibility threshold and resulting number of flexibility events are not based on any specific system requirements or regulations from NERC, FERC, WECC, or any other regulatory agency. The flexibility events are solely a metric used for comparison purposes. Figure 9.6 shows the distribution of events where the flexibility score was 100 MW or greater, and Figure 9.7 shows the distribution of events where the flexibility score was 12 percent of net load or greater.

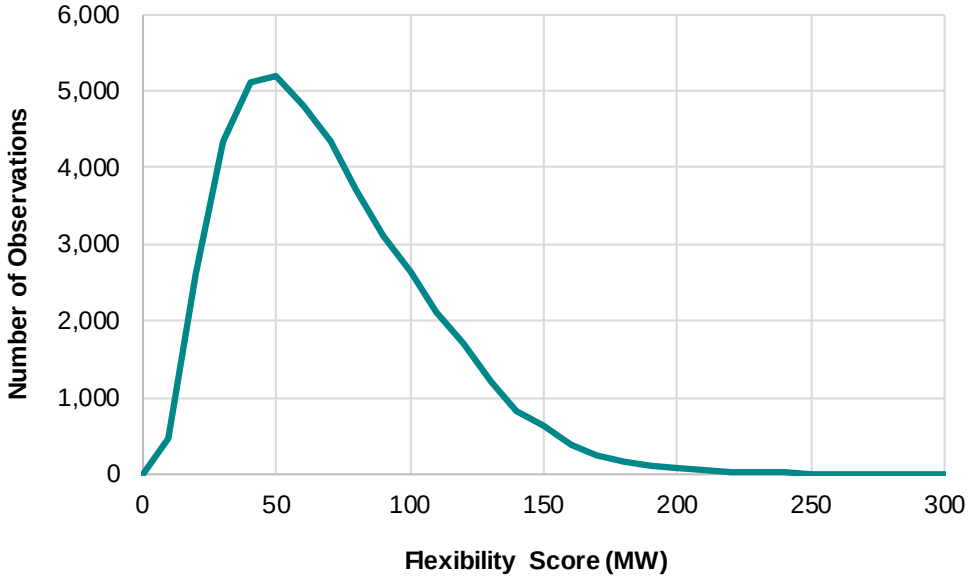

**Figure 9.6 Distribution of events with flexibility score 100 MW or greater**

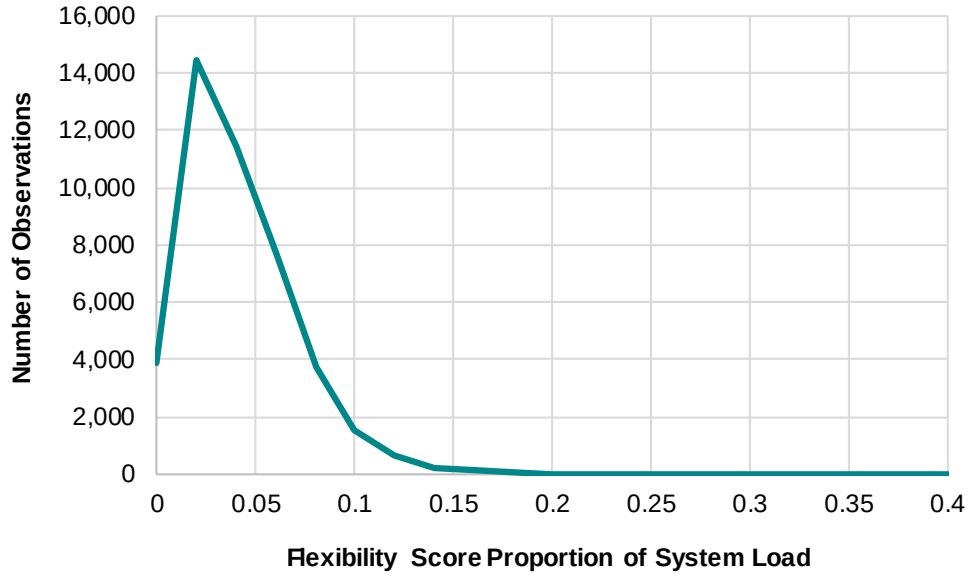

**Figure 9.7 Distribution of events with flexibility score 12 percent of net load or greater**

There were slightly over 600 hours during the five-year historical period that exceeded the flexibility threshold. The 600 hours represent slightly over 1.4 percent of the total hours in the historical period.

## Projected Flexibility Score in 2026

Idaho Power selected 2026 as a test year in the IRP analysis. Idaho Power estimated the flexibility score for 2026 using the same arithmetic techniques that were used to analyze the 2012 through 2016 historical period. Idaho Power used forecast hourly load and forecast independent power production from intermittent renewable resources. The independent power production from intermittent resources includes both wind and solar generation facilities in 2026. As with the historical analysis, Idaho Power calculated hourly net load, the change in net load, the four-hour moving average of the change in net load, and a flexibility score based on the same flexibility threshold:

$$Flexibility\ Score >= 100\ MW$$

AND

$$Flexibility\ Score/Hourly\ Net\ Load >= 0.12$$

There are 220 hours projected in 2026 that exceed the flexibility threshold, which represent about 2.5 percent of the hours in 2026. Table 9.12 shows the hours exceeding the flexibility threshold in 2026 by month, as well as the results from analyzing the historical period.

**Table 9.12 Hours exceeding flexibility threshold by month**

| | Yearly History, 2012–2016 | | 2026 Forecast | |
|---|---|---|---|---|
| **Month** | **Minimum** | **Maximum** | **Flex Score** | **Flex Need*** |
| January | 1 | 8 | 9 | + |
| February | 2 | 15 | 17 | + |
| March | 7 | 21 | 33 | ++ |
| April | 4 | 17 | 20 | + |
| May | 6 | 14 | 27 | ++ |
| June | 5 | 11 | 21 | ++ |
| July | 3 | 9 | 13 | + |
| August | 5 | 14 | 9 | |
| September | 5 | 18 | 27 | + |
| October | 7 | 26 | 30 | + |
| November | 5 | 18 | 12 | |
| December | 3 | 13 | 2 | |

* Plus signs indicate a forecast change in flexibility need.

Only three months in 2026—August, November, and December—are projected to have a flexibility need approximately equivalent to the flexibility need in the historical period. Three months—March, May, and June—are projected to have a significant increase in flexibility need when compared with the historical period. The other six months—January, February, April, July, September, and October—are projected to have a moderate increase in flexibility need.

March is projected to have the largest number of flexibility events at 33 in the forecast period. Idaho Power recorded 26 flexibility events in October during the historical period. The increase in flexibility events is anticipated to be manageable by comparison with the historical period. Flexibility management will likely require curtailment of intermittent renewable generation at times to maintain system stability.

The summary conclusion is that the changes in customer load and the increase in independent power production from intermittent renewable resources will increase Idaho Power's need for system flexibility in 2026.

## Solar Capacity Credit

Idaho Power updated the solar PV peak-hour capacity factors based on guidance from members of the solar work group in the 2015 IRP. The update used simulated solar generation for water years 2011 through 2013, specifically focusing the analysis on solar generation occurring during the highest 150 load hours from the three water years.

The solar capacity credit is expressed as a percentage of installed AC nameplate capacity. The solar capacity credit is used to determine the amount of peak-hour capacity delivered to Idaho Power's system from a solar PV plant considered as a new IRP resource option. The solar capacity credit values used in the 2015 and 2017 IRPs are reported in Table 9.13.

**Table 9.13 Solar capacity credit values**

| PV System Description | Peak-Hour Capacity Credit |
|---|---|
| South orientation | 28.4% |
| Southwest orientation | 45.5% |
| Tracking | 51.3% |

OPUC Docket No. UM 1719 examined the determination of solar capacity credit in several recently filed IRPs. The Docket No. UM 1719 settlement agreement required Idaho Power to conduct an LOLE study, or an approximation method, to validate that Idaho Power's analysis focusing on the highest 150 load hours adequately defines Idaho Power's capacity timing need. The LOLE was to include all 8,760 hours of a test year and result in an LOLP for each hour.

Idaho Power selected 2025 for examination using an approximation method for a complete LOLE study. The evaluation used median hydro and load forecasts and the AURORA hourly

preferred portfolio output as a starting point. An Excel workbook was used to simulate 500 years of random outages. The 500 years of random outages resulted in an LOLE of approximately 2.07 hours per year. The 2.07 hours per year equates to an LOLE of approximately 1 day in 10 years, a frequently used standard in determining a system as resource adequate.

The hourly LOLP of the 500 iterations for 2025 is shown in Table 9.14.

**Table 9.14 Hourly LOLP of 500 iterations for 2025**

A large percentage of the LOLP hours occur in June and July and are coincident with the 150 highest load hours used in defining the capacity credit used in the 2015 and 2017 IRPs. However, a number of the LOLP hours occur outside the hourly periods containing the 150 highest load hours. The winter-hour LOLPs are especially interesting. December, January, and February contain 33 percent of the LOLP hours identified in the study compared to 0 percent of the hours evaluated in the 150 highest hours.

The distribution of the 150 highest load hours for 2013 to 2015 is given in the following monthly hour probability table (Table 9.15).

**Table 9.15 Monthly probabilities**

The LOLE study identifying LOLP outside of the 150 highest load hours methodology leads Idaho Power to re-evaluate the 150-hour methodology and update the solar capacity credit with the best available information. This analysis will be conducted in the interim between the 2017 and 2019 IRPs, and resulting updates to the solar capacity credit will be included in the 2019 IRP.

## LOLE

The solar capacity credit LOLE study Excel workbook described in the preceding section was also used to evaluate the LOLE sufficiency of Idaho Power's future system plan.
The 500 random outages resulted in an LOLE of approximately 2.07 hours per year.
The 2.07 hours per year equates to an approximately 1-day-in-10-years LOLE, a standard used in determining a system as resource adequate.

# 10. PREFERRED PORTFOLIO AND ACTION PLAN

## Preferred Portfolio

The cost analysis performed for the IRP included an analysis of resource portfolio costs under planning-case conditions for natural gas price, hydroelectric production, and system load. The cost analysis also included an analysis of resource portfolio costs under a range of sensitivities for natural gas price, a key cost driver. A third element of the cost analysis was the stochastic risk analysis, in which resource portfolio costs were computed for 100 different iterations (or futures) for the studied stochastic risk variables: natural gas price, hydroelectric production, and system load. The B2H-based P7 consistently outperformed the other portfolios in the cost analysis. In addition to the B2H transmission line in 2026, P7 includes 180 MW of reciprocating engines and a 300-MW CCCT in the 2030s. P7 also assumes Jim Bridger units 1 and 2 are retired early at year-end 2032 and year-end 2028, respectively, without installing SCRs.

A qualitative risk analysis found that P7 does not carry greater exposure to qualitative risk factors relative to other resource portfolios. In fact, P7 has unique qualitative benefits in a future where the electric grid is a critical element to the successful development of automated energy markets (i.e., western EIM) and the integration of expanded intermittent renewable resources. Further, P7 is consistent with Idaho Power's expressed goals related to the measured and responsible transition away from coal-fired generating capacity. Following the retirement of Jim Bridger units 1 and 2, Idaho Power's coal-fired generating capacity will have dropped to approximately one-third of the capacity on-line in 2017. Based on the analysis for the 2017 IRP, P7 is selected as the preferred portfolio. A listing of the resource additions included in P7 is provided in Table 10.1.

**Table 10.1 P7 Resources**

| Date | Resource | Installed Capacity |
|---|---|---|
| 2026 | B2H | 500 MW transfer capacity, Apr–Sep<br>200 MW transfer capacity, Oct–Mar |
| 2031 | Reciprocating engines | 36 MW |
| 2032 | Reciprocating engines | 36 MW |
| 2033 | CCCT (1x1) | 300 MW |
| 2035 | Reciprocating engines | 54 MW |
| 2036 | Reciprocating engines | 54 MW |

## Action Plan (2017–2021)

The expressed objective of the portfolio design for the 2017 IRP was to inform the action plan regarding SCR investments at Jim Bridger units 1 and 2 and the B2H transmission line. Idaho Power characterized these two key resource actions as pivotal to this IRP, recognizing that

an essential function of the 2017 IRP is to inform the direction of these resource decisions. With respect to B2H, the action plan includes not only actions to continue permitting and planning, but also necessary preliminary construction and construction activities extending beyond 2021. These activities are described in Chapter 6.

The IRP portfolio analysis indicates a pivot away from making the SCR investments on Jim Bridger units 1 and 2. Therefore, the action plan includes actions consistent with the planning and negotiations necessary to facilitate the units' continued operation without SCRs and their ultimate 2028 and 2032 retirement. A baseline assumption common to all portfolios is the retirement of North Valmy units 1 and 2 at year-end 2019 and year-end 2025, respectively. Actions necessary to achieve these North Valmy retirement dates and assess the import dependability from northern Nevada are included in the action plan.

The Gateway West transmission line continues to be identified as a beneficial future upgrade to Idaho Power and the region, creating additional capacity and promoting continued grid reliability in a time of expanding variable energy resources. Therefore, in support of Idaho Power's agreement with our project partner, PacifiCorp, the action plan includes actions related to the continued permitting and planning associated with the Gateway West project.

The action plan also includes the following items:

- Continued pursuit of cost-effective energy efficiency, working with stakeholder groups, such as EEAG and regional groups, such as the Northwest Energy Efficiency Alliance (NEEA)
- Continued preparation for participation in the western EIM beginning in April 2018
- Continued involvement as a stakeholder in CAA Section 111(d) proceedings or alternative regulations constraining carbon emissions
- Investigation of solar PV contribution to peak and LOLP for use in the 2019 IRP

Table 10.2 provides actions with dates for the action plan period.

**Table 10.2 Action plan (2017–2021)[19]**

| Year | Resource | Action | Action Number |
|---|---|---|---|
| 2017–2018 | EIM | Continue planning for western EIM participation beginning in April 2018. | 1 |
| 2017–2018 | Loss-of-load and solar contribution to peak | Investigate solar PV contribution to peak and loss-of-load probability analysis. | 2 |
| 2017–2019 | North Valmy Unit 1 | Plan and coordinate with NV Energy Idaho Power's exit from coal-fired operations by year-end 2019. Assess import dependability from northern Nevada. | 3 |
| 2017–2021 | Jim Bridger units 1 and 2 | Plan and negotiate with PacifiCorp and regulators to achieve early retirement dates of year-end 2028 for Unit 2 and year-end 2032 for Unit 1. | 4 |
| 2017–2020 | B2H | Conduct ongoing permitting, planning studies, and regulatory filings. | 5 |
| 2018–2026[20] | B2H | Conduct preliminary construction activities, acquire long-lead materials, and construct the B2H project. | 6 |
| 2017–2021 | Boardman | Continue to coordinate with PGE to achieve cessation of coal-fired operations by year-end 2020 and the subsequent decommission and demolition of the unit. | 7 |
| 2017–2021 | Gateway West | Conduct ongoing permitting, planning studies, and regulatory filings. | 8 |
| 2017–2021 | Energy efficiency | Continue the pursuit of cost-effective energy efficiency. | 9 |
| 2017–2021 | Carbon emission regulations | Continue stakeholder involvement in CAA Section 111(d) proceedings, or alternative regulations affecting carbon emissions. | 10 |
| 2017–2021 | North Valmy Unit 2 | Plan and coordinate with NV Energy Idaho Power's exit from coal-fired operations by year-end 2025. | 11 |

## Idaho Power and the Utility of the Future

A new energy world, driven by technological innovation and changing customer preferences, is emerging, one that is efficient, green, resilient, and interconnected. In the new energy world, conventional generation and increasingly complex grid connectivity will continue to exist and remain indispensable for ensuring a reliable, round-the-clock supply of power. Idaho Power is focused on transforming unidirectional powerlines into smart energy networks that incorporate renewables, providing customers with options while increasing system reliability and resiliency.

The company is investing in next-generation communication and monitoring capabilities that will facilitate the more complex web of power flow that the future will bring. Idaho Power is

[19] The B2H short-term action plan is 2017 to 2026. All other action plan items are for 2017 to 2021.

[20] B2H in-service date of 2024 or later, subject to coordination of activities with project co-participants.

laying the groundwork for future tools that will allow more automated power routing, self-healing capabilities, and enhanced power quality. The company is incorporating big-data tools and predictive analytics to anticipate issues, power flow, and usage patterns, etc., to facilitate proactive management of issues before they occur. Technological developments and capabilities will continue to occur at a rapid pace, and Idaho Power is actively, but judicially, evaluating the costs and benefits of these opportunities to take advantage of them when appropriate.

## Conclusion

Hemingway Substation

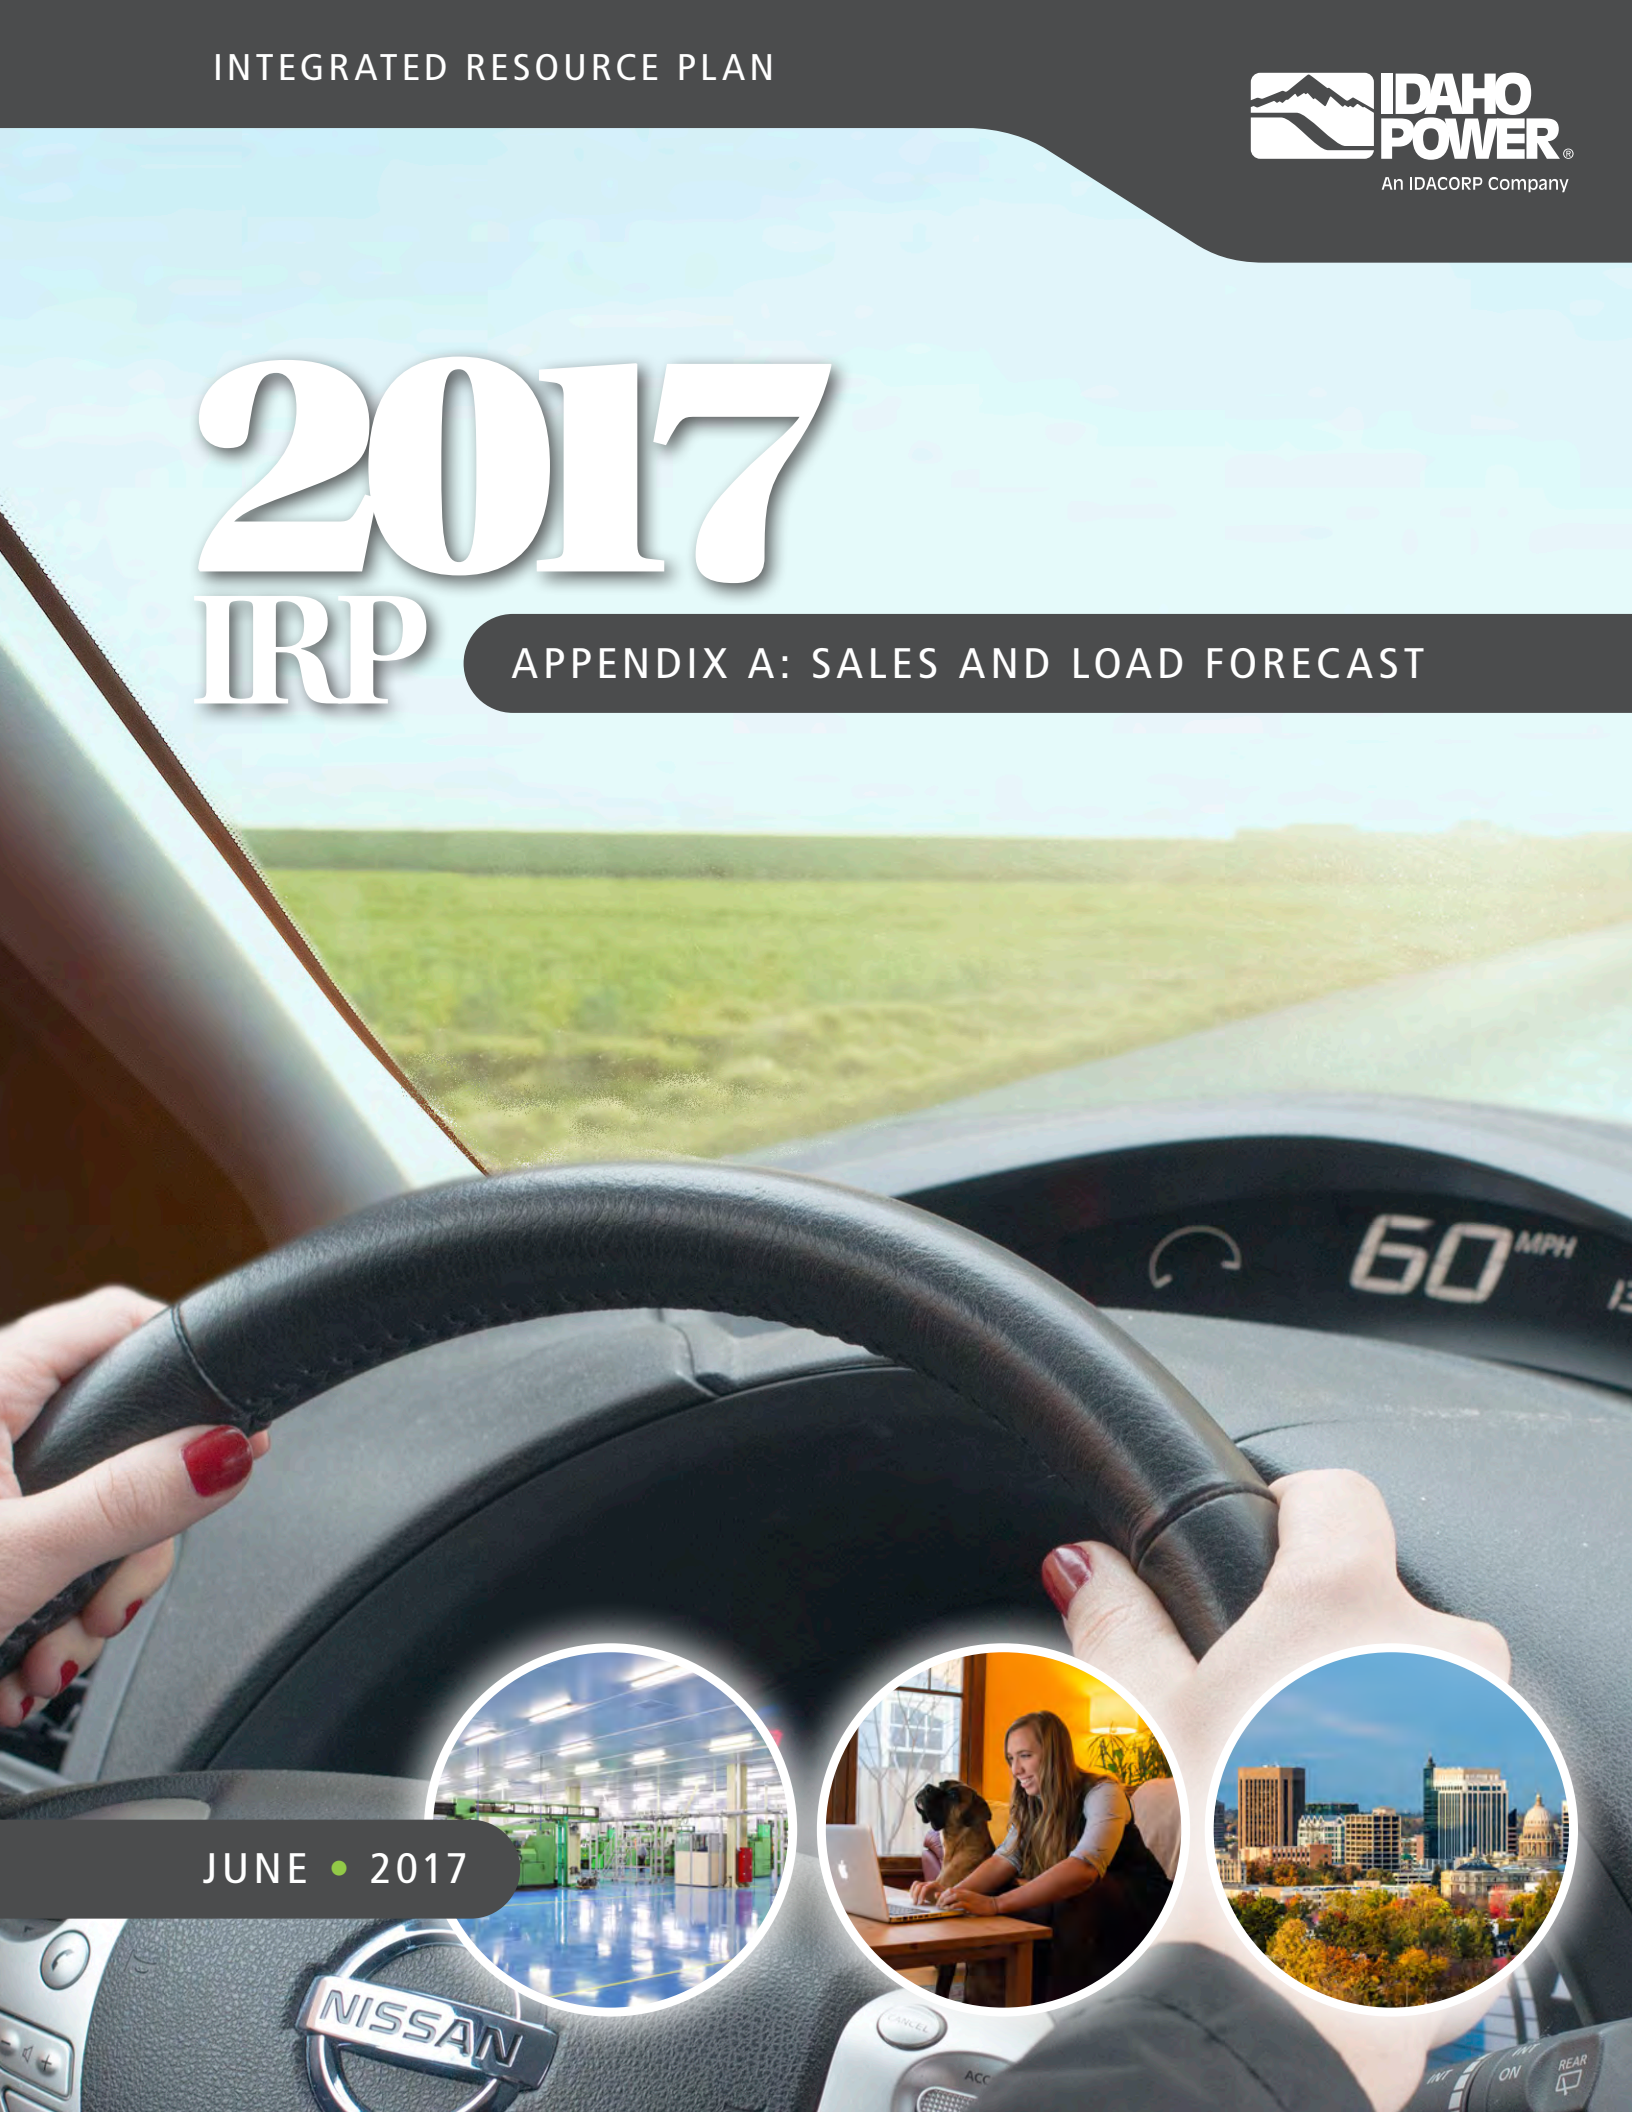
The 2017 IRP indicates favorable economics associated with the B2H transmission line, the early retirement of Valmy units 1 and 2, and the early retirement (and corresponding avoided SCR investments) for Jim Bridger units 1 and 2. B2H has been treated as an uncommitted resource in every IRP beginning with the 2006 IRP. The 2017 IRP continues to show B2H as a top-performing resource alternative, capable of providing low-cost energy and capacity, as well as increasingly critical flexibility. Moreover, B2H positions Idaho Power and the region well in a future in which automated energy markets and enabling grid resources are likely to become increasingly important.

Idaho Power has expressed the objective to transition away from reliance on coal-fired generating capacity, provided this transition can be conducted in a responsible, economically beneficial, and measured manner. The findings of the 2017 IRP are consistent with this objective. The Boardman coal plant is scheduled for a 2020 retirement. A baseline assumption for the IRP is the retirement of North Valmy units 1 and 2 in 2019 and 2025, respectively. The preferred portfolio assumes the retirement of Jim Bridger Unit 2 in 2028 and Jim Bridger Unit 1 in 2032. While the North Valmy and Jim Bridger retirement dates are planning targets and subject to planning considerations with plant co-owners and/or negotiations with regulatory agencies, it can generally be asserted that over the next 15 years Idaho Power will retire more than 730 MW of coal-fired generating capacity.

Idaho Power focused the portfolio analysis for the 2017 IRP on the pivotal decisions related to SCR investments in Jim Bridger units 1 and 2 and the B2H transmission line and proffered a portfolio analysis designed to isolate these factors. However, the company recognizes resources achieving only modest market penetration to date, including notably electrochemical energy

storage, are likely to achieve greater market penetration in the coming years and may outcompete the low-cost natural gas-fired resources of today. Idaho Power recognizes the importance of understanding the cost and value characteristics of all emerging resources to effective long-term resource planning.

Idaho Power strongly supports public involvement in the planning process. Idaho Power thanks the IRPAC members and the public for their contributions to the 2017 IRP. The IRPAC discussed many technical aspects of the 2017 resource plan, along with a significant number of political and societal topics at the meetings. Idaho Power's resource plan is better because of the contributions from IRPAC members and the public.



Idaho Power prepares an IRP every two years, and the next plan will be filed in 2019. The electric energy industry is experiencing what many consider a transformational era, and undoubtedly new challenges and questions necessarily addressed in integrated resource planning will be encountered in the 2019 IRP. Idaho Power will monitor the trends in the electric energy industry and adjust as necessary in the 2019 IRP.

## APPENDIX A: SALES AND LOAD FORECAST

# ACKNOWLEDGEMENT

Resource planning is an ongoing process at Idaho Power. Idaho Power prepares, files, and publishes an Integrated Resource Plan (IRP) every two years. Idaho Power expects that the experience gained over the next few years will likely modify the 20-year resource plan presented in this document.

Idaho Power invited outside participation to help develop the 2017 IRP. Idaho Power values the knowledgeable input, comments, and discussion provided by the Integrated Resource Plan Advisory Council and other concerned citizens and customers.

It takes approximately one year for a dedicated team of individuals at Idaho Power to prepare the IRP. The Idaho Power team is comprised of individuals that represent many departments within the company. The IRP team members are responsible for preparing forecasts, working with the advisory council and the public, and performing all the analyses necessary to prepare the resource plan.

Idaho Power looks forward to continuing the resource planning process with customers, public-interest groups, regulatory agencies, and other interested parties. You can learn more about the Idaho Power resource planning process at idahopower.com.

# INTRODUCTION

Idaho Power has prepared *Appendix A—Sales and Load Forecast* as part of the *2017 Integrated Resource Plan* (IRP). Appendix A includes details on the energy sales and load forecast of future demand for electricity within the company's service area. The above-mentioned forecast covers a 20-year period from 2017 through 2036.

The expected-case monthly average load forecast is Idaho Power's estimate of the most probable outcome for load growth during the planning. To account for inherent uncertainty and variability, four additional load forecasts were prepared in addition to the expected-case—a low case, a 70$^{th}$-percentile case, a 90$^{th}$-percentile case, and a high case, all of which are described in more detail in this report. The high and low economic growth scenarios provide a range of possible load growths over the planning period due to variable economic, demographic, and other non-weather-related influences. Additional cases are developed around the 70$^{th}$-percentile and 90$^{th}$-percentile load forecast scenarios to assist Idaho Power in reviewing the resource requirements that would result from variable loads due to variable weather conditions for temperatures and rainfall. It is important to note that in the IRP resource planning process, Idaho Power uses the 70$^{th}$-percentile load forecast to account for the risk associated with weather impacts on load.

In the expected-case scenario, Idaho Power's system load is forecast to increase to 2,142 average megawatts (aMW) by 2036 from 1,810 aMW in 2017, representing an average yearly growth rate of 0.9 percent over the 20-year planning period (2017–2036). In the more critical 70$^{th}$-percentile load forecast used for resource planning, the system load is forecast to reach 2,193 aMW by 2036 (0.9% average annual growth)[1]. Additionally, the number of Idaho Power active retail customers is expected to increase from the December 2016 level of 533,400 customers to nearly 755,000 customers by year-end 2036 (see footnote 1).

For capacity planning purposes, it is forecasted that Idaho Power's system will grow to 4,641 megawatts (MW) in 2036 from the all-time system peak of 3,407 MW that occurred on Tuesday, July 2, 2013, at 4:00 p.m. Idaho Power's system peak increases at an average growth rate of 1.4 percent per year over the 20-year planning period (2017–2036).

The numerous external factors influencing the forecast are primarily economic and demographic in nature. Moody's Analytics serves as the primary provider for this data. The national, state, metropolitan service area (MSA), and county economic and demographic projections are tailored to Idaho Power's service area using an in-house economic database. Specific demographic projections are also developed for the service area from national and local census data.

[1] Recent company disclosures forecast load growth during the 2016 to 2035 planning period at 1.0 percent for average energy demand and 1.4 percent for peak-hour demand.

Additional data sources used to substantiate Moody's data include the Idaho Department of Labor, Woods & Poole, Construction Monitor, and Federal Reserve economic databases.

Economic growth assumptions influence several classes of service growth rates. The number of households in Idaho is projected to grow at an annual rate of 1.2 percent during the forecast period. The growth in the number of households within individual counties in Idaho Power's service area is projected to grow faster than the remainder of the state over the planning period. The number of households in the Boise –Nampa MSA is projected to grow even faster than the state of Idaho, at an annual rate of 1.6 percent during the forecast period. The Boise MSA (or the Treasure Valley) is an area that encompasses Ada, Boise, Canyon, Gem, and Owyhee counties in southwestern Idaho. In addition, the number of households, incomes, employment, economic output, real retail electricity prices, and customer consumption patterns are used to develop load projections.

In addition to the economic assumptions used to drive the expected-case forecast scenario, several assumptions were incorporated into the forecasts of the residential, commercial, industrial, and irrigation sectors. Further discussions of these assumptions are presented below.

Conservation influences on the load forecast, including Idaho Power energy efficiency demand-side management (DSM) programs, statutory programs, and non-programmatic trends in conservation, are included in the load forecasts of each sector. Idaho Power DSM programs are described in detail in Idaho Power's *Demand-Side Management 2016 Annual Report,* which is incorporated into this IRP document as Appendix B.

During the 20-year forecast horizon, major shifts in the electric utility industry (e.g., state and federal regulations and varying electricity prices) could influence the load forecast. In addition, the price and volatility of substitute fuels, such as natural gas, may also impact future demand for electricity. The high degree of uncertainty associated with such changes is reflected in the economic high and low load growth scenarios described previously. The alternative sales and load scenarios in *Appendix A—Sales and Load Forecast* were prepared under the assumption that Idaho Power's geographic service area remains unchanged during the planning period.

Data describing the historical and projected figures for the sales and load forecast are presented in Appendix A1 of this report.

# 2017 IRP SALES AND LOAD FORECAST

## Average Load

The economic and demographic variables driving the 2017 forecast have the impact of increasing current annual sales levels throughout the planning period. The delay in the expected "robust lift-off" of the business cycle recovery process after the Great Recession in 2008 for the national and, to a lesser extent, service-area economy halted load growth post-recession through 2011. However, in 2012, the extended recovery process was evident, and on-balance stronger growth was exhibited in most economic drivers relative to recent history at that time. It is expected that economic conditions return to long-term fundamentals during the 2017 forecast period. Significant factors and considerations that influenced the outcome of the 2017 IRP load forecast include the following:

- The load forecast used for the 2017 IRP reflects a continuance of the recovery in the service-area economy following a severe recession in 2008 and 2009. As customer growth was at a near standstill until 2012, acceleration of in-migration and business investment resulted in renewed growth in the residential and commercial connections along with increased industrial activity. As of 2017, customer additions have approached sustainable growth rates experienced prior to the housing bubble (2000–2004) and are expected to continue.

- The electricity price forecast used to prepare the sales and load forecast in the 2017 IRP reflects the impact of additional plant investment and associated variable costs of integrating new resources identified in the 2015 IRP preferred portfolio Compared to the electricity price forecast used to prepare the 2015 IRP sales and load forecast, the 2017 IRP price forecast yields lower future prices. The retail prices are most evident after the first two years of the planning period and can impact the sales forecast positively, a consequence of the inverse relationship between electricity prices and electricity demand.

- There continues to be significant uncertainty associated with the industrial and special-contract sales forecasts due to the number of parties that contact Idaho Power expressing interest in locating operations within Idaho Power's service area, typically with an unknown magnitude of the energy and peak-demand requirements. Nonetheless, the expected load forecast reflects only those industrial customers that have made a sufficient and significant binding investment, indicating a commitment of the highest probability of locating in the service area. Therefore, the large numbers of prospective businesses that have indicated an interest in locating in Idaho Power's service area but have not made sufficient commitments are not included in the current sales and load forecast.

- Conservation impacts, including DSM energy efficiency programs and codes and standards, and other naturally occurring efficiencies are considered and integrated into the sales forecast. Impacts of demand response programs (on peak) are accounted for in the load and resource balance analysis within supply-side planning (i.e., are treated as a supply-side peaking resource). The amount of committed and implemented DSM programs for each month of the planning period is shown in the load and resource balance in *Appendix C—Technical Appendix*.

- The 2017 irrigation sales forecast is higher than the 2015 IRP forecast throughout the entire forecast period due to the significant trend toward more water-intensive crops, primarily alfalfa and corn, due to growth in the dairy industry. Also, farmers have put high-lift acreage back into production. Additionally, load increases have come from the conversion of flood/furrow irrigation to sprinkler irrigation, primarily related to farmers trying to reduce labor costs.

## Peak-Hour Demands

As average demands as discussed in the preceding section are an integral component to the load forecast, so are the impact of the peak-hour demands on the system. The peak-hour forecasting regressions are expressed as a function of the sales forecast as well as the impact of peak-day temperatures. The peak forecast results and comparisons with previous forecasts differ for many reasons that include the following:

- The all-time system summer peak demand was 3,407 MW (recorded on Tuesday, July 2, 2013, at 4:00 p.m.). The system peak-hour load record was nearly matched on June 30, 2015, at 4:00 p.m., when the system peak reached 3,402 MW. Idaho Power's winter peak-hour load record is 2,527 MW, recorded on January 6, 2017, at 9:00 a.m. and matched the previous record peak dated December 10, 2009, at 8:00 a.m.

- The peak model develops peak-scenario impacts based on historical probabilities of peak-day temperatures at the 50$^{th}$, 90$^{th}$, and 95$^{th}$ percentiles of occurrence for each month of the year. The 95$^{th}$ percentile forecast of peak-hour demand is utilized for peak capacity planning purposes. These normal average peak-day temperature drivers are calculated over the 1986 to 2015 time period (the most recent 30 years).

- The 2017 IRP peak-demand forecast considers the impact of the current actualized committed and implemented energy efficiency DSM programs on peak demand.

# OVERVIEW OF THE FORECAST

The sales and load forecast is constructed by developing a separate energy forecast for each of the major customer classes: residential, commercial, irrigation, industrial, and special contracts. In conjunction with this energy (or sales) forecast, an hour peak-load forecast was prepared. In addition, several probability cases were developed for the energy and peak forecasts. Assumptions for each of the individual categories, the peak hour impacts, and probabilistic case methodologies are described in greater detail in the following sections.

## Forecast Probabilities

### *Load Forecasts Based on Weather Variability*

The future demand for electricity by customers in Idaho Power's service area is represented by three load forecasts reflecting a range of load uncertainty due to weather. The expected-case average load forecast represents the most probable projection of system load growth during the planning period and is based on the most recent national, state, MSA, and county economic forecasts and the resulting derived economic forecast for Idaho Power's service area.

The expected-case average load forecast assumes median temperatures and median precipitation (i.e., there is a 50% chance loads will be higher or lower than the expected-case loads due to colder-than-median or hotter-than-median temperatures or wetter-than-median or drier-than-median precipitation). Since actual loads can vary significantly depending on weather conditions, alternative scenarios were developed that address load variability due to varying weather conditions.

For example, Idaho Power's maximum annual average load occurs when the highest recorded levels of heating degree days (HDD) are assumed in winter and the highest recorded levels of cooling and growing degree days (CDD and GDD) combined with the lowest recorded level of precipitation are assumed in summer. Conversely, the minimum annual average load occurs when the opposite of what is described above takes place. In the 70$^{th}$-percentile residential and commercial load forecasts, temperatures in each month were assumed to be at the 70$^{th}$ percentile of HDD in wintertime and at the 70$^{th}$ percentile of CDD in summertime. In the 70$^{th}$-percentile irrigation load forecast, GDD were assumed to be at the 70$^{th}$ percentile and precipitation at the 30$^{th}$ percentile, reflecting drier-than-median weather. The 90$^{th}$-percentile load forecast was similarly constructed.

For example, the median HDD in December from 1986 to 2015 (the most recent 30 years) was 1,029, at the Boise Weather Service office. The 70$^{th}$-percentile HDD is 1,060 and would be exceeded in 3 out of 10 years. The 90$^{th}$-percentile HDD is 1,170 and would be exceeded in 1 out of 10 years. As an example, for a single month, the 100$^{th}$-percentile HDD (the coldest December over the 30 years) is 1,449, which occurred in December 1990. This same concept was applied in

each month throughout the year for the weather-sensitive customer classes: residential, commercial, and irrigation.

Since Idaho Power loads are highly dependent on weather, and the development of the above mentioned two scenarios allows the careful examination of load variability and how it may impact future resource requirements. It is important to understand that the probabilities associated with these forecasts apply to each month. This assumes temperatures and precipitation would maintain at the 70th-percentile or 90th-percentile level continuously, throughout the entire year. For Idaho Power to properly plan for future resource requirements, a similar methodology is needed for the hour of maximum demand for the year (referred to as peak demand). Table 1 summarizes the load scenarios prepared for the 2017 IRP.

**Table 1. Average load and peak-demand forecast scenarios**

| Scenario | Weather Probability | Probability of Exceeding | Weather Driver |
|---|---|---|---|
| **Forecasts of Average Load** | | | |
| 90th Percentile | 90% | 1 in 10 years | HDD, CDD, GDD, precipitation |
| 70th Percentile | 70% | 3 in 10 years | HDD, CDD, GDD, precipitation |
| Expected Case | 50% | 1 in 2 years | HDD, CDD, GDD, precipitation |
| **Forecasts of Peak Demand** | | | |
| 95th Percentile | 95% | 1 in 20 years | Peak-day temperatures |
| 90th Percentile | 90% | 1 in 10 years | Peak-day temperatures |
| 50th Percentile | 50% | 1 in 2 years | Peak-day temperatures |

The analysis of resource requirements is based on the 70th-percentile average load forecast coupled with the 95th-percentile peak-demand forecast to provide a more adverse representation of the average load and peak demand to be considered. In other Idaho Power planning, such as the preparation of the financial forecast or the operating plan, the expected-case (50th percentile) average-load forecast and the 90th-percentile peak-demand forecast are typically used.

## *Load Forecasts Based on Economic Uncertainty*

The expected-case load forecast is based on the most recent economic forecast for Idaho Power's service area and represents Idaho Power's most probable outcome for load growth during the planning period.

To provide risk assessment to economic uncertainty, two additional load forecasts for Idaho Power's service area were prepared based on the expected case forecast. The forecasts provide a range of possible load growth rates for the 2017 to 2036 planning period due to high and low economic and demographic conditions. The average growth rates for these high and low growth scenarios were derived from the historical distribution of one-year growth rates over the past 25 years (1992–2016).

Of the three scenarios 1) the expected forecast is the median growth path, 2) the standard deviation observed during the historical time period is used to estimate the dispersion around the expected-case scenario, and 3) the variation in growth rates will be equivalent to the variation in growth rates observed over the past 25 years (1992–2016).

From the above methodology, two views of probable outcomes from the forecast scenarios—the probability of exceeding and the probability of occurrence—were developed and are reported in Table 2. The probability of exceeding the likelihood the actual load growth will be greater than the projected growth rate in the specified scenario. For example, over the next 20 years, there is a 10-percent probability the actual growth rate will exceed the growth rate projected in the high scenario; additionally, it can be inferred that for the stated periods there is an 80 percent probability the actual growth rate will fall between the low and high scenarios.

The second probability estimate, the probability of occurrence, indicates the likelihood the actual growth will be closer to the growth rate specified in that scenario than to the growth rate specified in any other scenario. For example, there is a 26-percent probability the actual growth rate will be closer to the high scenario than to any other forecast scenario for the entire 20-year planning horizon.

**Table 2. Forecast probabilities**

| Probability of Exceeding | | | | |
|---|---|---|---|---|
| **Scenario** | **1-year** | **5-year** | **10-year** | **20-year** |
| Low Growth | 90% | 90% | 90% | 90% |
| Expected Case | 50% | 50% | 50% | 50% |
| High Growth | 10% | 10% | 10% | 10% |
| **Probability of Occurrence** | | | | |
| **Scenario** | **1-year** | **5-year** | **10-year** | **20-year** |
| Low Growth | 26% | 26% | 26% | 26% |
| Expected Case | 48% | 48% | 48% | 48% |
| High Growth | 26% | 26% | 26% | 26% |

This probabilistic analysis was applied to Idaho Power's system load forecast. Its impact on the system load forecast is the sum of the individual loads of residential, commercial, industrial, and irrigation customers, as well as special contracts (including past sales to Astaris, Inc.) and on-system contracts (including past sales to Raft River Coop and the City of Weiser).

Results of Idaho Power's system load projections are reported in Table 3 and shown in Figure 1. The expected-case system load-forecast growth rate averages 0.9 percent per year over the 20-year planning period. The low scenario projects the system load will increase at an average rate of 0.4 percent per year throughout the forecast period. The high scenario projects a load growth of 1.3 percent per year. Idaho Power has experienced both the high- and low-growth rates in the past. These forecasts provide a range of projected growth rates that cover approximately 80 percent of the probable outcomes as measured by Idaho Power's historical experience.

**Table 3. System load growth (aMW)**

| Growth | 2017 | 2021 | 2026 | 2036 | Annual Growth Rate 2017–2036 |
|---|---|---|---|---|---|
| Low | 1,748 | 1,765 | 1,810 | 1,891 | 0.4% |
| Expected | 1,810 | 1,894 | 1,990 | 2,142 | 0.9% |
| High | 1,835 | 1,968 | 2,111 | 2,351 | 1.3% |

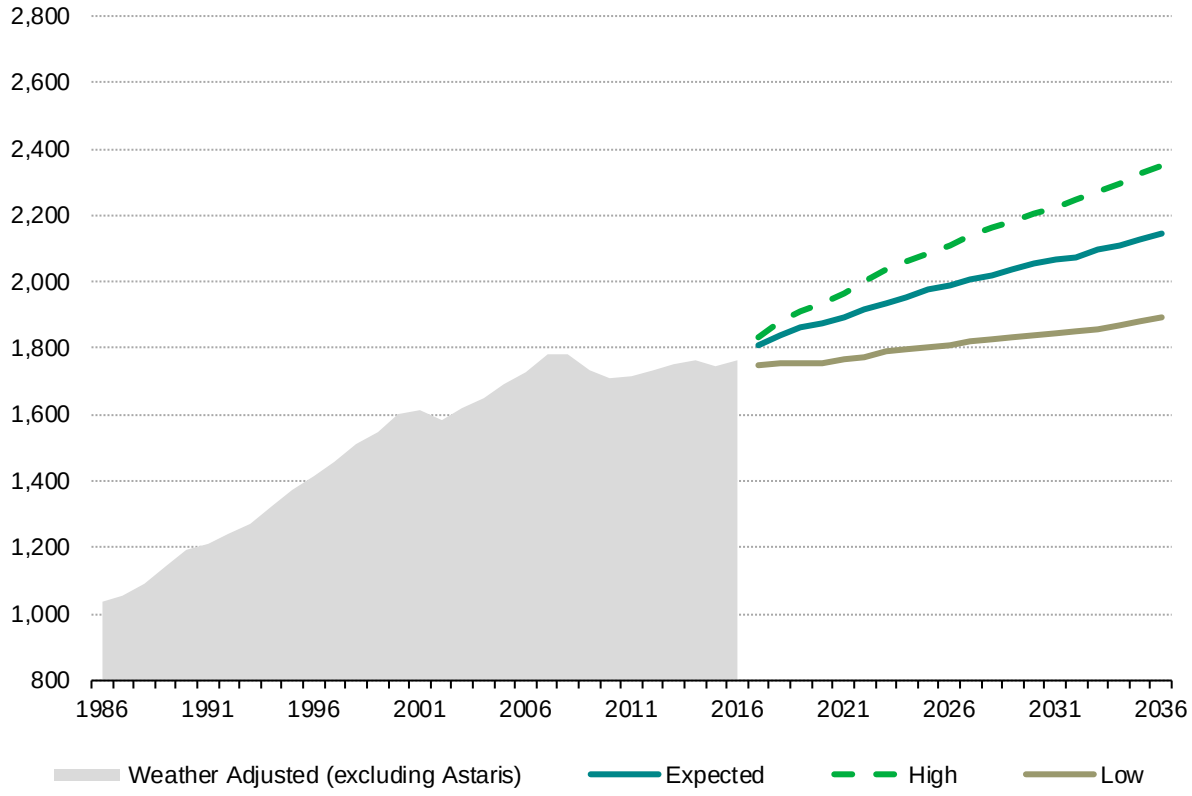

**Figure 1. Forecast system load (aMW)**

# RESIDENTIAL

The expected-case residential load is forecast to increase from 594 aMW in 2017 to 747 aMW in 2036, an average annual compound growth rate of 1.2 percent. In the 70th-percentile scenario, the residential load is forecast to increase from 612 aMW in 2017 to 772 aMW in 2036, matching the expected-case residential growth rate. The residential load forecasts are reported in Table 4 and shown in Figure 2.

**Table 4. Residential load growth (aMW)**

| Growth | 2017 | 2021 | 2026 | 2036 | Annual Growth Rate 2017–2036 |
|---|---|---|---|---|---|
| 90th Percentile | 643 | 681 | 730 | 810 | 1.2% |
| 70th Percentile | 612 | 648 | 695 | 772 | 1.2% |
| Expected Case | 594 | 628 | 673 | 747 | 1.2% |

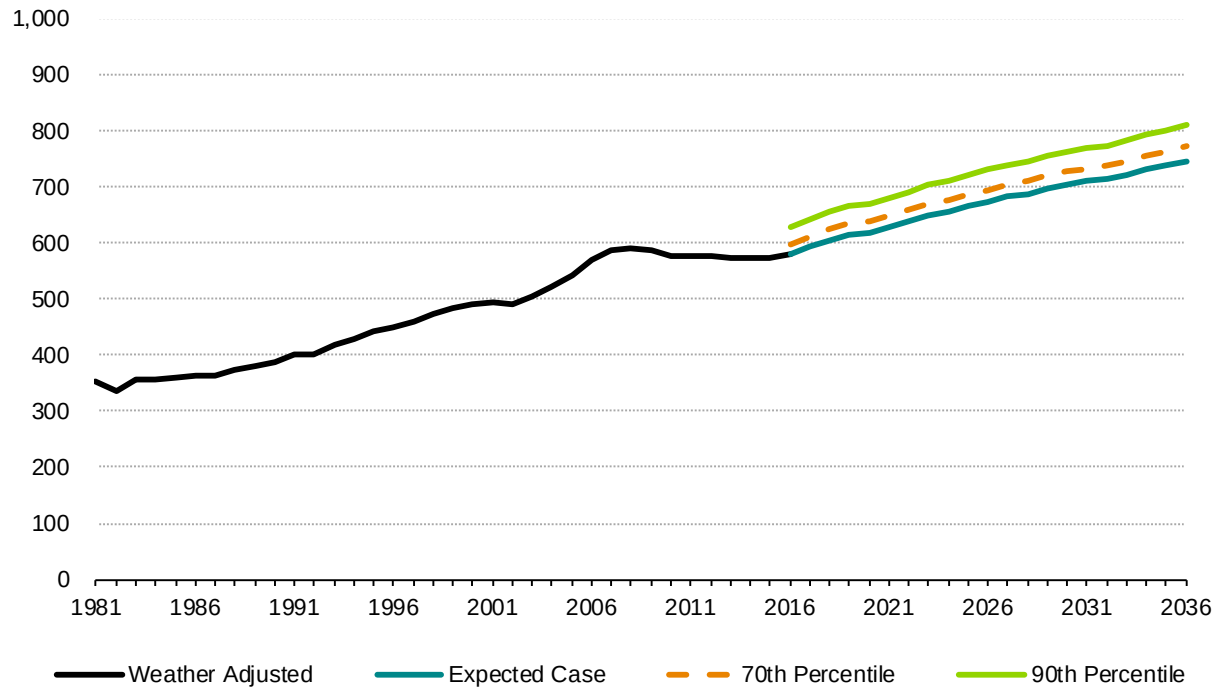

**Figure 2. Forecast residential load (aMW)**

Sales to residential customers made up 32 percent of Idaho Power's system sales in 1986 and 36 percent of system sales in 2016. The residential customer proportion of system sales is forecast to be approximately 38 percent in 2036. The number of residential customers is projected to increase to approximately 632,000 by December 2036.

The average sales per residential customer increased to over 14,700 kilowatt-hours (kWh) in 1980 before declining to 13,100 kWh in 2001. In 2002 and 2003, residential use per customer dropped dramatically—nearly 500 kWh per customer from 2001—the result of two years of significantly higher electricity prices in those years combined with a weak national and service-area economy. The reduction in electricity prices in June 2003 and a recovery in the service-area economy caused residential use per customer to stabilize through 2007. However, the recession in 2008 and 2009 and conservation efforts further reduced residential use per customer. This trend is expected to continue, as the average sales per residential customer are expected to decline to approximately 10,500 kWh per year in 2036. Average annual sales per residential customer are shown in Figure 3.

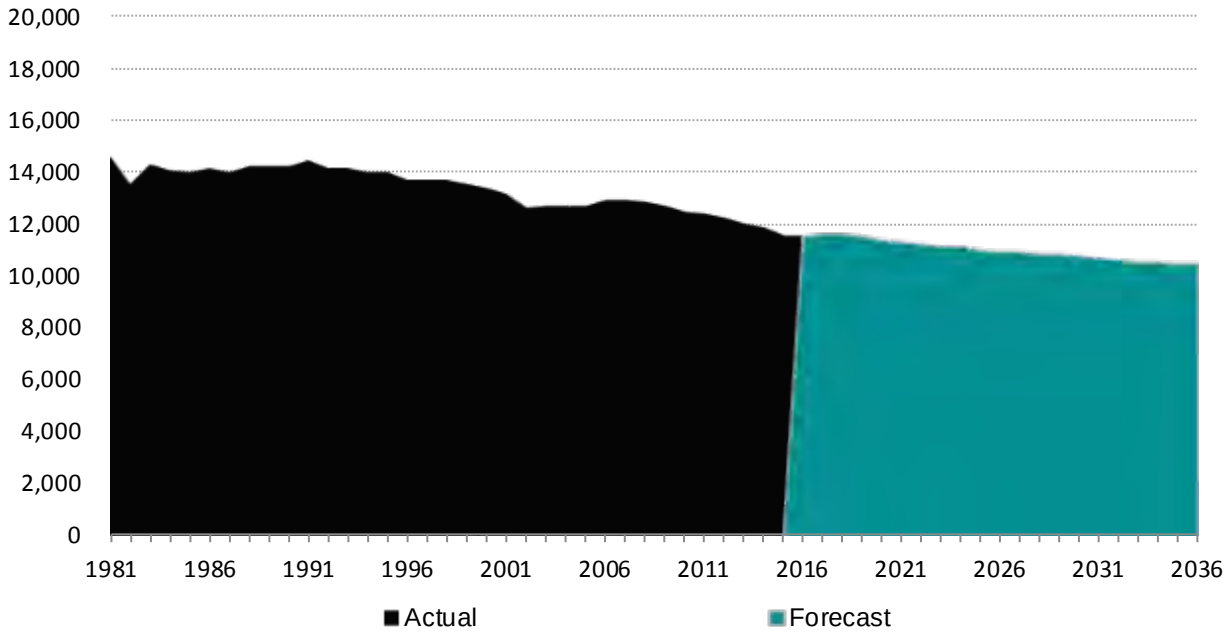

**Figure 3. Forecast residential use per customer (weather-adjusted kWh)**

Residential customer growth in Idaho Power's service area is a function of the number of new service-area households as derived from Moody's Analytics' May 2016 forecast of county housing stock and demographic data. The residential-customer forecast for 2017 to 2036 shows an average annual growth rate of 1.8 percent.

Sales to residential retail customers is an equation that considers several factors affecting electricity sales to the residential sector. Residential sales are a function of HDD (wintertime); CDD (summertime); the number of service-area households; the real price of electricity; and the real price of natural gas.

# COMMERCIAL

The commercial category is primarily made up of Idaho Power's small general-service and large general-service customers. Other customers associated with this category include unmetered general service, street-lighting service, traffic-control signal lighting service, and dusk-to-dawn customer lighting.

Within the expected-case scenario, the commercial load is projected to increase from 466 aMW in 2017 to 535 aMW in 2036 (Table 5). The average annual compound-growth rate of the commercial load is 0.7 percent during the forecast period. The commercial load in the 70$^{th}$-percentile scenario is projected to increase from 471 aMW in 2017 to 543 aMW in 2036. The commercial load forecasts are illustrated in Figure 4.

**Table 5. Commercial load growth (aMW)**

| Growth | 2017 | 2021 | 2026 | 2036 | Annual Growth Rate 2017–2036 |
|---|---|---|---|---|---|
| 90$^{th}$ Percentile | 480 | 498 | 517 | 556 | 0.8% |
| 70$^{th}$ Percentile | 471 | 489 | 507 | 543 | 0.7% |
| Expected Case | 466 | 482 | 500 | 535 | 0.7% |

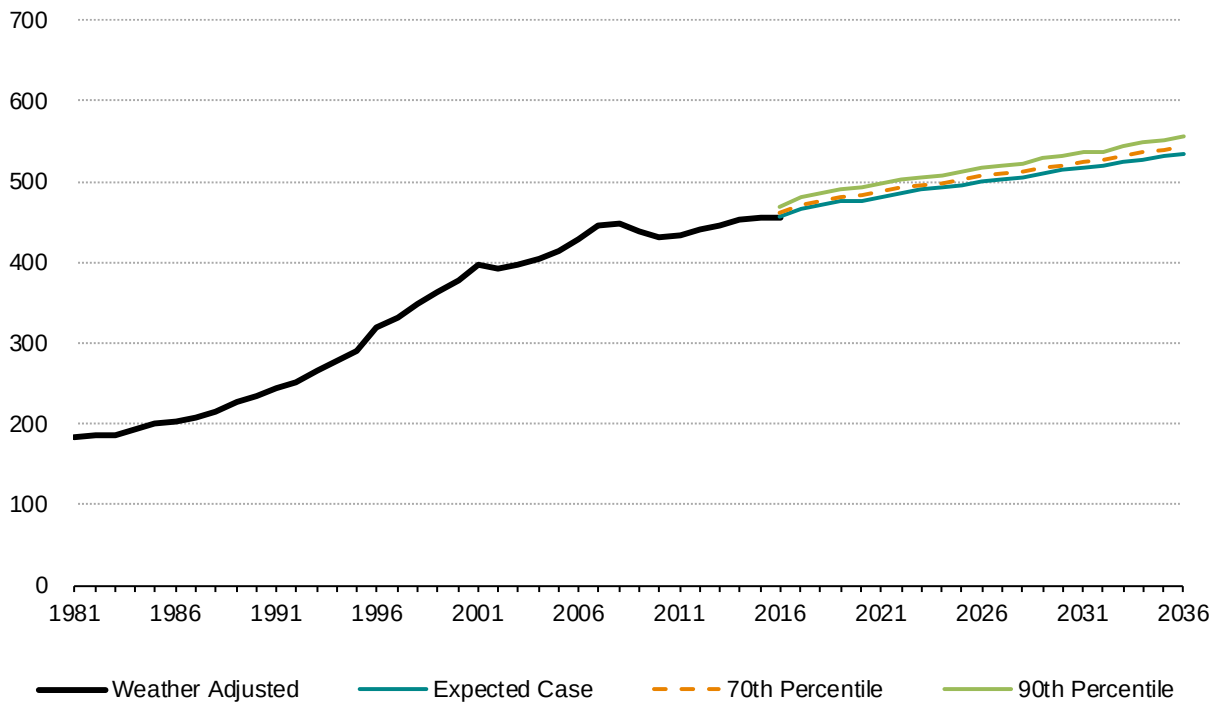

**Figure 4. Forecast commercial load (aMW)**

With a customer base of nearly 69,000, the commercial class represents the diversity of the service area economy, ranging from residential subdivision pressurized irrigation to

manufacturing. Due to this diversity, the category is further segmented into categories associated with common elements of energy-use influences, such as economic variables (e.g., employment), industry (e.g., manufacturing), and building structure characteristics (e.g., offices). Figure 5 shows the breakdown of the categories and their relative sizes based on 2016 billed energy sales.

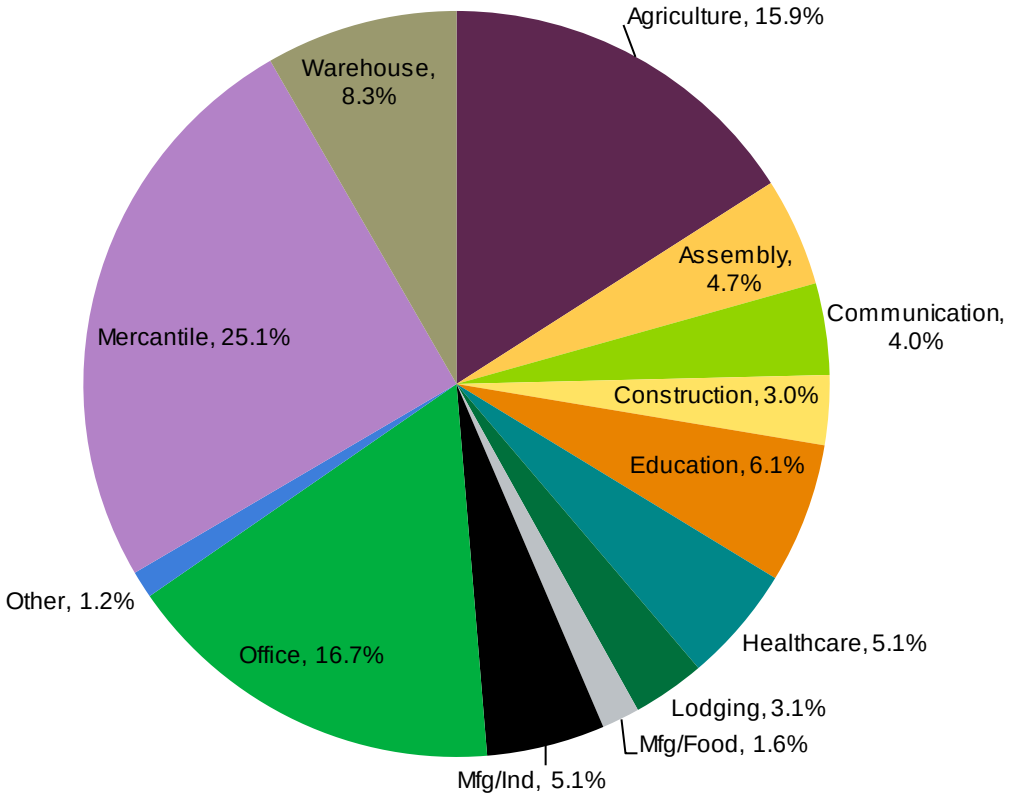

**Figure 5. Commercial building share—energy bills**

As indicated in Figure 5, the retail goods and service providers of the Mercantile category represent the largest commercial category of energy use, with 25.1% percent of total 2016 use. Total usage in this category has moderated, even considering the growth in total number of customers. This moderation is primarily due to customer consolidation, growth in internet-based sales, and energy efficient retrofit and new-construction technology implementation (particularly in the area of lighting) has grown. Categories showing significant post-recession (2011 to 2016) energy growth include Industrial/Manufacturing (+19.0%), Health Care (+19.2%), and Wholesale Trade (+17.6%).

The number of commercial customers is expected to increase at an average annual rate of 1.8 percent, reaching 97,500 customers by December 2036. The commercial customer forecast for 2017 to 2036 shows an average annual growth rate of 1.8 percent.

In 1986, customers in the commercial category consumed approximately 18 percent of Idaho Power system sales, growing to 28 percent by 2016. This share is forecast to remain at the upper end of this range throughout the planning period.

Figure 6 shows historical and forecast average use per customer (UPC) for the entire category. The commercial-use-per-customer metric in Figure 6 represents an aggregated metric for a highly diverse group of customers with significant differences in total energy use per customer, but it is instructive in aggregate for comparative purposes.

The UPC peaked in 2001 at 67,400 kWh and has declined at approximately 1.00 percent compounded annually to 2016. The UPC is forecast to decrease at an annual rate of 1.0 percent over the planning period. For this category, common elements that drive use down include increases in electricity prices, business-cycle recessions, and the adoption of energy efficiency technology. Within the commercial class UPC varies widely, reflecting the diversity of customer mix and range of operational size.

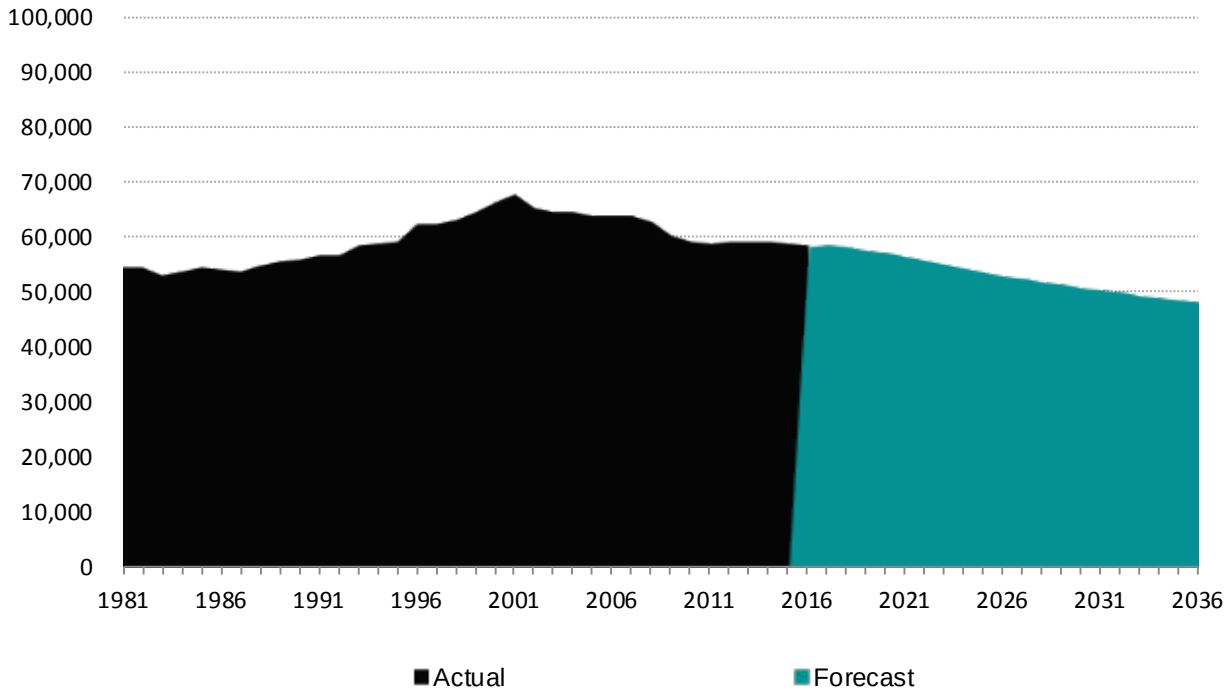

**Figure 6. Forecast commercial use per customer (weather-adjusted kWh)**

Figure 7 shows the diversity in the commercial segment's UPC as well as the trend for these sectors. The figure shows the 2016 UPC for each segment relative to the 2011 UPC. A value greater than 1.0 indicates the UPC has risen over the period. The figure supports the general decline of the aggregated trend of Figure 6 but highlights differences in energy and economic dynamics within the heterogeneous commercial category not evident in the residential category.

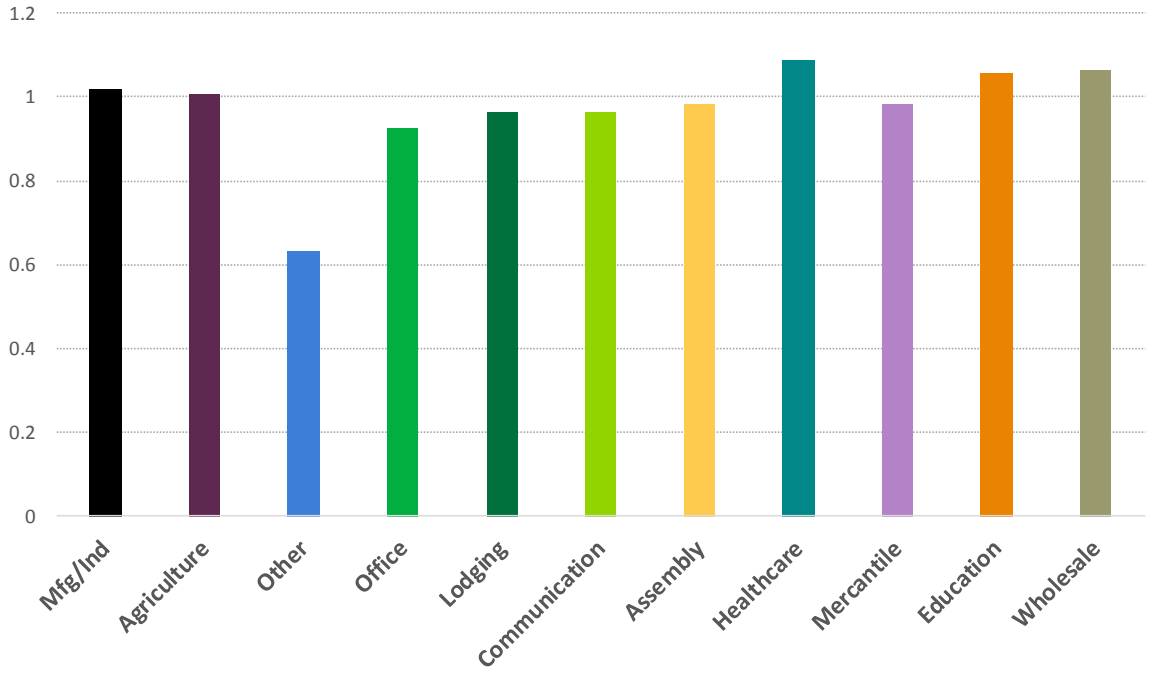

**Figure 7. Commercial categories UPC, 2016 relative to 2011**

Energy efficiency implementation is a large determinant in UPC decline over time. In the commercial sector, the primary DSM technology impact has come from lighting. The categories of Mercantile and Office are particularly dominant in this implementation as indicated by the UPC trend. Faster growing categories, such as Wholesale and Healthcare tend to show positive UPC trends. Other influences on UPC include differences in price sensitivity, sensitivity to business cycles and weather, and degree and trends in automation. In addition, category UPC can vary when a customer's total use increases to the point where it must, by tariff rules, migrate to an industrial (Rate 19) category. Due to tariff migration, which occurs at the boundary of Schedule 9P (large primary commercial) and Schedule 19 (large industrial), the forecast models aggregate the energy use of these two schedules to ensure continuity in the dependent variable.

The commercial-sales forecast equations consider several varying factors, as informed by the regression models, and vary depending on the sub-category. Typical variables include weather: HDD (wintertime); CDD (summertime); specific industry growth characteristics and outlook; service-area demographics and their derivatives, such as households, employment, and small business conditions; the real price of electricity; and energy efficiency adoption.

# IRRIGATION

The irrigation category is comprised of agricultural irrigation service customers. Service under this schedule is applicable to power and energy supplied to agricultural-use customers at one point-of-delivery for operating water pumping or water-delivery systems to irrigate agricultural crops or pasturage.

The expected-case irrigation load is forecast to increase slowly from 221 aMW in 2017 to 246 aMW in 2036, an average annual compound growth rate of 0.6 percent. The expected-case, 70$^{th}$-percentile, and 90$^{th}$-percentile scenarios forecast slow growth in irrigation load from 2017 to 2036. In the 70$^{th}$-percentile scenario, irrigation load is projected to be 235 aMW in 2017 and 260 aMW in 2036. The individual irrigation load forecasts are summarized in Table 6 and illustrated in Figure 8.

**Table 6. Irrigation load growth (aMW)**

| Growth | 2017 | 2021 | 2026 | 2036 | Annual Growth Rate 2017–2036 |
|---|---|---|---|---|---|
| 90$^{th}$ Percentile | 254 | 259 | 266 | 279 | 0.5% |
| 70$^{th}$ Percentile | 235 | 240 | 247 | 260 | 0.5% |
| Expected Case | 221 | 226 | 233 | 246 | 0.6% |

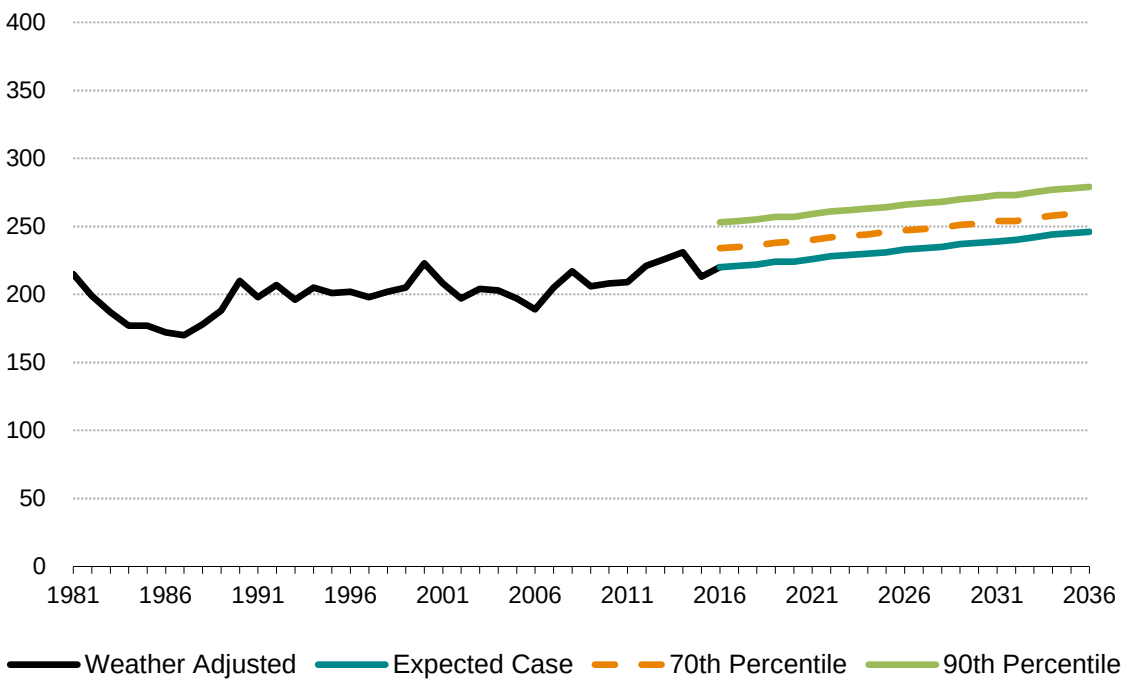

**Figure 8. Forecast irrigation load (aMW)**

The annual average loads in Table 6 and Figure 8 are calculated using the 8,760 hours in a typical year. In the highly seasonal irrigation sector, over 97 percent of the annual energy is

billed during the six months from May through October, and nearly half of the annual energy is billed in just two months, July and August. During the summer, hourly irrigation loads can reach nearly 900 MW. In a normal July, irrigation pumping accounts for roughly 25 percent of the energy consumed during the hour of the annual system peak and nearly 30 percent of the energy consumed during July for general business sales. The 2017 irrigation sales forecast is higher than the 2015 IRP forecast throughout the forecast period due to the trend toward more water-intensive crops, primarily alfalfa and corn, due to growth in the dairy industry. Also, farmers have put high-lift acreage back into production. Additionally, the increased customer count from the conversion of flood/furrow irrigation to sprinkler irrigation, primarily related to farmers trying to reduce labor costs, explains most of the increased energy consumption in recent years.

The 2017 irrigation sales forecast model considers several factors affecting electricity sales to the irrigation class, including temperature; precipitation; spring rainfall; Palmer Z Index (calculated by the National Ocean and Atmospheric Administration [NOAA] from a combination of precipitation, temperature, and soil moisture data); Moody's Gross Product*: Agriculture, for Idaho*; *Moody's Producer Price Index: Prices Received by Farmers, All Farm Products*; and the real price of electricity. Considerations were made for the unusually low electricity consumption in the 2001 crop year due to a voluntary load-reduction program.

Actual irrigation electricity sales have grown from the 1970 level of 816,000 megawatt-hours (MWh) to a peak amount of 2,097,000 MWh in 2013. In 1977, irrigation sales reached a maximum proportion of 20 percent of Idaho Power system sales. In 2016, the irrigation proportion of system sales was 14 percent due to the much higher relative growth in other customer classes. By 2036, irrigation customers are projected to consume about 12 to 13 percent of Idaho Power system sales.

Regarding customer growth, in 1980, Idaho Power had about 10,850 active irrigation accounts. By 2016, the number of active irrigation accounts had increased to 20,042 and is projected to be nearly 26,000 at the end of the planning period in 2036.

As with other sectors, average use per customer is an important consideration. Since 1988, Idaho Power has experienced growth in the number of irrigation customers but slow growth in total electricity sales (weather-adjusted) to this sector. The number of customers has increased because customers are converting previously furrow-irrigated land to sprinkler-irrigated land. The conversion rate is slow and the kWh use per customer is substantially lower than the average existing Idaho Power irrigation customer. This is because water for sprinkler conversions is drawn from canals and not pumped from deep groundwater wells. In future forecasts, factors related to the conjunctive management of ground and surface water and the possible litigation associated with the resolution will require consideration. Depending on the resolution of these issues, irrigation sales may be impacted.

# INDUSTRIAL

The industrial category is comprised of Idaho Power's large power service (Schedule 19) customers requiring monthly metered demands between 1,000 kilowatts (kW) and 20,000 kW. The category name "Industrial" is reflective of load requirements and not necessarily indicative of the industrial nature of the customers' business.

In 1980, Idaho Power had about 112 industrial customers, which represented about 12 percent of Idaho Power's system sales. By December 2016, the number of industrial customers had risen to 118, representing approximately 17 percent of system sales. As mentioned earlier in the commercial discussion, customer counts in this tariff class are impacted by migration from and to the commercial class as dictated by the tariff rules. However, generally speaking, customer count growth is primarily illustrative of the positive economic conditions in the service area. Customers with load greater than Schedule 19 ranges are known as special contract customers and are addressed in the Additional Firm Load section of this document.

In the expected-case forecast, industrial load grows from 281 aMW in 2017 to 320 aMW in 2036, an average annual growth rate of 0.7 percent (Table 7). To a large degree, industrial load variability is not associated with weather conditions as is the case with residential, commercial, and irrigation; therefore, the forecasts in the 70$^{th}$- and 90$^{th}$-percentile weather scenarios are identical to the expected-case industrial load scenario. The industrial load forecast is pictured in Figure 9.

**Table 7. Industrial load growth (aMW)**

| Growth | 2017 | 2021 | 2026 | 2036 | Annual Growth Rate 2017–2036 |
|---|---|---|---|---|---|
| Expected Case | 281 | 297 | 305 | 320 | 0.7% |

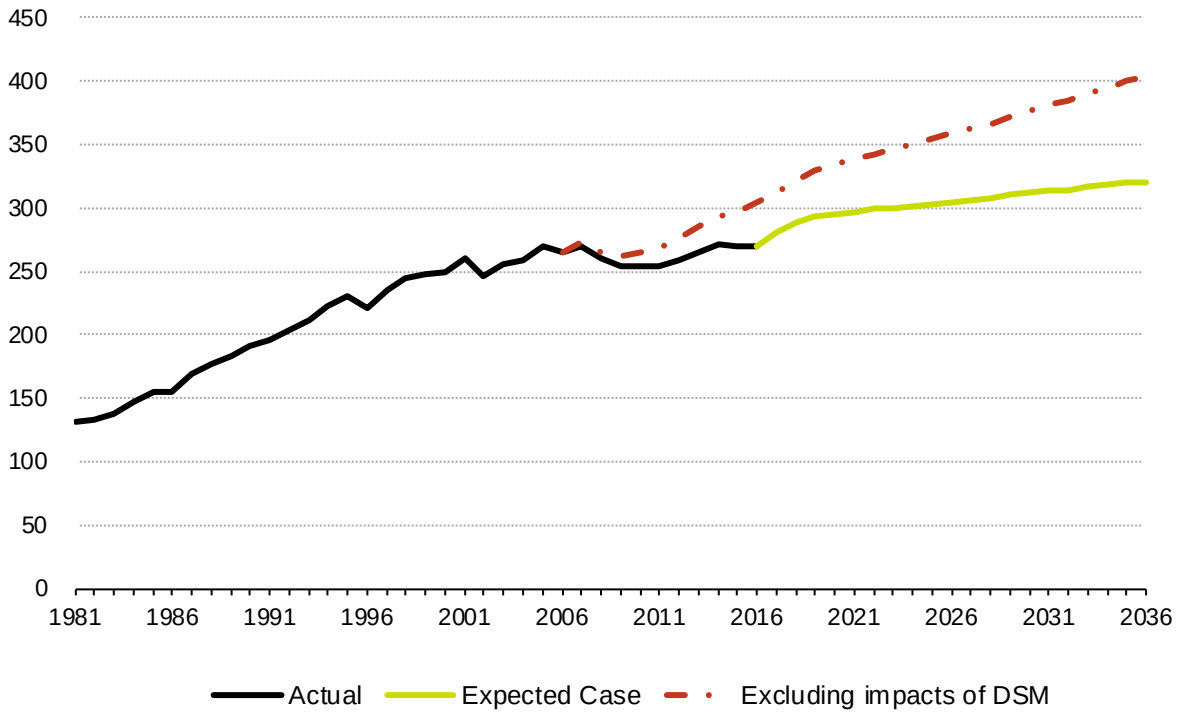

**Figure 9. Forecast industrial load (aMW)**

As indicated in the figure, the load growth variability is impacted by both economic and other non-weather factors, most particularly the impacts of DSM. The figure highlights the magnitude of DSM on actual and forecast sales. In developing the forecast, customer-specific DSM implementation is isolated, and the actual energy use is adjusted to remove the impacts of DSM to optimize the causal influence of non-DSM causal variables. The history and forecast of DSM is provided by the DSM specialists within Idaho Power. The economic and other independent variables for the regression models are provided by third-party data providers and internally derived time-series for Idaho Power's service area.

Figure 10 illustrates the 2016 share of each of the categories within the Rate 19 customers. By far, the largest share of electricity was consumed by the food manufacturing sector (36%), followed by dairy (18.7%) and electronics/technology (Electech) (7%). The categorization scheme includes a range of industrial building types (assembly, lodging, mercantile, warehouse, office, education, health care). These provide the basis for capturing, modeling, and forecasting the shifting economic landscape that influences industrial category electricity sales.

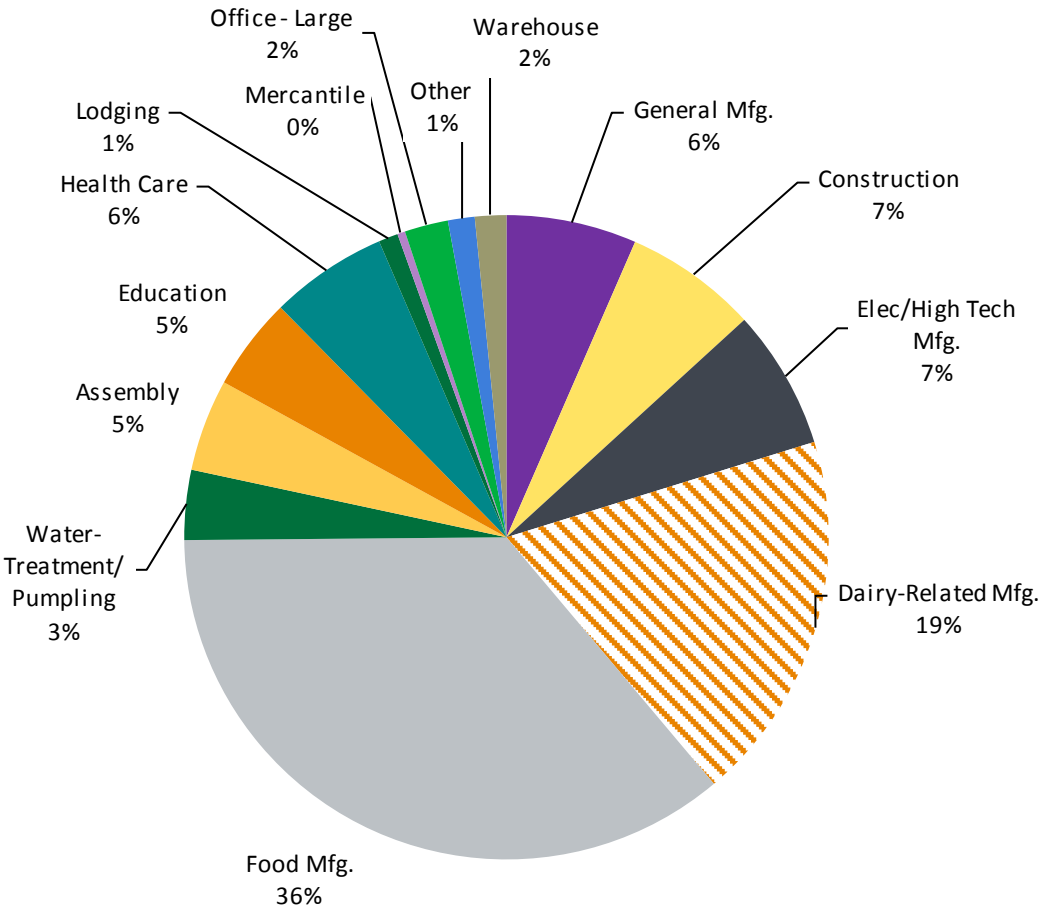

**Figure 10. Industrial electricity consumption by industry group (based on 2016 sales)**

The regression models and associated explanatory variables resulting from the categorization establish the relationship between historical electricity sales and historical independent economic, price, technological, demographic, and other influences in the form of estimated coefficients from the industry group regression models applied to the appropriate forecasts of independent time series of energy use. From this output, the history and forecast of DSM is subtracted.

This page left blank intentionally.

# ADDITIONAL FIRM LOAD

The additional firm load category consists of Idaho Power's largest customers. Idaho Power's tariff requires the company serve requests for electric service greater than 20 MW under a special-contract schedule negotiated between Idaho Power and each large-power customer. The contract and tariff schedule are approved by the appropriate regulatory body. A special contract allows customer-specific, cost-of-service analysis and unique operating characteristics to be accounted for in the agreement.

Individual energy and peak-demand forecasts are developed with for special-contract customers, including Micron Technology, Inc.; Simplot Fertilizer Company (Simplot Fertilizer); and the Idaho National Laboratory (INL). These three special-contract customers comprise the forecast category labeled additional firm load.

In the expected-case forecast, additional firm load is expected to increase from 108 aMW in 2017 to 124 aMW in 2036, an average growth rate of 0.7 percent per year over the planning period (Table 8). The additional firm load energy and demand forecasts in the 70$^{th}$- and 90$^{th}$-percentile scenarios are identical to the expected-load growth scenario. The scenario of projected additional firm load is illustrated in Figure 11.

**Table 8. Additional firm load growth (aMW)**

| Growth | 2017 | 2021 | 2026 | 2036 | Annual Growth Rate 2017–2036 |
|---|---|---|---|---|---|
| Expected Case..... | 108 | 112 | 124 | 124 | 0.7% |

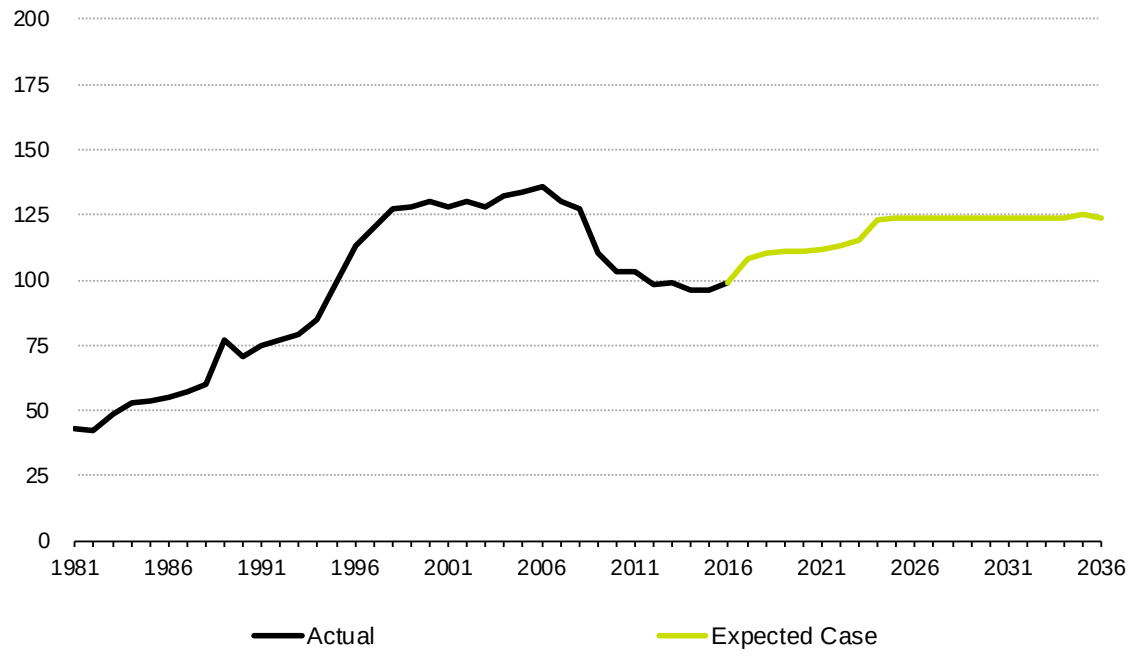

**Figure 11. Forecast additional firm load (aMW)**

## Micron Technology

Micron Technology represents Idaho Power's largest electric load for an individual customer and employs approximately 5,000 workers in the Boise MSA. The company operates its research and development fabrication facility in Boise and performs a variety of other activities, including product design and support, quality assurance, systems integration and related manufacturing, corporate services, and general services. Micron Technology's electricity use is a function of the market demand for their products.

## Simplot Fertilizer

The Simplot Fertilizer plant is the largest producer of phosphate fertilizer in the western United States (US). The future electricity usage at the plant is expected to grow slowly through 2016, then stay flat throughout the remainder of the planning period.

## Idaho National Laboratory

INL is part of the US Department of Energy's (DOE) complex of national laboratories. INL is the nation's leading center for nuclear energy research and development. The DOE provided an energy-consumption and peak-demand forecast through 2036 for the INL. The forecast calls for loads to increase through 2024 and levelize throughout the forecast period.

# ENERGY EFFICIENCY AND DEMAND RESPONSE

Energy efficiency and demand response impacts are treated differently in the forecasting and planning process. Energy efficiency impacts (reductions in energy use) are explicitly integrated into the forecast models. Demand response impacts are explicitly *excluded* from the forecast models; the impacts of demand response are modeled in the load and resource balance as a supply-side resource for reducing peak-demand periods.

## Energy Efficiency

Energy efficiency (EE) influences on past and future load consist of utility programs, statutory codes, and manufacturing standards for appliances, equipment, and building materials that reduce energy consumption. As the influence of statutory codes and manufacturing standards on residential and commercial customers has increased in importance relative to utility programs, Idaho Power forecast models have been modified to ensure they capture these influences. For residential models, the physical unit flow of energy-efficient products is captured through shipment data to resellers and installers. The source for this data is the DOE (the data also serves as input to the DOE National Energy Model [NEM]), and the data is refined by Itron for utility-specific applications. This data captures energy-efficient installations regardless of the source (e.g., programs, standards, and codes). However, Idaho Power closely monitors the assumptions and impacts of DOE data to ensure the model correctly captures all energy efficiency impacts.

Energy Efficiency data for irrigation customers and some commercial and industrial customers is not directly surveyed and collected by the DOE; therefore, models for efficiency impacts have been developed derived from methodologies established in Itron's white paper, *Incorporating DSM into the Load Forecast*.[2] These approaches include; isolating historical efficiency data and removing the impacts from historical sales (as previously discussed in application to the industrial customers); applying historical and forecast EE as an independent variable in the regression model (this method was utilized for the commercial customers); and marginal comparison of DSM growth rates for historical versus forecast trend. If there is a significant change in future trends (i.e., trends unseen by the regression model of historical energy and conservation trends), the forecast output is adjusted to realize the trend change embedded in the regression output. These alternate models utilize energy efficiency data provided by Idaho Power's internal DSM group. The DSM group develops an independent energy efficiency/DSM forecast in collaboration with AEG consultants. This data served as direct input into the commercial, industrial, and irrigation models. The forecast developed by Idaho Power coincides

[2] Stuart McMenamin and Mark Quan. *Incorporating DSM into the Load Forecast*. Itron, https://www.itron.com/na/PublishedContent/Incorporating%20DSM%20into%20the%20Load%20Forecast.pdf (accessed February 3, 2011).

with models that AEG developed. Output for all category forecasts are compared to the AEG output as well as data from DOE Form 861 of utility-reported data. Data from regional utility acquisition is compared to Idaho Power data to ensure the regional assumptions are consistent with Idaho Power assumptions in capturing all energy savings.

Energy savings from utility energy efficiency programs are typically measured and reported at the point of delivery (customer's meter). Therefore, energy efficiency savings are increased by the amount of energy lost in transmitting the electricity from the generation source to the customer's meter.

## Demand Response

Beginning with the 2009 IRP, the reduction in load associated with demand response programs has been effectively treated as a supply-side resource and accounted for in the load and resource balance. Demand response program data, including operational targets for demand reduction, program expenses, and cost-effective summaries are detailed in *Appendix C—Technical Appendix*.

As supply-side resources, demand response program impacts are not incorporated into the sales and load forecast. In the load and resource balance, the forecast of existing demand response programs is subtracted from the peak-hour load forecast prior to accounting for existing supply-side resources. Likewise, the performance of new demand response programs is accounted for prior to determining the need for additional supply-side resources. However, because energy efficiency programs have an impact on peak demand reduction, a component of peak-hour load reduction is integrated into the sales and load forecast models. This provides a consistent treatment of both types of programs, as energy efficiency programs are considered in the sales and load forecast, while all demand response programs are included in the load and resource balance.

A thorough description of each of the energy efficiency and demand response programs is included in *Appendix B—Demand Side Management 2016 Annual Report*.

# COMPANY SYSTEM PEAK

System peak load includes the sum of the coincident peak demands of residential, commercial, industrial, and irrigation customers, as well as special contracts (including Astaris, historically) and on-system contracts (Raft River and the City of Weiser, historically).

The all-time system summer peak demand was 3,407 MW, recorded on Tuesday, July 2, 2013, at 4:00 p.m. That record was approached when the peak demand reached 3,402 MW on Tuesday, June 30, 2015, at 4:00 p.m. The system summer peak load growth accelerated from 1998 to 2008 as a record number of residential, commercial, and industrial customers were added to the system and air conditioning (A/C) became standard in nearly all new residential homes and new commercial buildings.

Idaho Power has two peak periods: 1) a winter peak, resulting primarily from space-heating demand that normally occurs in December, January, or February and 2) a larger summer peak that normally occurs in late June or July, which coincides with cooling load and irrigation pumping demand.

For resource planning purposes in the 95$^{th}$-percentile forecast, the system summer peak load is expected to increase from 3,586 MW in 2017 to 4,641 MW in 2036. In the 90$^{th}$-percentile forecast, the system summer peak load is expected to increase from 3,566 MW in 2017 to 4,613 MW in 2036, an average growth rate of 1.4 percent per year over the planning period (Table 9).

**Table 9. System summer peak load growth (MW)**

| Growth | 2017 | 2021 | 2026 | 2036 | Annual Growth Rate 2017–2036 |
|---|---|---|---|---|---|
| 95$^{th}$ Percentile | 3,586 | 3,819 | 4,102 | 4,641 | 1.4% |
| 90$^{th}$ Percentile | 3,566 | 3,797 | 4,078 | 4,613 | 1.4% |
| 50$^{th}$ Percentile | 3,446 | 3,668 | 3,937 | 4,449 | 1.4% |

The three scenarios of projected system summer peak loads are illustrated in Figure 12. Much of the variation in peak load is due to weather conditions. Although not entirely, unique economic events as occurred in the summer of 2001, when the summer peak was dampened by the nearly 30-percent curtailment in irrigation load due to the 2001 voluntary load-reduction program.

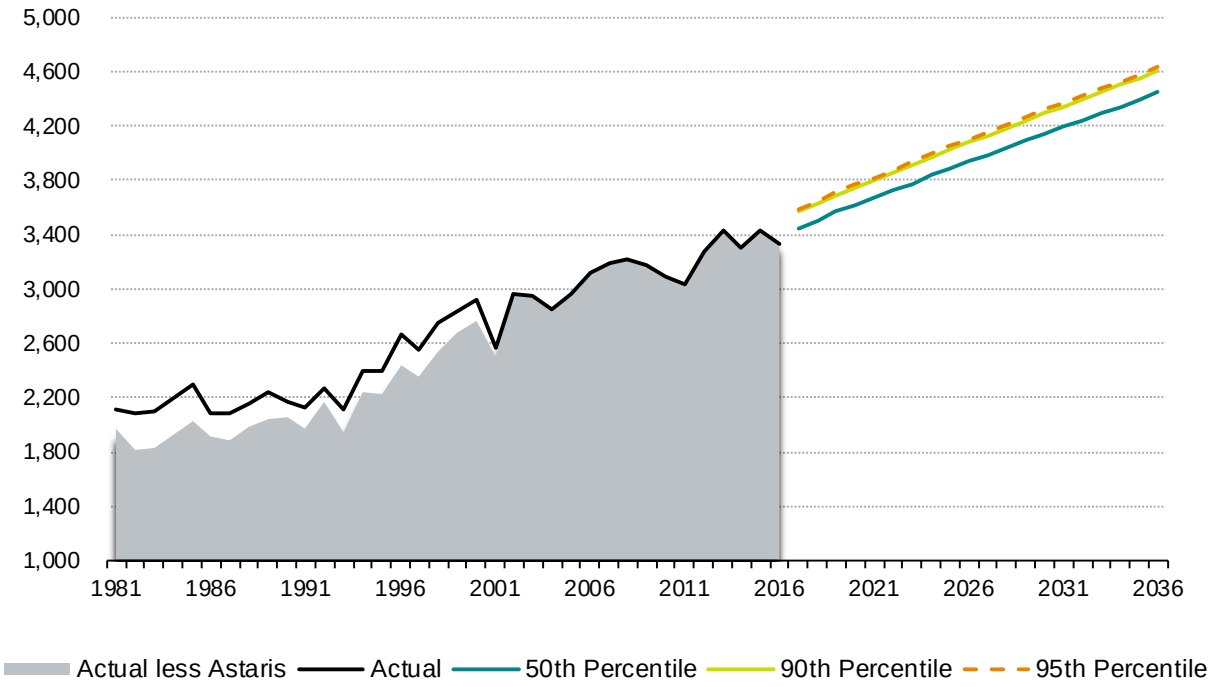

**Figure 12. Forecast system summer peak (MW)**

As of December 31, 2016, the all-time system winter peak demand was 2,527 MW, reached on Thursday, December 10, 2009, at 8:00 a.m. and January 06, 2017, at 9:00am. As shown in Figure 13, the historical system winter peak load is much more variable than the summer system peak load. This is because the variability of peak-day temperatures in winter months is more significant than the variability of peak-day temperatures in summer months. The wider spread of the winter peak forecast lines in Figure 13 illustrates the higher variability associated with winter peak-day temperatures.

For resource planning purposes, 95$^{th}$-percentile forecast, the system winter peak load is expected to increase from 2,611 MW in 2017 to 2,896 MW in 2036, an average growth rate of 0.5 percent per year over the planning period (Table 10). In the 90$^{th}$-percentile forecast, the system winter peak load is expected to increase from 2,517 MW in 2017 to 2,846 MW in 2036, an average growth rate of 0.9 percent per year over the planning period (Table 10). The three scenarios of projected system winter peak load are illustrated in Figure 13.[3]

[3] Idaho Power uses a median peak-day temperature driver in lieu of an average peak-day temperature driver in the 50/50 peak-demand forecast scenario. The median peak-day temperature has a 50-percent probability of being exceeded. Peak-day temperatures are not normally distributed and can be skewed by one or more extreme observations; therefore, the median temperature better reflects expected temperatures within the context of probabilistic percentiles. The weighted average peak-day temperature drivers are calculated over the 1986 to 2015 time period (the most recent 30 years).

**Table 10. System winter peak load growth (MW)**

| Growth | 2017 | 2021 | 2026 | 2036 | Annual Growth Rate 2017–2036 |
|---|---|---|---|---|---|
| 95th Percentile | 2,611 | 2,691 | 2,769 | 2,896 | 0.5% |
| 90th Percentile | 2,517 | 2,596 | 2,675 | 2,846 | 0.7% |
| 50th Percentile | 2,294 | 2,415 | 2,534 | 2,732 | 0.9% |

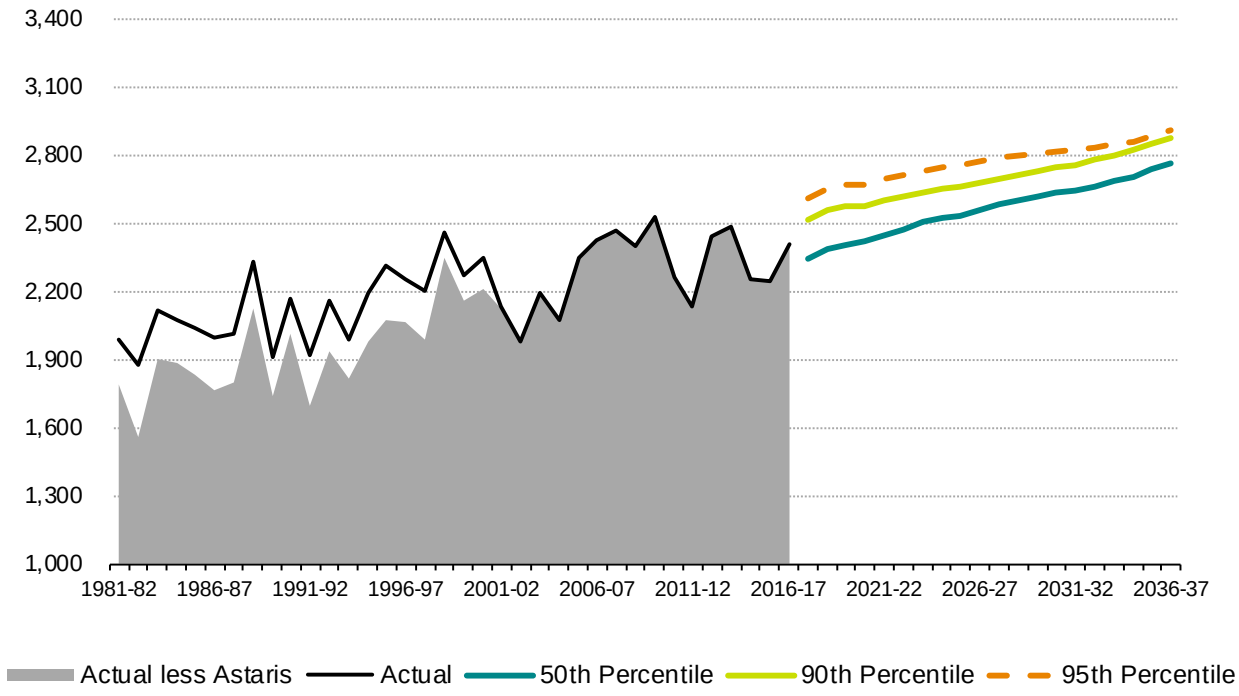

**Figure 13. Forecast system winter peak (MW)**

Additionally, note the 2017 IRP peak-demand forecast model explicitly excludes the impact of demand response programs to establish peak impacts. The exclusion allows for planning for demand response programs and supply-side resources in meeting peak demand. Demand response program impacts are accounted for in the IRP load and resource balance and are reflected as a reduction in peak demand.

# COMPANY SYSTEM LOAD

System load is the sum of the individual loads of residential, commercial, industrial, and irrigation customers, as well as special contracts (including past sales to Astaris) and on-system contracts (including past sales to Raft River and the City of Weiser). The system load excludes all long-term, firm, off-system contracts.

The expected-case system load forecast is based on the output of the regression and forecasting models referenced previously and represents Idaho Power's most probable load growth during the planning period. The expected-case forecast system load growth rate averages 0.9 percent per year from 2017 to 2036. Company system load projections are reported in Table 11 and shown in Figure 14.

In the expected-case forecast, the company system load is expected to increase from 1,810 aMW in 2017 to 2,142 aMW in 2036. In the 70$^{th}$-percentile forecast, the company system load is expected to increase from 1,853 aMW in 2017 to 2,193 aMW by 2036, an average growth rate of 0.9 percent per year over the planning period (Table 11).

**Table 11. System load growth (aMW)**

| Growth | 2017 | 2021 | 2026 | 2036 | Annual Growth Rate 2017–2036 |
|---|---|---|---|---|---|
| 90$^{th}$ Percentile | 1,917 | 2,006 | 2,108 | 2,269 | 0.9% |
| 70$^{th}$ Percentile | 1,853 | 1,939 | 2,037 | 2,193 | 0.9% |
| Expected Case | 1,810 | 1,894 | 1,990 | 2,142 | 0.9% |

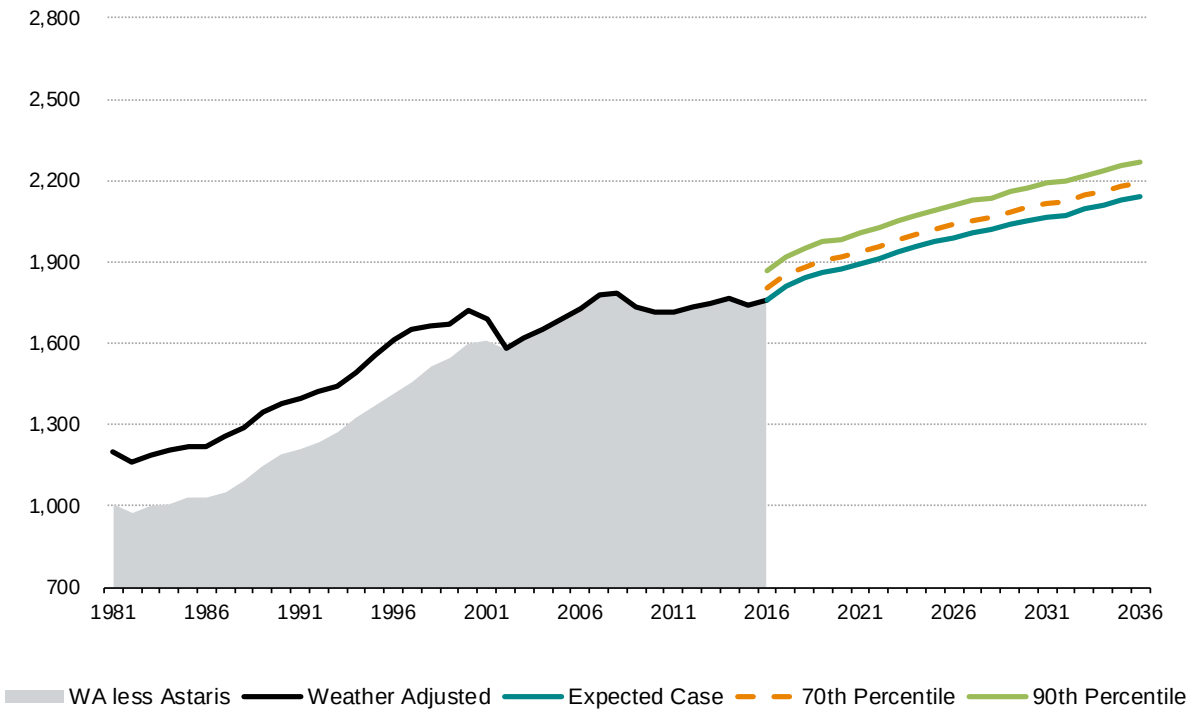

**Figure 14. Forecast system load (aMW)**

The system load, excluding Astaris[4], portrays the current underlying general business growth trend within the service area. However, the system load with Astaris is instructive in regard to the impact of a new large-load customer on system load. As noted previously, the forecast excludes any such prospective large-load customers.

Accompanied by an outlook of moderate economic growth for Idaho Power's service area throughout the forecast period, continued growth in Idaho Power's system load is projected. Total load is made up of system load plus long-term, firm, off-system contracts. At this time, there are no contracts in effect to provide long-term, firm energy off-system.

The composition of system company electricity sales by year is shown in Figure 15. Residential sales are forecast to be nearly 26 percent higher in 2036, gaining 1.4 million MWh over 2017. Commercial sales are also expected to be 15 percent higher, or 0.6 million MWh, than in 2017, followed by industrial (15 percent higher, or 0.4 million additional MWh) and irrigation (12 percent higher in 2036 than 2017).

[4] The Astaris elemental phosphorous plant (previously FMC) was located at the western edge of Pocatello, Idaho. Although no longer a customer of Idaho Power, Astaris had been Idaho Power's largest individual customer and, in some years, averaged nearly 200 aMW each month. In April 2002, the special contract between Astaris and Idaho Power was terminated.

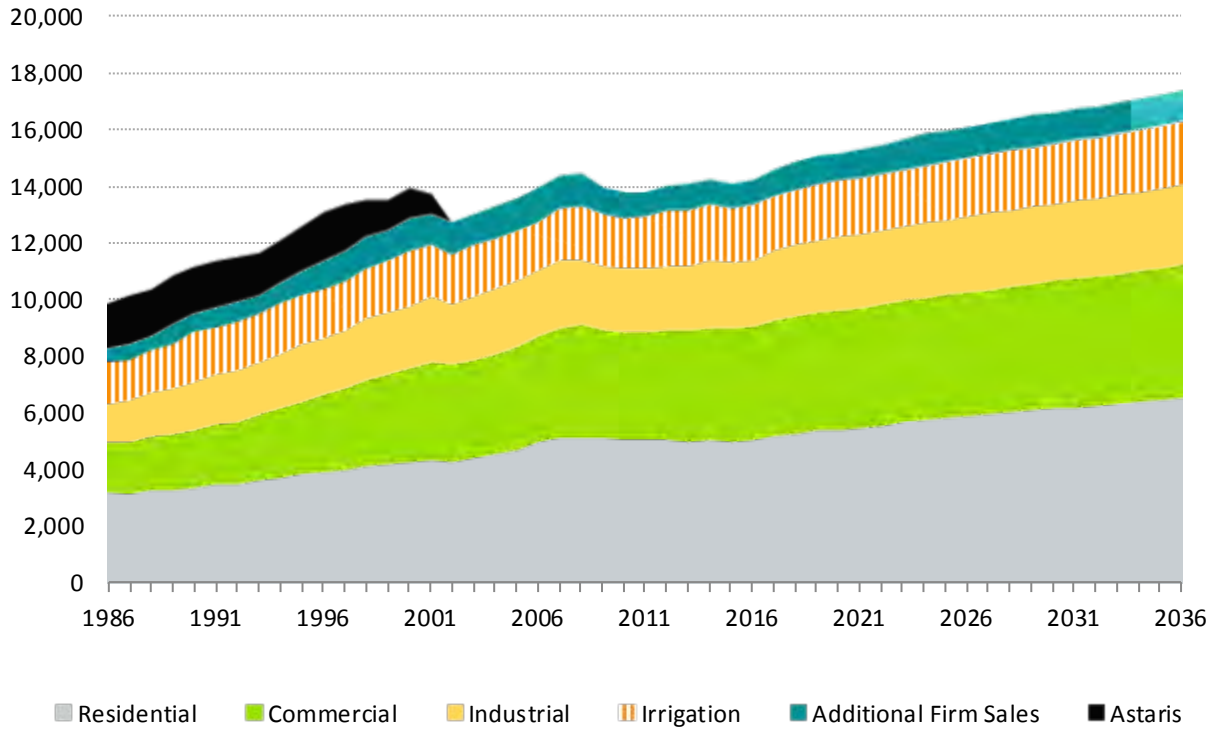

**Figure 15. Composition of system company electricity sales (thousands of MWh)**

## Fuel Prices

Fuel prices, in combination with service-area demographic and economic drivers, impact long-term trends in electricity sales. Changes in relative fuel prices can also impact the future demand for electricity. Class-level and economic-sector-level regression models were used to identify the relationships between real historical electricity prices and their impact on historical electricity sales. The estimated coefficients from these models were used as drivers in the individual sales forecast models.

Short-term and long-term nominal electricity price increases are generated internally from Idaho Power financial models. The US Energy Information Administration (EIA) provides the forecasts of long-term changes in nominal natural gas prices. The nominal price estimates are adjusted for projected inflation by applying the appropriate economic deflators to arrive at real fuel prices. The projected average annual growth rates of fuel prices in nominal and real terms (adjusted for inflation) are presented in Table 12. The growth rates shown are for residential fuel prices and can be used as a proxy for fuel-price growth rates in the commercial, industrial, and irrigation sectors.

**Table 12. Residential fuel-price escalation (2017–2036) (average annual percent change)**

| | Nominal | Real* |
|---|---|---|
| Electricity—2017 IRP | 1.2% | -0.7% |
| Electricity—2015 IRP | 2.0% | 0.0% |
| Natural Gas | 3.7% | 1.7% |

* Adjusted for inflation

Figure 16 illustrates the average electricity price paid by Idaho Power's residential customers over the historical period 1980 to 2016 and over the forecast period 2017 to 2036. Both nominal and real prices are shown. In the 2017 IRP, nominal electricity prices are expected to climb to about 13 cents per kWh by the end of the forecast period in 2036. Real electricity prices (inflation adjusted) are expected to decline over the forecast period at an average rate of 0.7 percent annually. In the 2015 IRP, nominal electricity prices were assumed to climb to about 15 cents per kWh by 2036, and real electricity prices (inflation adjusted) were expected to remain flat over the forecast period at an average rate of 0.0 percent annually.

The electricity price forecast used to prepare the sales and load forecast in the 2017 IRP reflected the additional plant investment and variable costs of integrating the resources identified in the 2015 IRP preferred portfolio. When compared to the electricity price forecast used to prepare the 2015 IRP sales and load forecast, the 2017 IRP price forecast yielded lower future prices. The retail prices are more evidently lower in the second 10 years of the planning period and impact the sales forecast positively, a consequence of the inverse relationship between electricity prices and electricity demand.

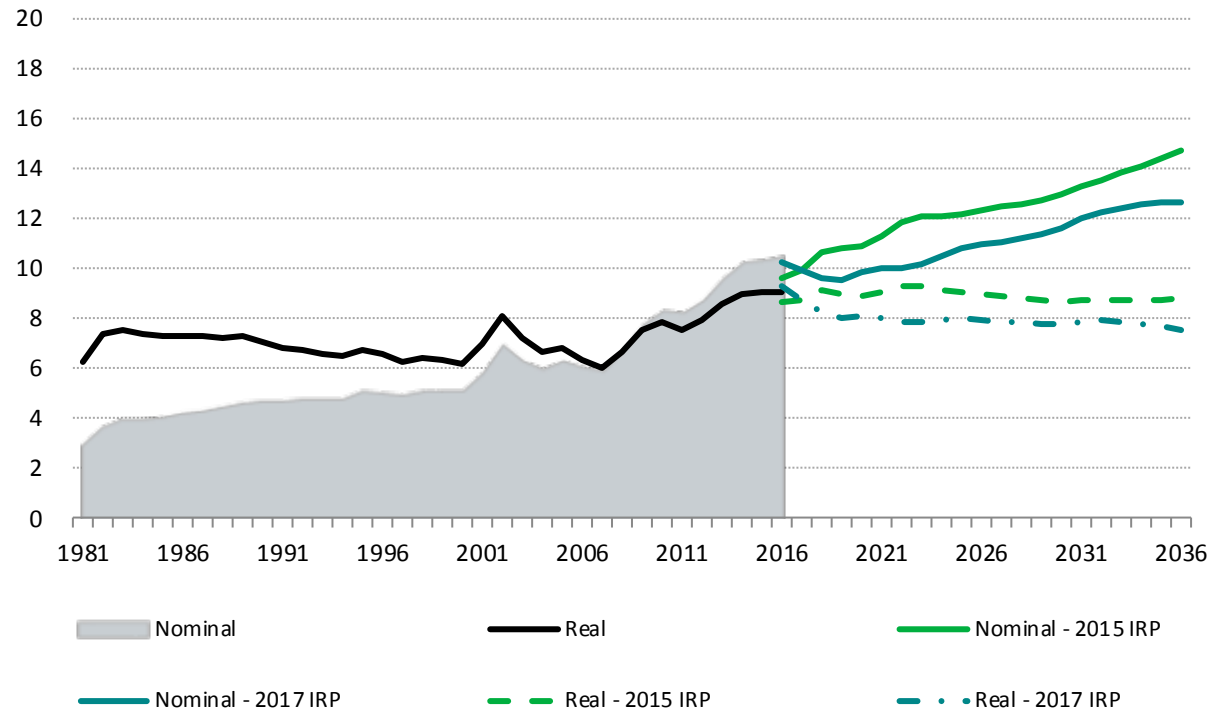

**Figure 16. Forecast residential electricity prices (cents per kWh)**

Electricity prices for Idaho Power customers increased significantly in 2001 and 2002 because of the power cost adjustment (PCA) impact on rates, a direct result of the western US energy crisis of 2000 and 2001. Prior to 2001, Idaho Power's electricity prices were historically quite stable. From 1990 to 2000, nominal electricity prices rose only 8 percent overall, an annual average compound growth rate of 0.8 percent annually. More recently, over the period 2006 to 2016, nominal electricity prices rose 72 percent overall, an annual average compound growth rate of 5.6 percent annually.

Figure 17 illustrates the average natural gas price paid by Intermountain Gas Company's residential customers over the historical period 1981 to 2015 and forecast prices from 2016 to 2036. Natural gas prices remained stable and flat throughout the 1990s before moving sharply higher in 2001. Since spiking in 2001, natural gas prices moved downward for a couple of years before moving sharply upward in 2004 through 2006. Since 2006, natural gas prices have declined about 30 percent, compared to 2015. Nominal natural gas prices are initially expected to drop by 8 percent in 2016, then rise at a steady pace throughout the remainder of the forecast period until more than doubling by 2036, growing at an average rate of 3.7 percent per year. Real natural gas prices (adjusted for inflation) are expected to increase over the same period at an average rate of 1.7 percent annually.

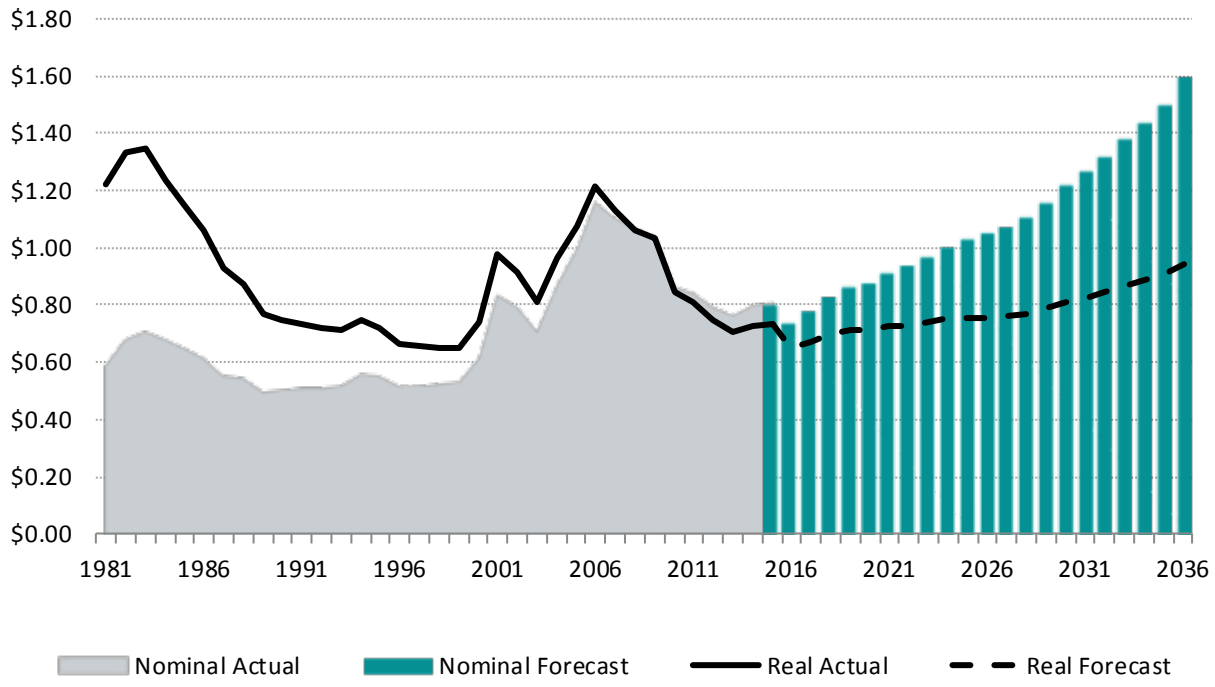

**Figure 17. Forecast residential natural gas prices (dollars per therm)**

If future natural gas price increases outpace electricity price increases, the operating costs of space heating and water heating with electricity would become more advantageous when compared to that of natural gas. However, in the 2017 IRP price forecast, the long-term growth rates of electricity and natural gas prices are nearly identical.

## Electric Vehicles

The load forecast includes an update of the impact of plug-in electric vehicles (PEV) on system load to reflect the future impact of this relatively new and evolving source of energy use. While PEV consumer adoption rates in Idaho Power's service area remain relatively low, with continued technological advancement, limiting attributes of vehicle range and re-fueling time continue to improve the competitiveness of these vehicles to non-electric models.

Since the first introduction of the Chevy Volt and Nissan Leaf, the number of PEVs offered in the marketplace has proliferated to over 50 models since 2007. Early in this period, PEVs were sold with unique model names (e.g., VOLT); however, as the market grows, the plug-in technology is increasingly offered as an option to existing models (e.g., Ford Focus).

Initially, the Idaho Power forecast for PEV impact relied on third-party forecasts from the Electric Power Research Institute (EPRI) and Oak Ridge National Laboratory due to a lack of service-area vehicle registration data; however, beginning with the 2011 IRP,

sufficient service-area data became available via vehicle registration data provided by the Idaho Transportation Department (ITD). This data provides a basis from which to develop service-area adoption rates and support the collection of charging behavior. The methodology continues to integrate the fuel and technology share forecasts of the DOE's NEM. The Idaho Power vehicle share forecast uses these models as well as a Bass consumer adoption model as informed by registration data. Load impacts from the share model output are derived from assumptions of battery-only and hybrid plug-in shares evident from Idaho Power observations and informed by the DOE.

Currently, the registration data collection methodology is being revised to capture vehicles sold with PEV technology as an option (e.g., Ford Focus). The methodology will require the unique string of characters within the vehicle identification number (VIN) to be identified and serve as a key value in the ITD data extraction.

The PEV forecast in the IRP did include registration data for the Toyota Prius PEV but did not capture all models for which PEV technology is sold as an option; however, to capture the impact of these models on future adoption, the forecast used the forecast national share assumptions from the DOE. The net effect was to rely less on the registration data than the 2015 IRP model and more on third-party assumptions, as was the case in earlier forecasts.

## Net Metering

In recent years, the number of customers signing up for net-metering service (Schedule 84) has raised dramatically, especially for residential customers. Currently, there are approximately 900 residential and 100 commercial net-metering customers. While the recent adoption of solar is relatively strong for our service area, the current population of net-metering customers comprises around one-fifth of 1 percent of the population of retail customers.

The installation of generating and storage equipment at customer sites will cause the demand for electricity delivered by Idaho Power to be reshaped throughout the year. It is important to measure the overall and future impact on the sales forecast. Therefore, this year's long term sales forecast was adjusted downward to reflect the impact of the increase in the number of net-metering customers, specifically solar, connecting to our system.

Schedule 84 (net-metering) customer billing histories were compared to billing histories prior to said customer becoming a net-metering customer. The resulting average monthly impact-per-customer (in kWh) was then multiplied by a forecast of the Schedule 84 residential and commercial customer count to estimate the future energy impact on the sales forecast. The forecast of net metering customers serves as a function of historical trends and current policy considerations.

The resulting forecast of net-metering customers multiplied by the estimated use-per-customer sales impact per customer resulted in a monthly downward adjustment to the sales forecast for each class. At the end of the forecast period, 2036, the annual residential sales reduction was about 18 aMW, and the commercial reduction was less than 1 aMW.

# OTHER CONSIDERATIONS

Since the residential, commercial, irrigation, and industrial sales forecasts provide a forecast of sales as billed, it is necessary to adjust these billed sales to the proper time frame to reflect the required generation needed in each calendar month. To determine calendar-month sales from billed sales, the billed sales must first be converted from billed periods to calendar months to synchronize them with the time period in which load is generated. The calendar-month sales are then converted to calendar-month average load by adding losses and dividing by the number of hours in each month.

Loss factors are determined by Idaho Power's Transmission Planning department. The annual average energy loss coefficients are multiplied by the calendar-month load, yielding the system load, including losses. A system loss study of 2012 was completed in May 2014. The results of the study concluded that on average, the revised loss coefficients were lower than those applied to generation forecasts developed prior to the 2015 IRP and were used in the development of the 2017 IRP sales and load forecast. This resulted in a one-time permanent reduction of nearly 20 aMW to the load forecast annually.

This page left blank intentionally.

# CONTRACT OFF-SYSTEM LOAD

The contract off-system category represents long-term contracts to supply firm energy to off-system customers. Long-term contracts are contracts effective during the forecast period lasting for more than one year. At this time, there are no long-term contracts.

The historical consumption for the contract off-system load category was considerable in the early 1990s; however, after 1995, off-system loads declined through 2005. As intended, the off-system contracts and their corresponding energy requirements expired as Idaho Power's surplus energy diminished due to retail load growth. In the future, Idaho Power may enter additional long-term contracts to supply firm energy to off-system customers if surplus energy is available.

INTEGRATED RESOURCE PLAN

IDAHO POWER®
An IDACORP Company

# 2017 IRP

## APPENDIX B: DSM ANNUAL REPORT

MARCH 15 • 2017

## SAFE HARBOR STATEMENT

This document may contain forward-looking statements, and it is important to note that the future results could differ materially from those discussed. A full discussion of the factors that could cause future results to differ materially can be found in Idaho Power's filings with the Securities and Exchange Commission.

Printed on recycled paper

IDAHO POWER®
An IDACORP Company

# 2017 IRP

## APPENDIX B: DSM ANNUAL REPORT

# ACKNOWLEDGEMENT

Resource planning is an ongoing process at Idaho Power. Idaho Power prepares, files, and publishes an Integrated Resource Plan (IRP) every two years. Idaho Power expects that the experience gained over the next few years will likely modify the 20-year resource plan presented in this document.

Idaho Power invited outside participation to help develop the 2017 IRP. Idaho Power values the knowledgeable input, comments, and discussion provided by the Integrated Resource Plan Advisory Council and other concerned citizens and customers.

It takes approximately one year for a dedicated team of individuals at Idaho Power to prepare the IRP. The Idaho Power team is comprised of individuals that represent many departments within the company. The IRP team members are responsible for preparing forecasts, working with the advisory council and the public, and performing all the analyses necessary to prepare the resource plan.

Idaho Power looks forward to continuing the resource planning process with customers, public-interest groups, regulatory agencies, and other interested parties. You can learn more about the Idaho Power resource planning process at idahopower.com.

*Supplement 2: Evaluation*
NEEA Market Effects Evaluations (included on CD with Supplement 2)

# EXECUTIVE SUMMARY

In 2016, Idaho Power celebrated providing electric service to the residents of southern Idaho for 100 years. Since starting as a small company in 1916, Idaho Power has grown to serve over 500,000 customers in over 24,000 square miles in southern Idaho and eastern Oregon. In 2002, Idaho Power revitalized its energy efficiency programs and began the Idaho and Oregon Energy Efficiency Riders (Rider) to fund the pursuit of cost-effective energy efficiency. Energy efficiency and demand response provide economic and operational benefits to the company and its customers and supports the wise use of energy by Idaho Power customers.

Idaho Power's portfolio of energy efficiency program energy savings for 2016 increased to 170,792 megawatt-hours (MWh), including the estimated savings from the Northwest Energy Efficiency Alliance (NEEA), enough energy to power more than 14,000 average homes a year in Idaho Power's service area. This is a 4-percent increase from the 2015 energy savings of 163,672 MWh. In 2016, the company's energy efficiency portfolio was cost-effective from both the total resource cost (TRC) test and the utility cost (UC) test perspectives with ratios of 2.56 and 3.58, respectively. The portfolio was also cost-effective from the participant cost test ratio was 2.93. The savings from Idaho Power's energy efficiency programs alone, excluding NEEA savings, increased to 146,177 MWh in 2016 from 140,633 MWh in 2015.

Idaho Power successfully operated all three of its demand response programs in 2016. The total demand reduction achieved from the company's programs was 378 megawatts (MW) from an available capacity of 392 MW. Energy efficiency and demand response is an important aspect of Idaho Power's resource planning process. Idaho Power's 2016 achievements in energy savings exceeded the annual savings target identified in Idaho Power's *2015 Integrated Resource Plan* (IRP).

Total expenditures from all funding sources on demand-side management (DSM) activities increased by nearly 10 percent, to $43 million in 2016 from $39 million in 2015. DSM program funding comes from the Idaho and Oregon Riders, Idaho Power base rates, and the annual power cost adjustment (PCA). Idaho incentives for the company's demand response programs are recovered through base rates and the annual PCA, while Oregon demand response incentives are funded through the Oregon Rider.

With a goal of using customers' funds wisely, Idaho Power employees and leaders strive to provide conscientious, prudent, and responsible action and activities that result in cost-effective energy efficiency. This report's content offers descriptions of the 2016 activities and savings.

In 2016, Idaho Power expanded the reach and frequency of its residential energy efficiency campaign, added a Smart-saver Pledge to engage and encourage customers to make an energy-saving behavior change, significantly increased the amount of energy efficiency-related social media posts, and began marketing the company's commercial and industrial energy efficiency offerings as a single program. Idaho Power's residential energy efficiency advertising campaign was awarded second place at the E Source Forum in the category of Best Ad Campaign for an Investor-owned Utility.

Idaho Power continued to use stakeholder input to enhance its programs. The company met regularly with its Energy Efficiency Advisory Group (EEAG) and individual customers seeking input on program improvement. To keep growth in the program portfolio, the company relied on its Program Planning Group (PPG), initiated in 2014, and NEEA's Regional Emerging Technology Advisory Committee (RETAC) to fill the pipeline with ideas for offerings to its energy efficiency programs. Additionally, Idaho Power continued program improvement to make it easier for its customers to participate in programs.

In 2016, Idaho Power distributed Energy-Saving Kits (ESK) at no additional cost to customers on request. By the end of the year, the company had distributed over 34,000 kits to customers in Idaho and Oregon. The ESK included light-emitting diodes (LED) lightbulbs, digital thermometers, shower timers, water flow-rate test bags, LED night lights, and educational materials. Additionally, by the end of the year, Idaho Power employees had personally delivered energy-efficiency messages and distributed nearly 25,000 lightbulbs directly to customers.

This *Demand-Side Management 2016 Annual Report* provides a review of the company's DSM activities and finances throughout 2016 and outlines Idaho Power's plans for future DSM activities. This report also satisfies the reporting requirements set out in the Idaho Public Utilities Commission's (IPUC) Order Nos. 29026 and 29419. Idaho Power will provide a copy of the report to the Public Utility Commission of Oregon (OPUC) under Oregon Docket Utility Miscellaneous (UM) No. 1710.

# INTRODUCTION

In 2016, Idaho Power celebrated its 100th anniversary. For the last sixteen years, the company has pursued cost-effective energy efficiency as a primary objective. Energy efficiency and demand response provide economic and operational benefits to the company and its customers. Idaho Power provides information and programs to ensure customers have opportunities to learn about their energy use, how to use energy, and participate in programs.

This report focuses on Idaho Power's demand-side management (DSM) activities and results for 2016 and previews planned activities for 2017. The appendices provide historical and detailed information on the company's DSM activities and detailed financial information from 2002 through 2016. The two supplements provide detailed cost-effectiveness data and copies of Idaho Power's evaluations, reports, and research conducted in 2016.

Idaho Power's main objectives for DSM programs are to achieve prudent, cost-effective energy efficiency savings and to provide an optimal amount of demand reduction from its demand response programs as determined through the Integrated Resource Plan (IRP) planning process. Idaho Power considers cost-effective energy efficiency the company's least-cost resource and pays particular attention to ensuring the best value to Idaho Power's customers. Idaho Power strives to provide customers with programs and information to help them manage their energy use wisely.

The company achieves these objectives through the implementation and careful management of programs that provide energy and demand savings and through outreach and education. For economic and administrative efficiency and to reduce customer confusion, Idaho Power endeavors to implement identical programs in its Idaho and Oregon service areas. Idaho Power has been locally operated since 1916 and serves nearly 530,000 customers throughout a 24,000-square-mile area in southern Idaho and eastern Oregon.

Figure 1. 2016 Idaho Power service area map

Idaho Power's energy efficiency programs focus on reducing energy use by identifying homes, buildings, equipment, or components for which an energy-efficient design, replacement, or repair can achieve energy savings. Energy efficiency programs sometimes include behavioral components, including the Residential Energy Efficiency Education Initiative and both the Smart-saver Pledge and the School Cohort, which began in 2016. Energy efficiency programs are available to all customer sectors in Idaho Power's service area.

Savings from these programs are measured in terms of kilowatt-hour (kWh) or megawatt-hour (MWh) savings. These programs usually supply energy savings throughout the year at different times depending on the energy-efficiency measure put in place. Idaho Power shapes these savings based on the end use to estimate energy reduction at specific times of the year and day. Idaho Power's energy efficiency offerings include programs in residential and commercial new construction (lost-opportunity savings); residential and commercial retrofit applications; and irrigation and industrial system improvement or replacement. Custom programs under the irrigation and industrial sectors offer a wide range of opportunities for Idaho Power and its customers to design and execute energy-saving projects.

Energy efficiency program and demand response funding comes from the Idaho and Oregon Energy Efficiency Riders (Rider), Idaho Power base rates, and the annual power cost adjustment (PCA). Idaho incentives for the company's demand response programs are recovered through base rates and the annual PCA, while Oregon demand response incentives are funded through the Oregon Rider. Total expenditures from all funding sources on DSM-related activities increased by about 10 percent, from $39 million in 2015 to $43 million in 2016.

Idaho Power started its modern demand response programs in 2002, and now has over 10 percent of its all-time peak load available under demand response programs. The goal of demand response at Idaho Power is to minimize or delay the need to build new supply-side peaking resources. The company estimates future capacity needs through the IRP planning process and plans resources to mitigate any system peak deficits that exist. Demand response programs are measured by the amount of demand reduction, in megawatts (MW), available to the company during system peak periods.

## DSM Programs Performance

The 2016 savings consisted of 42,269 MWh from the residential sector, 88,161 MWh from the commercial/industrial sector, and 15,747 MWh from the irrigation sector. This represents a 4-percent increase from 2015 program savings. The industrial Custom Projects (formerly Custom Efficiency) program in the Commercial and Industrial Energy Efficiency Program contributed 33 percent of Idaho Power's direct program savings, while the residential sector Energy Efficient Lighting and Educational Distributions programs contributed 86 percent of the residential savings.

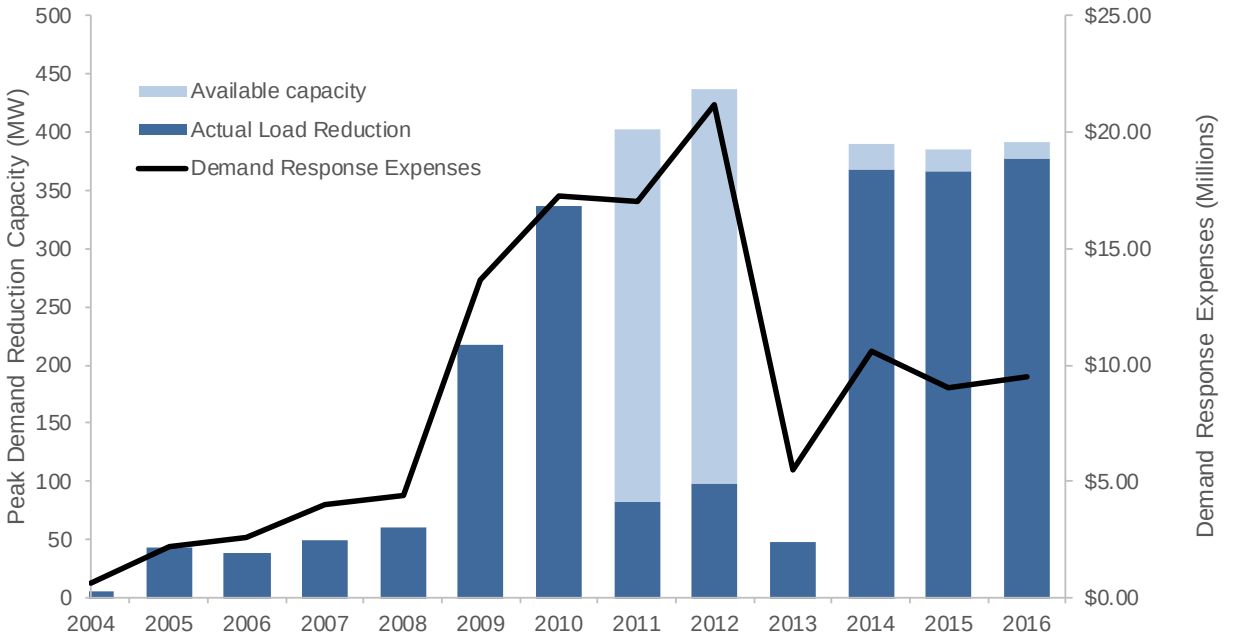

Figure 2. Peak demand-reduction capacity and demand response expenses, 2004–2016 (MW and millions [$])

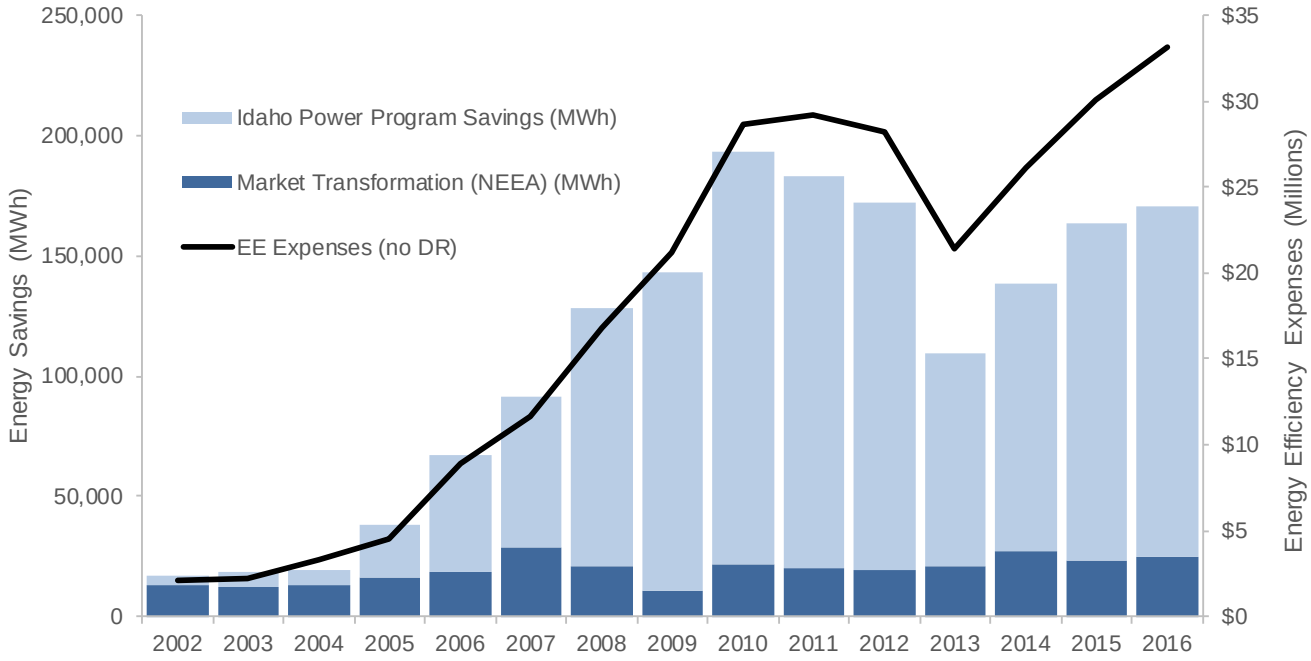

Figure 3. Annual energy savings and energy efficiency program expenses, 2002–2016 (MWh and millions [$])

Figure 3 demonstrates that as Idaho Powers energy-efficiency portfolio matures, and some savings become more difficult and costly to achieve, the expense per incremental savings increases.

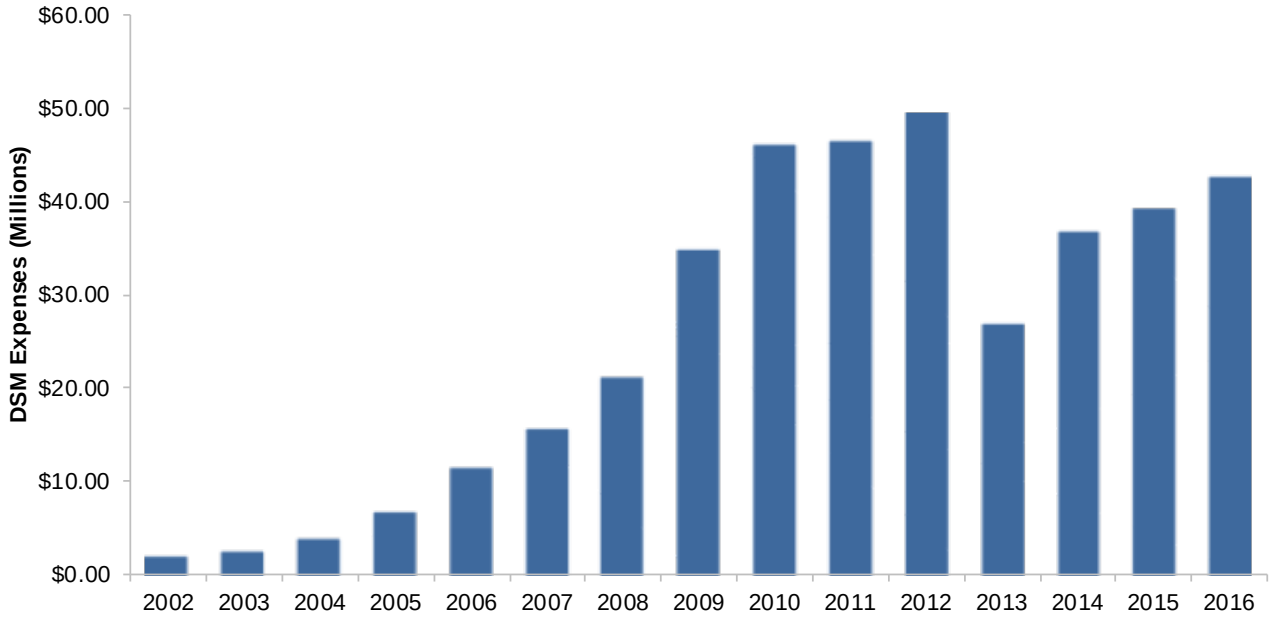

Figure 4. Total DSM expense history, including energy efficiency, demand response, and NEEA expenses, 2002–2016 (millions [$])

Energy efficiency and demand response is an important aspect of Idaho Power's resource planning process. Idaho Power's 2016 achievements in energy savings exceeded the annual savings target identified in Idaho Power's *2015 Integrated Resource Plan*. On a cumulative basis, the company's energy savings have exceeded the IRP targets every year since 2002.

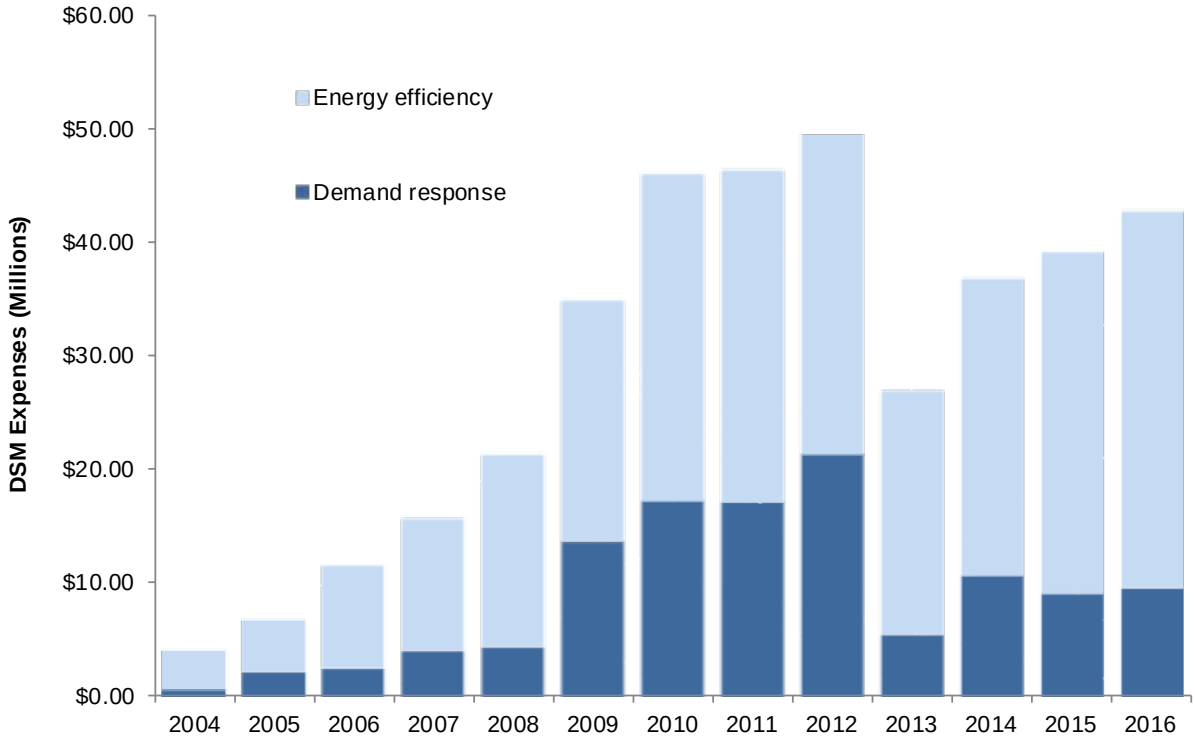

Figure 5. DSM expense history by program type, 2004–2016 (millions [$])

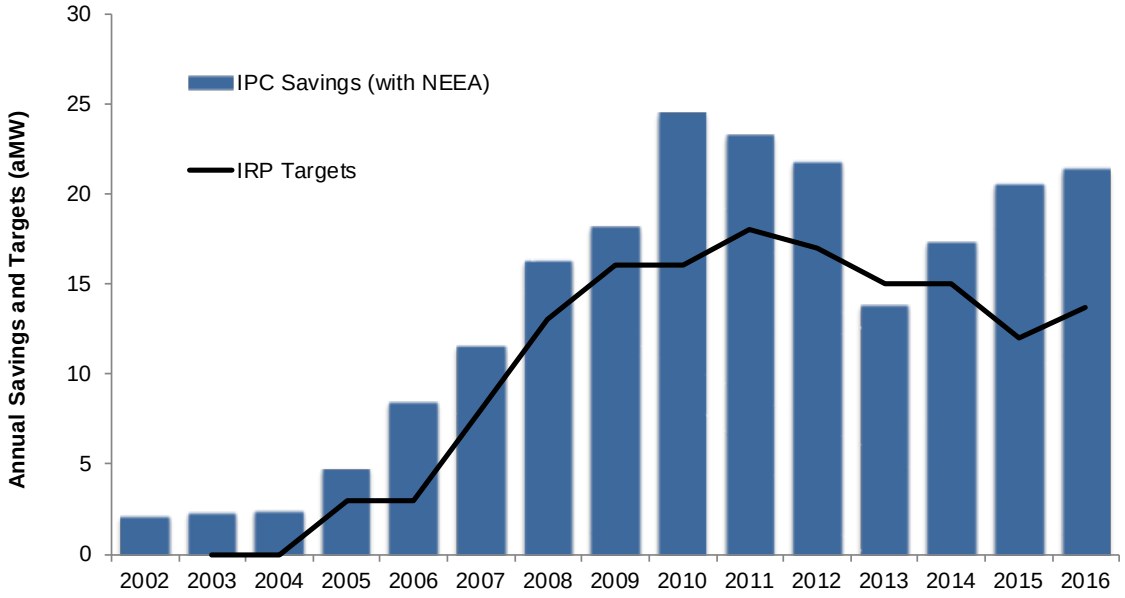

Figure 6. Annual incremental energy efficiency savings (aMW) compared with IRP targets, 2002–2016

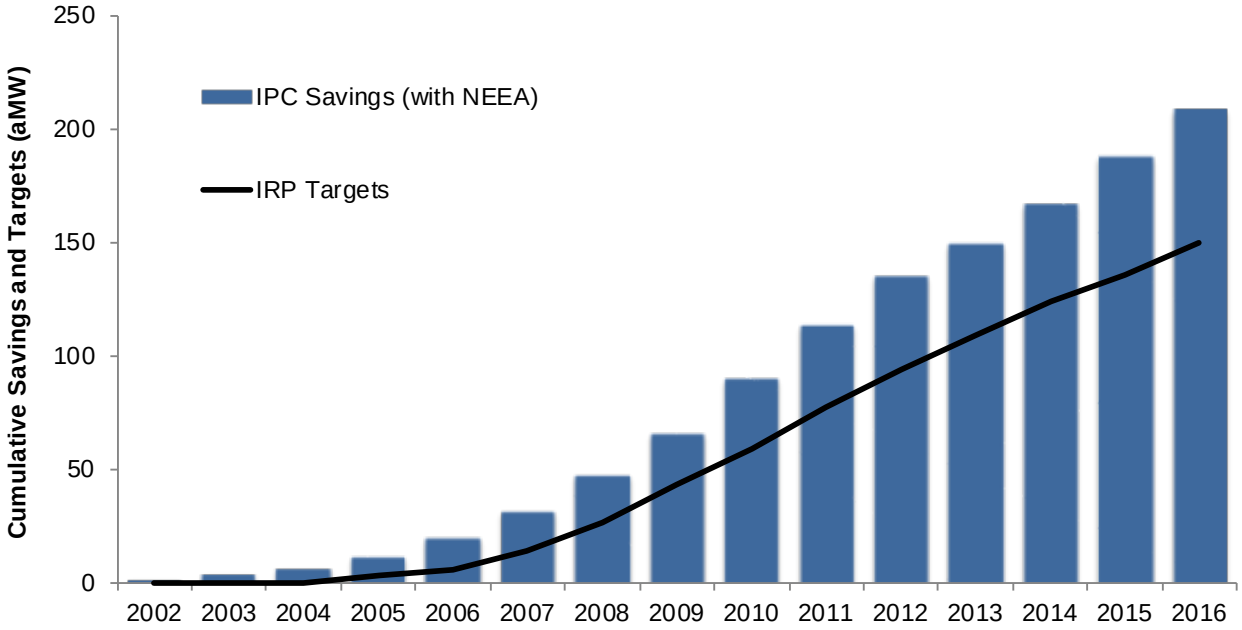

Figure 7. Annual cumulative energy efficiency savings (aMW) compared with IRP targets, 2002–2016

Idaho Power further increased its energy efficiency presence in the community by providing energy efficiency and program information through 92 outreach activities, including events, presentations, trainings, and other activities. In addition, Idaho Power customer representatives delivered 189 presentations to local organizations addressing energy efficiency programs and wise energy use.

In 2016, Idaho Power's community education representatives presented *The Power to Make a Difference* 91 times to 2,350 students and gave 53 classroom presentations of *Saving a World Full of Energy* to 1,411 students. At events and presentations, company staff distributed over 24,000 light-emitting

diodes (LED) lightbulbs in custom packaging that highlighted the advantages of energy-efficient lighting and encouraged participation in Idaho Power's myAccount online portal. The company also distributed over 34,000 Energy-Saving Kits (ESK) by request across its service area. On February 8, 2016, Idaho Power filed a request with the Public Utility Commission of Oregon (OPUC) to implement the Educational Distributions program in Oregon. The company received approval of Oregon Schedule 71 on March 9, 2016. This enabled Idaho Power to provide ESKs and LEDs to its Oregon customers.

Since 2008, commercial and industrial training activities have informed and educated commercial and industrial customers regarding energy efficiency, increased awareness of and participation in existing commercial and industrial energy efficiency and demand response programs, and enhanced customer satisfaction regarding the company's energy efficiency initiatives. Raising the knowledge level of commercial and industrial customers regarding the wise use of energy in their daily operations is important to the continued success of Idaho Power's commercial and industrial energy efficiency programs.

Idaho Power continued its internal commitment to energy efficiency in 2016. Idaho Power upgraded the company's substation buildings across its service area, renovated portions of the corporate headquarters (CHQ) in downtown Boise in 2016, and redesigned the heating, ventilation, and air conditioning (HVAC) delivery system for the Maintenance and Electrical Shop. Also in 2016, the new Twin Falls Operation Center was constructed to replace the 1951-built center used to house the operations staff. The design incorporates energy-efficient lighting, heating and cooling, daylight harvesting, and a rooftop solar array.

## Demand Response Programs

In summer 2016, Idaho Power had a combined maximum actual non-coincidental load reduction from all three programs of 378 MW at the generation level. The amount of capacity available for demand response varies based on weather, the time of year, and how programs are used and managed. The 2016 capacity of demand response programs was 392 MW. The demand response capacity is calculated using total enrolled MW from participants with an expected maximum realization rate for those participants. This maximum realization rate is not always achieved for every program in any given event. This realization rate is expected to be approximately 73 percent of billing demand for Irrigation Peak Rewards and 100 percent of actual non-coincidental load reduction for A/C Cool Credit and the Flex Peak Program.

On Wednesday, June 29, 2016, the company used the Irrigation Peak Rewards program and reached a system peak of 3,085 MW. Had the program not been used, the company estimates the load would have been approximately 3,327 MW. Idaho Power's 2016 summer peak occurred on June 28 with a peak of 3,299 MW while the all-time summer peak was 3,407 MW on July 2, 2013.

## Energy Efficiency Programs

Idaho Power's portfolio of energy efficiency program energy savings for 2016 increased to 170,792 MWh, including the estimated Northwest Energy Efficiency Alliance (NEEA) savings. This is a 4-percent increase from the 2015 energy savings of 163,672 MWh and enough to power over

14,000 average-sized homes a year in Idaho Power's service area. In 2016, the company's energy efficiency portfolio is cost effective from both the total resource cost (TRC) test and the utility cost (UC) test perspectives with ratios of 2.56 and 3.58, respectively. The savings from Idaho Power's energy efficiency programs alone (excluding NEEA savings) increased to 146,177 MWh in 2016 from 140,633 MWh in 2015.

Table 1. 2016 DSM programs by sector, operational type, location, and energy savings/demand reduction

| Program by Sector | Operational Type | State | Savings/Demand Reduction |
|---|---|---|---|
| **Residential** | | | |
| A/C Cool Credit | Demand Response | ID/OR | 34 MW |
| Easy Savings | Energy Efficiency | ID | 403 MWh |
| Educational Distributions | Energy Efficiency | ID/OR | 15,150 MWh |
| Energy Efficient Lighting | Energy Efficiency | ID/OR | 21,094 MWh |
| Energy House Calls | Energy Efficiency | ID/OR | 510 MWh |
| ENERGY STAR® Homes Northwest | Energy Efficiency | ID/OR | 150 MWh |
| Fridge and Freezer Recycling Program (See ya later, refrigerator®) | Energy Efficiency | ID/OR | 632 MWh |
| Heating & Cooling Efficiency Program | Energy Efficiency | ID/OR | 1,114 MWh |
| Home Energy Audit | Energy Efficiency | ID | 207 MWh |
| Home Improvement Program | Energy Efficiency | ID | 500 MWh |
| Multifamily Energy Savings Program | Energy Efficiency | ID/OR | 150 MWh |
| Oregon Residential Weatherization | Energy Efficiency | OR | 3 MWh |
| Rebate Advantage | Energy Efficiency | ID/OR | 411 MWh |
| Shade Tree Project | Other Programs and Activities | ID | n/a |
| Simple Steps, Smart Savings™ | Energy Efficiency | ID/OR | 577 MWh |
| Weatherization Assistance for Qualified Customers | Energy Efficiency | ID/OR | 746 MWh |
| Weatherization Solutions for Eligible Customers | Energy Efficiency | ID | 622 MWh |
| **Commercial/Industrial** | | | |
| Commercial and Industrial Efficiency Program | | | |
| Custom Projects (Custom Efficiency) | Energy Efficiency | ID/OR | 47,519 MWh |
| New Construction (Building Efficiency) | Energy Efficiency | ID/OR | 12,393 MWh |
| Retrofits (Easy Upgrades) | Energy Efficiency | ID/OR | 28,125 MWh |
| Flex Peak Program | Demand Response | ID/OR | 42 MW |
| Green Motors—Industrial | Energy Efficiency | ID/OR | 124 MWh |
| Oregon Commercial Audits | Energy Efficiency | OR | n/a |
| **Irrigation** | | | |
| Green Motors—Irrigation | Energy Efficiency | ID/OR | 74 MWh |
| Irrigation Efficiency Rewards | Energy Efficiency | ID/OR | 15,674 MWh |
| Irrigation Peak Rewards | Demand Response | ID/OR | 303 MW |
| **All Sectors** | | | |
| Northwest Energy Efficiency Alliance | Market Transformation | ID/OR | 24,616 MWh |

Table 2. 2016 program sector summary and energy usage/savings/demand reduction

| | Energy Efficiency Program Impacts [a] | | | | Idaho Power System Sales | | |
|---|---|---|---|---|---|---|---|
| | Program Expenses | Energy Savings (kWh) | Average Energy (aMW) | Peak-Load Reduction (MW)[b] | Sector Total (MWh) | Percentage of Energy Usage | Number of Customers |
| Residential | $10,724,671 | 42,268,823 | 4.8 | | 4,907,730 | 34.92% | 444,431 |
| Commercial/Industrial | $14,961,753 | 88,160,599 | 10.1 | | 7,198,357 | 51.22% | 69,462 |
| Irrigation | $2,372,352 | 15,747,130 | 1.8 | | 1,948,079 | 13.86% | 20,638 |
| Market Transformation | $2,676,387 | 24,615,600 | 2.8 | | | | |
| Demand Response | $9,471,367 | n/a | n/a | 378 | | | |
| Direct Overhead | $293,039 | n/a | n/a | | | | |
| **Total Direct Program Expenses** | **$40,499,570** | **170,792,152** | **19.5** | **378** | **14,054,166** | **100.0%** | **534,531** |

[a] Energy, average energy, and expense data have been rounded to the nearest whole unit, which may result in minor rounding differences.
[b] Includes peak-load reduction from both demand response and energy efficiency programs. Includes 9.7% peak line loss assumptions.

## Program Evaluation Strategy

Idaho Power considers program evaluation an essential component of its DSM operational activities. The company uses third-party contractors to conduct impact, process, and other evaluations on a scheduled and as required basis.

Third-party contracts are generally awarded using a competitive bid process managed by Idaho Power's Strategic Sourcing department. In some cases, research and analysis is conducted internally and managed by Idaho Power's Research and Analysis team within the Customer Relations and Energy Efficiency (CR&EE) department. Third-party evaluations are specifically managed by the company's energy efficiency evaluator.

Idaho Power uses industry standard protocols for its internal and external evaluation efforts, including the National Action Plan for Energy Efficiency—Model Energy Efficiency Program Impact Evaluation Guide, the California Evaluation Framework, the International Performance Measurement and Verification Protocol (IPMVP), the Database for Energy Efficiency Resources, and the Regional Technical Forum's (RTF) evaluation protocols.

The company also supports regional and national studies to promote the ongoing cost-effectiveness of programs, the validation of energy savings and demand reduction, and the efficient management of its programs. Idaho Power considers primary and secondary research, cost-effectiveness analyses, potential assessments, impact and process evaluations, and customer surveys to be important resources in providing accurate and transparent program-savings estimates. Recommendations and findings from evaluations research and industry best practices are used to continuously refine Idaho Power's DSM programs. Historical evaluation plans, plans for 2017, and copies of 2016 evaluations and research can be found in *Supplement 2: Evaluation.*

## Cost-Effectiveness

Idaho Power considers cost-effectiveness of primary importance in the design, implementation,

and tracking of energy efficiency and demand response programs. Idaho Power's energy efficiency and demand response opportunities are preliminarily identified through the IRP process. Idaho Power uses third-party energy efficiency potential studies to identify achievable cost-effective energy efficiency potential that is added to the resources included in the IRP. Because of Idaho Power's diversified portfolio of programs, most of the new potential for energy efficiency in Idaho Power's service area is based on additional measures to be added to existing programs rather than developing new programs.

Prior to the actual implementation of energy efficiency or demand response programs, Idaho Power performs a cost-effectiveness analysis to assess whether a potential program design or measure will be cost-effective from the perspective of Idaho Power and its customers. Incorporated in these models are inputs from various sources that use the most current and reliable information available.

Additionally, Idaho Power relies on the results of program impact evaluations and recommendations from consultants. In 2016, Idaho Power contracted with ADM Associates, Inc. (ADM); Applied Energy Group (AEG); CLEAResult Consulting, Inc. (CLEAResult); and Tetra Tech, MA for program evaluations and research.

Idaho Power's goal is for all programs to have benefit/cost (B/C) ratios greater than one for the TRC test, UC test, and participant cost test (PCT) at the program and measure level where appropriate. Each cost-effectiveness test provides a different perspective, and Idaho Power believes each test provides value when evaluating program performance. If a particular measure or program is pursued even though it will not be cost-effective from each of the three tests, Idaho Power works with the Energy Efficiency Advisory Group (EEAG) to get input. The company believes this aligns with the expectations of the Idaho Public Utilities Commission (IPUC) and OPUC.

Details on the cost-effectiveness assumptions and data are included in *Supplement 1: Cost-Effectiveness*.

## Future Plans

Idaho Power will continue to pursue all prudent cost-effective energy efficiency as identified by third-party potential studies, and an appropriate amount of demand response based on the demand response settlement agreement approved in IPUC Order No. 32923 and OPUC Order No. 13-482. The forecast level of energy efficiency and the needed level of demand response are included in Idaho Power's biennial IRP planning process. Idaho Power includes all achievable cost-effective energy savings as identified in its potential studies in each IRP. Idaho Power considers this achievable potential a reasonable 20-year planning estimate. However, the company does not consider the achievable potential as a ceiling limiting energy efficiency acquisition. The IRP is developed in a public process that details Idaho Power's strategy for economically maintaining the adequacy of its power system into the future. The IRP process balances reliability, cost, risk, environmental concerns, and efficiency to develop a preferred portfolio of future resources to meet the specific energy needs of Idaho Power's customers.

Planning activities conducted in 2016 identified an opportunity for Idaho Power to increase its focus on small and medium business customers to build relationships and promote participation in energy

efficiency programs. A new position titled customer solutions advisor has been developed as a result of this effort. Eight customer solutions advisor positions have been developed and are scheduled to be in place and performing their assigned duties by May 1, 2017. The customer solutions advisors will focus on customer outreach by phone to "on-board" new business customers and support existing business customers by familiarizing them with Idaho Power's rates, billing and payment options, and energy-usage information available through myAccount and by answering any questions they may have about services and programs offered by Idaho Power. A primary function of the customer solutions advisor role will be promoting and educating business customers on energy efficiency and demand response programs.

The company will continue to explore new energy savings potential through third-party resources, conferences, and regional organizations, and will continue to assess and develop new program offerings through its Program Planning Group (PPG). Idaho Power will work in consultation with the EEAG to expand or modify its energy efficiency portfolio. Future plans for individual programs are included under each program's *2017 Program and Marketing Strategies*.

In 2017, Idaho Power will continue to enhance its marketing and outreach efforts as described in the Marketing section of this report and within each program section. Idaho Power will continue to work with NEEA on its market transformation activities during the 2015 to 2019 funding cycle.

The company will complete its research and evaluation, measurement, and verification (EM&V) projects included in the evaluation plan in *Supplement 2: Evaluation*.

Idaho Power will incorporate energy efficiency equipment and practices into its own facilities. In 2017, the company will continue renovations at the CHQ in downtown Boise. Idaho Power plans to remodel the ninth floor of the CHQ, exchanging the old T-12 parabolic lighting fixtures with T-8 lighting, and incorporating energy efficiency measures, such as lower partitions, lighting retrofits, and automated lighting controls.

In 2016, Idaho Power redesigned the HVAC delivery system for the Maintenance and Electrical Shops; construction on these projects is planned for 2018. Idaho Power estimates that with these improvements the shops may reduce their usage by 300,000 kWh in coming years.

## DSM Annual Report Structure

The *Demand-Side Management 2016 Annual Report* consists of the main document and two supplements. *Supplement 1: Cost Effectiveness* shows the standard cost effectiveness tests for Idaho Power programs and includes a table that reports expenses by funding source and cost category. In 2016, the company continued its commitment to third party evaluation activities. Included in *Supplement 2: Evaluation* are copies of all of Idaho Power's 2016 evaluations, evaluations conducted by its regional partners, customer surveys and reports, Idaho Power's evaluation plans, general energy efficiency research, and demand response research. Additionally, the report and supplements will be provided under Oregon Docket UM 1710 to provide the OPUC and its staff information on the company's DSM programs and expenses.

This main *Demand-Side Management 2016 Annual Report* is organized primarily by the customer sectors residential, commercial/industrial, and irrigation. Each sector has a description, which is followed by information regarding programs in that sector. Each program description includes a table containing 2016 and 2015 program metrics, followed by a general description, 2016 activities, cost-effectiveness, customer satisfaction/evaluation, and 2017 plans. Each program section contains detailed information relating to program changes and the reasoning behind those changes, including information on cost-effectiveness and evaluation. Following the sector and program sections of the report are descriptions of Idaho Power's activities in other programs and activities, including market transformation, and Idaho Power's regulatory initiatives. Appendices 1 through 5 follow the written sections and contain a table on 2016 expenses and savings and historic information for all energy efficiency programs and demand response activities at Idaho Power.

In 2016, Idaho Power's commercial and industrial energy efficiency programs were combined in one umbrella program, the Commercial and Industrial Energy Efficiency Program, with options named to describe their purpose: New Construction (formerly Building Efficiency), Retrofits (formerly Easy Upgrades), and Custom Projects (formerly Custom Efficiency). The specific expenses and savings data are reported in the appendices separately for comparative purposes.

Also in 2016, Idaho Power filed with the IPUC to combine the Weatherization Assistance for Qualified Customers (WAQC) report, formerly filed with the IPUC annually on April 1, with Idaho Power's *Demand-Side Management 2016 Annual Report*. This change was approved by the IPUC in January 23, 2017, Order No. 33702 IPC-E-16-30, and the information formerly included in the WAQC annual report is now included in this report.

This page left blank intentionally.

# 2016 PROGRAM ACTIVITY

## DSM Expenditures

Funding for DSM programs in 2016 came from several sources. The Idaho and Oregon Rider funds are collected directly from customers on their monthly bills. For 2016, the Idaho Rider was 4 percent of base rate revenues; the 2016 Oregon Rider was 3 percent of base rate revenues. Additionally, Idaho demand response program incentives were paid through base rates and the annual PCA mechanism. Energy efficiency and demand response related expenses not funded through the Rider are included as part of Idaho Power's ongoing operation and maintenance (O&M) costs.

Total DSM expenses funded from all sources were $43 million in 2016. At the beginning of 2016, the Idaho Rider balance was approximately $6.6 million, and by December 31, 2016, the positive balance was $10.7 million. At the beginning of the year, the Oregon Rider negative balance was approximately $4.5 million, and by year-end, the negative balance was $5.6 million.

Table 3 shows the total expenditures funded by the Idaho Rider, $31,291,579; the Oregon Rider, $2,168,868; and non-rider funding, $9,303,017, resulting in Idaho Power's total DSM expenditures of $42,763,464. The non-rider funding category includes Idaho Power demand response incentives, WAQC expenses, and O&M costs.

Table 3. 2016 funding source and energy savings

| Funding Source | Expenses | kWh Savings |
|---|---|---|
| Idaho Rider | $ 31,291,579 | 162,765,429 |
| Oregon Rider | 2,168,868 | 7,280,560 |
| Non-Rider Funding | 9,303,017 | 746,162 |
| **Total** | **$ 42,763,464** | **170,792,152** |

Table 4 and Figure 8 indicate 2016 DSM program expenditures by category. The Materials & Equipment category includes items that directly benefit customers: ESKs and LED lightbulbs distributed at customer events ($2,105,557), and direct-install weatherization measures ($125,000). The expenses in the Other Expense category include marketing ($1,208,731), program evaluation ($198,210), program training ($455,117), and program audits ($174,861). The Purchased Services category includes payments made to NEEA and third-party contractors who help deliver Idaho Power's programs.

Table 4. 2016 DSM program expenditures by category

| | Total | % of Total |
|---|---|---|
| Incentive Expense | $23,676,667 | 55% |
| Labor/Administrative Expense | 3,580,600 | 8% |
| Materials & Equipment | 2,417,071 | 6% |
| Other Expense | 2,111,683 | 5% |
| Purchased Services | 10,977,442 | 26% |
| **Total 2016 DSM Expenditures, by Category** | **$42,763,464** | **100%** |

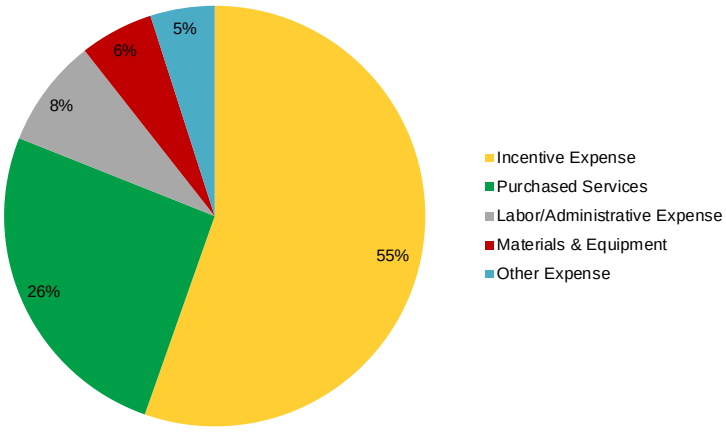

Figure 8. 2016 DSM program expenditures by category

Table 5 and Figure 9 describe the amount and percentage of incentives paid by segment and sector. There are two incentive segments (demand response and energy efficiency) and three sectors (residential, commercial/industrial, and irrigation). The incentives are funded by three mechanisms: the Idaho Rider, the Oregon Rider, and Idaho Power base rates. Market transformation related payments made to NEEA and payments made to third-party community action partners under the WAQC and Weatherization Solutions for Eligible Customers programs are not included in the incentive amounts.

Table 5. 2016 DSM program incentives totals by program type and sector

| Program Type—Sector | Total | % of Total |
|---|---|---|
| DR[a]—Residential | $ 424,565 | 2% |
| DR—Commercial/Industrial | 639,611 | 3% |
| DR—Irrigation | 6,406,340 | 27% |
| EE[b]—Irrigation | 2,007,311 | 8% |
| EE—Residential | 2,680,473 | 11% |
| EE—Commercial/Industrial | 11,518,366 | 49% |
| **Total Incentive Expense** | **$ 23,676,667** | **100%** |

[a] DR = demand response
[b] EE = energy efficiency

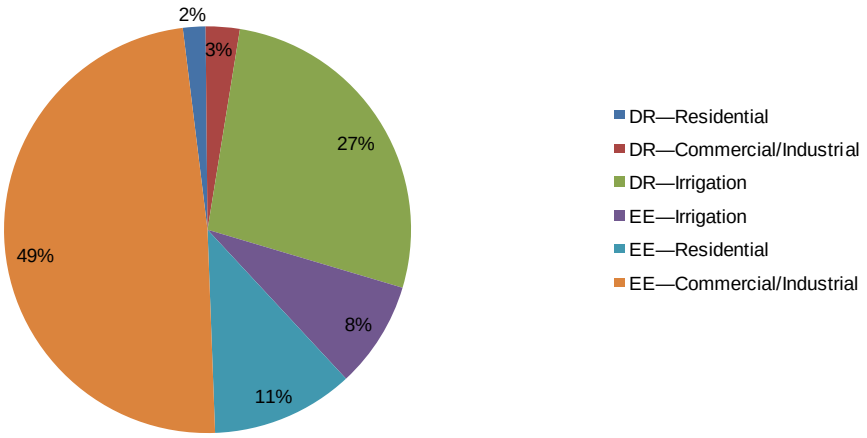

Figure 9. 2016 DSM program incentives by segment and sector

# Marketing

Idaho Power used a variety of marketing, public relations, and research in 2016 to improve communication with its customers. Idaho Power takes advantage of all types of media and marketing. Owned media (social, website, newsletters) and paid media (advertising, sponsorships) allow Idaho Power to control content. Earned unpaid media (news outlets, Idaho Power's *News Briefs* sent to reporters, third-party publications, and television news appearances) gives Idaho Power access to an audience through other channels. Though Idaho Power has less control of the content with earned unpaid media, the value is established from the third-party endorsement.

The following describes a selection of the methods, approaches, and tactics used by Idaho Power to engage with customers regarding energy efficiency, along with their results.

## *All Sectors*

### Social Media

Approximately 17 percent of the company's total social media content promoted energy efficiency in 2016, a significant increase from 8 percent in 2015. Idaho Power distributed more than 200 messages about energy efficiency throughout the year via Facebook, Twitter, LinkedIn, and Instagram. Idaho Power also enjoyed the benefit from many energy efficiency-related organic posts on social media outlets. An organic post is one that originates from the customer.

In 2016, Idaho Power continued its *#TipTuesday* posts on Facebook and Twitter, a tactic launched in late 2015. *#TipTuesday* posts provide Idaho Power's Facebook and Twitter followers with a new energy efficiency tip or program information every Tuesday of the year. The posts use photos, when applicable, and include the hashtag *#TipTuesday* so the tips can be categorized together and easily searched by social media users. The company also posted information about several energy efficiency programs, sponsorships, and events on its social media pages.

### Website

Idaho Power tracked the number of page views to the main energy efficiency pages—also known as landing pages—on the company's website. In 2016, the company's energy efficiency homepage received 34,938 page views; 74,984 page views on the residential landing page; 7,748 page views on the business landing page; and 1,829 page views on the irrigation landing page. The company uses Google Analytics to analyze web activity. Google's definition of page views is the total number of pages viewed, with repeated views of a single page being counted.

### Bill Inserts

A January bill insert was sent to 371,600 customers with winter energy-saving tips. In February, 373,189 customers received a bill insert promoting Idaho Power's em**powered** community. Other program-specific bill inserts were also sent throughout the year. Information about those can be found in each program later in this report.

### Print

Idaho Power updated the look and content of its print collateral, including a brochure and information card that provides a description of each energy efficiency program offering.

### Public Relations

Public relations supported energy efficiency programs and activities through multiple channels: *Connections*, a monthly customer newsletter distributed in approximately 420,000 monthly bills and available online; *News Briefs*, a weekly email of interesting news items sent to all media in the company's service area; pitching and participating in news stories; KTVB (Boise/Twin Falls) and KPVI (Pocatello/Blackfoot) monthly energy-efficiency news segments; news releases and events (such as check presentations).

In 2016, the October and April issues of *Connections* were devoted to energy efficiency. The cover story of the March issue of *Connections* highlighted a customer who applied energy efficient measures on the job, by participating in Idaho Power's Commercial and Industrial Energy Efficiency Program, and at home. Other public relations activities are noted later in this report.

### Staff

NEEA and Idaho Power staff held regular meetings throughout 2016 to coordinate, collaborate, and facilitate marketing. Monthly meetings were held via conference call, and meetings in person occurred in July and August in Portland, and September and November in Boise. All marketing activities are reviewed each month for progress, results, and collaborative opportunities.

To build marketing networks and to learn what works in other regions, Idaho Power staff attended the Chartwell Marketing and Communications Conference in March in Atlanta, the NEEA Efficiency Exchange in April in Coeur d'Alene, and the E Source Utility Marketing Executive Council and E Source Forum held in September in Denver.

## Residential

Idaho Power ran a multi-faceted advertising campaign in the spring (March and April) and fall (September and October) to raise awareness of Idaho Power's energy efficiency programs for residential customers, and to demonstrate that saving energy doesn't have to be challenging. These campaigns included radio, television, newspaper advertisements (ads), digital ads, Facebook ads, *News Briefs* sent to the media, the *Connections* newsletter, and Idaho Power's website to reach a variety of demographics. In 2016, the company added a Smart-saver Pledge to the campaign to engage and encourage customers to make an energy-saving behavior change.

Figure 10 is an example of the campaign materials in 2016.

Figure 10. 2016 energy efficiency awareness campaign

The goals of the campaign are to raise awareness of the programs collectively rather than by individual program; use a variety of methods to reach various customer demographics; use all the methods in the same month to increase customer exposure to the message; and to let customers know they have options when it comes to saving energy. Messaging focused on many ways to create an energy-efficient home with Energy Savings Made Easy as a central theme, illustrating how easy energy efficiency can be with Idaho Power's help. The campaign was awarded second place in the category of Best Ad Campaign for an Investor-owned Utility at the E Source Utility Ad Awards.

Outside of the campaign, Idaho Power also deployed a number of marketing tactics to promote energy saving tips and the company's energy efficiency programs throughout the year. Results of the campaign and other marketing tactics are included below.

### Television

Idaho Power used network television advertising for the spring and fall campaign. The campaign focused on primetime and news programming that reaches the highest percentage of the target market, adults age 35 to 64. Results of the spots were provided for the three major markets—Boise, Pocatello, and Twin Falls.

During the spring campaign, 95 percent of customers in Idaho Power's target audience viewing network television were exposed to the commercial. Targeted customers in Boise saw the ad an average of

13 times, while targeted customers in Pocatello and Twin Falls each saw the ad an average of 12 times. During the fall campaign, 95 percent of targeted customers saw the commercial. Targeted customers in Boise saw the ad an average of 13 times, 18 times in Pocatello, and 12 times in Twin Falls.

### Radio

As part of its spring and fall campaign, Idaho Power ran 30-second radio spots on major commercial radio stations, Spanish speaking radio stations, and National Public Radio (NPR) stations in the service area. The commercial stations that ran the spots had a variety of station formats to obtain optimum reach, including classic rock, news/talk, country, adult alternative, adult contemporary, and classic hits. The message was targeted toward adults ages 35 to 64 throughout Idaho Power's service area.

Results of the spots were provided for the three major markets: Boise, Pocatello and Twin Falls. During the spring campaign, the spots reached 55 percent of the target audience in Boise and 60 percent of the target audience in Pocatello and Twin Falls. The target audience in Boise was exposed to the ad approximately nine times, 17 times in Pocatello, and 15 times in Twin Falls. During the fall campaign, the spots reached 60 percent of the target audience in all three major markets. The target audience was exposed to the message eight times in Boise and 16 times in both Pocatello and Twin Falls during the fall campaign.

In summary, Idaho Power ran 2,616 radio spots during the spring campaign and 2,590 spots during the fall campaign, totaling 5,206 radio spots in 2016.

In April and October, these 30-second spots also ran with accompanying visual banner ads on Pandora internet radio accessed by mobile and web-based devices. In April, records show 1,416,990 impressions and 2,427 banner clicks to the Idaho Power residential energy efficiency web page. October yielded 1,430,376 impressions and 2,058 banner clicks. Impressions are defined as the number of times the ad was displayed, regardless of the media type.

### Print

As part of the spring and fall campaign, print advertising ran in the major daily and weekly newspapers throughout the service area. The ads conveyed individual energy efficiency programs or tips to customers, such as using insulation to keep cool air in and hot air out in summer. The ads were scheduled for 1,902,246 impressions in the spring and 2,087,983 impressions in the fall.

### Social Media

Idaho Power Facebook ads reached 242,224 people and received 3,238,288 impressions and 11,399 clicks to the Idaho Power website during the spring campaign. The company also initially placed a video ad on Instagram, but discontinued the ad a few days later due to low views and click-through rates, and reallocated those funds to Facebook. During the fall campaign, the company reached 223,280 people, and the ad resulted in 1,918,264 impressions and 10,883 clicks to the Idaho Power website.

Throughout the year, Idaho Power also used Facebook boosts for various programs. A boosted post resembles a traditional Facebook post, but, for a fee, Facebook promotes the post higher in users'

News Feeds, increasing the likelihood that the targeted audience will see it. Boosting posts can help increase audience engagement and get more people interacting with the content.

### Pledge

In 2016, Idaho Power launched a new offering, the Smart-saver Pledge (pledge), to encourage customers in Idaho to make an energy saving behavior change. Customers were asked to commit to making an energy-saving behavior change for 21 days, choosing from one of the following: turn thermostat down 1 to 3 degrees; wash full loads of laundry in cold water and hang dry when possible; register for myAccount, and review your energy use once a week; have a "no electronics" night once a week; and use the crockpot or barbeque once a week instead of the stove. In return, pledge participants were entered to win an ENERGY STAR® electric appliance. The pledge was primarily promoted through a bill insert that went to 367,221 customers, social media, *News Briefs*, the October issue of *Connections*, and television news segments on KTVB and KPVI.

Figure 11. The 2016 the Smart-saver Pledge bill insert

Idaho Power received 937 pledges throughout the pledge period and hundreds of additional pledges after the pledge ended. The company also received numerous positive notes from customers about the pledge and their energy habits. The company felt the participants were highly engaged and that the results were generally positive, providing good information for continuing the pledge in future years.

Customers were asked to complete a follow-up survey as part of the pledge. In return, participants were entered to win one $100 cash prize. Four hundred and eight customers responded to the follow-up survey. Highlights include the following:

- Ninety-six percent of respondents fulfilled all 21 days of their pledge.
- Of respondents who answered the question regarding whether they would continue their energy-saving changes, all but one respondent plans to continue with the energy saving changes since the pledge ended.
- Fifty-four percent of respondents indicated they were "very likely" to seek out additional ways to save energy.
- After taking the pledge, just over 97 percent of respondents are "somewhat likely" or "very likely" to participate in an Idaho Power energy efficiency program.

A copy of the full survey results can be found in *Supplement 2: Evaluation*.

### Campaign Results

The response to the spring and fall Energy Savings Made Easy campaign was measured using Idaho Power's em**powered** community, an on-line panel of over 1,000 customers asked to share perceptions and feedback on a variety of topics each month. The following 2016 spring campaign survey results were obtained from 254 community members who hadn't participated in the 2015 campaign survey:

- Forty-four percent of respondents remember seeing or hearing one of the ads.
- Fifty percent of respondents recalled the television ads, the highest rate of recall.
- Eighty-six percent of respondents indicated they are "very likely" or "somewhat likely" to make energy-saving changes in their home after seeing the ads.
- Eighty-three percent are "very interested" or "somewhat interested" in more information about energy savings programs.
- Eighty-two percent of the respondents who recalled seeing or hearing the ads felt positive about them.

A copy of the results of the study is located in *Supplement 2: Evaluation*.

### Energy-Saving Improvements Survey

In early 2016, Idaho Power used its em**powered** community to measure customer's planned energy-saving improvements and their motivation for making changes to their home. Key findings include the following:

- Nearly 74 percent of respondents were “somewhat” or “very likely” to make energy-saving improvements to their home in the next two to three years. The most common improvement is lighting, followed by windows, appliances, insulation, and other.
- The primary motivator for making energy-saving improvements is to save money.
- The biggest barriers to making energy-saving improvements are cost or already making improvements to the home, followed by the perception that these improvements are not needed.
- Financial incentives and free products and services are the top motivators for customers to participate in an Idaho Power energy-saving program.

A copy of the results of the study is located in *Supplement 2: Evaluation*.

## Commercial and Industrial

In mid-2016, Idaho Power renamed the offerings under the overall Commercial and Industrial Energy Efficiency Program to better describe that the program offers customers financial incentives for New Construction, Custom Projects, and Retrofits. The company redesigned much of the program’s marketing materials, and began marketing these offerings, along with Flex Peak, as a single entity with something for every business customer. Marketing activities were targeted toward business customers, architects, engineers, and other design professionals.

### Airport Advertising

Idaho Power expanded its use of airport signage in 2016. Each year, three million people travel through the Boise Airport. Fifty-nine percent of travelers have made purchasing decisions for their companies in the past year. To reach the business customer, Idaho Power placed two backlit display ads. One ad is located at the baggage claim and the other rotates throughout the airport display boards based on availability. Idaho Power also purchased digital network ads which played 10-second Idaho Power video clips on 15 television screens throughout the terminal as part of a three-minute advertising loop. The videos played an estimated 216,000 times per month.

### Print

Several print ads ran in 2016, promoting the Commercial and Industrial Energy Efficiency Program. Ads ran in Alaska Airline’s *Horizon Air Magazine*, Building Owners and Managers Association (BOMA) membership directory and symposium program, American Institute of Architects Idaho Chapter membership directory, Business Insider, Grow Smart Awards event program. The company also placed an ad in the *Idaho Business Review* as part of the publication’s Top Projects Awards that congratulated the 10 companies that had the most energy savings throughout the year.

Revision and updating of the Commercial and Industrial Energy Efficiency Program brochure, business card, and industry specific energy efficiency tip brochures also began in 2016.

### Bill Insert

In August, a bill insert promoting Idaho Power's Commercial and Industrial Energy Efficiency Program was included in 39,742 business customers' bills highlighting how Idaho Power's incentives can save customers money.

### Newsletters

Idaho Power promotes energy efficiency and its programs through the company's *Energy@Work* newsletter. Written for small- and medium-sized business customers, Idaho Power published this newsletter in May and September 2016. Content included customer success stories and information on training opportunities, energy efficiency programs, electric vehicles, reduced wattage T-8 lightbulbs, the water supply optimization cohort (WSOC), and more.

Idaho Power also sends an email newsletter, *Energy Insights*, quarterly to large industrial customers. Topics included how businesses use energy, Idaho Power's environmental efforts, energy efficiency success stories, LED advantages, power quality devices, and more.

### Public Relations

Idaho Power provides public relations support to commercial and industrial customers who want to publicize the work they have done to become more energy efficient. Upon request, Idaho Power creates large-format checks that are used for media events and/or board meetings. Idaho Power will continue to assist customers with public relations opportunities by creating certificates for display within the building and having an Idaho Power representative speak at press events, if requested.

### Sponsorships

Idaho Power's Commercial and Industrial Energy Efficiency Program supports a number of associations and events, including sponsoring the Grow Smart awards, Top Projects Awards, BOMA symposium, American Society of Heating, Refrigeration, and Air Conditioning Engineers (ASHRAE) Technical Conference, and the Idaho Energy and Green Building Conference.

Idaho Power sponsored the BOMA Commercial Real Estate Symposium February 9, in Boise. Idaho Power Vice President of Customer Operations, Vern Porter, spoke about why energy efficiency makes good business sense, how Idaho Power's programs can help businesses save energy and money, and provided an example of a recent energy efficiency project and a reminder about the importance of putting down your phone in the car to Just Drive.

Idaho Power and NEEA were also major sponsors of the Idaho Energy and Green Building Conference, and had two members on the planning committee. The conference, held November 1 and 2 at The Wyndham Garden Boise Airport Hotel, provided four training tracks on energy efficiency and green building, and attracted over 100 participants. The conference targeted policy makers, developers, architects, code officials, engineers, energy professionals, and industrial plant managers and operators.

## *Irrigation*

See the Irrigation Efficiency Rewards section for 2016 irrigation-related marketing activities.

## 2017 Marketing Activities

In 2017, the Idaho Power marketing department plans on several approaches to reach and educate customers: updating the Residential Energy Efficiency Awareness Campaign, developing new Commercial and Industrial Energy Efficiency ads, and enhancing the company website.

The marketing team will refresh the Residential Energy Efficiency Awareness Campaign with new ads that promote different programs and tips. However, the campaign will continue to use the Energy Savings Made Easy theme and cartoon artwork that has resonated with customers. The team will also continue exploring a consistent look and feel for all residential program materials, and consider the potential for email marketing.

A new ad campaign will be implemented for the Commercial and Industrial Energy Efficiency Program. The campaign features former program participants and iconic local landscapes to capture the readers' attention. The ads will speak to small to large businesses, and show that saving energy and money is for everyone. Several of the customers in the ad campaign will be featured in videos about businesses that took advantage of Idaho Power's incentives and the resulting benefits. The ads will be placed in business and association publications, and event programs.

Idaho Power will also move toward a consistent look and feel for marketing materials for business customers. The company will update the remaining industry-specific energy efficiency tip brochures, and may add new industries and inserts highlighting the incentives available for each industry. Customer representatives will use these brochures on customer visits, and the company will consider mailing them to targeted customers.

The company will continue to support various organizations and programs, including the Intermountain Building Operators Association, Building Operators Certification, Center for Advanced Energy Studies Industrial Assessment Center, and more. Idaho Power will market the organizations' services during customer site visits and at technical training workshops and provide discounted registration when appropriate.

Additionally, the company will consider an ad campaign similar to the new Commercial and Industrial Energy Efficiency Program campaign for its irrigation programs.

Idaho Power will also redesign its website to an adaptive framework, including updating navigation for a better customer experience. The company's interactive approach, which began with myAccount in 2015, and saw additional user improvements in 2016, is scheduled for completion in 2017. Idaho Power's new adaptive site will enhance navigation to make energy efficiency program information easier to find. An adaptive website recognizes the device accessing the website and automatically responds or adapts to the dimensions of that device (e.g., a smart phone).

## Cost-Effectiveness

In 2016, most of Idaho Power's energy-efficiency programs were cost-effective, except the Fridge and Freezer Recycling Program, Home Improvement Program and the weatherization programs for income-qualified customers.

The Fridge and Freezer Recycling Program has a UC of 0.92 and TRC of 1.31. In November 2015, the program vendor JACO Environmental, Inc. (JACO), entered receivership and ceased operations. Idaho Power then contracted with Appliance Recycling Center of America (ARCA) and re-launched the program in June 2016. Due to the mid-year launch, the company had forecasted that participation would be at 1,000 units, and the program would likely not be cost-effective from the UC perspective but would be cost-effective from the TRC perspective. This was discussed with the EEAG in February 2016. When considering individual measures within the program, both freezers and refrigerators fail the UC test with a ratio of 0.79 and 0.91 respectively. However, both freezers and refrigerators pass the TRC. However, by allowing the less cost-effective freezers into the program, it increase overall participation and increases the program cost-effectiveness by spreading the portion of the fixed administrative costs across more units.

The Home Improvement Program has a UC of 2.54, TRC of 0.60 and PCT of 0.80. The RTF reduced savings for single-family home weatherization projects in 2015. With the changes, average savings estimates per project for both 2015 and 2016 were just under 50 percent of 2014 projects. These new savings were a result of the nearly 18-month RTF process to calibrate residential savings models. Additionally, in early 2016, the RTF finished calibrating the savings models for multifamily weatherization. These lower savings as well as the DSM avoided costs from the 2015 IRP further reduces the TRC and PCT of the program. Idaho Power analyzed ways to modify the program to improve the cost-effectiveness, but the company concluded that the program would remain not cost-effective. At the November EEAG meeting, the company presented the non-cost-effective aspects of the Home Improvement Program, the result of the company's analysis, and informed EEAG of the company's plan to end the program in 2017.

WAQC had a TRC of 0.65 and a UC ratio of 0.73, and Weatherization Solutions for Eligible Customers had a TRC of 0.70 and a UC ratio of 0.59. The programs showed increased savings and increased cost-effectiveness ratios over 2015. Idaho Power performed a billing analysis of the 2013–2014 weatherization projects from both WAQC and Weatherization Solutions for Eligible Customers. The billing analysis was needed to reflect the increased replacement of forced-air electric resistance heat systems with efficient heat pump systems.

Eleven individual measures in various programs are shown to not be cost-effective from either the UC or TRC perspective. These measures will be discontinued, analyzed for additional NEBs, modified to increase potential per-unit savings, or monitored to examine their impact on the specific program's overall cost-effectiveness.

Table 6. Cost-effectiveness summary by program

| Program/Sector | UC | TRC | Ratepayer Impact Measure (RIM) | PCT |
|---|---|---|---|---|
| Easy Savings | 1.69 | 2.04 | 0.55 | n/a |
| Educational Distributions | 3.63 | 6.33 | 0.65 | n/a |
| Energy Efficient Lighting | 4.27 | 2.52 | 0.68 | 3.17 |
| Energy House Calls | 2.11 | 2.75 | 0.56 | n/a |
| ENERGY STAR ® Homes Northwest | 1.79 | 1.00 | 0.63 | 1.46 |
| Fridge and Freezer Recycling Program | 0.92 | 1.31 | 0.43 | n/a |
| Heating & Cooling Efficiency Program | 2.33 | 1.26 | 0.71 | 1.76 |
| Home Improvement Program | 2.54 | 0.60 | 0.64 | 0.80 |
| Multifamily Energy Savings Program | 1.43 | 2.55 | 0.51 | n/a |
| Rebate Advantage | 3.89 | 3.33 | 0.62 | 6.45 |
| Simple Steps, Smart Savings | 2.40 | 1.33 | 0.61 | 2.13 |
| Weatherization Assistance for Qualified Customers | 0.73 | 0.65 | 0.41 | n/a |
| Weatherization Solutions for Eligible Customers | 0.59 | 0.70 | 0.36 | n/a |
| **Residential Energy Efficiency Sector** | **2.74** | **2.36** | **0.63** | **4.10** |
| Commercial and Industrial Energy Efficiency Program | | | | |
| Custom Projects | 5.26 | 2.86 | 1.44 | 1.92 |
| New Construction | 4.40 | 3.07 | 0.96 | 3.19 |
| Retrofits | 3.83 | 2.64 | 0.93 | 2.83 |
| **Commercial/Industrial Energy Efficiency Sector *** | **4.67** | **2.81** | **1.19** | **2.31** |
| Irrigation Efficiency | 4.95 | 3.21 | 1.34 | 2.78 |
| **Irrigation Energy Efficiency Sector **** | **5.00** | **3.17** | **1.35** | **2.73** |
| **Energy Efficiency Portfolio** | **3.58** | **2.56** | **0.95** | **2.93** |

* Commercial/Industrial Energy Efficiency Sector cost-effectiveness ratios include savings and participant costs from Green Motors projects.
** Irrigation Energy Efficiency Sector cost-effectiveness ratios include savings and participant costs from Green Motors projects.

Details on the cost-effectiveness assumptions and data are included in *Supplement 1: Cost-Effectiveness*.

## Customer Satisfaction

Based on surveys conducted in 2015, Idaho Power ranked fifth out of seven utilities included in the west region midsize segment of the J.D. Power and Associates *2016 Electric Utility Business Customer Satisfaction Study*. Forty-one percent of the business customer respondents in this study indicated they were aware of Idaho Power's energy efficiency programs, and those customers were more satisfied with Idaho Power than customers who are unaware of the programs.

Based on surveys conducted in the last six months of 2015 and the first six months of 2016, Idaho Power ranked third out of 13 utilities included in the west region midsize segment of the J.D. Power and Associates *2016 Electric Utility Residential Customer Satisfaction Study*. Forty-nine percent of the residential respondents in this study indicated they were aware of Idaho Power's energy efficiency programs, and those customers were more satisfied with Idaho Power than customers who are unaware of the programs.

Idaho Power employs Burke, Inc., an independent, third-party research vendor, to conduct quarterly customer relationship surveys to measure the overall customer relationship and satisfaction with Idaho Power. The Burke Customer Relationship Survey measures the satisfaction of a number of aspects of the customer's relationship with Idaho Power, including energy efficiency at a very high level. However, it is not the intent of this survey to measure all aspects of energy efficiency programs offered by Idaho Power.

The 2016 results of Idaho Power's customer relationship survey showed an increase in overall satisfaction from the previous year. Sixty-five percent of customers indicated their needs were met or exceeded by Idaho Power encouraging energy efficiency among its customers.

Figure 12 depicts the annual change in the percent of customers who indicated Idaho Power met or exceeded their needs concerning energy efficiency efforts encouraged by Idaho Power. In 2016, offering energy efficiency programs was one of the overall top five attributes with a positive change in the Burke Customer Relationship Survey.

In 2016, offering energy efficiency programs was one of the overall top five attributes with a positive change in the Burke Customer Relationship Survey. Three questions related to energy efficiency programs in the general relationship survey continued in the 2016 survey: 1) Have you participated in any of Idaho Power's energy efficiency programs? 2) Which energy efficiency program did you participate in? and 3) Overall, how satisfied are you with the energy efficiency program? In 2016, 44 percent of the survey respondents across all sectors indicated they participated in at least one Idaho Power energy efficiency program, and 93 percent were "very" or "somewhat" satisfied with the program they participated in.

Idaho Power will not survey most energy efficiency program participants annually. This is due primarily to a concern of over-surveying program participants and because the measures and specifics of most program designs do not change annually. To ensure meaningful research in the future, Idaho Power will conduct program research periodically (every two to three years), unless there have been major program changes.

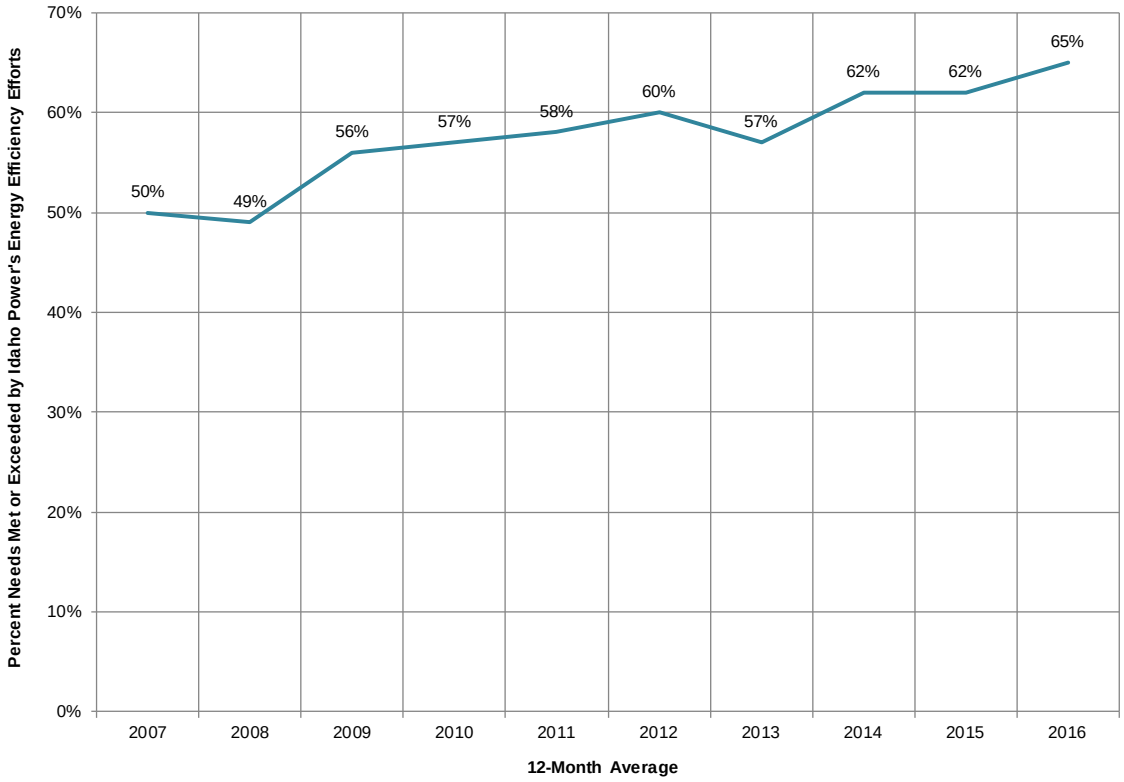

Figure 12. Customers' needs "met" or "exceeded" (percent), 2007–2016

In 2015, Idaho Power created the em**powered** community, an on-line community of residential customers, to measure customer perceptions on a variety of company-related topics, including energy efficiency. Recruiting for the community is conducted annually primarily through billing inserts and mailed postcards. The community has just over 1,000 active members. The em**powered** community includes customers from across Idaho Power's service area. Idaho Power sends out at least one survey per month to active members. Energy efficiency-related survey topics in 2016 included likelihood to install energy-saving improvements, recall of the spring 2016 energy efficiency marketing campaign, energy-efficient lighting, an engagement survey on air conditioning efficiency, thermostatic shower shut-off valves, an engagement survey on using energy-efficient cooking methods and holiday lighting. The average response rate for surveys conducted with the online community is 61.3 percent.

Results of these studies are included in *Supplement 2: Evaluation*.

## Evaluations

In 2016, Idaho Power contracted with Leidos Engineering (Leidos) to conduct four program impact evaluations and two program process evaluations. Impact evaluations were performed for the Retrofit (Easy Upgrades), New Construction (Building Efficiency), Rebate Advantage, and Irrigation Efficiency Rewards programs. Process evaluations were performed for the Rebate Advantage and Irrigation Efficiency Rewards programs. CLEAResult, conducted impact evaluations of the A/C Cool Credit, and Flex Peak programs' 2016 demand response events.

Throughout 2016, Idaho Power administered several surveys regarding energy efficiency programs to measure customer satisfaction. Some surveys were administered by a third-party contractor; other surveys were administered by Idaho Power either through traditional means or through the company's em**powered** community on-line survey.

Final reports from all evaluations, research, and surveys completed in 2016 and an evaluation schedule is provided in *Supplement 2: Evaluation*.

# Residential Sector Overview

Idaho Power's residential sector consists of over 444,431 customers. In 2016, the residential sector's number of customers increased by 8,329, an increase of 1.9 percent from 2015. The residential sector represents 43 percent of Idaho Power's actual total electricity usage and 35 percent of overall revenue in 2016.

Table 7 shows a summary of 2016 participants, costs, and savings from the residential energy efficiency programs.

Table 7. 2016 residential program summary

| Program | Participants | | Total Cost | | Savings | |
|---|---|---|---|---|---|---|
| | | | Utility | Resource | Annual Energy (kWh) | Peak Demand (MW) |
| **Demand Response** | | | | | | |
| A/C Cool Credit | 28,315 | homes | $1,103,295 | $ 1,103,295 | n/a | 34 |
| **Total** | | | **$1,103,295** | **$ 1,103,295** | **n/a** | **34** |
| **Energy Efficiency** | | | | | | |
| Easy Savings | 2,001 | kits | $127,587 | 127,587 | 402,961 | |
| Educational Distributions | 67,065 | kits/lightbulbs | 2,392,884 | 2,392,884 | 15,149,605 | |
| Energy Efficient Lighting | 1,442,561 | lightbulbs | 3,080,708 | 10,770,703 | 21,093,813 | |
| Energy House Calls | 375 | homes | 206,437 | 206,437 | 509,859 | |
| ENERGY STAR® Homes Northwest | 110 | homes | 142,158 | 297,518 | 150,282 | |
| Fridge and Freezer Recycling Program (See ya later, refrigerator®) | 1,539 | refrigerators/freezers | 257,916 | 257,916 | 632,186 | |
| Heating & Cooling Efficiency Program | 486 | projects | 594,913 | 1,404,625 | 1,113,574 | |
| Home Energy Audit | 539 | homes | 289,812 | 289,812 | 207,249 | |
| Home Improvement Program | 482 | homes | 324,024 | 1,685,301 | 500,280 | |
| Multifamily Energy Savings Program | 3 | projects | 59,046 | 59,046 | 149,760 | |
| Oregon Residential Weatherization | 7 | homes | 3,930 | 5,900 | 2,847 | |
| Rebate Advantage | 66 | homes | 111,050 | 148,142 | 411,272 | |
| Shade Tree Project | 2,070 | trees | 76,642 | 76,642 | n/a | |
| Simple Steps, Smart Savings | 7,880 | appliances/ showerheads | 153,784 | 379,752 | 577,320 | |
| Weatherization Assistance for Qualified Customers | 246 | homes/non-profits | 1,289,809 | 1,934,415 | 746,162 | |
| Weatherization Solutions for Eligible Customers | 232 | homes | 1,323,793 | 1,323,793 | 621,653 | |
| **Total** | | | **$10,434,493** | **$21,360,473** | **42,268,823** | **34** |

**Notes:**
See Appendix 3 for notes on methodology and column definitions.
Totals may not add up due to rounding.

In 2016, the company added two new residential programs and reintroduced or modified others. The Multifamily Energy Savings Program was added in March, the ESK program launched in May, and the Fridge and Freezer Recycling program was re-introduced in June. The Home Energy Audits program was extended to customers with non-electric heat sources and a smart thermostat incentive was added to the Heating and Cooling Efficiency (H&CE) Program. Additionally, the residential team supported a Drying Rack Pilot Project.

Idaho Power conducts the Burke Customer Relationship Survey each year. In 2016, 54 percent of residential survey respondents indicated Idaho Power is meeting or exceeding their needs with information on how to use energy wisely and efficiently.

Sixty-three percent of residential respondents indicated Idaho Power is meeting or exceeding their needs by encouraging energy efficiency with its customers. Forty-eight percent of Idaho Power residential customers surveyed in 2016 indicated Idaho Power is meeting or exceeding their needs in offering energy efficiency programs, and 34 percent of the residential survey respondents indicated they have participated in at least one Idaho Power energy efficiency program. Of the residential survey respondents who have participated in at least one Idaho Power energy efficiency program, 86 percent are "very" or "somewhat" satisfied with the program. In 2016, offering energy efficiency programs was one of the residential top five attributes with a positive change in the Burke Customer Relationship Survey.

Forty-nine percent of the Idaho Power residential customers included in the *2016 J.D. Power and Associates Electric Utility Residential Customer Satisfaction Study* indicated they are familiar with Idaho Power's energy efficiency programs.

In 2016, the em**powered** community was surveyed regarding customer recall of the energy efficiency marketing campaign, shut-off shower valves, air conditioning efficiency, energy-efficiency tips, cooking methods, and holiday lighting. Results of these studies are included in *Supplement 2: Evaluation*.

During 2016, presentations to community groups and businesses continued to be an important method of communicating with Idaho Power customers. The company's customer representatives and community education representatives made hundreds of presentations in communities in Idaho Power's service area.

## A/C Cool Credit

| | Utility Benefit/Cost Ratio | n/a | n/a |
| | Total Resource Benefit/Cost Ratio | n/a | n/a |

### Description

Originating in 2003, A/C Cool Credit is a voluntary, dispatchable demand response program for residential customers in Idaho and Oregon. Using communication hardware and software, Idaho Power cycles participants' central air conditioning (A/C) units or heat pumps off and on via a direct load control device installed on the A/C unit. This program enables Idaho Power to reduce system capacity needs during times when summer peak load is high.

Customers' A/C units are controlled using switches that communicate by powerline carrier (PLC). A switch is installed on each customer's A/C unit and allows Idaho Power to cycle the customer's A/C unit during a cycling event.

The cycling season is June 15 through August 15. The maximum number of cycling hours available per season is 60 hours, with a minimum of three cycling events per season. The cycling rate is the percentage of an hour that the A/C unit will be turned off by the switch. For instance, with a 55 percent cycling rate, the switch should be off for 33 minutes of each hour on average, though not 33 consecutive minutes. Instead, the switch turns the A/C unit off for a period of time and then back on for a period of time.

Idaho Power measures the communication levels to validate whether the signal reaches the switches. Interruptions may be caused by a malfunctioning or broken switch, or by an A/C unit that is not powered on. The incentive is $15 per season, paid as a $5 bill credit on the July, August, and September bills. The program is not available on weekends or holidays, and the maximum length of an event is four hours.

## Program Activities

In 2016, over 28,000 customers participated in the program. Three cycling events occurred, and all were successfully deployed.

The first event was Thursday, June 30 from 4 p.m. to 7 p.m. Communication levels were between 92.10 percent and 94.78 percent. The cycling rate was 55 percent. The Boise area temperature was 97 degrees, and the Pocatello/Twin Falls area temperature was 97 degrees. The expected demand reduction for the event was 1.02 kilowatt (kW) per participant for Boise and 0.7 kW per participant for Pocatello/Twin Falls for a total reduction of 27.63 MW. Analysis results show a max reduction of 1.11 kW per participant in Boise, 0.84 kW per participant in Pocatello/Twin Falls, and a total reduction of 30.165 MW. This is 109 percent of expected demand reduction.

The second event was Tuesday, July 26 from 4 p.m. to 7 p.m. Communication levels were between 93.6 percent and 93.99 percent. The cycling rate was 55 percent. The Boise area temperature was 99 degrees, and the Pocatello/Twin Falls area temperature was 95 degrees. The expected demand reduction for the event was 1.09 kW per participant for Boise and 0.68 kW per participant for Pocatello/Twin Falls for a total reduction of 29.23 MW. Analysis results show a max reduction of 1.1 kW per participant in Boise and 0.86 kW per participant in Pocatello/Twin Falls for a total reduction of 29.77 MW. This is 102 percent of expected demand reduction.

The third event was Thursday, July 28 from 4 p.m. to 7 p.m. Communication levels were between 93.99 percent and 94.25 percent. The cycling rate was 55 percent. The Boise area temperature was 99 degrees, and the Pocatello/Twin Falls area temperature was 95 degrees. The expected demand reduction for the event was 1.09 kW per participant for Boise and 0.68 kW per participant for Pocatello/Twin Falls for a total reduction of 29.15 MW. Analysis results show a max reduction of 1.13 kW per participant in Boise, 0.93 kW per participant in Pocatello/Twin Falls, and a total reduction of 30.935 MW. This is 106 percent of expected demand reduction.

## Marketing Activities

Per the settlement agreement reached in Idaho Case No. IPC-E-13-14 and Oregon Case No. UM 1653, Idaho Power did not actively market the A/C Cool Credit program in 2016; however, Idaho Power did actively communicate with participants about the program in an effort to maintain participant retention.

Before the cycling season began, Idaho Power sent current participants a postcard reminding them of the program specifics. Idaho Power also attempted to recruit customers who had moved into a home that already had a load control device installed and previous participants who changed residences to a location that may or may not have a load-control device installed. The company used postcards, phone calls, direct-mail letters, and home visits, leaving door hangers for those not home, to recruit these customers. At the end of the summer, a thank-you postcard was sent to program participants.

## Cost-Effectiveness

Idaho Power determines cost-effectiveness for it demand response program under the terms of IPUC Order No. 32923 and OPUC Order No. 13-482. Under the terms of the orders and the settlement, all of Idaho Power's demand response programs were cost-effective for 2016.

The A/C Cool Credit program was dispatched for 9 event hours and achieved a maximum demand reduction of 33.94 MW. The total expense for 2016 was $1,103,295 and would have remained the same if the program was fully used for 60 hours because there is no variable incentive paid for events beyond the three required events.

In 2016, the cost of operating the three demand response programs was $9.47 million. Idaho Power estimates that if the three programs were dispatched for the full 60 hours, the total costs would have been approximately $12.87 million and would have remained cost-effective.

A complete description of Idaho Power cost-effectiveness of its demand response programs is included in *Supplement 1: Cost-effectiveness.*

## Customer Satisfaction and Evaluations

Idaho Power conducted no customer satisfaction surveys for this program in 2016.

Idaho Power contracted with CLEAResult to complete an impact evaluation of the 2016 A/C Cool Credit program. The goal of the evaluation was to estimate demand reduction achieved during three curtailment events and update the existing predictive model to incorporate results from the 2016 curtailment events.

CLEAResult completed analyses of curtailment events held on June 30, July 26, and July 28, each with a three-hour duration. Results of the analyses showed maximum single hour demand reductions of 1.07 kW, 1.06 kW, and 1.11 kW per participant, respectively, for the three events. The results of the curtailment event analyses showed maximum generation-level demand reductions of 33.09, 32.66, and 33.94 MW, respectively, for the three events. The results of the curtailment event analyses showed maximum meter-level demand reductions of 30.2, 29.8, and 30.9 MW, respectively, for the three events.

The results of the impact evaluation demonstrated that Idaho Power's A/C Cool Credit program functions as intended, and if properly maintained, can be relied on to provide dispatchable demand reduction to the electricity grid. Due to the distinct weather patterns between Boise and Pocatello/Twin Falls, each curtailment event analysis included region-specific results. A copy of the report is included in *Supplement 2: Evaluation*.

## 2017 Program and Marketing Strategies

Idaho Power anticipates no program changes in 2017.

Per the terms of the above-mentioned settlement agreements, Idaho Power will not actively promote the A/C Cool Credit program to solicit new participants through marketing but will accept new participants who request to participate, regardless of whether they were previous participants in the program.

Attempts will continue to be made to recruit previous participants who have moved, as well as new customers moving into homes that already have a load control device installed.

## *Easy Savings*

| | 2016 | 2015 |
|---|---|---|
| **Participation and Savings** | | |
| Participants (kits) | 2,001 | 2,068 |
| Energy Savings (kWh) | 402,961 | 624,536 |
| Demand Reduction (MW) | n/a | n/a |
| **Program Costs by Funding Source** | | |
| Idaho Energy Efficiency Rider | $0 | $0 |
| Oregon Energy Efficiency Rider | $0 | $0 |
| Idaho Power Funds | $127,587 | $127,477 |
| Total Program Costs—All Sources | $127,587 | $127,477 |
| **Program Levelized Costs** | | |
| Utility Levelized Cost ($/kWh) | $0.035 | $0.021 |
| Total Resource Levelized Cost ($/kWh) | $0.035 | $0.021 |
| **Benefit/Cost Ratios** | | |
| Utility Benefit/Cost Ratio | 1.69 | 2.61 |
| Total Resource Benefit/Cost Ratio | 2.04 | 2.95 |

### Description

The desired outcomes of the Easy Savings program are to educate recipients about saving energy in their homes by using energy wisely, to allow hands-on experience while installing low-cost measures, and to reduce the energy burden for energy assistance/Low Income Home Energy Assistance Program (LIHEAP) recipients.

As a result of IPUC Case No. IPC-E-08-10 under Order Nos. 30722 and 30754, Idaho Power committed to fund energy efficiency education for low-income customers and provide $125,000 to Community Action Partnership (CAP) agencies in the Idaho Power service area on a prorated basis. These orders specified that Idaho Power provide educational information to customers who heat their homes with electricity provided by Idaho Power in Idaho. This is accomplished through the development and distribution of kits containing low cost, self-install energy efficiency items and educational materials.

Initiated in 2009, the Easy Savings program straddles two calendar years. The LIHEAP program cycle starts annually in November at CAP agencies and follows the federal fiscal calendar, while Idaho Power summarizes activities annually based on a January to December cycle. However, the following report summarizes activities from November 2015 through October 2016 and covers future plans for the 2016 to 2017 program.

### Program Activities

By April 2016, 2,001 kits from the 2015 to 2016 program year were distributed by regional CAP agencies to Idaho Power customers approved to receive LIHEAP benefits on their Idaho Power bills.

Each kit contained the following low-cost and no-cost energy-saving items and a survey:

- Three LED lightbulbs—9 watts (W)
- Set of draft stopping outlet gaskets
- Digital thermometer
- 1.5 gallons per minute (gpm) kitchen faucet aerator
- One single-line indoor clothesline
- LED nightlight with photocell and a set of reminder stickers and magnets
- Easy Savings Quick Start Guide to installation
- Mail-in survey and energy-savings information

### Marketing Activities

Idaho Power does not actively market this program.

### Cost-Effectiveness

The RTF LED giveaway deemed savings values are used for the three LED lightbulbs included in the kit because the savings are discounted to reflect the potential that all the kit items may not be installed. For the faucet aerator, the RTF does not provide a deemed savings estimate. In Idaho Power's 2012 *Energy Efficiency Potential Study*¸ AEG estimates the annual faucet aerator savings to be 106 kWh. For the single-line clothes line, Idaho Power used the assumptions for the clothes drying racks and discounted the annual savings to be 68 kWh. For further information regarding the clothes drying rack savings, see the *Cost-Effectiveness* section for the Educational Distributions program.

### Customer Satisfaction and Evaluations

A mail-in survey inquiring about installation experiences and actions taken to reduce energy use was included in the 2,001 kits distributed. Returned surveys were analyzed to track the effectiveness and educational impact of the program.

There were 213 completed surveys received from customers describing their experience in installing kit items in their homes during the 2015 to 2016 program. The survey included questions about whether the customer took specific actions to reduce energy use as a result of receiving the kit, as well as questions confirming the installation of kit items.

Over 92 percent of respondents reported they have, or will lower their heat during the day, and just over 90 percent reported they have, or will lower their heat at night. Just over 85 percent of the respondents reported installing at least one of the LEDs provided in the kit. Just over 38 percent of the respondents reported installing the high indoor clothesline and another 30 percent reported they planned to install it.

Overall, survey results showed that almost 39 percent of the respondents installed all kit items. Just over 77 percent of the respondents reported learning a lot about saving energy and money in their home after

completing the *Easy Savings Quick Start Guide*. Copies of the survey and survey results can be found in *Supplement 2: Evaluation*.

During the 2015 to 2016 program, three gift certificates valued at $100 each were provided by Community Action Partnership Association of Idaho, Inc. (CAPAI), to encourage survey completion. A drawing from all returned surveys was held, and three households won a $100 gift certificate.

Idaho Power conducted no program evaluations in 2016.

### 2016 to 2017 Program and Marketing Strategies

For the 2016 to 2017 program period, Idaho Power sent checks totaling $125,000 in October to the five Idaho regional CAP agencies. Each agency signed a Memorandum of Understanding (MOU) agreeing to use 30 percent of the agency's allotment to cover expenses for administering the program at their agency. The 30 percent includes the provision for an agency certified energy educator to inform kit recipients about installation techniques and energy efficiency information.

CAP agencies ordered 2,470 kits in October 2016, and received them from the vendor in November. These kits, which include five LED lightbulbs and an indoor clothesline, will be distributed to customers throughout the 2016 to 2017 LIHEAP season.

Upon completion of kit distribution and receipt of corresponding surveys, Idaho Power and CAPAI will consider program changes for the future.

## Educational Distributions

| | | 2016 | 2015 |
|---|---|---|---|
| **Participation and Savings** | | | |
| | Participants (kits/lightbulbs) | 67,065 | 28,197 |
| | Energy Savings (kWh) | 15,149,605 | 1,669,495 |
| | Demand Reduction (MW) | n/a | n/a |
| **Program Costs by Funding Source** | | | |
| | Idaho Energy Efficiency Rider | $2,334,206 | $432,185 |
| | Oregon Energy Efficiency Rider | $56,164 | $0 |
| | Idaho Power Funds | $2,514 | $0 |
| | Total Program Costs—All Sources | $2,392,884 | $432,185 |
| **Program Levelized Costs** | | | |
| | Utility Levelized Cost ($/kWh) | $0.016 | $0.026 |
| | Total Resource Levelized Cost ($/kWh) | $0.016 | $0.026 |
| **Benefit/Cost Ratios** | | | |
| | Utility Benefit/Cost Ratio | 3.63 | 2.05 |
| | Total Resource Benefit/Cost Ratio | 6.33 | 2.60 |

### Description

Designated as a specific program in 2015, the Educational Distributions effort is administered through the Residential Energy Efficiency Education Initiative and seeks to use low-cost and no-cost channels to deliver energy efficiency items with energy savings directly to customers. As with the initiative, the goal for these distributions is to drive behavior change and create awareness of and demand for energy efficiency programs in Idaho Power's service area.

Items selected for distribution have an initial cost-effectiveness analysis that indicates the installed measure is either currently cost-effective or is expected to be cost-effective in the near future. Typically, selected items have additional benefits beyond traditional energy savings, such as educating customers about energy efficiency, expediting the opportunity for customers to experience newer technology, or allowing Idaho Power to gather data or validate potential energy savings resulting from behavior change.

Idaho Power recognizes that behavioral measures and programs require appropriate education and guidance to optimize savings and will plan education accordingly. Items may be distributed at events, presentations, through direct-mail, or home visits conducted by customer representatives.

#### *Drying Rack Pilot Project*

Idaho Power distributed drying racks to determine whether customers can comfortably shift about 25 percent of their clothes drying from an automatic dryer to a drying rack.

#### *Energy-Saving Kits*

Idaho Power knows that managing household energy use can be a challenge. To help make it easier for families, Idaho Power works with a kit vendor to provide two versions of free ESKs—one for homes

with electric water heaters and one for homes with alternate-source water heaters. Customers enroll online at idahopower.com/save2day, by calling 800-465-6045, or by returning a postcard. Kits are sent directly to the customer's home.

Each ESK contains nine LED lightbulbs—six 60-watt equivalent lightbulbs, three 45-watt equivalent lightbulbs, a digital thermometer (to check refrigerator, freezer and water temperatures), a shower timer, a water flow-rate test bag, an LED night light and educational materials. In addition, the kit for homes with electric water heaters contains a high-efficiency showerhead and three faucet aerators.

Figure 13. Ad for Idaho Power residential customers to order a 2016 ESK

***LED Lightbulbs as Giveaways***

LED lightbulbs are a welcome and effective way to connect Idaho Power with customers, and to begin productive conversations around energy efficiency. Idaho Power field staff and energy efficiency program managers seek opportunities to educate customers about LEDs, and to offer customers a free lightbulb to use immediately in their own homes.

***Student Energy Efficiency Kit Program***

The Student Energy Efficiency Kit (SEEK) program provides fourth- to sixth-grade students in schools in Idaho Power's service area with quality, age-appropriate instruction regarding the wise use of electricity. Each child who participates receives an energy efficiency kit. The products in the kit are selected specifically to encourage energy savings at home and engage families in activities that support and reinforce the concepts taught at school.

Once a class enrolls in the program, teachers receive curriculum and supporting materials. Students receive classroom study materials, a workbook, and a take-home kit containing three LED lightbulbs, a high-efficiency showerhead, an LED nightlight, a furnace filter alarm, a digital thermometer for measuring water, refrigerator and freezer temperatures, a water flow-rate test bag, and a shower timer. At the conclusion of the program, students and teachers return feedback to the vendor indicating how the program was received and which measures have been installed. The vendor uses this feedback to provide a comprehensive program summary report showing program results and savings.

Unlike other residential programs offered by Idaho Power, SEEK results are reported on a school-year basis.

## Program Activities

On February 8, 2016, Idaho Power filed a request with the OPUC seeking authority to implement the Educational Distributions program in Oregon. The company received approval of Oregon Schedule 71 on March 9, 2016.

### *Drying Rack Pilot Project*

Idaho Power gave away approximately 1,300 drying racks at eight events, primarily in the Treasure Valley and Pocatello areas. In the Boise area, attendees at select 2015 fall events filled out a card expressing interest in receiving a free drying rack. Idaho Power representatives explained the enrollment and distribution process, and enrollment emails were sent early in January 2016. Most participants enrolled online, confirming their eligibility and completing a survey about their current laundry habits. Customer distribution events in Boise and Nampa occurred in late January.

The first Pocatello event was held in Fort Hall in March with a slightly different distribution model—customers were enrolled on-site when they presented a current Idaho Power bill. Idaho Power staff administered the pre-survey verbally to each Fort Hall participant.

The Salmon and Pocatello events followed—again with the on-line enrollment strategy. The remaining drying racks were given to American Falls residents in August using a third distribution model. Participants were not pre-enrolled. Instead, customers reviewed eligibility requirements and signed an agreement confirming their eligibility and committing to take the survey within 24 hours of receiving the drying rack.

Education and information regarding efficient laundry practices was conveyed via the website enrollment tool, the enrollment survey, at each event via a "Ways to Save" card addressing ways to "Lighten Your Laundry Load," and through follow-up email prompts.

### *Energy-Saving Kits*

By the end of 2016, 34,546 kits had been shipped—19,715 kits to homes with electric water heaters and 14,831 to homes with alternate-source water heaters. Kits were distributed to all geographic regions within Idaho Power's service area, including 33,682 to Idaho residences and 864 to Oregon homes.

### *LED Lightbulbs as Giveaways*

Field staff distributed over 8,000 lightbulbs at Spring Home and Garden Shows in Pocatello, Twin Falls, and Boise. Participants in Earth Day Events and employee sustainability fairs in Caldwell, Nampa, and Pocatello received lightbulbs. In Boise at Wells Fargo and Hewlett Packard (HP) World Environment Day events attendees received lightbulbs. Oregon customers received lightbulbs at a St. Alphonsus's Safety Fair, Platt Electric Days and a Home Depot children's safety fair. LEDs were also distributed at the Smart Women, Smart Money Conference, West Valley Medical Center employee meetings, Paint the Town™, the Mountain Home Air Force Base, FitOne™ Expo, and through presentations at chambers of commerce and senior centers.

By the end of the year, Idaho Power employees had personally delivered a brief energy efficiency message and distributed 24,913 lightbulbs directly to customers.

#### *SEEK Program*

During the 2015 to 2016 school year, Idaho Power community education representatives actively recruited fourth- to sixth-grade teachers to participate in SEEK. As a result, Resource Action Programs (RAP) delivered 6,305 kits to 219 classrooms in 70 schools within Idaho Power's service area. This resulted in 1,542 MWh of savings.

## Marketing Activities

#### *Drying Rack Pilot Project*

In the Boise area, attendees at select 2015 fall events filled out a card expressing interest in receiving a free drying rack. In other areas, flyers, posters, print ads, online calendars and social media marketing boosted participation to the desired levels. The cover story of the October *Connections* featured customers who had participated in the project, and KPVI in Pocatello ran a news story on the distribution of the drying racks.

#### *Energy-Saving Kits*

Marketing efforts included a direct-mail campaign from the kit vendor to about 15,000 customers in May, publicity via television news segments in May and June on KPVI and KTVB, and social media posts. The program was greatly bolstered by unsolicited social media—in one case, a single Facebook post garnered over 10,000 kit requests.

#### *LED Lightbulbs as Giveaways*

In 2016, Idaho Power field staff and energy efficiency program managers continued to seek opportunities to educate customers about LEDs, and offer customers a free LED lightbulb to use immediately in their own homes.

#### *Student Energy Efficiency Kit Program*

During the 2015 to 2016 school year, Idaho Power community education representatives actively recruited fourth- to sixth-grade teachers to participate in SEEK. In addition, community education representatives appeared on both KPVI (September) and KTVB (October) news segments sharing information about the kits.

## Cost-Effectiveness

In situations where Idaho Power manages the education and distribution through existing distribution channels, the cost-effectiveness calculations will be based on the actual cost of the items. Conversely, if outside vendors are used to assist with distribution, the cost-effectiveness calculations will include all vendor-related charges.

#### *Drying Rack Pilot Project*

Idaho Power is currently assessing if this is an energy-saving and cost-effective measure to continue in the future. To determine an estimate of the potential savings for the drying rack, Idaho Power used estimates from NEEA's *2011 Residential Building Stock Assessment: Single-Family Characteristics and*

*Energy Use (RBSA)*. Based on the Residential Building Stock Assessment (RBSA), study participants in Idaho wash 5.71 loads of laundry per week. Approximately 87.4 percent of those washer loads are dried in a clothes dryer. According to a RTF clothes washer workbook, the baseline dryer uses between 1.36 to 1.27 kWh per load. Using a simple average of these two values, Idaho Power estimates that clothes dryers use approximately 342 kWh per year. However, it must be noted that the NEEA 2014 RBSA Laundry Study estimates that dryers use 805 to 915 kWh per year. For a conservative estimate, Idaho Power kept the 342 kWh per year estimate and assumed that if customers shifted 25 percent of their drying load to a drying rack, they could save at least 85.5 kWh per year.

#### *Energy-Saving Kits*

The RTF provides mail-by-request deemed savings for LED lightbulbs and 1.75 gpm low-flow showerheads. The RTF mail-by-request deemed savings values are discounted to reflect the potential that all of the kit items may not be installed. The LED lightbulbs have a deemed savings value of 10 to 11 kWh per year depending on the lumens of the lightbulb. The 1.75 gpm low-flow showerhead is estimated to save 187 kWh per year. For the faucet aerator, the RTF does not provide a deemed savings estimate. In Idaho Power's 2012 *Energy Efficiency Potential Study*¸ AEG estimates the annual faucet aerator savings to be 106 kWh. The annual savings for an ESK for a home with an electric water heater is 601 kWh. The annual savings for a kit for a home with a non-electric water heater is 96 kWh.

#### *LED Lightbulbs as Giveaways*

In 2016, Idaho Power used the same savings and assumptions as were used in 2014. For the LED giveaways, Idaho Power used the giveaway deemed savings provided by the RTF. The RTF-deemed annual savings of 9 kWh includes assumptions regarding the installation rate, efficiency levels of the existing equipment, and the location of the installation.

#### *SEEK Program*

The cost-effectiveness analysis for the SEEK offering is based on the savings reported by RAP during the 2015 to 2016 school year. RAP calculated the annual savings based on information collected from the participants' home surveys and the installation rate of the kit items. Questions on the survey included the number of individuals in each home, water-heater fuel type, flow rate of old showerheads, and the wattage of any replaced lightbulbs. The response rate for the survey was nearly 71 percent. The survey gathers information on the efficiency level of the existing measure within the home and which efficient measure is installed. The energy savings will vary for each household based on the measures offered within the kit, the number of items installed, and the existing measure that is replaced. Based on the feedback received from the 2015 to 2016 school year, each kit saved approximately 245 kWh annually per household on average. A copy of the report is included in *Supplement 2: Evaluation*.

## Customer Satisfaction and Evaluations

#### *Drying Rack Pilot Project*

When customers enrolled in this pilot, they completed a survey about their current laundry habits. Combined with the post-survey conducted in 2017, the company will analyze the results and determine the potential energy savings of a drying rack. While approximately 1,300 drying racks were distributed in 2016, 2,120 customers completed the pre-survey. Several hundred customers completed the survey, but did not pick up a drying rack

Of customers who own a clothes washer, nearly 35 percent of respondents indicated they have a washer that is less than 5 years old while just over 42 percent of respondents indicated they have a washer that is 5 to 10 years old. Approximately 50 percent of respondents said they own a top-loading clothes washer with a center agitator. Just over 51 percent of respondents wash 3 to 5 loads of laundry each week, while nearly 31 percent of respondents wash 6 to 10 loads of laundry each week.

Of customers who own a clothes dryer, nearly 30 percent of respondents reported that their dryer is less than 5 years old, while nearly 43 percent of respondents indicate their dryer is 5 to10 years old. Just over 29 percent of respondents said they dry 100 percent of their laundry in the dryer, while nearly 53 percent indicated they dry 75 to 99 percent of their laundry in the dryer. Of customers who indicated they dry some of their clothes outside of a clothes dryer, 72 percent of respondents indicated they hang their clothes to dry indoors. When asked how likely they would shift an additional 25 percent or more of their drying to the drying rack, nearly 72 percent of respondents said “very likely,” while just over 26 percent of respondents said “somewhat likely.” A copy of this report is included in *Supplement 2: Evaluation*.

At pickup events, customers were engaged and grateful, tweeting and sharing Facebook posts to let their friends and family know what they were doing.

Figure 14. Customer picking up his drying rack, 2016

Other customers sent emails: “Thank you for the clothes drying rack. I have already used it after picking it up on Saturday at 5 Mile and Franklin. The people were very kind and cheerful and all was organized well. Just wanted to say thank you”

The following Facebook post was indicative of those posted by a number of customers.

Figure 15. Screenshot showing customer appreciation for the drying rack, 2016

But the best part was when participants began to share their stories.

- One customer emailed saying "My drying rack has been so wonderful. About 99% of my laundry is on it. I bought a second one so I can hang the entire weekly batch. Thank you."
- Another emailed, "I am using the drying rack right at the moment! I have loved it. I really appreciate receiving it; I know we have saved energy because of it this summer.
- Another stopped by Idaho Power's booth at the FitOne Expo and raved about her drying rack, stating that she was saving $20 each month.

Other customers' stories were featured in the October edition of *Connections*.

#### *Energy-Saving Kits*

When customers ordered a kit, they completed a short enrollment survey. Upon receipt of the kit, they were encouraged to return a more in-depth survey to indicate which measures had been installed and how satisfied they were with the ordering process. Results from both surveys are included in Supplement 2: *Evaluation*.

Of the 19,715 electric kits distributed, RAP received 2,790 returned surveys for a response rate of just over 14 percent. Of the 14,831 non-electric kits distributed, RAP received 2,588 returned surveys for a response rate of over 17 percent. The overall response rate was over 15 percent.

Approximately 95 percent of respondents indicated they were "very satisfied" with the kit ordering process with 4 percent indicating they "somewhat satisfied." Nearly 94 percent of respondents said they were "very likely" to tell a friend or family member to order a kit. While just over 54 percent of respondents said they were not aware of that Idaho Power had energy efficiency programs and incentives prior to receiving their kit, 99 percent said they were either "very likely" or "somewhat likely" to participate in another energy efficiency program.

Customers organically promoted the ESKs through numerous social media posts similar to the one below. This single post generated tremendous buzz, receiving over 3000 shares and generating over 10,000 enrollments.

Figure 16. Screenshot showing customer excitement on Facebook about the Energy-Saving Kits, 2016

Another customer from Midvale reached out to Idaho Power via the website with this message, "After receiving the free package of LED light bulbs you offered, we have since retrofitted our home and shop with all LED light bulbs, and we love the increased brightness. Thank you for prompting us to make these changes. We definitely want to conserve energy and reduce our power bill to boot!"

***LED Lightbulbs as Giveaways***

Idaho Power conducted no customer satisfaction surveys for this offering in 2016.

Customers at events and presentations continued to readily express appreciation for receiving free LED lightbulbs.

#### *SEEK Program*

The SEEK program is evaluated annually regarding participant satisfaction. For more details on the SEEK program, view the most recent annual report, *Energy Wise® Program Summary Report* located in *Supplement 2: Evaluation*.

Teachers continued to be pleased with the program. One hundred percent of teachers who completed surveys would recommend the program to other colleagues, and 97 percent would conduct the program again. Student engagement remained high as well—71 percent of student surveys were returned, and 69 percent indicated their families changed the way they used energy as a result of the program. Parents also responded favorably, indicating the program was easy to use, they would like to see it continued in local schools, and they would continue to use the kit items at home after completion of the program.

Some participants posted YouTube videos reviewing their kits and the home activities: youtube.com/watch?v=0UrhdTP4ZKc and youtube.com/watch?v=-lyHxacMqvo.

### 2017 Program and Marketing Strategies

#### *Drying Rack Pilot Project*

The Drying Rack Project will be fully evaluated and analyzed to determine how effective the drying racks were in producing the desired behavior change, i.e., reducing automatic dryer use by at least 25 percent. If the project results are favorable, the project may be offered again.

#### *Energy-Saving Kits*

Idaho Power will augment its ESK program with an opportunity to use the basic non-electric water-heating kit as a giveaway, in limited quantities, to garner additional interest and participation at presentations and small events. Promotional materials will be readily available for staff-use at larger events. Social media posts and advertising in the semi-annual *Energy Efficiency Guide*s, *Connections*, and Idaho Power's website will all be used to promote ESKs. Direct and targeted digital marketing campaigns will be considered, as needed, to boost participation with more challenging geographic or demographic populations.

#### *LED Lightbulbs as Giveaways*

Idaho Power plans to continue to offer LED lightbulbs to customers at community events, presentations, and customer visits.

#### *Other Educational Distributions*

Idaho Power will continue to look for opportunities to engage customers with new technologies that stress the importance of energy-efficient behaviors at home. Idaho Power is currently evaluating thermostatic shower valves.

#### *SEEK Program*

Plans for the 2016 to 2017 school year include updating the marketing flyer and developing an electronic marketing piece for distribution to more remote schools and districts. The company will continue to leverage the positive relationships Idaho Power's community education representatives have

within the schools to maintain program participation levels and will heighten visibility to enrollments to add an element of competition amongst the geographic regions. Curriculum will be reviewed for continued relevance to state standards.

## *Energy Efficient Lighting*

| | | 2016 | 2015 |
|---|---|---|---|
| **Participation and Savings** | | | |
| | Participants (lightbulbs) | 1,442,561 | 1,343,255 |
| | Energy Savings (kWh) | 21,093,813 | 15,876,117 |
| | Demand Reduction (MW) | n/a | n/a |
| **Program Costs by Funding Source** | | | |
| | Idaho Energy Efficiency Rider | $3,009,970 | $1,997,292 |
| | Oregon Energy Efficiency Rider | $63,200 | $60,800 |

### Description

Idaho Power and other regional utilities participate in the Simple Steps, Smart Savings™ program, managed by CLEAResult. Idaho Power promotes Simple Steps, Smart Savings offerings to customers in two areas: this lighting program and the appliance promotion program (see the Simple Steps, Smart Savings section of this report).

Initiated in 2002, the Energy Efficient Lighting program follows a markdown model that provides incentives directly to the manufacturers or retailers, with savings passed on to the customer at the point of purchase. The benefits of this model are low administration costs, better availability of products to the customer, and the ability to provide an incentive for specific products. The program goal is to help Idaho Power's Idaho and Oregon residential customers afford to adopt more efficient lighting technology.

ENERGY STAR® lightbulbs, including compact fluorescent lightbulbs (CFL) and LEDs, are a more efficient alternative to standard incandescent and halogen incandescent lightbulbs. Lightbulbs come in a variety of wattages, colors, and styles, including lightbulbs for three-way lights and dimmable fixtures. ENERGY STAR lightbulbs use 70 to 90 percent less energy and last 10 to 25 times longer than traditional incandescent lightbulbs.

Idaho Power pays a flat fee for each kWh savings achieved. The minimum base amount goes directly to buy down the price the product was reduced; the amount applied to administration and marketing varies and can be used for things like retailer promotions. Promotions may include special product placement, additional discounts, and other retail merchandising tactics designed to increase sales.

In addition to managing the program's promotions, CLEAResult is responsible for contracting with retailers and manufacturers, providing marketing materials at the point of purchase, and supporting and training to retailers.

### Program Activities

In 2016, LED lightbulbs comprised 59 percent of lightbulb sales each month, an increase from the 32 percent of lightbulb sales in 2015. LED fixtures comprised approximately 5 percent of lighting sales, up from 3 percent of lighting sales in 2015.

Idaho Power continued to participate in the Bonneville Power Administration (BPA) Simple Steps, Smart Savings program focusing on ENERGY STAR CFLs and LEDs and light fixtures.

In 2016, Idaho Power worked with 16 participating retailers, representing 89 individual store locations throughout its service area. Of those participating retailers, 55 percent were smaller grocery, drug, and hardware stores, and the remaining 45 percent are big box retailers.

### Marketing Activities

In 2016, CLEAResult and participating Simple Steps, Smart Savings utility partners decided the current logo was outdated and needed a new look. CLEAResult developed several new designs, and the utility partners decided the new logo would have a simple message: Simple + Smart. The logo colors were selected so they would standout on shelves to help customers identify qualifying products. Throughout the year, the old point-of-purchase pieces were replaced with the new Simple + Smart pieces.

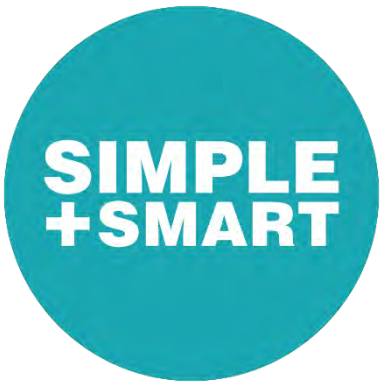

Figure 17. The new 2016 Simple + Smart logo

Several Simple Steps, Smart Savings promotions were conducted through CLEAResult at retail stores in 2016. These promotions generally involved special product placement and signs. CLEAResult staff continued to conduct monthly store visits in 2016 to check on stock, point-of-purchase signs, and displays.

Additional activities in 2016 involved education and marketing. During events where Idaho Power staffed a booth and distributed LED lightbulbs, customers were informed about the importance of using energy-efficient lighting, the quality of LED lightbulbs, and the special pricing available for the Simple Steps, Smart Savings products.

The company continued to host an Energy Efficient Lighting program website; to make available a *Change a Light* program brochure, designed to help customers select the right lightbulb for their needs; and to discuss energy-efficient lighting with customers at community events. Also, ads for the Fridge and Freezer Recycling Program promoted the free LED lightbulb offer. Several #*TipTuesday* posts on social media throughout the year also focused on energy-efficient lighting.

The Idaho Power winter *Energy Efficiency Guide* included two lighting-related articles, and the summer *Energy Efficiency Guide* included a mini-home assessment where customers could gauge how efficient their behaviors are in areas including, lighting, heating and cooling, and more. During energy efficiency segments in November on the KPVI morning news (broadcast in Pocatello) and on KTVB news (broadcast in Boise and Twin Falls), the discussion focused on energy-efficient holiday lighting, timers, inflatables, and laser lights.

### Cost-Effectiveness

In 2016, the Energy Efficient Lighting program provided 50 percent of all energy savings derived from residential energy efficiency customer programs.

In 2016, Idaho Power used the same RTF-deemed savings for both CFLs and LEDs as were used in 2015. For other non-RTF lightbulb types, Idaho Power used the site savings approved by the BPA for the Simple Steps, Smart Savings promotion.

In August 2015, RTF updated and revisited the assumptions for both CFLs and LEDs to account for market changes due to the federal standards compliance. The number of lightbulb types was further reduced to combine three-ways with the general purpose and dimmables. Additionally, the lumen categories were shifted to reflect current consumer trends. Due to the timing of the RTF's update, BPA and CLEAResult did not implement the new savings in the Simple Steps, Smart Savings promotion in 2016.

For detailed cost-effectiveness assumptions, metrics, and sources, see *Supplement 1: Cost-Effectiveness*.

### Customer Satisfaction and Evaluations

Idaho Power conducted no customer satisfaction surveys or program evaluations in 2016.

### 2017 Program and Marketing Strategies

Idaho Power will continue to participate in the Simple Steps, Smart Savings lighting program in 2017 by contracting with CLEAResult, who was awarded the annual BPA implementation contract. New savings will be calculated using the new RTF workbook, version 4.2.

Idaho Power will continue to monitor the number of participating retailers and geographic spread of these retailers, and to develop on-line promotions that allow customers to access promotional pricing regardless of location.

CLEAResult will continue to manage marketing at retailers, including point-of-purchase signs, special product placement, and displays. The program specialist and customer representatives will continue to staff educational events to promote the importance of using energy-efficient lighting.

## *Energy House Calls*

| Utility Benefit/Cost Ratio | 2.11 | 2.81 |
| Total Resource Benefit/Cost Ratio | 2.75 | 2.96 |

### Description

Initiated in 2002, the Energy House Calls program gives homeowners of electrically heated manufactured homes an opportunity to reduce electricity use by improving the home's efficiency. Specifically, this program provides free duct-sealing and additional efficiency measures to Idaho Power customers living in Idaho or Oregon who use an electric furnace or heat pump. Participation is limited to one service call per residence.

Services and products offered through the Energy House Calls program include duct testing and sealing according to Performance Tested Comfort System (PTCS) standards set by the RTF and adopted by the BPA; installing up to eight LED lightbulbs; testing the temperature set on the water heater; installing water heater pipe covers when applicable; up to two low-flow showerheads and bathroom faucet aerators; a kitchen faucet aerator; two replacement furnace filters with installation instructions; and energy efficiency educational materials appropriate for manufactured-home occupants.

Idaho Power provides contractor contact information on its website and marketing materials. The customer schedules an appointment directly with one of the certified contractors in their region. The contractor verifies the customer's initial eligibility by testing the home to determine if it qualifies for duct-sealing. Additionally, contractors have been instructed to install LED lightbulbs only in high-use areas of the home and install bathroom aerators and showerheads only if the upgrade can be performed without damage to a customer's existing fixtures.

The actual energy savings and benefits realized by each customer depend on the measures installed and the repairs and/or adjustments made. Although participation in the program is free, a typical cost for a similar service call would be $400 to $600, depending on the complexity of the repair and the specific measures installed.

## Program Activities

Since the addition of the direct-install measures in March 2015, there has been a slight increase in participation. In 2016, 375 homes received products and/or services through this program, resulting in 509,859 kWh savings (Figure 18).

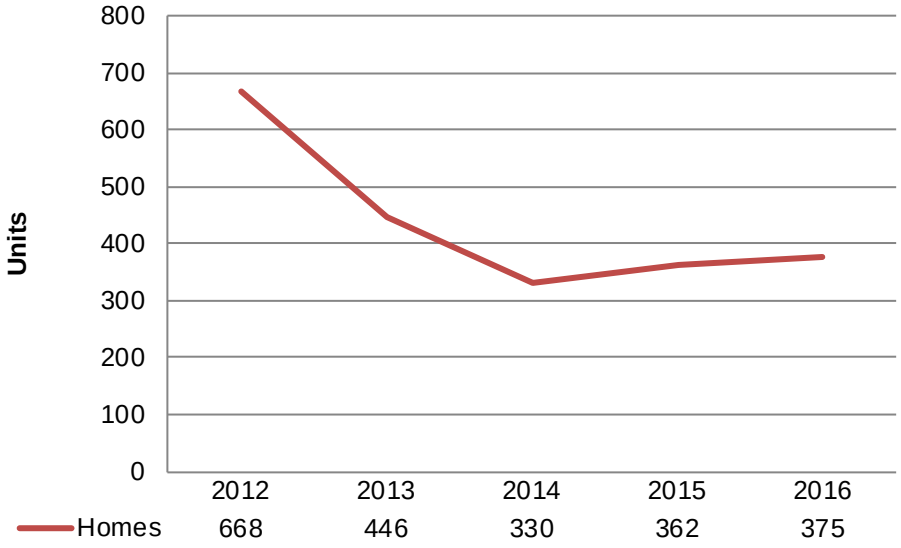

Figure 18. 2012–2016 participation in the Energy House Calls program

Of the total participating homes, 48 percent were located in the Canyon–West Region, 26 percent were located in the Capital Region, and 26 percent were located in the South–East Region.

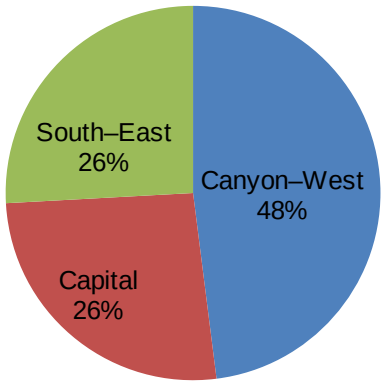

Figure 19. 2016 Energy House Calls participation by region

***Duct-Sealing***

Each year, a number of customers who apply for the Energy House Calls program cannot be served because the ducts do not require duct-sealing or cannot be sealed, for various reasons. These jobs are billed as a test-only job. Some reasons may be the home is too difficult to seal, or the initial duct blaster test identifies the depressurization with respect to the outdoors is less than 150 cubic feet per minute (CFM) and sealing is not needed. Additionally, if, after sealing the duct work, the contractor is unable to reduce leakage by 50 percent, the contractor will bill the job as a test-only job. Prior to 2015, these test-only jobs were not reported in the overall number of jobs completed for that year, because

there was no kWh savings to report. Because Idaho Power now offers direct-install measures in addition to the duct-sealing component, all homes are reported. While some homes may not have been duct sealed, they all would have had some of the direct-install measures included, which would allow us to report kWh savings for each home. Of the 375 homes that participated in 2016, 52 homes were serviced as test-only.

If a home had a blower door and duct blaster test completed, and it is determined that only duct-sealing is necessary, it will be billed as test and seal. For a home with a crossover duct system that needs replaced in addition to the duct-sealing, it will be charged as an x-over. When a home requires the existing belly return system to be decommissioned and have a new return installed along with the duct-sealing, it will be billed as a complex system. A complex system that also requires the installation of a new crossover and duct-sealing will be billed as a complex system and x-over job.

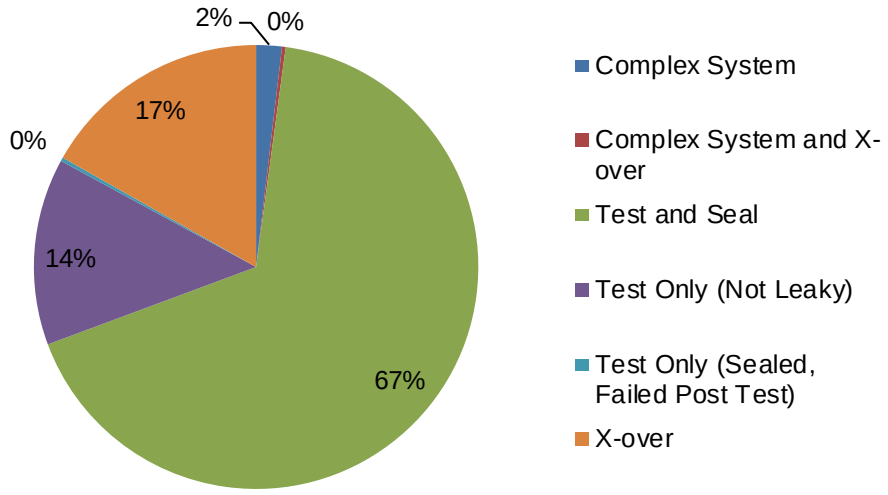

Figure 20. 2016 Energy House Calls participation by job type

***Direct-Install Measures***

In 2016, contractors installed 3,079 LED lightbulbs, 206 showerheads, 351 bathroom aerators and 233 kitchen faucet aerators.

## Marketing Activities

Idaho Power updated all marketing materials in late 2015 and began using them in 2016 to better highlight the program as a free service for manufactured homes and to capture the attention of the target audience. Idaho Power sent two bill inserts to all residential customers in Idaho and Oregon. The March bill insert was shared with the Rebate Advantage program and sent to 374,301 customers, and the October bill insert promoted only the Energy House Calls program and was sent to 378,955 customers. The company sent postcards in February and September to residents of electrically heated manufactured homes who had not yet participated in the program. Written in English and Spanish, 9,042 postcards were delivered in February and 8,650 in September.

Idaho Power also used Facebook ads in February and July. The February ad reached 40,044 people and resulted in 707 website clicks and an increase in enrollments. The July ad reached 60,288 people and resulted in 1,303 website clicks and an increase in enrollment. In addition, Idaho Power customer

representatives and customer service representatives knowledgeable about the program continued to promote the program to qualified customers.

### Cost-Effectiveness

In late 2015, RTF updated savings for performance-based duct-sealing in manufactured homes based on both the Simplified Energy Enthalpy Model (SEEM) calibration and the move toward prescriptive savings only. RTF approved the removal of PTCS requirements for duct-sealing. As a result of these changes, the 2016 deemed savings for duct-sealing are 19 to 60 percent lower than the deemed savings used in 2015.

Savings and a cost-effectiveness analysis for the direct-install measures, including low-flow showerheads, faucet aerators, and LED lightbulbs, were completed using deemed savings from the RTF.

For more detailed information about the cost-effectiveness savings and assumptions, see *Supplement 1: Cost-Effectiveness*.

### Customer Satisfaction and Evaluations

Again this year, Idaho Power contractors reported that customers appreciated receiving the program services and direct-install measures, with most positive comments regarding the free LED lightbulbs. Customers continue to be pleased with the program.

To monitor quality assurance (QA) in 2016, third-party verifications were conducted by Momentum, LLC on approximately 5 percent of the 375 participant homes, resulting in 19 home audits. Homes were selected at random. The QA reports indicate customers were pleased with the work sub-contractors completed in their homes. Each home inspection included an on-site visual confirmation that the reported work had been completed. Weather permitting, blower door and duct blaster tests were also conducted to verify the results submitted by the sub-contractor.

### 2017 Program and Marketing Strategies

Idaho Power will continue to provide free duct-sealing and selected direct-install efficiency measures for all-electric manufactured/mobile homes in its service area.

Idaho Power will continue to include program promotional materials in its bill, to send direct-mail postcards, and to use social media and other proven marketing tactics. Contractors and customer representatives will also distribute door hangers in mobile-home parks and program literature at appropriate events and presentations. Idaho Power will continue to provide Energy House Calls program postcards to CAP agencies for distribution to customers who need assistance but do not qualify to receive weatherization assistance through these agencies.

### Description

Initiated at Idaho Power in 2003, this program targets the lost-opportunity energy savings and summer-demand reduction that is achieved by increasing the efficiency of the residential-building envelope and air-delivery system above current building codes and building practices.

An ENERGY STAR® certified home is a home that has been inspected and tested by an independent, third-party ENERGY STAR Residential Services Network (RESNET)-certified rater working under a RESNET certified provider. The rater is hired by the builder to ensure the stringent ENERGY STAR requirements have been met. In addition to verifying the installation of building components and equipment during on-site inspections, the rater ensures the home passes a blower door test, an air-duct leakage test, and combustion back-draft tests. The ENERGY STAR Homes Northwest residential construction program promotes homes that use electric heat pump technology and are at least 15 percent more energy-efficient than those built to standard Idaho and Oregon code.

ENERGY STAR homes are more efficient, comfortable, and durable than homes constructed to standard building codes. Homes that earn the ENERGY STAR certification must meet six specifications: 1) effective insulation, 2) high-performance windows, 3) air-tight construction and sealed ductwork, 4) energy-efficient lighting, 5) ENERGY STAR qualified appliances, and 6) efficient heating and cooling equipment.

Prior to January 1, 2016, this ENERGY STAR Homes Northwest program was supported by a partnership between Idaho Power and NEEA's Northwest ENERGY STAR Homes to improve and promote the construction of energy-efficient homes using regional program guidelines approved by the United States (US) Environmental Protection Agency (EPA). NEEA has ended their oversight of the regional, single-family Northwest ENERGY STAR Homes program as of January 1, 2016.

All homes throughout the Northwest that were permitted on or after January 1, 2016, are now required to meet national EPA's ENERGY STAR program certification requirements. To receive the Idaho Power program incentive, certified homes in the company's service area must meet the national EPA Version 3, ENERGY STAR Homes requirements and be electrically heated. Additionally, an ENERGY STAR Homes RESNET-certified rater must enter home-related data into the regional AXIS database, which is maintained by NEEA. The AXIS database allows for utility tracking and review. The rater must also generate a Northwest Compliance Report that is consistent with Northwest REM/Rate™ modeling guidelines.

All single-family homes permitted prior to January 1, 2016 and certified by September 30, 2016, were allowed to be certified under the pre-existing NEEA Northwest ENERGY STAR Homes specifications. The regional Northwest ENERGY STAR Homes program retains oversight of multi-family ENERGY STAR Home certifications. To qualify for an Idaho Power Multifamily ENERGY STAR Homes incentive, the rater must certify the homes according to the Northwest Multifamily Builder Option Package (BOP) 1. The rater must enter the multi-family units into the AXIS database for utility tracking and review.

## Program Activities

To encourage the construction of ENERGY STAR homes, the program offered qualified builders a $1,000 incentive per home built to the Northwest ENERGY STAR Single and Multifamily Homes requirements with heat pump technology. Builders who entered their homes in a Parade of Homes were eligible to receive the standard $1,000 incentive plus an additional $500 marketing incentive to cover their expenses for ENERGY STAR signage and brochures. Builders benefit by earning the right to use the ENERGY STAR Homes logo and the ENERGY STAR name to promote themselves as an ENERGY STAR qualified builder.

A large part of the program's role in 2016 was to provide support for the building contractors associations (BCA) throughout Idaho Power's service area.

The regional trend toward increased ENERGY STAR certifications for multi-family homes continued in 2016. Out of 110 total incentives paid through Idaho Power's program, 108 were for multi-family dwellings. The other two were for single-family homes located in McCall as part of NEEA's Next Step Home (NSH) pilot program.

## Marketing Activities

Idaho Power maintained a strong presence in the building industry by supporting the Idaho Building Contractors Association (IBCA) and several of its local affiliates throughout Idaho Power's service area in 2016. The company presented the Energy Efficient Design and Construction Awards to builders who integrated energy efficiency features in their parade homes at the Building Contractors Association of Southwest Idaho (BCASWI) Parade of Homes awards banquet. In addition, the company participated in the BCASWI builder's expo and the Snake River Valley Building Contractors Association (SRVBCA) builder's expo.

Idaho Power supported Parade of Homes events with full-page ENERGY STAR ads in the Parade of Homes magazines of the following BCAs: The Magic Valley Builders Association (MVBA), the BCASWI, SRVBCA, and the Building Contractors Association of Southeast Idaho (BCASEI). Idaho Power also ran ads in the April 20 *Business Insider* and June 10 *Idaho Business Review* targeting residential contractors. Inserts were added to residential customers' billing statements in April and May informing them of Parade of Homes events in their area. Due to a change in tactics, one bill insert was not used in 2016 as originally planned. Instead, social media and a weekly *News Briefs* article to media were used to promote ENERGY STAR Homes and local Parade of Homes events. These tactics allowed Idaho Power to better target potential participants. In addition, the company sponsored the IBCA annual winter and summer meetings.

The program, in collaboration with NEEA, sponsored a Lunch & Learn course on September 27, 2016. This was a two-hour course presented by energy professionals from Advanced Energy. The purpose of this course was to facilitate a summit of residential real estate professionals to explore solutions leading to the increased market value of energy-efficient and green homes. The 35 professionals in attendance included sales agents, brokers, lenders, home inspectors, and home energy experts.

### Cost-Effectiveness

Savings and cost-effectiveness assumptions for the primary multi-family-style home for 2016 were the same compared with 2015. The townhome/multi-family homes in the Boise–Nampa–Caldwell climate zone were cost-effective from a UC and a TRC perspective with the inclusion of the non-energy benefits (NEB). No single-family homes were certified in 2016. Two homes in NEEA's NSH pilot program were completed and incentives were paid in 2016.

For more detailed information about the cost-effectiveness savings and assumptions, see *Supplement 1: Cost-Effectiveness*.

### Customer Satisfaction and Evaluations

Idaho Power conducted no customer satisfaction surveys for this program in 2016.

Independent, RESNET-certified program providers verified the rater's input for accuracy and confirmed that program requirements had been met. The provider then certified each home within the AXIS database. Providers performed file and on-site field QA, and offered technical assistance to the raters who had contracted with them. Per RESNET guidelines, the provider performed QA on minimum of 10 percent of files or desk checks and 1 percent QA on-site field QA of all projects. In 2016, the raters reported no issues resulting from the QAs.

### 2017 Program and Marketing Strategies

Idaho Power will continue to support NEEA's NSH, high-performance specification pilot program. This specification is designed to build homes that are 30 percent more efficient than homes built to standard building codes. Though NEEA is no longer recruiting homes for the pilot, it plans to analyze the data collected through in-home monitoring from all three phases of the pilot. Results are expected by the second quarter of 2017. Homes built during Phase III incorporated NSH minimum requirements,

guidelines, and best practices learned from Phase I and II. When completed, the final version of the NSH specification will be made available to utilities interested in offering NSH incentives. At this time, NEEA does not plan to offer a branded, customer-facing program, based on this specification, to the region.

Idaho Power plans to continue marketing efforts to promote this program to builders and new homebuyers. These marketing efforts include Parade of Homes ads in parade magazines for the BCASWI, SRVBCA, MVBA, and the BCASEI. The company also plans to continue supporting the general events and activities of the IBCA and its local affiliates. Bill inserts, social media, and other advertising will be considered based on past effectiveness.

## *Fridge and Freezer Recycling Program (See ya later, refrigerator®)*

| | Utility Benefit/Cost Ratio | 0.92 | 1.21 |
| | Total Resource Benefit/Cost Ratio | 1.31 | 1.53 |

### Description

Since 2009, the Fridge and Freezer Recycling program (formerly See ya later, refrigerator®) achieves energy savings by removing and recycling qualified refrigerators and stand-alone freezers from residential homes throughout Idaho Power's service area.

Idaho Power uses a third-party contractor to provide most services for this program, including customer service and scheduling, unit pickup, unit recycling, and reporting. Applicants enroll online or by phone, and the contractor screens each to confirm the refrigerator or freezer unit under consideration meets these initial program eligibility requirements: residential grade; at least 10 cubic feet ($ft^3$) as measured using inside dimensions, but no larger than 30 $ft^3$; and in working condition. Idaho Power then screens each applicant to confirm participation eligibility; the program targets older, extra refrigerator and freezer units for maximum savings.

### Program Activities

In late November 2015, Idaho Power learned the program vendor, JACO had entered into receivership and ceased operations. After multiple internal conversations and consulting with EEAG, Idaho Power reintroduced the program using a new vendor, Appliance Recycling Center of America (ARCA), and a new name, Fridge and Freezer Recycling Program. Idaho Power re-launched the program on June 1, 2016.

Despite temporarily suspending the program and reintroducing the program mid-year, Idaho Power received almost as many participants in 2016 as it did in 2015. Idaho Power was invoiced by JACO for 292 units that it picked up in October and November 2015. The invoices were received after JACO entered into receivership. To allow time to ensure all appliances were disposed of according to the terms

of the contract, Idaho Power paid the invoices in 2016. Because no savings from these units were claimed in 2015, the unit count and savings will be claimed in 2016.

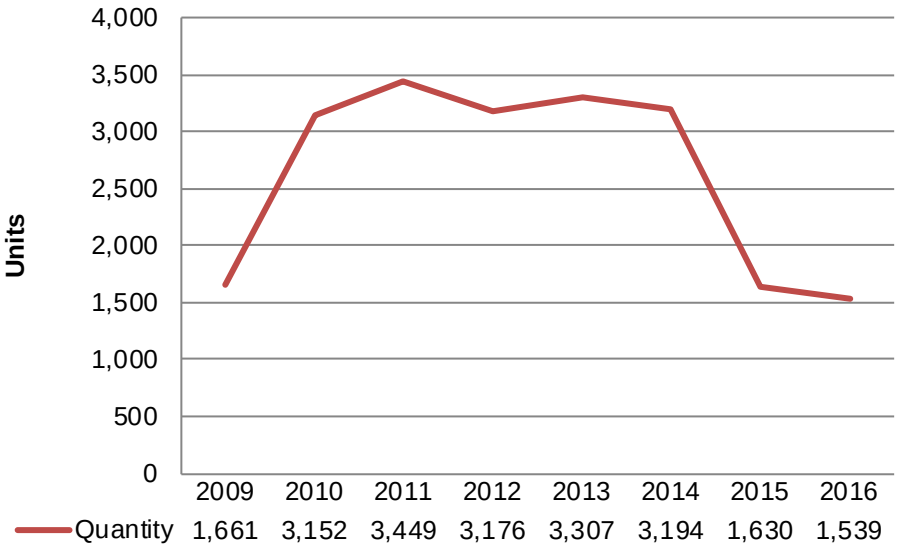

Figure 21. 2009–2016 Fridge and Freezer Recycling Program (See ya later, refrigerator®) participation by year

## Marketing Activities

Idaho Power re-launched the program in June with a new name, new look, and updated web page. The marketing materials used the theme "Retire Your Old Fridge (or Freezer)" with images of a refrigerator retiring on the beach, lake, and Europe among other locations (Figure 22). The new messaging and imagery was chosen to resonate with the program's primary target audience, customers age 35 to 64, but skewing 55 and older. Idaho Power used bill inserts, direct-mail, Facebook, and earned media to promote the program.

Figure 22. 2016 Fridge and Freezer Recycling Program customer postcard

A *News Briefs* email was sent to reporters in June to alert the media and customers of the re-launch of the program. Bill inserts were sent to 228,961 residential customers in June; 377,345 customers in July; 378,671 customers in August; and 378,243 customers in September. In September, a postcard was

mailed to 15,000 customers thought to have a higher propensity to own a second fridge or freezer. The September issue of *Connections* included an ad for the Fridge and Freezer Recycling Program, and the re-launch of the program was mentioned in further detail in the October issue of *Connections*.

Idaho Power placed a Facebook ad in July targeted to customers ages 35 to 65 or older who have an interest in energy efficiency, home improvement, and do-it-yourself efforts. The ad reached nearly 35,000 customers and resulted in 615 clicks to the Fridge and Freezer Recycling Program web page.

In June, Idaho Power promoted the program and the savings that can occur as a result of recycling an older or second fridge or freezer on Pocatello's KPVI live morning news.

Although appliance retailers also refer customers to the program, Idaho Power does not pursue this marketing channel because the goal of the program is to promote the removal of secondary units rather than replacing existing units.

### Cost-Effectiveness

In 2016, Idaho Power used the same savings and assumptions used in 2015. When Idaho Power re-introduced the program in mid-2016, the company forecasted that participation would be at 1,000 units, and the program would likely not be cost-effective from the UC perspective but would be cost-effective from the TRC perspective. Idaho Power discussed this with EEAG in February 2016. When the company filed for program reinstatement in Oregon, the company requested a cost-effectiveness exception as outlined in OPUC Order No. 94-590. The exception was approved by the OPUC in Advice No. 16-07.

Despite the temporary suspension of the program, 1,539 units were recycled in 2016. As a result, the program had a TRC of 1.31 and a UC of 0.92. Had the program been operational for the full 12 months, it is likely that the program would have passed the UC test. In late 2016, RTF revisited and approved new, lower savings for freezer and refrigerator decommissioning, as well as LED bulbs. Idaho Power believes the Fridge and Freezer Recycling Program could be cost-effective in 2017 at the TRC level because of the non-energy benefits associated with decommissioning a refrigerator and freezer. However, the program may not pass the UC test. The company will re-evaluate the program in 2017.

For cost-effectiveness details and assumptions, see *Supplement 1: Cost-Effectiveness*.

### Customer Satisfaction and Evaluations

ARCA tracks individual statistics for each unit collected, including information on how customers heard about the program and when customers enrolled. Statistics about the unit collected include the age of the unit, its location on the customer's property, and other data.

The 2016 unit data showed 19 percent of units the program picked up were stand-alone freezers, and 81 percent of the units were refrigerators. Sixty-nine percent of the units were secondary, 27 percent were primary, and 4 percent were unknown. In 2016, 21 percent of the units collected were manufactured between 1965 and 1990, which generally represents the least efficient years of refrigerator

manufacturing. By comparison, in 2015, 34 percent of the units collected through this program were of this vintage.

ARCA and Idaho Power also tracked data related to the marketing effectiveness of the program. Results of customer tracking information indicate 42 percent of customers learned of the program through bill inserts, and 11 percent from a friend or neighbor.

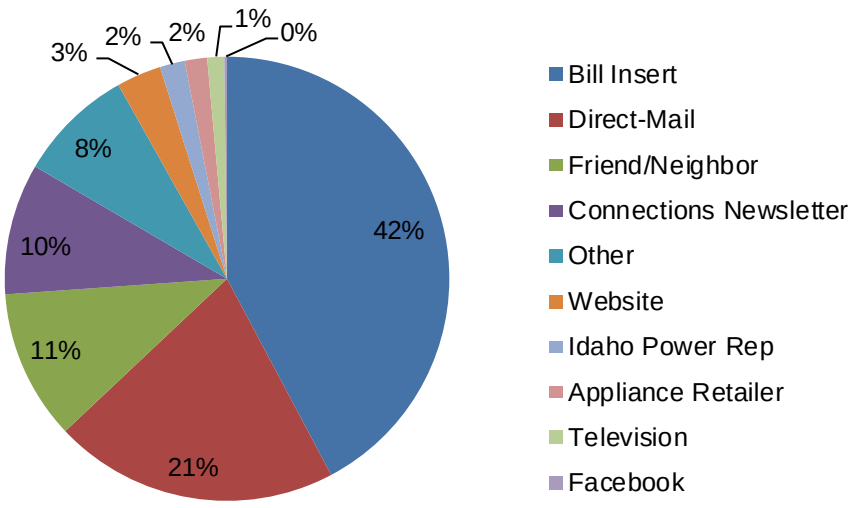

Figure 23. How customers heard about Fridge and Freezer Recycling Program in 2016

Figure 23 indicates ways customers heard about the program. The "Other" category includes sources, such as community events, repeat customers, the truck wrap ad, and unknown sources.

Sixty-seven percent of customers who enrolled used the toll-free telephone number, and 33 percent used the on-line enrollment form.

### 2017 Program and Marketing Strategies

Idaho Power plans to continue the Fridge and Freezer Recycling Program using the current program strategy in 2017, and to monitor its cost-effectiveness for long-term viability.

Idaho Power will continue to use customer information ARCA collected and the surveys from in-house evaluations to target future marketing efforts and increase the effectiveness of marketing. The company plans to use bill inserts, direct-mail, and paid and organic social media posts, and to reach out to customers at community events.

## *Heating & Cooling Efficiency Program*

| | 2016 | 2015 |
|---|---|---|
| **Participation and Savings** | | |
| Participants (projects) | 486 | 427 |

### Description

The Heating & Cooling Efficiency (H&CE) Program provides incentives to residential customers in Idaho Power's Idaho and Oregon service area for the purchase and proper installation of qualified heating and cooling equipment and services.

Initiated in 2007, the objective of the program is to acquire energy savings by providing customers with energy-efficient options for electric space heating and cooling. Incentive payments are provided to the residential customers for all measures. Three of the measures also include a payment to the installing contractor. The available measures in 2016 include ducted air-source heat pumps, ducted open-loop water-source heat pumps, ductless air-source heat pumps, duct-sealing, whole-house fans (WHF), electronically commutated motors (ECM), evaporative coolers, and smart thermostats.

Idaho Power requires licensed contractors to perform the installation services related to these measures, with the exception of evaporative coolers that can be self-installed. A licensed contractor must also be an Idaho Power participating contractor for the ducted air-source heat pump, ducted open-loop water-source heat pump, ductless air-source heat pump, and duct-sealing measures.

The H&CE Program's list of measures and incentives includes the following:

- Customer incentive for replacing an existing ducted air-source heat pump with a new ducted air-source heat pump is $250 for a minimum efficiency 8.5 Heating Seasonal Performance Factor (HSPF).

- Customer incentive for replacing an existing oil or propane heating system with a new ducted air-source heat pump is $400 for a minimum efficiency 8.5 HSPF. Participating homes must be located in areas where natural gas is unavailable.
- Customer incentive for replacing an existing electric forced-air or zonal electric heating system with a new ducted air-source heat pump is $800 for a minimum efficiency 8.5 HSPF.
- Incentive for customers or builders of new construction installing a ducted air-source heat pump in a new home is $400 for a minimum efficiency 8.5 HSPF. Participating homes must be located in areas where natural gas is unavailable.
- Customer incentive for replacing an existing ducted air-source heat pump with a new ducted open-loop water-source heat pump is $500 for a minimum efficiency 3.5 coefficient of performance (COP).
- The customer incentive for replacing an existing electric forced-air or zonal electric, oil, or propane heating system with a new ducted open-loop water-source heat pump is $1,000 for a minimum efficiency 3.5 COP. Participating homes with oil or propane heating systems must be located in areas where natural gas is unavailable.
- The incentive for customers or builders of new construction installing a ducted open-loop water-source heat pump in a new home is $1,000 for a minimum efficiency 3.5 COP. Participating homes must be located in areas where natural gas is unavailable.
- The customer incentive for displacing a zonal electric heating system with a new ductless air-source heat pump is $750.
- The customer incentive for duct-sealing services performed in an existing home with an electric forced-air heating system or a heat pump is $350.
- The customer incentive for a WHF installed in an existing home with central A/C, zonal cooling, or a heat pump is $200.
- The customer incentive for replacing a Permanent Split Capacitor (PSC) air handler motor with an ECM in an existing home with oil or propane or natural gas forced-air heat, electric forced-air heat, or a heat pump is $50.
- The customer incentive for installing an evaporative-cooler is $150.
- The customer incentive for a smart thermostat installed in an existing home with an electric forced-air furnace or a heat pump is $75.

Idaho Power uses Honeywell, Inc., a third-party contractor, to review and enter incentive applications into the Idaho Power system. Honeywell reviews and submits incentive applications for Idaho Power payment using a program database portal developed by Idaho Power. This allows Idaho Power to maintain the database within the company's system, which is secure yet accessible to the third-party contractor. They also perform on-site verifications (OSV) and provide technical support to the customer representatives and contractors. Honeywell offers local program and technical assistance to contractors through on-site visits at their businesses.

## Program Activities

Idaho Power began offering one new measure through the program on March 31, 2016. The measure provided a cash incentive to customers who installed a smart thermostat. During the development stage of this measure, the company provided updates and requested input from EEAG at quarterly meetings. EEAG's feedback regarding the measure was generally positive. With EEAG's recommendation, Idaho Power piloted the measure in 2016, and additional recommendations will be considered when the pilot expands.

The expansion of Idaho Power's network of participating contractors remained a key growth strategy for the program. Idaho Power's goal is to support contractors currently in the program while adding new contractors. The company held meetings with several prospective contractors to support this strategy, and added 15 new companies to the program as authorized participating contractors in 2016.

To qualify to participate in this program, a contractor must first complete the required training regarding program guidelines and technical information on HVAC equipment. Idaho Power held 13 of these training sessions for contractors in 2016.

The 2016 Heating and Cooling Efficiency Program paid incentives are listed in Table 8.

Table 8. H&CE Program incentives paid in 2016 Program incentives paid in 2016

| Incentive Measure | 2016 Project Quantity |
|---|---|
| Ducted Air-Source Heat Pump | 169 |
| Ducted Open-Loop Water-Source Heat Pump | 17 |
| Ductless Heat Pump | 150 |
| Evaporative Cooler | 22 |
| Whole-House Fan | 19 |
| Electronically Commutated Motor | 50 |
| Duct-Sealing | 3 |
| Smart Thermostat | 56 |

The customer representatives, Idaho Power's program contractor, and the program specialist continually engaged with over half of the participating contractors to help them increase participation in the program. Some of the barriers to participation were uncovered anecdotally. One barrier stems from, in many cases, a need for improved technical skills in the HVAC technicians. Employee turnover and a lack of having a repeatable sales process are other barriers addressed. These barriers were addressed by the program specialist through one-on-one discussions with the participating contractors, usually in person. The program has 109 participating contractors therefore much more work will be done in this area.

## Marketing Activities

Idaho Power used multiple marketing methods for its H&CE Program. The company mailed a bill insert to 374,173 residential customers in April and 378,239 residential customers in September. The H&CE Program was also mentioned in the April issue of *Connections*, mailed to all residential customers with

their bill. Several *#TipTuesday* social media posts throughout 2016 focused on heating- and cooling-related tips. Two versions of a direct-mail postcard were sent to a total of 39,457 residential customers in November. The two versions were used as an A/B test (or a comparative test) to determine which new look resonated best with customers.

On several occasions, Idaho Power marketed the new smart thermostat incentive separate from the overall H&CE Program: on May 23, Idaho Power sent a *News Briefs* article to local media that was picked up by 1310 KLIX in Twin Falls; a May *#TipTuesday* social media post; the summer *Energy Efficiency Guide*; and the October issue of *Connections*.

In 2016, emphasis on Idaho Power's contractor portal was reduced since it was not being used by contractors and was found to be of lesser value compared to other support tactics, such as ongoing training on the program process and HVAC technical skills for new and existing contractor employees.

### Cost-Effectiveness

Idaho Power implemented numerous changes to the H&CE Program measures for 2016 savings. Most changes were related to the measure definitions of heat pumps that were adopted by RTF in 2015.

Savings values for retrofit air source heat pumps were changed in 2015 by RTF to reflect different savings values that result from differing weatherization levels of the homes. The updated measure standard requires that a home's savings be assigned by whether the level of insulation is considered, "good," "fair," or "poor." Because of the quality installation component of the program, the overall condition of the home could be determined through contractor worksheets. Most homes had an insulation level of "fair" or "good" resulting in a slight decrease in savings than would have been seen from the previous measure definition not requiring judgment on the home's overall level of insulation.

For the measure level cost-effectiveness, cost data from RTF was used in lieu of actual project costs reported by customers. RTF costs contain updated baseline information for electric forced-air furnaces and air conditioning systems that was not available through local contractor surveys for 2016.

Air-source heat pumps installed in new construction or installed to replace existing less efficient heat pumps saw their claimed savings for 2016 drop significantly from approximately 2,500 kWh per unit to between 55 to 90 kWh depending on the climate zone. The drop was caused by the increased federal manufacturing standard for split system air source heat pumps in January 2015. This change was the biggest reason savings in the program dropped from 2015 levels while overall program participation increased. The air-source heat pump replacing an existing air-source heat pump measure, as with all heat pump measures in the program, mandates proper equipment commissioning, control setting, and sizing (CCS). CCS allows for an additional claimed savings of between 630 and 1,014 kWh per installed heat pump as deemed by RTF.

RTF geothermal heat pump savings, while specifically designed around closed loop systems, were deemed appropriate by RTF to be applied to open loop heat installations. Idaho Power replaced its previous engineering estimate of savings with the savings from the RTF workbook resulting in an

increase in average retrofit savings of 900 kWh and a decline of 300 kWh in annual savings for new construction situations.

Ductless heat pumps (DHP) continue to be not cost-effective using RTF regional costs rather than prices reported on customer applications. RTF costs were used for 2016 cost-effectiveness analysis because the DHP measure definition was changed to reflect differing heating system performance factors. The company does not have sufficient cost data from its projects to split out costs by different levels of efficiency.

For more detailed information about the cost-effectiveness savings, sources, calculations, and assumptions, see *Supplement 1: Cost-Effectiveness*.

## Customer Satisfaction and Evaluations

Honeywell performed random OSV on 47 (10 percent) of the completed installations in Idaho Power's service area. These OSVs confirmed that the information submitted on the paperwork matched what was installed at customers' sites. Overall, the OSV results were favorable with respect to the contractors' quality of work. The program specialist continues to work with contractors to help them understand the importance of accurate documentation and quality installations.

Idaho Power accessed additional information from other sources. In 2016, NEEA provided two reports with identical content that updated the DHP Initiative. A copy of each is included on the CD accompanying *Supplement 2: Evaluation*. The following are highlights from the reports.

#### *NEEA Reports E16-334 and E16-337, released July 2016*

NEEA published this fifth Market Progress Evaluation Report (MPER) for the NW Ductless Heat Pump Project (Initiative). The report discusses findings obtained through extensive surveys, interviews, and focus groups comprised of homeowners, utilities, installers, and supply chain actors. The initiative was launched as a pilot in 2008 to demonstrate that DHPs were a viable technology to displace electric resistance heat in existing homes. The report describes the Initiative as well-designed and continuing to have a positive influence on the market. Some of the findings include the indication that interest continues to grow although lack of awareness remains a barrier. Word of mouth continues to be an initial source of information. DHP owners relied on their own research when making their purchasing decision. Financial considerations can be an opportunity or barrier because while DHPs can provide energy savings they can also be seen as expensive. The report provides detailed recommendations for NEEA to consider in the future.

## 2017 Program and Marketing Strategies

Idaho Power will provide program training to existing and prospective contractors to assist them in meeting program requirements and further their product knowledge. Sessions will be held on-site at contractor businesses and at Idaho Power facilities. Training sessions remain an important part of the program because they create opportunities to invite additional contractors into the program. The sessions also provide refresher training for existing participating contractors, and help them increase their customers' participation while improving the contractors' work quality. An additional dozen other interested companies will be taken through the authorization process by the program specialist.

Developing the existing network of participating contractors remains a key strategy for the program. The performance of the program is substantially dependent on the contractors' abilities to promote and leverage the measures offered. Idaho Power's primary goal in 2017 is to develop contractors currently in the program while adding new contractors. To meet this objective, the program specialist, along with Idaho Power customer representatives, will arrange frequent individual meetings to discuss the program with contractors in 2017.

The 2017 marketing strategy will include several tactics previously used, such as bill inserts, direct-mail, and social media, and will explore using additional tactics to market individual measures and the program as a whole.

## Home Energy Audit

### Description

The current Home Energy Audit program is based on the insights gained from the Boise City Home Audit project conducted in 2011 and 2012, as described in the *Demand-Side Management 2012 Annual Report*. In 2014, the audit project became the Home Energy Audit program under Idaho Power's management.

The Home Energy Audit program is an in-home energy evaluation by a certified, third-party home performance specialist (HPS). It is used to identify areas of concern, and to provide specific recommendations to improve the efficiency, comfort, and health of the home. An audit includes a visual inspection of the crawl space and attic, a health and safety inspection, and a blower door test to identify and locate air leaks. In addition to the evaluation, some energy-saving improvements are installed at no additional cost to the customer if appropriate. After the audit is complete, the customer is supplied with a hardcopy or password-protected electronic copy of the HPS's findings and recommendations. Improvements available from Idaho Power include installation of the following:

- Up to 20 efficient lightbulbs (CFLs and LEDs)
- One high-efficiency showerhead
- Pipe insulation from the water heater to the home wall (approximately 3 feet)

To qualify for the Home Energy Audit program, a participant must live in Idaho and be the Idaho Power customer of record for a home. The home must be an existing site built home, and up until 2016, homes had to be all electric. Renters may participate with prior written permission from the landlord. Single-family homes, duplexes, triplexes, and fourplexes qualify, though multi-family homes must have

discrete heating units and meters for each unit. Manufactured homes, new construction, or buildings with more than four units do not qualify.

Participating customers pay $99 (all-electric homes) or $149 (other homes: gas, propane or other fuel sources) for the audit and installation of measures, with the remaining cost covered by the Home Energy Audit program. The difference in cost covers the additional testing that is necessary for homes that are not all-electric. These types of energy audits normally cost $300 or more, not including the select energy saving measures, materials, and labor. The retail cost of the materials installed in each home averages $145.

### Program Activities

In 2016, this became a fuel-neutral program. This change allows more customers to participate and learn ways to be energy efficient. Even if the space or water heating source in a home is not electric, often there can be many opportunities to use electricity wisely.

Seven HPS companies served the program in 2016. Homes were randomly assigned to the HPSs serving each service area, grouping locations for each HPS to save on travel time and expense. When the program became fuel-neutral, Idaho Power required HPSs who hadn't had previous training in Combustion Appliance Zone (CAZ) testing within the last six months to participate in Idaho Power's CAZ refresher class, or to attend a refresher class offered through another source. Although all HPSs had previous CAZ training, Idaho Power provided a refresher course in February 2016, and all HPSs participated.

In 2016, the program completed 539 energy audits. The average age of participating homes was 34 years old. The homes were built between 1898 and 2015. Home sizes ranged from 288 square feet ($ft^2$) to 8,500 $ft^2$, with 2,403 $ft^2$average home size. Figure 24 depicts the program's reach across Idaho Power's service area, and Figure 25 depicts the space and water heating fuel types.

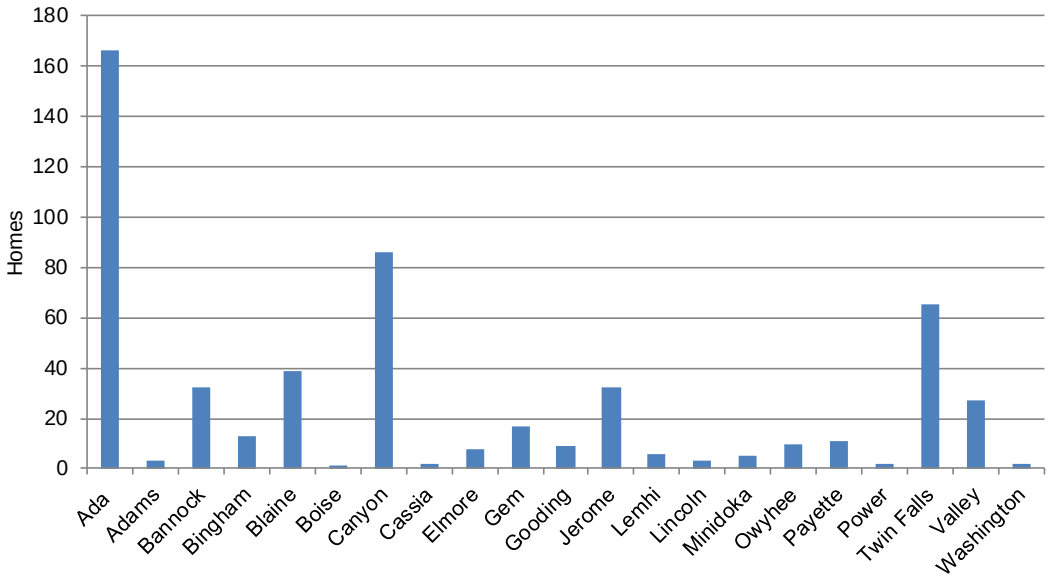

Figure 24. Home Energy Audit summary of participating homes in 2016, by county

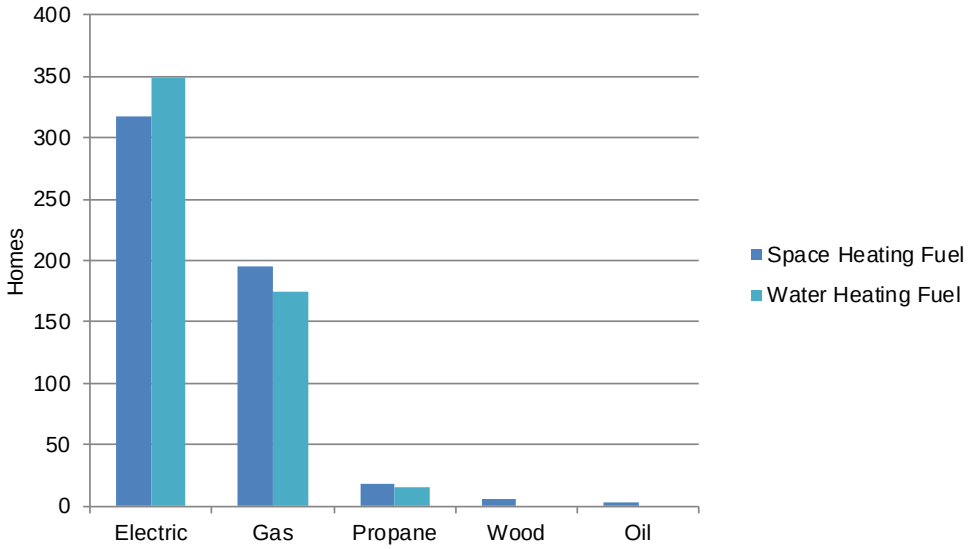

Figure 25. Home Energy Audit summary of space and water heating fuel types, 2016

The HPSs collected information on types and quantities of appliances and lighting in each home. The average number of incandescent lights per home was 21, and the average number of fluorescent or LED lights was 13. When performing an audit, the HPS determined which available measures were appropriate for the home, and, with homeowner approval, those measures were installed. Figure 26 indicates the total quantity of items installed by measure.

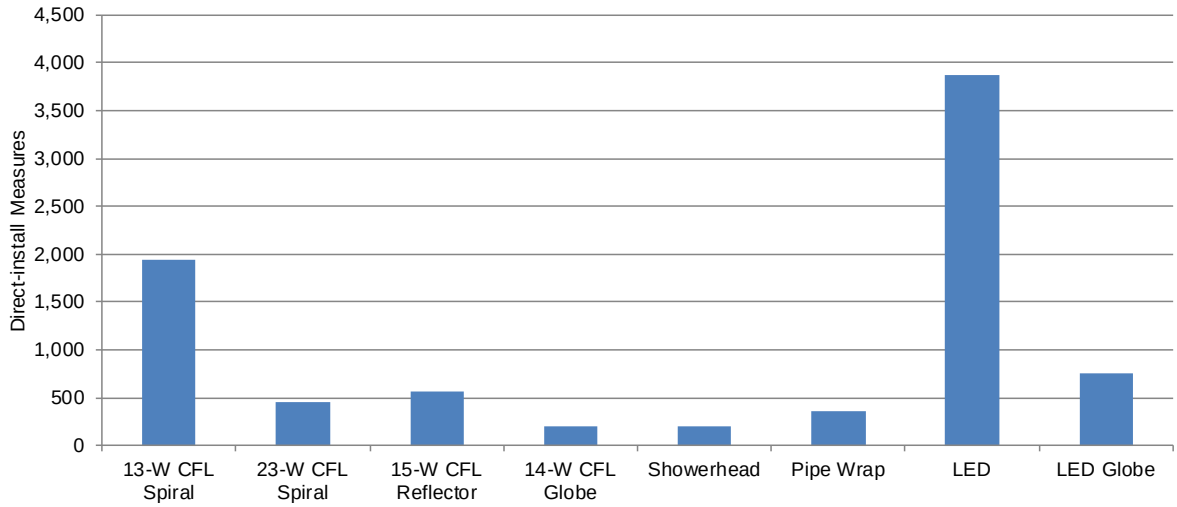

Figure 26. Home Energy Audit measures installed in participating homes in 2016

As Idaho Power's existing stock of CFLs has been used and the cost of LEDs has come down, all new lightbulb orders are for LEDs. With the exception of the CFL 15-watt reflectors, all lightbulbs being installed by the end of 2016 were LEDs.

The QA goal for the program was inspection of 10 percent of all audits, translating into approximately 53 audits in 2016. Ultimately, 34 QAs were completed in 2016, with all audits passing inspection. The 10 percent goal was unmet in 2016 because it was challenging to find participants willing to allow

the auditor into their home for a 1- to 2-hour period, especially if the participant worked outside the home.

### Marketing Activities

In January 2016, all program materials including the website were updated to promote eligibility changes to include all Idaho residential customers, regardless of fuel type. Additionally, an infographic was designed and used online and in social media to provide a visual representation and additional detail on what occurs during the audit.

Idaho Power recruited participants for the program through small batches of 1,000 to 2,000 direct-mail letters. Customers interested in participating were directed to a website for additional information and the on-line application. Those who did not have internet access or were uncomfortable using the on-line application were encouraged to call Idaho Power to apply. A program brochure was added to some mailings, but did not result in an increase in enrollment compared to mailings without the brochure.

In October 2016, Idaho Power partnered with the University of Idaho's Valley County Extension Office to host an energy efficiency workshop in McCall, Idaho. Direct-mail letters were sent to residents, and posters were hung at local businesses inviting the community to attend the evening workshop. Attendees learned how to check their homes for efficiency, how to make improvements, and how to use myAccount. The Home Energy Audit program was emphasized as were various other Idaho Power efficiency programs. For attending, each person was given an LED lightbulb.

Bill inserts were sent to 369,000 residential customers in June and 355,000 residential customers in December. Articles highlighting the Home Energy Audit program were also included in the April and October issues of *Connections*, which is mailed along with the customer's bill.

The Home Energy Audit program was mentioned in the Idaho Power *Winter Energy Efficiency Guide* as a way to improve your home's performance. In addition, the program was the focus of the Idaho Power energy-efficiency segment on the KTVB afternoon news program in March.

Idaho Power used social media, including boosted Facebook posts, throughout 2016 to highlight the Home Energy Audit program. In May, a boosted post targeted to Idaho homeowners ages 35 and older with an interest in home improvement or energy efficiency reached 45,495 people, resulting in 1,745 post engagements (likes, comments and shares). In November and December, Idaho Power used boosted posts targeted to South–East Region customers. These boosted posts reached 44,662 people with 1,229 engagements, 97 shares, and 694 post clicks.

For several months throughout 2016, a short article about the program was also placed in the Pocatello-Chubbuck Chamber of Commerce e-newsletter.

Digital re-targeting advertising was also used to target the South-East Region customers. Customers who visited the Idaho Power website and then moved onto a different website were "followed" by a Home Energy Audits digital ad. Overall, 787,293 impressions were served resulting in 1,993 clicks with a total

click-through rate of 0.25 percent. The total click-through rate was 3.6 times higher than the national average.

## Cost-Effectiveness

One of the goals of the Home Energy Audit program is to increase participants' understanding of how their home uses energy and to encourage their participation in Idaho Power's energy efficiency programs. Since the Home Energy Audit program is primarily an educational and marketing program, the company does not apply the traditional cost-effectiveness tests to the program.

For the items installed directly in the homes, Idaho Power used the same assumptions during 2016 as were used in 2015. Idaho Power used RTF savings for direct-install bulbs, which range from 17 to 30 kWh per year. RTF savings for 2.0 gpm showerheads directly installed in a home are 139 to 166 kWh per year. In Idaho Power's *Energy Efficiency Potential Study*, AEG estimates that pipe wraps save 150 kWh per year. Savings for both showerheads and pipe wrap were only counted for homes with electric water heaters.

In 2015 and 2016, the RTF reviewed and updated the savings assumptions for CFLs, LEDs, and showerheads. These new savings will be applied in 2017.

## Customer Satisfaction and Evaluations

Throughout 2016, a survey was sent to 482 customers who had participated in the program between October 2015 and September 2016. The purpose of the survey was to assess customers' satisfaction with program enrollment, scheduling, the auditor, the personalized report, and information learned. Participants who supplied an email address on the initial program enrollment form were sent an electronic survey (320 participants); those without an email address were sent a hardcopy of the survey with a postage-paid envelope (162 participants). The response rate was just over 43 percent, with 208 participants responding. Program strengths and areas for improvement were also assessed. Results were reviewed for the program as a whole and for responses related to individual HPSs.

When asked a series of questions about their experience with the program, 96 percent of respondents "strongly agree" or "somewhat agree" they would recommend the program to a friend or relative, and just over 94 percent of respondents "strongly agree" or "somewhat agree" they were satisfied with their overall experience with the program. And, over 97 percent of the respondents indicated it was "very easy" or "somewhat easy" to apply for the program.

Over 34 percent of respondents reported accessing their report online through an email address supplied to Idaho Power on the enrollment application, while over 37 percent reported receiving a paper copy, and 28 percent reported receiving their report both ways. Of those who accessed their report online, nearly 64 percent indicated that accessing the report online was "very easy" or "somewhat easy."

HPSs were rated on a number of attributes including courteousness, professionalism, explanation of work/measurement to be performed, explanation of audit recommendations, and overall experience with the HPS. Respondents rated their HPSs as "good" or "excellent" 93 to 100 percent of the time.

When asked how strongly they agree or disagree with statements about what they learned during the audit process, just over 95 percent of respondents "strongly agree" or "somewhat agree" they were more informed about the energy use in their home. Over 81 percent reported they "strongly agree" or "somewhat agree" they were more informed about energy efficiency programs available through Idaho Power. Just over 89 percent indicated they "strongly agree" or "somewhat agree" they learned what additional no- to low-cost actions they could take.

According to the survey, nearly 48 percent of respondents indicated they visited the Idaho Power website after the audit, just over 50 percent unplugged appliances when not in use, over 33 percent signed up for myAccount, and just over 72 percent shared their experience with relatives and/or friends. Just over 78 percent of the respondents reported they replaced additional incandescent lightbulbs with CFLs or LEDs. Just over 37 percent indicated they serviced their heating equipment, and almost 35 percent serviced cooling equipment. Additional information on the actions respondents indicated they already completed or planned to do within the next year are shown in the survey results included in *Supplement 2: Evaluation*.

Survey participants were asked to identify all of the benefits they experienced from participating in the program. Over 73 percent of respondents indicated the biggest benefit they found in the audit was personal satisfaction, with over 75 percent citing raised awareness of energy use, almost 61 percent citing cost savings, nearly 49 percent citing home improvement, approximately 44 percent citing comfort, and almost 37 percent citing benefit to the environment. When survey participants were asked to identify all of the barriers they encounter when making energy-saving changes in their home, over 77 percent of respondents indicated the biggest barrier was cost. Figure 27 shows participant benefits experienced by category and percent.

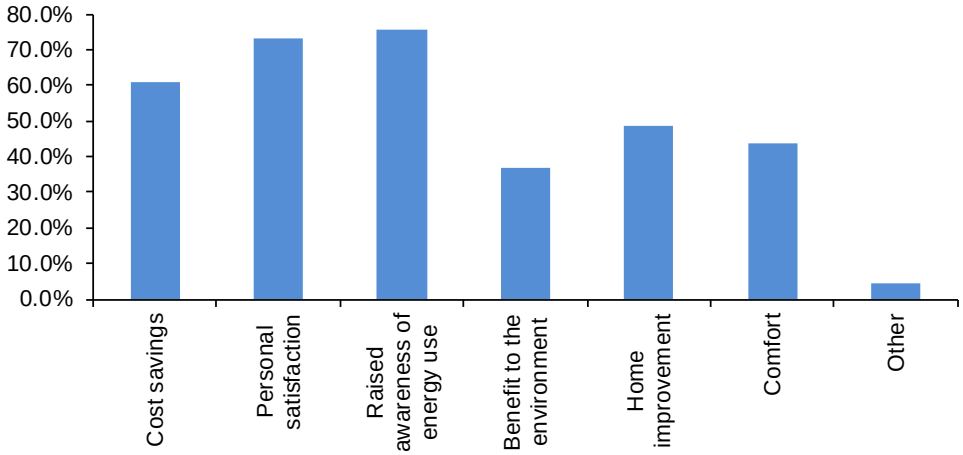

Figure 27. Home Energy Audit program participants' benefits experienced in 2016

Idaho Power conducted no program evaluations in 2016.

## 2017 Program and Marketing Strategies

The 2017 program goal is 500 participants, with approximately half being for all-electric homes and half for homes with other fuel sources for space and water heating. When the Home Energy Audit program

began, the company's goal was to perform QA on 10 percent of the homes audited. The cost of this level of QA was justified to make sure the auditors were complying with the program's specifications. The program is now more established and the QA is verifying that the auditors are meeting and exceeding the requirements. The company believes it is more reasonable to reduce the QA to 5 percent in addition to the online QA and survey results review. Additionally, the company has found it logistically difficult to find 10 percent of the participants who will take the additional time to allow a second visit by a QA auditor.

In 2017, Idaho Power will continue recruiting participants through small batches of direct-mail, social media, advertising, bill inserts and through the use of the trade show booth backdrop at select events. Additional digital advertising may be considered if the program needs to be strategically promoted in specific regions.

## Home Improvement Program

| | Utility Benefit/Cost Ratio | 2.54 | 1.91 |
| | Total Resource Benefit/Cost Ratio | 0.60 | 0.67 |

### Description

Since 2008, the Home Improvement Program has offered incentives for upgrading insulation and windows in electrically heated homes/units. To qualify for an incentive under this program, the home must be a single-family home, a multi-family structure with individually metered residential units, or a manufactured home in Idaho Power's service area in Idaho. The home/units must have an electric heating system serving at least 80 percent of the home's conditioned floor area. The heating system can be a permanently installed electric furnace, heat pump, or electric zonal heating system.

#### *Insulation*

Insulation must be professionally installed between conditioned and unconditioned space by an insulation contractor.

- Customer incentives are 15 cents per $ft^2$ for attic insulation and 50 cents per $ft^2$ for wall and under-floor insulation for additional insulation professionally installed by Idaho residential customers, multi-family building owners, and property managers in Idaho Power's Idaho service area.
- Existing attic insulation must be an R-20 or less to qualify, and the final R-value must meet the local energy code. Idaho Power's service area includes climate zones 5 and 6, resulting in an R-38 requirement for climate zone 5 and R-49 requirement for climate zone 6.
- The existing insulation level in walls must be R-5 or less, and the final R-value must be R-19 or fill the cavity.
- The existing insulation level under floors must be R-5 or less, and the final R-value must be R-30 or fill the cavity.

#### *Windows*

Windows must be professionally installed.

- Customer incentives are $2.50 per $ft^2$ of window area to Idaho residential customers for installing energy-efficient windows and/or sliding glass doors with a U-factor of 0.30 or lower.
- Pre-existing windows/sliding glass doors must be single- or double-pane aluminum or single-pane wood.
- Customers must use a participating contractor to qualify for the Idaho Power incentive, which is processed by Idaho Power.

### Program Activities

During 2016, the Home Improvement Program paid incentives on 482 window and insulation upgrades. Attic insulation accounted for 20 percent, under-floor insulation accounted for 9 percent, wall insulation accounted for 2 percent and windows accounted for 69 percent of completed jobs. Both multi-family and single-family homes took advantage of these program incentives.

### Marketing Activities

In early 2016, Idaho Power developed a new look for all Home Improvement Program marketing materials to better capture the attention of customers, including multi-family building owners, and highlight available incentives. Based on customer feedback, the application form became a part of the updated brochure. The brochure also included a checklist of required documentation to enhance clarification for the customer.

To promote the program, the company ran a series of newspaper ads multiple times during February, March, and September 2016. Idaho Power placed ads in newspapers in rural areas with a higher concentration of electrically heated homes (a program eligibility requirement). The company also sent bill inserts to 361,455 customers in February; 362,473 customers in April; and 364,100 customers in May and a targeted direct-mail letter to 40,000 customers in April and November 2016.

Idaho Power ran Facebook ads in September and reached 86,631 customers, resulting in 10,586 link clicks, 83 likes, 12 shares and had a total cost-per-click of $0.19. Anything at or under that level is good; the $0.19 cost-per-click is considered above expectations for a utility company niche product.

In the April energy efficiency issue of *Connections*, the cover story focused on a customer who had participated in the Home Improvement Program and saw a large reduction in her bill since replacing 13 windows in her home. The *Connections* issue and the customer story was promoted through a *News Briefs* item in April.

### Cost-Effectiveness

In 2015 and 2016, the Home Improvement Program was not cost-effective from the TRC perspective. RTF reduced savings for single-family home weatherization projects between 2013 and 2014, and the reduced savings were updated prior to the 2015 program year. With the changes, average savings

estimates per project were just under 50 percent of 2014 savings levels. These savings estimates were a result of an 18-month RTF process to calibrate residential savings models to billing and housing-characteristic data collected in the northwest, including Idaho, during 2011 as part of the RBSA. As a consequence, the majority of measure combinations in the Home Improvement Program are no longer cost-effective from the TRC perspective--neither is the overall program.

There are several factors that are impacting cost-effectiveness beyond the reduced regional average savings estimates. The few measure combinations that are cost-effective (insulations levels with R-values near zero or existing single-pane windows) are not common in single-family homes. Very little savings from weatherization measures occurs during the summer peak which limits the peak capacity cost-effectiveness benefits in the program.

Home Improvement Program was the only program in Idaho Power's energy efficiency portfolio requiring customer investment where the PCT B/C ratio was less than one at 0.80, which means the customer investment in weatherization on average exceeds the lifetime energy savings benefits, or that for every $1.00 invested by the customer to participate in the program, the customer only sees a $0.80 return through bill savings over 45 years.

For more detailed information about the cost-effectiveness calculations and assumptions, see *Supplement 1: Cost-Effectiveness*.

### Customer Satisfaction and Evaluations

For QA purposes, third-party contractors performed random reviews of at least 5 percent of all installations completed in the Home Improvement Program. QA contractors verified the correct installation of measures. In addition, the QA contractors assisted and educated the contractors on program requirements. Of the 30 QA inspections completed in 2016, no major issues were reported.

The program incentive application form included an optional question asking customers how they heard about the program. The 482 projects came in on 459 applications. Customers answered the marketing question on 437 applications. The results are as follows:

- 248 respondents (56.8%) heard about the program from a program contractor.
- 114 respondents (26.1%) heard about the program from an Idaho Power bill insert.
- 45 respondents (10.3%) heard about the program from the Idaho Power website.
- 18 respondents (4.1%) received a referral from a friend or acquaintance.
- 4 respondents (.9%) heard about the program from a direct-mail piece.
- 8 respondents (1.8%) heard about the program from a newspaper, online, or television/radio ad.
- 0 respondents (0%) heard about the program from a home improvement show or fair.

## 2017 Program and Marketing Strategies

As reported in the *Demand-Side Management 2015 Annual Report*, the recalibrated savings from the RTF resulted in four of the six measures not being cost-effective from the TRC perspective. This program was not cost-effective from a TRC perspective in 2015. In 2016, the program was not cost-effective from a TRC or PCT perspective but was cost-effective from the UC perspective.

In 2016, the company evaluated the non-cost-effective measures and the potential impact of those measures on the program's overall cost-effectiveness. Idaho Power first discussed the concerns it had regarding the continued deterioration in cost-effectiveness of the Home Improvement Program with EEAG during the August 30, 2016 EEAG meeting, and Idaho Power committed to presenting its preliminary 2016 cost-effectiveness findings at the November 3, 2016 EEAG meeting.

At the November meeting, the company informed EEAG that the program was not cost-effective in 2016 based on preliminary savings information. The company advised EEAG that under the scenarios it evaluated, the cost-effectiveness of the Home Improvement Program would not improve. The company assured EEAG it would continue to encourage customers through education to continue to upgrade these measures even though an incentive may no longer be offered and asked for suggestions from EEAG members as to how Idaho Power could best sunset the program.

At this meeting, EEAG suggested the company wait until 2017 to end the program to ensure customers had adequate time to benefit from program incentives and look at a more targeted approach for the program.

Idaho Power analyzed different scenarios to modify the program to improve its cost-effectiveness. One scenario was to consider only offering the highest savings measure combinations in only the coldest climate zone (heating zone 3). These areas produce on average less than 5 percent of the projects annually. Under this scenario, the modified program would fail all the cost-effectiveness tests except the PCT.

In another scenario, Idaho Power analyzed offering only those measure combinations closest to being cost-effective; this modified program would only include window replacements in situations where there are existing single pane window, and insulation incentives where the existing home's R-value is essentially zero. Under this scenario, the program would remain not cost-effective under all tests except the UC test which would decrease from 2.54 as the program exists today to 1.42.

Due to the continued lack of cost-effectiveness, Idaho Power ceased marketing the program in the fourth quarter of 2016. The company plans to sunset the Home Improvement Program beginning on June 30, 2017. Customers will have 90 days from the day the job is started to submit their incentive applications, and those customers whose jobs were started on or before June 30, 2017, will qualify for an incentive.

## *Multifamily Energy Savings Program*

| | 2016 | 2015 |
|---|---|---|
| **Participation and Savings** | | |
| Participants (projects) | 3 | n/a |
| Energy Savings (kWh) | 149,760 | n/a |
| Demand Reduction (MW) | n/a | n/a |
| **Program Costs by Funding Source** | | |
| Idaho Energy Efficiency Rider | $55,758 | n/a |
| Oregon Energy Efficiency Rider | $0 | n/a |
| Idaho Power Funds | $3,288 | n/a |
| Total Program Costs—All Sources | $59,046 | n/a |
| **Program Levelized Costs** | | |
| Utility Levelized Cost ($/kWh) | $0.040 | n/a |
| Total Resource Levelized Cost ($/kWh) | $0.040 | n/a |
| **Benefit/Cost Ratios** | | |
| Utility Benefit/Cost Ratio | 1.43 | n/a |
| Total Resource Benefit/Cost Ratio | 2.55 | n/a |

### Description

The Multifamily Energy Savings Program provides for the direct installation of energy-saving products in electrically heated, multi-family dwellings in Idaho and Oregon. The definition of multi-family dwelling is a building consisting of five or more rental units. The products are: ENERGY STAR® LED lightbulbs, high-efficiency showerheads, kitchen and bathroom faucet aerators, and water heater pipe insulation, and are installed at no cost to the property owner/property manager or the tenant. To ensure energy savings and applicability, each building is pre-approved by the contracted energy efficiency measure installation contractor.

### Program Activities

The program began in March 2016 with a successful pilot project in Pocatello. This was followed by direct install projects in Boise and Twin Falls in September and December respectively. Between all three projects, a total of 196 apartment units received some if not all of the following; ENERGY STAR LED lightbulbs, high-efficiency showerheads, kitchen and bathroom faucet aerators, and water heater pipe insulation.

- Fairway Apartments, Pocatello: 73 units
- Greenbriar Apartments, Boise: 43 units
- Washington Park Apartments, Twin Falls: 80 units

### Marketing Activities

Tenants in participating apartment complexes received a door hanger before the service date informing them that contractors would be entering their home to install energy-saving products. Once installation

was complete, Idaho Power left materials to explain the new energy efficiency measures and to provide contact information should the tenant have any questions.

### Cost-Effectiveness

The RTF provides deemed savings for LED lightbulbs and 2.0 gpm low-flow showerheads. The LED lightbulbs have a deemed savings value of 11 to 32 kWh per year depending on the type and lumens of the lightbulb. The 2.0 gpm low-flow showerhead is estimated to save 139 kWh per year. For the faucet aerator and pipe wrap, RTF does not provide a deemed savings estimate. In Idaho Power's 2012 *Energy Efficiency Potential Study*¸ AEG estimated the annual faucet aerator savings to be 106 kWh and the annual pipe wrap savings to be 150 kWh.

### Customer Satisfaction and Evaluations

Idaho Power included a satisfaction survey on the leave behind materials for the Pocatello pilot project. Both an online and mail-in option were offered. The response rate was very low with only six of the 73 residents responding by mailing in the stamped survey cards, no on-line surveys were submitted. These results will be considered with the expansion of this program.

### 2017 Program and Marketing Strategies

In 2017, Idaho Power plans to expand the program to include a minimum of two, energy-efficient measure direct-installation projects in multi-family dwellings in each of our three regions. The satisfaction survey will be revised and included in 2017 leave behind materials for all projects. Property managers/owners will also be surveyed.

Idaho Power will continue to use informative pre-installation door hangers and post-installation informational marketing pieces. Use of direct-mail will be explored to encourage engagement and participation from property owners/managers, and to increase program visibility.

## Oregon Residential Weatherization

| | 2016 | 2015 |
|---|---|---|
| **Participation and Savings** | | |
| Participants (audits/projects) | 7 | 19 |
| Energy Savings (kWh) | 2,847 | 11,910 |
| Demand Reduction (MW) | n/a | n/a |
| **Program Costs by Funding Source** | | |
| Idaho Energy Efficiency Rider | $0 | $0 |
| Oregon Energy Efficiency Rider | $3,906 | $5,341 |
| Idaho Power Funds | $24 | $467 |
| Total Program Costs—All Sources | $3,930 | $5,808 |
| **Program Levelized Costs** | | |
| Utility Levelized Cost ($/kWh) | $0.079 | $0.028 |
| Total Resource Levelized Cost ($/kWh) | $0.118 | $0.050 |
| **Benefit/Cost Ratios** | | |
| Utility Benefit/Cost Ratio | n/a | n/a |
| Total Resource Benefit/Cost Ratio | n/a | n/a |

### Description

Idaho Power offers free energy audits for electrically heated customer homes within the Oregon service area. This is a program required by Oregon Revised Statute (ORS) 469.633 offered under Oregon Tariff Schedule 78 since 1980. Upon a customer's request, an Idaho Power customer representative visits the home to analyze it for energy efficiency opportunities. An estimate of costs and savings for specific measures is given to the customer. Customers may choose either a cash incentive or a 6.5-percent interest loan for a portion of the costs for weatherization measures.

### Program Activities

Seven customers returned a card from the brochure indicating interest in a home energy audit, weatherization loan, or incentive payment. Seven customers requested audits, three audits met the program requirements and were completed, and three customers did not have electric heat and were advised to contact their heating source supplier for program information. One customer did not move forward with the recommended energy efficiency upgrades. Two incentives were paid.

Idaho Power issued two incentives totaling $426.44 for 2,847 kWh savings. Both incentives and related savings were for ceiling insulation measures. There were no loans made through this program during 2016.

### Marketing Activities

During May, as required, Idaho Power sent every Oregon residential customer an informational brochure about energy audits and home weatherization financing.

## Cost-Effectiveness

The Oregon Residential Weatherization program is a statutory program described in Oregon Schedule 78, and includes a cost-effectiveness definition of this program. Pages three and four of the schedule identify the measures determined to be cost-effective and the specified measure life cycles for each. This schedule also includes the cost-effective limit (CEL) for measure lives of seven, 15, 25, and 30 years.

Two savings projects were completed under this program in 2016; both consisted of increasing attic insulation. Combined, the projects' annual energy savings is 2,847 kWh at a levelized TRC of $0.12 per kWh over the 30-year attic insulation measure life compared to a CEL of $0.85 per kWh as defined by Oregon Schedule 78.

## Customer Satisfaction and Evaluations

Idaho Power conducted no customer satisfaction surveys or program evaluations in 2016.

## 2017 Program and Marketing Strategies

Idaho Power will complete requested audits and fulfill all incentives deemed cost-effective and loan applications as required by under Tariff Schedule 78. The company will continue to market the program to customers with a bill insert/brochure in their May bill.

## *Rebate Advantage*

| | 2016 | 2015 |
|---|---|---|
| **Participation and Savings** | | |
| Participants (participants) | 66 | 58 |
| Energy Savings (kWh) | 411,272 | 358,683 |
| Demand Reduction (MW) | n/a | n/a |
| **Program Costs by Funding Source** | | |
| Idaho Energy Efficiency Rider | $103,056 | $80,243 |
| Oregon Energy Efficiency Rider | $6,392 | $4,351 |
| Idaho Power Funds | $1,602 | $843 |
| Total Program Costs—All Sources | $111,050 | $85,438 |
| **Program Levelized Costs** | | |
| Utility Levelized Cost ($/kWh) | $0.016 | $0.014 |
| Total Resource Levelized Cost ($/kWh) | $0.022 | $0.020 |
| **Benefit/Cost Ratios** | | |
| Utility Benefit/Cost Ratio | 3.89 | 4.54 |
| Total Resource Benefit/Cost Ratio | 3.33 | 3.45 |

### Description

Initiated in 2003, the Rebate Advantage program helps Idaho Power customers in Idaho and Oregon with the initial costs associated with purchasing a new, energy-efficient, ENERGY STAR® qualified manufactured home. This enables the homebuyer to enjoy the long-term benefit of lower electric bills and greater comfort provided by these homes. The program also provides an incentive to the sales consultants to encourage more sales of ENERGY STAR qualified homes and more discussion of energy efficiency with their customers during the sales process.

In addition to offering financial incentives, the Rebate Advantage program promotes and educates buyers and retailers of manufactured homes about the benefits of owning energy-efficient models. The Northwest Energy Efficient Manufactured (NEEM) housing program establishes quality control (QC) and energy efficiency specifications for qualified homes. NEEM is a consortium of manufacturers and state energy offices in the Northwest. In addition to specifications and quality, NEEM tracks the production and on-site performance of ENERGY STAR qualified manufactured homes.

### Program Activities

Idaho Power residential customers who purchased a new, all-electric, ENERGY STAR qualified manufactured home in 2016, and sited it in Idaho Power's service area were eligible for a $1,000 incentive through the Rebate Advantage program. Salespersons received $200 for each qualified home they sold.

During 2016, Idaho Power paid 66 incentives on new manufactured homes, which accounted for 411,272 annual kWh savings.

### Marketing Activities

One bill insert, shared with the Energy House Calls program, was sent to 374,301 customers in Idaho and Oregon in March. A second bill insert and Facebook ads were not used because the program had exceeded its goal, and both techniques identified had limited options to target potential participants and proved less successful than direct dealer support.

Idaho Power continued to support dealerships in 2016 by providing them with Rebate Advantage program brochures, banners, and applications as needed. The program specialist and the customer representatives visited some of these dealerships to distribute materials, promote the program, and answer salespersons' questions.

### Cost-Effectiveness

In 2016, Idaho Power used the same savings and assumptions as were used in 2015. The measures remained cost-effective for 2016.

### Customer Satisfaction and Evaluations

Idaho Power conducted no customer satisfaction surveys for this program in 2016.

In 2016, Idaho Power contracted with Leidos to perform an impact and process evaluation for this program. The impact evaluation found that submitted applications were accurately assigned ex-ante unit energy savings values according to assigned equipment type, cooling zone, and heating zone codes in the tracking database.

Equipment type was determined to vary between ENERGY STAR with electric resistance heating, Eco-Rated with electric resistance heating, and ENERGY STAR with electric heat pump heating. This equipment appeared to be accurately coded in the tracking database (with the exception of two Eco-Rated projects which were assigned "regular" ENERGY STAR savings values). Accuracy of cooling zone and heating zone coding for each project could not be verified due to lack of information about how these codes were assigned. Overall, this impact evaluation found an ex-post savings realization rate that exceeds 100 percent.

The process evaluation found that the program processes in place are effective, efficient, and result in a high degree of accuracy in program tracking.

A copy of the evaluation can be found in *Supplement 2: Evaluation.*

### 2017 Program and Marketing Strategies

Idaho Power plans to distribute a bill insert to Idaho and Oregon customers and will look for additional opportunities to engage potential manufactured home buyers. Idaho Power will also continue to support dealers by providing them with program materials.

## *Shade Tree Project*

*Reversal of a 2014 charge to the Oregon Rider.

### Description

The Shade Tree Project began as a pilot in 2013. According to the US Department of Energy (DOE), a well-placed shade tree can reduce energy used for summer cooling by 15 percent or more. Utility programs throughout the country report high customer satisfaction with shade tree programs and an enhanced public image for the utility related to sustainability and environmental stewardship. Other utilities report energy savings between 40 kWh per year (coastal climate San Diego) and over 200 kWh per year (Phoenix) per tree planted.

To be successful, trees should be planted to maximize energy savings and ensure survivability. Two technological developments in urban forestry—the state-sponsored Treasure Valley Urban Tree Canopy Assessment and the Arbor Day Foundation's Energy-Saving Trees tool—provided Idaho Power with the information to facilitate a shade tree project.

The Shade Tree Project operates in Ada and Canyon counties (Idaho), offering free shade trees to residential customers. Participants enroll using the on-line Energy-Saving Trees tool and pick up their tree at specific events. Unclaimed trees are donated to city partners and schools.

Using the on-line enrollment tool, participants locate their home on a map, select from a list of available trees, and evaluate the potential energy savings associated with planting in different locations. During enrollment, participants learn how trees planted to the west and east save more energy over time than trees planted to the south and north.

Ensuring the tree is planted properly helps it grow to provide maximum energy savings. At the tree pickup events, participants receive additional education on where to plant trees for maximum energy

savings and other tree care guidance from experts. Local specialists include city arborists from Boise, Kuna, Nampa, and Meridian; Idaho Power utility arborists; Canyon County master gardeners; and College of Western Idaho horticulture students.

In August each year, Idaho Power sends participants from the previous two offerings a newsletter filled with reminders on proper tree care and links to resources, such as tree care classes and educational opportunities in the region. This newsletter was developed after the 2015 field audits identified common customer tree care questions and concerns.

### Program Activities

In 2016, Idaho Power distributed 2,070 shade trees to residential customers through the Shade Tree Project. Because the best time to plant shade trees is in the spring and fall, Idaho Power held offerings in April and October, with 701 trees and 1,369 trees distributed, respectively. Idaho Power purchased the trees from a local wholesale nursery in advance of each event. The species offered for each event depended on the trees available at the time of purchase. Idaho Power worked with city and state arborists to select a variety of large-growing, deciduous trees that traditionally grow well in the climate and soils of the two participating counties.

Participants picked up the trees at events throughout the Treasure Valley—four in the spring and four in the fall. By offering several pickup days, locations, and times, 88 percent of spring trees and 90 percent of fall trees were distributed to homeowners.

Idaho Power continues to track the program data in the DSM database. The database is also used to screen applicants during enrollment to determine whether participants meet the eligibility requirements for the project, such as residential status within the eligible counties (customer type and location).

In 2016, this project was partially funded by a US Forest Service Western Competitive States Grant, which was used to purchase all of the trees for both offerings. The grant also funded the development of an instructional tree planting video posted to Idaho Power's website.

### Marketing Activities

For both offerings, Idaho Power developed a direct-mailing list using the state-sponsored Treasure Valley Urban Tree Canopy Assessment tool (tvcanopy.net/). The tool is the result of a geographic information system (GIS)-based study that mapped land use throughout the Treasure Valley, including existing trees and vegetation, buildings, roads, waterways, and parking lots. The study identified areas where a large-growing shade tree could be planted. Idaho Power used the tool to identify residential properties with potential planting sites to the west of the homes.

For both offerings, Idaho Power also sent emails to customers who had requested information about the project through Idaho Power's website. Project partners, such as the cities of Nampa, Kuna, Meridian and Boise, shared information through their networks. Idaho Power announced its Shade Tree Project to allied groups, such as the Idaho Conservation League, Idaho Chapter of the US Green Building Council (USGBC), and Treasure Valley Canopy Network. Information was sent to Green

Team leads at large employers, such as HP, Wells Fargo, Ch2MHill, and Citi Bank. The company also distributed program flyers at local events, where appropriate.

An Idaho Power Facebook post in the spring reached 1,478 people and resulted in 20 shares, 3 comments, 30 likes and 68 link clicks. A boosted Facebook post was used in the fall and reached 16,668 people and resulted in 909 post engagements (which includes likes, shares and comments). The boosted post cost-per-engagement was $0.07. The company also promoted the program in specific neighborhoods on Nextdoor.com in the spring and fall. This combination of marketing tactics was successful. The spring offering filled in 20 days; the fall offering filled in 16 days.

### Cost-Effectiveness

Idaho Power does not calculate the cost-effectiveness tests for this program since no savings are currently being attributed to this program. The company plans to begin counting energy saving for the Shade Tree Program when the originally planted trees are five years old.

### Customer Satisfaction and Evaluations

After each offering, a survey was emailed to participants. The survey asked questions related to program marketing, tree-planting education, and participant experience with the enrollment and tree pickup processes. Results are compared, offering to offering, to look for trends to ensure the program processes are still working, and to identify opportunities for improvement. Data are also collected about where and when the participant planted the tree. This data will be used by Idaho Power to refine energy-savings estimates.

In total, the survey was sent to 1,112 Shade Tree Project participants. The company received 531 responses for a response rate of 48 percent. Participants were asked how much they would agree or disagree that they would recommend the project to a friend; nearly 96 percent of respondents said they "strongly agree," and just over 3 percent said they "somewhat agree." Participants were asked how much they would agree or disagree that they were satisfied with the overall experience with the Shade Tree Project; nearly 93 percent of respondents indicated they "strongly agree," and just over 6 percent "somewhat agree" they were satisfied. View survey information in *Supplement 2: Evaluation*.

Idaho Power conducted no program evaluations in 2016.

### 2017 Program and Marketing Strategies

Idaho Power plans to continue the Shade Tree Project in 2017 using the Arbor Day enrollment tool; trees will be distributed at multiple events. This will be the last year of US Forest Service grant funding to help support the program. Idaho Power will use these funds to purchase some trees, and to send a representative to visit a subset of planting sites to collect data on tree placement and health.

Idaho Power will also explore expanding the program to new areas in western Idaho, such as Elmore County (Mountain Home) and the Payette area.

Idaho Power will continue to market the program through direct-mail, focusing on customers identified using the Urban Tree-Canopy Assessment. In addition, Idaho Power maintains a waiting list of

customers who were unable to enroll before previous offerings filled. Idaho Power will reach out to these customers through direct-mail or email for the 2017 offerings. Idaho Power will continue to leverage allied interest groups, and will use social media and boosted Facebook posts if enrollment response rates decline.

### Description

Initiated in 2015, the Simple Steps, Smart Savings™ program is a promotion-based appliance program that aims to increase sales of qualified energy-efficient appliances. The payments provided by Idaho Power through this program are applied during special promotions, which align with holidays or events throughout the year at retail stores. Incentives are shared between the retailer, manufacturer, and the customer, though they may differ between promotions and between retailers and manufacturers.

Retailer and manufacturer incentives may be provided as co-marketing dollars to the retailer or manufacturer to fund activities such as promotional events, special product placement, point-of-purchase signage, retailer activities, event kits, sales associate training, training material, and other marketing activities during the promotional periods.

Customer rewards may include, but are not limited to, retailer gift cards, retailer credit to the customer or free laundry products for the purchase of qualified products. These promotions are available in Idaho and Oregon.

The program also includes promotions using retailer markdowns and retailer/manufacturer incentives. Markdowns reduce retail-end prices to the customer at the point-of-purchase. Retailer/manufacturer incentives drive the manufacture, distribution, and promotion of more energy-efficient consumer products. For example, since 2010 Idaho Power has offered retailer markdowns for low-flow showerheads. Program payments reduce the cost of the showerheads for customers at the retail level, as well as to retailers and manufacturers to drive the manufacture, distribution, and promotion of these products.

Idaho Power also participates in the BPA-sponsored, Simple Steps, Smart Savings energy-efficient lighting program, which is discussed further in the Energy Efficient Lighting program section of this report.

All Simple Steps, Smart Savings promotions are administered by the BPA and coordinated by CLEAResult.

## Program Activities

On May 18, 2016, Idaho Power received approval to begin offering the appliance promotion to our customers in Oregon.

### *Appliances*

In 2016, Idaho Power participated in five major Simple Steps, Smart Savings appliance promotions with these retailers: Sears, Sears Hometown, Dell's Home Appliance, Home Depot, and RC Willey. At each event, CLEAResult personnel staffed a table and answered customer questions about the appliance promotion. To further educate customers about the promotions, CLEAResult created an Idaho Power-branded promotional landing page that highlights promotion details and participating retailers.

The five promotions took place on the following dates: 1) the 2015 Black Friday took place in November through the first week of December—because these sales data were delayed, the sales from this promotion will be included with the remaining four 2016 promotions; 2) the President's Day promotion ran for two weeks in February; 3) the Memorial Day promotion ran for the last week in May and first week in June; 4) the Independence Day promotion ran for the last week in June and first two weeks in July; and 5) the Labor Day promotion ran for the last week in August and first week in September. In-store events were held at all participating retailers in Idaho Power's service area during the promotion.

Incentives for the purchase of an ENERGY STAR® clothes washer included a $10 gift card at Sears and Home Depot; a 180-load supply of free laundry detergent at Sears Hometown; a gift of free laundry products at Dell's Home Appliances; and a $25 gift card at RC Willey. RC Willey added their own $15 to the $10 provided to allow them to offer a $25 gift card to customers.

### *Showerheads*

In early 2016, The Home Depot's contract to offer buy downs on qualified showerheads ended. Due to the length of time to prepare monthly reports for these sales, they declined to continue participating in the showerhead buy down. To make up for the decrease in showerhead sales after The Home Depot's departure, CLEAResult engaged Costco and Lowe's to begin offering qualified showerheads to their list of available buy down products.

## Marketing Activities

In 2016, CLEAResult and participating Simple Steps, Smart Savings utility partners, decided the marketing was outdated and needed a new, fresh look. Several new designs were presented, and it was decided that the new logo would be Simple + Smart. See Figure 17 to see the updated logo. All table

tents and clings used for the 2016 Simple Steps, Smart Savings appliance promotions used the new Simple + Smart logo.

To help support the promotions, table tents and static clings were displayed on all qualifying appliances. These pieces informed customers about the promotion and the incentive they would receive. In-store gift cards were placed in gift card holders that displayed the Idaho Power logo. For purchases from Sears Hometown, where the customer received an instant markdown, customers also received a thank-you card with the Idaho Power logo.

During the promotions, Idaho Power placed Facebook and Twitter posts to notify customers of the details.

### Cost-Effectiveness

Idaho Power used the same savings and cost assumptions for showerheads in 2016 as were used in 2015. In 2015 and 2016, RTF reviewed and updated the savings assumptions for showerheads, and Idaho Power will adopt those in 2017. The parameters that impacted the savings for showerheads the most were changes to the baseline showerhead, the showers per person per year, and the annual usage of each showerhead. Due to the timing of RTF's update, BPA and CLEAResult did not implement the new savings in the Simple Steps, Smart Savings promotion in 2016. The new RTF workbook, version 2.4, will be used in 2017.

In 2016, Idaho Power participated in five clothes washer promotions. Idaho Power applied the per-unit savings from the approved BPA's unit energy savings (UES) Measure List. While BPA applies the annual generator busbar savings of 73 kWh per unit, Idaho Power applies the annual site savings of 67 kWh per unit. This difference is due to the different line losses applied by Idaho Power and BPA. For the NEBs, Idaho Power used RTF's clothes washer workbook to determine the water and wastewater savings for the ENERGY STAR clothes washers.

For detailed information for all measures within the Simple Steps, Smart Savings program, see *Supplement 1: Cost-Effectiveness*.

### Customer Satisfaction and Evaluations

Idaho Power conducted no customer satisfaction surveys or program evaluations in 2016.

### 2017 Program and Marketing Strategies

Idaho Power has committed to participate in the 2017 Simple Steps, Smart Savings appliance promotions. Five promotions are scheduled: 1) February for President's Day, 2) May to June for Memorial Day, 3) July for Independence Day, 4) August to September for Labor Day, and 5) November to December for Black Friday. Current participating retailers are Sears, Sears Hometown, RC Willey, and Dell's Home Appliance.

CLEAResult is in the process of working with local independent retailers to encourage their participation in the program. For each promotion, Idaho Power will provide incentives only for products that meet Idaho Power's cost-effectiveness requirements.

Idaho Power will also continue participation in the Simple Steps, Smart Savings energy-efficient showerheads buy-down program in 2017.

CLEAResult will continue to manage marketing at retailers, including point-of-purchase signs, Idaho Power-branded gift card holders, and thank-you cards. When provided, Idaho Power will continue to use Idaho Power-branded promotion landing pages and Facebook posts to notify customers of the promotions.

### Description

The Weatherization Assistance for Qualified Customers (WAQC) program provides financial assistance to regional CAP agencies in Idaho Power's service area. This assistance helps fund weatherization costs of electrically heated homes occupied by qualified customers who have limited incomes. The WAQC program also provides a limited pool of funds for the weatherization of buildings occupied by non-profit organizations serving primarily special-needs populations, regardless of heating source, with priority given to buildings with electric heat. Weatherization improvements enable residents to maintain a more comfortable, safe and energy-efficient home while reducing their monthly electricity consumption. Improvements are available at no cost to qualified customers who own or rent their homes. These customers also receive educational materials and ideas on using energy wisely in their homes. Local CAP agencies determine participant eligibility according to federal and state guidelines.

In 1989, Idaho Power began offering weatherization assistance in conjunction with the State of Idaho Weatherization Assistance Program (WAP). In Oregon, Idaho Power offers weatherization assistance in conjunction with the State of Oregon WAP. Through the WAQC program, Idaho Power provides supplementary funding to state-designated CAP agencies for additional weatherization of electrically heated homes occupied by qualified customers and buildings occupied by non-profit organizations that serve special-needs populations. This allows CAP agencies to combine Idaho Power funds with federal LIHEAP weatherization funds to serve more customers in electrically heated homes with special needs.

Idaho Power has an agreement with each CAP agency for the WAQC program that specifies the funding allotment, billing requirements, and program guidelines. Currently, Idaho Power oversees the program in Idaho through five regional CAP agencies: Eastern Idaho Community Action Partnership (EICAP), El Ada Community Action Partnership (EL ADA), Aging, Weatherization and Human Services (CCOA,

now Metro Community Services), South Central Community Action Partnership (SCCAP), and Southeastern Idaho Community Action Agency (SEICAA). In Oregon, Community Connection of Northeast Oregon, Inc. (CCNO), and Community in Action (CINA) provide weatherization services for qualified customers in Idaho Power's service area.

The Idaho Department of Health and Welfare (IDHW) uses the energy audit program (EA5) for the Idaho WAP and therefore, the Idaho CAP agencies use the EA5. The EA5 is a software program approved for use by the DOE.

Annually, Idaho Power physically verifies approximately 10 percent of the homes that were weatherized under the WAQC program. This is done through two methods. The first method includes the Idaho Power program specialist participating in Idaho's and Oregon's state monitoring process that reviews weatherized homes. The process involves utility representatives; weatherization personnel from the CAP agencies; CAPAI; and a Building Performance Institute (BPI)-certified quality control inspector hired by the state reviewing homes weatherized by each of the CAP agencies.

The second method involves Idaho Power contracting with two companies—The Energy Auditor, Inc. (The Energy Auditor), and Momentum, LLC (Momentum)—that employ certified building performance specialists to verify installed measures in customer homes. The Energy Auditor verifies homes weatherized for the WAQC program in Idaho Power's eastern and southern Idaho regions. The owner of The Energy Auditor is certified by PTCS and is an ENERGY STAR® HPS. Momentum verifies weatherization services provided through the WAQC program in the Capital and Canyon–West regions of Idaho and in the company's Oregon service area. The owner of Momentum is a RESNET® certified home energy rater. After these companies verify installed measures, any required follow-up is done by the CAP agency personnel.

## Regulatory Compliance

Idaho Power reports the activities related to the WAQC program in compliance with the IPUC Order No. 29505, as updated in Case No. IPC-E-16-30, Order No. 33702. This order approved Idaho Power's request to modify Order No. 29505 to consolidate the WAQC Annual Report with the DSM Annual Report.

## Program Activities

All information previously available in the WAQC Annual Report is available in this section of the DSM Annual Report. In the future, WAQC activities will be reported solely in this manner. This report includes the following topics:

- Review of weatherized homes and non-profit buildings by county
- Review of measures installed
- Overall cost-effectiveness
- Customer education and satisfaction
- Plans for 2017

***Weatherized Homes and Non-Profit Buildings by County***

In 2016, Idaho Power made $1,250,693 available to Idaho CAP agencies. Of the funds provided, $1,186,192 were paid to Idaho CAP agencies in 2016, while $64,501 were accrued for future funding. Of the funds paid in 2016, $1,055,649 directly funded audits, energy efficiency measures, and health and safety measures for qualified customers' homes (production costs) in Idaho, and $105,565 funded administration costs to Idaho CAP agencies for those homes weatherized.

These funds provided for the weatherization of 231 Idaho homes and 3 Idaho non-profit buildings. The production cost of the non-profit building weatherization measures was $22,707, while $2,271 in administrative costs were paid for the Idaho non-profit building weatherization jobs. In Oregon, Idaho Power paid $29,742 in production costs for 12 qualified homes and $2,974 in CAP agency administrative costs for homes in Malheur and Baker Counties. Table 9 shows each CAP agency, the number of homes weatherized, production costs, the average cost per home, administration payments, and total payments per county made by Idaho Power.

Table 9. 2016 WAQC activities and Idaho Power expenditures by agency and county

| Agency<br>Idaho Homes | County | Number of Homes | Production Cost | Average Cost[1] | Administration Payment to Agency | Total Payment |
|---|---|---|---|---|---|---|
| CCOA | Adams | 1 | $ 6,313 | $ 6,313 | $ 631 | $ 6,944 |

| CINA | Malheur | 11 | 25,911 | 2,356 | 2,591 | 28,503 |
| | **Agency Total** | **11** | **$ 25,911** | **$ 2,356** | **$ 2,591** | **$ 28,503** |
| **Total Oregon Homes** | | **12** | **$ 29,742** | **$ 2,479** | **$ 2,974** | **$ 32,717** |
| **Total Program** | | **246** | **$ 1,108,098** | | **$ 110,810** | **$ 1,218,908** |

Note: Dollars are rounded.

The base funding for Idaho CAP agencies is $1,212,534 annually, which does not include carryover from the previous year. Idaho Power's agreements with CAP agencies include a provision that identifies a maximum annual average cost per home up to a dollar amount specified in the agreement between the CAP agency and Idaho Power. The intent of the maximum annual average cost is to allow CAP agency flexibility to service some homes with greater or fewer weatherization needs. It also provides a monitoring tool for Idaho Power to forecast year-end outcomes. The average cost per home weatherized is calculated by dividing the total annual Idaho Power production cost of homes weatherized by the total number of homes weatherized that the CAP agencies billed to Idaho Power during the year.
The maximum annual average cost per home the CAP agencies were allowed under the 2016 agreement was $6,000. In 2016, Idaho CAP agencies had a combined average cost per home weatherized of $4,570. In Oregon, the average was $2,479 per home weatherized.

There is no maximum annual average cost for the weatherization of buildings occupied by non-profit agencies.

CAP agency administration fees are equal to 10 percent of Idaho Power's per-job production costs. The average administration cost paid to agencies per Idaho home weatherized in 2016 was $457, and the average administration cost paid to Oregon agencies per Oregon home weatherized during the same period was $248. Not included in this report's tables are additional Idaho Power staff labor, marketing, home verification, and support costs for the WAQC program totaling $55,087 for 2016. These expenses were in addition to the WAQC program funding requirements in Idaho specified in IPUC Order No. 29505.

In compliance with IPUC Order No. 29505, WAQC program funds are tracked separately, with unspent funds carried over and made available to Idaho CAP agencies in the following year. In 2016, $38,159 in unspent funds from 2015 were made available for expenditures in Idaho. Table 10 details the funding base and available funds from 2015 and the total amount of 2016 spending. In 2015, the Idaho non-profit-pooled fund overspent by $10,529 which was deducted from the carryover amount to 2016.

Table 10. 2016 WAQC base funding and unspent funds made available

| Agency | 2016 Base | Available Funds from 2015 | Total 2016 Allotment | 2016 Spending |
|---|---|---|---|---|
| **Idaho** | | | | |
| CCOA | $ 302,259 | $ – | $ 302,259 | $ 301,999 |
| EICAP | 12,788 | – | 12,788 | 12,788 |
| EL ADA | 568,479 | – | 568,479 | 568,479 |
| SCCAP | 167,405 | 45,430 | 212,835 | 163,087 |
| SEICAA | 111,603 | 3,258 | 114,861 | 114,861 |
| Non-profit buildings | 50,000 | (10,529) | 39,471 | 24,978 |
| **Idaho Total** | **$ 1,212,534** | **$ 38,159** | **$ 1,250,693** | **$ 1,186,192** |
| **Oregon** | | | | |
| CCNO | 6,750 | 12,322 | 19,072 | 28,503 |
| CINA | 38,250 | 4,277 | 42,527 | 4,214 |
| **Oregon Total** | **$ 45,000** | **$ 16,599** | **$ 61,599** | **$ 32,717** |

Note: Dollars are rounded. Overspending of non-profit pooled fund in 2015 was deducted from 2016 non-profit available fund.

***Weatherization Measures Installed***

Table 11 details home and non-profit building counts for which Idaho Power paid all or a portion of each measure cost during 2016. The home counts column shows the number of times any percentage of that measure was billed to Idaho Power during the year. If totaled, measure counts would be higher than total homes weatherized because the number of measures installed in each home varies. For example, Table 11 shows 68 homes in Idaho received a lightbulb replacements measure. Each home received more than one lightbulb. Consistent with the Idaho WAP, the WAQC program offers several measures that have costs but do not necessarily save energy, or for which the savings cannot be measured. Included in this category are health and safety measures, vents, furnace repairs, other, and home energy audits. Health and safety measures are necessary to ensure weatherization activities do not cause unsafe situations in a customer's home or compromise a home's existing indoor air quality. Examples of health and safety items are smoke and carbon monoxide detectors, bathroom fans, and dryer vents.
Other non-energy-saving measures are allowed under this program because they interact with the energy-saving measures. Examples of items included in the other measure category include vapor barriers, dryer vent hoods, and necessary electrical upgrades.

Table 11. 2016 WAQC review of measures installed

| | Home Counts | | Production Costs |
|---|---|---|---|
| **Idaho Homes** | | | |

## Marketing Activities

Idaho Power provided educational materials to each CAP agency to help qualified customers who receive weatherization assistance learn how to use energy efficiently. Included in the materials were copies of the Idaho Power publications: *Energy Efficiency Guide, Maintenance of Your High-Efficiency Water Fixtures,* and *Energy Saving Tips*, which describe energy conservation tips for the heating and cooling seasons, saving water, and a pamphlet that describes the energy-saving benefits of using CFLs, LEDs, and other tips for choosing the right lightbulb. Idaho Power developed and distributed a brochure that provided information about both the WAQC program and Weatherization Solutions for Eligible Customers program. This was meant to help customers realize there is more than one way to qualify for weatherization services. Idaho Power actively informed customers about WAQC through energy and resource fairs and other customer contacts including communication from its Customer Service Center.

## Cost-Effectiveness

The WAQC program, while showing increases in savings and cost-effectiveness ratios, remains not cost-effective. The program had a total UC B/C ratio of 0.73, and a TRC B/C ratio of 0.65.

New savings values were introduced in 2016 that reflect an updated billing analysis completed in 2015. This analysis considered pre- and post-weather normalized consumption in homes weatherized during the 2013-2014 program years from both WAQC and Weatherization Solutions for Eligible Customers programs. The billing analysis was needed to reflect the increased replacement of forced-air electric resistance heat systems with efficient heat pump systems, and to ensure that the proper level of savings was captured for the average home. Variable-based degree-day analysis methods were used, consistent with other regional billing data studies and with whole-house consumption analysis methods published as part of the DOE's Uniform Methods project.

Table 12 shows the updated results that identify the difference between homes that only received weatherization versus homes that were weatherized and upgraded with an efficient heat pump.

Table 12. 2016 savings values for WAQC program

| Home Type | Weatherization only | | Weatherization and heating system change | |
|---|---|---|---|---|
| | kWh/project | kWh/project/ft$^2$ | kWh/project | kWh/project/ft$^2$ |
| Single-family Homes | 1,797 | 1.16 | 4,154 | 2.48 |
| Manufactured Homes | 1,734 | 1.36 | 4,418 | 4.30 |
| Multi-family Homes | n/a | 1.16 | n/a | 2.48 |
| Non-profit Buildings | n/a | 1.16 | n/a | 2.48 |

Table 12 also shows, as expected, weatherization combined with the installation of an efficient heat pump results in savings nearly twice that from just installing weatherization measures. Manufactured homes demonstrate a higher savings per square foot of weatherized space than single-family homes in both projects where only weatherization measures were installed and cases where heating system upgrades occurred.

Idaho Power used savings of 1.16 kWh/ft$^2$ of weatherized heated space for multi-family projects where only weatherization measures were installed and 2.48 kWh/ft$^2$ where heating system were changed. In 2016 and previous program years, there has been insufficient data from multi-family projects in both the WAQC and Weatherization Solutions for Eligible Customers programs to conduct a billing analysis so savings are assumed to be similar on a savings per square foot basis as single-family homes where like measures were installed.

Idaho Power used savings of 1.16 kWh/ft$^2$ of weatherized heated space for non-profit projects where only weatherization measures were installed, which is the average per square foot savings values for weatherized single-family homes from the updated billing analysis. It is not feasible at this time to conduct a post-weatherization billing analysis or to create a commercial whole building simulation model prior to weatherization for non-profit projects.

The initial phase for assessing cost-effectiveness occurs during the initial contacts between CAP agency weatherization staff and the customer. In customer homes, the agency weatherization auditor uses the EA5 to conduct the initial audit of potential energy savings for a home. The EA5 compares the efficiency of the home prior to weatherization to the efficiency after the proposed improvements and calculates the value of the efficiency change into a savings-to-investment ratio (SIR). The output of the SIR is similar to the PCT ratio. If the EA5 computes an SIR of 1.0 or higher, the CAP agency is authorized to complete the proposed measures. The weatherization manager can split individual measure costs between Idaho Power and other funding sources with a maximum charge of 85 percent of total production costs to Idaho Power. Using the audit form to pre-screen projects ensures that each weatherization project will result in energy savings. The use of the audit tool is one of the primary reasons that consistent results have been seen from recent billing analysis of weatherization projects.

The following recommendations from the IPUC Order No. 32788 were used for the 2016 cost-effectiveness analysis:

- Applying a 100-percent net-to-gross (NTG) value to reflect the likelihood that WAQC weatherization projects would not be initiated without the presence of a program
- Claiming 100 percent of project savings
- Including an allocated portion of the indirect overhead costs
- Applying the 10-percent conservation preference adder
- Claiming $1 of benefits for each dollar invested in health, safety, and repair measures
- Amortizing evaluation expenses over a three-year period

### Customer Satisfaction and Evaluations

Idaho Power used independent, third-party verification companies to ensure the stated measures were installed in the homes, and to discuss the program with these customers. In 2016, home verifiers visited 36 homes, requesting feedback about the program. When asked how much customers learned about saving electricity, 30 customers answered they learned "a lot" or "some." When asked how many ways they tried to save electricity, 31 customers responded "a lot" or "some."

A customer survey was used to assess major indicators of customer satisfaction throughout the service area. The *2016 Weatherization Programs Customer Survey* was provided to all program participants in all regions upon completion of weatherization in their homes. Survey questions gathered information about how customers learned of the program, reasons for participating, how much customers learned about saving energy in their homes, and the likelihood of household members changing behaviors to use energy wisely.

Idaho Power received survey results from 238 of 243 households weatherized by the program in 2016. Of the 238 completed surveys, 227 were from Idaho customers and 11 were from Oregon customers. Some highlights include the following:

- Over 37 percent of respondents learned of the program from a friend or relative, and another almost 23 percent learned of the program from an agency flyer. Nearly 8 percent learned about the weatherization program from direct-mail.
- Over 84 percent of the respondents reported that their primary reason for participating in the weatherization program was to reduce utility bills, and over 39 percent wanted to improve the comfort of their home.
- Over 73 percent reported they learned how air leaks affect energy usage, and just over 67 percent indicated they learned how insulation affects energy usage during the weatherization process.
- Over 56 percent of respondents said they learned how to use energy wisely. Seventy-five percent reported they were very likely to change habits to save energy, and almost 66 percent reported they have shared all of the information about energy use with members of their household.

- Over 87 percent of the respondents reported they think the weatherization they received will significantly affect the comfort of their home, and almost 94 percent said they were very satisfied with the program.
- Almost 86 percent of the respondents reported the habit they were most likely to change was turning off lights when not in use, and 61 percent said that washing full loads of clothes was a habit they were likely to adopt to save energy. Turning the thermostat up in the summer was reported by over 53 percent of the respondents, and turning the thermostat down in the winter was reported by 65 percent as a habit they and members of the household were most likely to adopt to save energy.

A summary of the report is included in the *Supplement 2: Evaluation*.

### 2017 Program and Marketing Strategies

As in previous years, unless directed otherwise, Idaho Power will continue to provide financial assistance to CAP agencies while exploring changes to improve program delivery. The company will continue to provide the most benefit possible to special-needs customers while working with Idaho and Oregon WAP personnel.

Idaho Power will continue to participate in the Idaho and Oregon state monitoring process of weatherized homes and will continue to verify approximately 10 percent of the homes weatherized under the WAQC program via certified home-verification companies.

In 2017, Idaho Power will support the whole-house philosophy of the WAQC program and Idaho and Oregon WAP by continuing to allow a $6,000 annual maximum average per-home cost. Based on the required funding, Idaho Power estimates approximately 182 homes and four non-profit buildings in Idaho will be weatherized, and approximately 11 homes in Oregon will be weatherized in 2017.

In Idaho during 2017, Idaho Power expects to contribute the base amount plus available funds from 2016 to total approximately $1,350,000 in weatherization measures and agency administration fees. Of this amount, approximately $64,490 will be provided to the non-profit pooled fund to weatherize buildings housing non-profit agencies that primarily serve qualified customers in Idaho.

## *Weatherization Solutions for Eligible Customers*

| | | 2016 | 2015 |
|---|---|---|---|
| **Participation and Savings** | | | |
| | Participants (homes) | 232 | 171 |
| | Energy Savings (kWh) | 621,653 | 432,958 |
| | Demand Reduction (MW) | n/a | n/a |

| | Utility Benefit/Cost Ratio | 0.59 | 0.45 |
| | Total Resource Benefit/Cost Ratio | 0.70 | 0.50 |

* Oregon Rider charges were reversed and charged to the Idaho Rider in February 2017.

### Description

Weatherization Solutions for Eligible Customers is an energy efficiency program designed to serve Idaho Power residential customers in Idaho whose income falls between 175 percent and 250 percent of the most current federal poverty level. Initiated in 2008, the program is designed to mirror the WAQC program. These customers often do not have disposable income to participate in other residential energy efficiency programs, and they typically live in similar housing as WAQC customers.

Potential participants are interviewed by a contractor to determine household occupant income eligibility, as well as to confirm the home is electrically heated. If the home is a rental, the landlord must agree to maintain the unit's current rent for a minimum of one year, and to help fund a portion of the cost of weatherization. If the customer is eligible, an auditor inspects the home to determine which upgrades will save energy, improve indoor air quality, and/or provide health and safety for the residents. To be approved, energy efficiency measures and repairs must have a SIR of 1.0 or higher, interact with an energy-saving measure, or be necessary for the health and safety of the occupants.

The Weatherization Solutions for Eligible Customers program uses a home audit tool called the HAT14.1 which is similar to the EA5 audit tool used in WAQC. The home is audited for energy efficiency measures and the auditor proposes upgrades based on the SIR ratio calculated by HAT14.1. As in WAQC, if the SIR is 1.0 or greater, the contractor is authorized to upgrade that measure. Measures considered for improvement are window and door replacement, ceiling, floor and wall insulation, HVAC repair and replacement, water heater repair and replacement and pipe wrap. Also included is the potential to replace lightbulbs and refrigerators. Contractors invoice Idaho Power for the project costs and if the home is a rental, a minimum landlord payment of 10 percent of the cost is required.

Idaho Power's agreement with contractors includes a provision that identifies a maximum annual average cost per home for the program. The intent of the maximum annual average cost is to allow Contractors the flexibility to service homes with greater or fewer weatherization needs. It also provides a monitoring tool for Idaho Power to forecast year-end outcomes.

### Program Activities

In 2016, a new contractor provided weatherization services to customers residing in Lemhi County, Idaho. Energy Solutions weatherized two homes in 2016 for the program with an average of approximately $4,125 each. With the addition of this new contractor, Idaho Power offers the Weatherization Solutions for Eligible Customers in all of its Idaho service area.

In 2016, the five contractors weatherized 232 Idaho homes for the program. In eastern Idaho, contractors Savings Around Power and Energy Solutions weatherized 26 homes. In Idaho Power's Canyon–West Region, Metro Contractors weatherized 56 homes. HEM-LLC weatherized 36 homes in south central Idaho, and Power Savers weatherized 114 homes in the Capital Region. Of those 232 homes weatherized, 148 were single-family and manufactured homes and 84 were low income multi-family apartments where LEDs, showerheads, kitchen and bath sink aerators, indoor clotheslines, and smoke detectors were installed.

### Marketing Activities

Marketing was adjusted in 2016 to reach more customers who live in electrically heated homes and income-eligible households to increase participation in the program. Inserts were included in 263,625 residential bills in February and 367,222 bills in October. The program was promoted throughout the year at seasonal, resource, and conservation fairs, as well as at other events targeting people with limited incomes, including seniors. Ads and articles promoted the program in the *Seniors BlueBook*, *Healthy Idaho Magazine*, *Idaho Senior News*, and the *Idaho State Journal* boomers' edition. The program was also mentioned in Idaho Power's winter *Energy Efficiency Guide*.

Idaho Power's community relations representatives and customer representatives promoted the program at meetings in their communities, with specific emphasis on smaller Idaho communities. The program specialist and customer representatives promoted the program to home healthcare provider groups, religious groups, and members of the Idaho Nonprofit Center. Customer representatives used updated brochures (in English and Spanish) that included current income qualifications and location-specific contractor information. New contractor door hangers and flyers were also created so the program could be promoted by canvassing specific neighborhoods. Weatherization tips were also mentioned in various social media postings.

### Cost-Effectiveness

While showing increases in savings and cost-effectiveness ratios from updated billing analysis and the addition of cost-effective direct-install options, the WAQC program remains not cost-effective. The 2016 program total UC B/C ratio is 0.59, and a TRC B/C ratio is 0.70. New savings values were introduced for 2016 that reflect an updated billing analysis completed in 2015 that analyzed pre- and post-weather normalized consumption in homes weatherized during the 2013-2014 program years from

both WAQC and Weatherization Solutions for Eligible Customers. The WAQC program section in this report offers a discussion of the billing analysis changes from previous versions.

Table 13 shows the updated savings results that identify the difference between homes that only received weatherization versus homes that were weatherized and upgraded with an efficient heat pump.

Table 13. 2016 savings values for Weatherization Solutions for Eligible Customers program

| | Weatherization | | Weatherization and heating system change | |
|---|---|---|---|---|
| **Home Type** | **kWh/project** | **kWh/project/ft²** | **kWh/project** | **kWh/project/ft²** |
| Single-family Homes | 1,453 | 0.83 | 6,321 | 3.47 |
| Manufactured Homes | 897 | 0.39 | 5,355 | 4.50 |
| Multi-family Homes | n/a | 0.83 | n/a | 3.47 |

Similar to billing analysis results for WAQC, weatherization combined with the installation of an efficient heat pump results in savings nearly twice that from just installing weatherization measures. Manufactured homes demonstrate a higher savings per square foot of weatherized space than single family homes in cases where both weatherization and heating system upgrades occurred.

Idaho Power used savings of .83 kWh/ft$^2$ of weatherized heated space for multi-family projects where only weatherization measures were installed and 3.47 kwh/ft$^2$ where heating system where changed. Prior to 2015, insufficient data from multi-family projects existed to conduct a billing analysis so savings are assumed to be similar on a savings per square foot basis as single-family homes where like measures were installed.

Weatherization Solutions for Eligible Customers projects, similar to WAQC program guidelines, benefit from a pre-screening of measures through a home audit process. The home audit process ensures that there is an adequate number of kWh savings to justify the project and provides more consistent savings for billing analysis. See WAQC cost-effectiveness for a discussion of the audit and prescreening process which are similar for both programs.

For further details on the overall program cost-effectiveness assumptions, see *Supplement 1: Cost-Effectiveness*.

## Customer Satisfaction and Evaluations

A 2016 customer survey was provided to all program participants upon completion of weatherization in their homes. Survey questions gathered information about how customers learned of the program, reasons for participating, the amount of information customers learned about saving energy in their homes, and the likelihood that household members would change their behavior to use energy wisely. Additionally, demographic information was gathered to determine future marketing strategies.

Idaho Power received survey results from 130 of the 232 households weatherized by the program in 2016. Some key highlights include the following:

- Almost 27 percent of respondents learned of the program through a letter in the mail and another 22 percent learned of the program from a friend or relative.
- Over 86 percent of the respondents reported their primary reason for participating in the weatherization program was to reduce utility bills.
- Almost 80 percent indicated they learned how insulation affects energy usage during the weatherization process, and over 85 percent reported they learned how air leaks affect energy usage. Another almost 60 percent of respondents said they learned how to use energy wisely.
- Over 79 percent reported they were very likely to change habits to save energy, and over 71 percent reported they have shared all of the information about energy use with members of their household.
- Almost 91 percent of the respondents reported they think the weatherization they received will significantly affect the comfort of their home, and nearly 92 percent said they were very satisfied with the program.

A summary of the report is included in *Supplement 2: Evaluation*.

Two independent companies performed random verifications of weatherized homes and visited with customers about the program. In 2016, 35 homes were verified, and 23 (66 percent), of those customers reported they learned "a lot" or "some" about saving electricity in their home. Another 33 customers (95 percent) reported they had tried "a lot" or "some" ways to save energy in their home.

### 2017 Program and Marketing Strategies

Idaho Power will update brochures to help spread the word about the program in all communities. Additional marketing for the program will include bill inserts and advertisements in *Healthy Idaho Magazine*, *Seniors BlueBook*, *Idaho Senior News*, and *Idaho State Journal* boomers, edition. Idaho Power will send a direct-mail letter to targeted residential customers mid-year, and use social media in an effort to reach a more customers. Customer testimonials will be posted online, and the door hangers produced late in 2016 will continue to be used when canvassing neighborhoods.

# Commercial/Industrial Sector Overview

Idaho Power's commercial sector consists of over 69,341 customers. In 2016, the commercial sector's number of customers increased by 830, an increase of a little over 1 percent from 2015. The energy usage of commercial customers varies from a few kWh each month to several hundred thousand kWh per month. The commercial sector represents 28 percent of Idaho Power's actual total electricity sales.

The industrial and special contracts customers are Idaho Power's largest individual energy consumers. There are 121 Rate 19 and special contract industrial customers. These customers account for approximately 23 percent of Idaho Power's total electricity sales.

In June 2016, the three Commercial and Industrial Energy Efficiency programs were combined into a single program. Previously, the programs were: Building Efficiency, Custom Efficiency, and Easy Upgrades. The measure offerings to the customers remained relatively unchanged with prescriptive measures for new construction and major renovations, custom incentives for complex projects, and prescriptive measures for simple retrofits. The programs were combined with the intention to clarify program offerings and to improve marketing to customers. The combined program continues to be successful, with a reported overall savings of 88,161 MWh on 1,903 projects.

The 2016 season was the second year of the internally managed Flex Peak Program. The results were greatly improved from 2015 as was participation, including 65 participants enrolled with 137 sites in the program. Of those 137 sites, 67 were new—a 90 percent increase over 2015. Idaho Power also offers the statutory-required Oregon Commercial Audits program to medium and small commercial customers. The program identifies opportunities for commercial building owners to achieve energy savings.

Table 14. 2016 commercial/industrial program summary

| | | Total Cost | | Savings | |
|---|---|---|---|---|---|
| **Program** | **Participants** | **Utility** | **Resource** | **Energy (kWh)** | **Demand (MW)** |
| **Demand Response** | | | | | |
| Flex Peak Program | 137 sites | $ 767,997 | $ 767,997 | n/a | 42 |
| **Total** | | **$ 767,997** | **$ 767,997** | | **42** |
| **Energy Efficiency** | | | | | |
| Custom Projects (Custom Efficiency) | 196 projects | $ 7,982,624 | $ 16,123,619 | 47,518,871 | |
| Green Motors—Industrial | 14 projects | | | 123,700 | |
| New Construction (Building Efficiency) | 116 projects | 1,931,222 | 4,560,826 | 12,393,249 | |
| Oregon Commercial Audits | 7 audits | 7,717 | 7,717 | n/a | |
| Retrofits (Easy Upgrades) | 1,577 projects | 5,040,190 | 8,038,791 | 28,124,779 | |
| **Total** | | **$ 14,961,753** | **$ 28,730,952** | **88,160,599** | **42** |

**Note:** See Appendix 3 for notes on methodology and column definitions.

## Customer Satisfaction and Evaluations

Customer satisfaction research by sector includes the Idaho Power quarterly customer relationship surveys that ask questions about customer perceptions related to Idaho Power's energy efficiency

programs. Sixty-five percent of Idaho Power's large commercial and industrial customers surveyed in 2016 for the Burke Customer Relationship Survey indicated Idaho Power was meeting or exceeding their needs in offering energy efficiency programs. Sixty-one percent of survey respondents indicated Idaho Power was meeting or exceeding their needs with information on how to use energy wisely and efficiently. Seventy-four percent of respondents indicated Idaho Power was meeting or exceeding their needs by encouraging energy efficiency with its customers. Overall, 78 percent of the large commercial and industrial survey respondents indicated they have participated in at least one Idaho Power energy efficiency program. Of the large commercial and industrial customers surveyed and who had participated in at least one Idaho Power energy efficiency program, 98 percent are "very" or "somewhat" satisfied with the program. In 2016, offering energy efficiency programs was one of the large commercial and industrial top five attributes with a positive change in the Burke Customer Relationship Survey.

The results from surveying Idaho Power's small business customers indicated 51 percent of these customers said Idaho Power was meeting or exceeding their needs in offering energy efficiency programs. Fifty-four percent of survey respondents indicated Idaho Power was meeting or exceeding their needs with information on how to use energy wisely and efficiently. Sixty-three percent of respondents indicated Idaho Power was meeting or exceeding their needs with encouraging energy efficiency with its customers. Overall, 39 percent of the small business survey respondents indicated they have participated in at least one Idaho Power energy efficiency program. Of small business survey respondents who have participated in at least one Idaho Power energy efficiency program, 92 percent are "very" or "somewhat" satisfied with the program.

Forty-one percent of the Idaho Power business customers included in the *2016 J. D. Power and Associates Electric Utility Business Customer Satisfaction Study* indicated they are familiar with Idaho Power's energy efficiency programs.

### Training and Education

Technical training and education continue to be important in helping Idaho Power commercial and industrial customers identify where they may have energy efficiency opportunities within their facilities. These activities increase awareness and participation in existing commercial and industrial energy efficiency and demand response programs, and enhance customer satisfaction regarding the company's energy efficiency activities.

Educating commercial and industrial customers requires working with and supporting multiple stakeholders and organizations. Examples of key stakeholders include the Integrated Design Lab (IDL), BOMA, USGBC, ASHRAE, and International Building Operators Association (IBOA). Through funding provided by Idaho Power, the IDL performed several tasks aimed at increasing the energy efficiency knowledge of architects, engineers, trade allies, and customers. Specific activities included sponsoring a Building Simulation Users Group (BSUG), conducting Lunch & Learn sessions held at various design and engineering firms, and offering a Tool Loan Library (TLL).

Idaho Power also used two newsletters to educate and inform our customers about energy efficiency. *Energy at Work*, which is new in 2016, was mailed to commercial and industrial customers twice in

2016; the major customer representatives emailed *Energy Insights* to 400 of Idaho Power's largest industrial customers each quarter.

Idaho Power delivered eight technical classroom-based training sessions in 2016. Of the eight sessions, one was a two-day class, and the others were one-day classes. Topics included industrial refrigeration, energy auditing, an introduction to unitary A/C, advanced unitary A/C, pump systems, motors, variable speed drives, and commercial refrigeration. A schedule of training events is posted on Idaho Power's website and marketed through *Energy at Work* and *Energy Insights*. Commercial and Industrial Energy Efficiency personnel or the major customer representatives also give an overview of the commercial and industrial programs during each technical training session offered to commercial and industrial customers.

The level of participation in 2016 remained high, with 217 attendees. Customer feedback indicated the average satisfaction level was 94 percent.

Idaho Power's average cost to deliver trainings in 2016 was approximately $5,300 per class. For NEEA's 2015 to 2019 funding period, Idaho Power chose not to participate in NEEAs industrial trainings. Prior to the current funding period from 2010 to 2014, NEEA offered an average of nine trainings per year at an approximate cost of $22,000 per class. By Idaho Power providing these trainings directly to Idaho Power customers, the company has realized significant cost reduction for its customers.

Idaho Power posted prior years' webinar recordings and related PDFs on the commercial and industrial training page on the Idaho Power website. Also, on Idaho Power's industrial training page is a listing of all IBOA events. Idaho Power covered at least 50 percent of cost for Idaho Power customers to take part in their educational classes including the Building Operator Certification Level 1, consisting of eight day-long classes, and Level 2, consisting of seven day-long classes. In 2016, 42 customers attended the Level 1 classes, and eight attended the Level 2 classes.

### Field Staff Activities

Idaho Power field staff are on-site with customers each day. The field staff uses a variety of Idaho Power-developed programs, tools, and services to help customers with their energy-related questions and challenges. The customer representatives and major customer representatives have specific goals related to proactive activities, such as a specific number of visits or projects, designed to engage commercial and industrial customers in the energy efficiency. Additionally, program specialists and engineers work closely with customer representatives and major customer representatives to use their established relationships with customers. Customer representatives and major customer representatives distribute informational materials to trade allies and other market participants who, in turn, support and promote Idaho Power's energy efficiency programs.

Customers regularly ask how to get the most out of their energy dollar. Idaho Power staff has been trained to properly advise customers in the wise use of energy-specific energy efficiency measures and, when needed, can recommend where to find answers. Idaho Power is equipped with experienced

engineers, technically proficient personnel, and an extensive network of nationally recognized organizations and energy efficiency clearing houses to handle energy-related questions.

## Commercial and Industrial Energy Efficiency Program

| | | 2016* | 2015* |
|---|---|---|---|
| **Participation and Savings** | | | |
| | Participants (projects) | 1,903 | 1,463 |
| | Energy Savings (kWh)** | 88,160,599 | 102,073,910 |
| | Demand Reduction (MW) | n/a | n/a |
| **Program Costs by Funding Source** | | | |
| | Idaho Energy Efficiency Rider | $14,319,999 | $14,629,149 |
| | Oregon Energy Efficiency Rider | $508,538 | $798,424 |
| | Idaho Power Funds | $125,500 | $97,921 |
| | Total Program Costs—All Sources | $14,954,036 | $15,525,494 |
| **Program Levelized Costs** | | | |
| | Utility Levelized Cost ($/kWh) | $0.014 | $0.014 |
| | Total Resource Levelized Cost ($/kWh) | $0.026 | $0.031 |
| **Benefit/Cost Ratios** | | | |
| | Utility Benefit/Cost Ratio | 4.67 | 4.48 |
| | Total Resource Benefit/Cost Ratio | 2.81 | 2.13 |

*Metrics for each option (New Construction, Custom Projects, and Retrofits) are reported separately in appendices and in *Supplement 1: Cost-Effectiveness.*

***2016 total includes 123,700 kWh of energy savings from 14 Green Motors projects.*

### Description

Three major program options targeting different energy efficiency projects are available to commercial/industrial customers in the company's Idaho and Oregon service areas.

#### *Custom Projects (Custom Efficiency)*

The Custom Projects option incentivizes energy efficiency modifications for new and existing facilities. The goal is to encourage commercial and industrial energy savings in Idaho and Oregon service areas by helping customers implement energy efficiency upgrades. Incentives reduce customers' payback periods for customize modifications that might not be completed otherwise. The Custom Projects option offers an incentive level 70 percent of the project cost or 18 cents per kWh for first year estimated savings, whichever is less. The Custom Projects option also offers energy auditing services to help identify and evaluate potential energy saving modifications or projects.

Interested customers submit applications to Idaho Power for potential modifications that have been identified by the customers, Idaho Power, or by a third-party consultant. Idaho Power reviews each application and works with the customer and vendors to gather sufficient information to support the energy-savings calculations.

Once completed, customers submit a payment application; in some cases, large, complex projects may take as long as two years to complete. Every payment application is verified by Idaho Power staff or an Idaho Power contractor. All lighting modifications utilize the Idaho Power lighting tool to determine incentive.

Each project is reviewed to ensure energy savings are achieved. Idaho Power engineering staff or a third-party consultant verifies the energy savings methods and calculations. Through the verification process, end-use measure information, project photographs, and project costs are collected.

On many projects, especially the larger and more complex projects, Idaho Power or a third-party consultant conducts on-site power monitoring and data collection before and after project implementation. The measurement and verification process helps ensure the achievement of projected energy savings. Verifying applicants' information confirms energy savings are obtained and are within program guidelines. If changes in scope take place in a project, a recalculation of energy savings and incentive amounts occurs based on the actual installed equipment and performance. The measurement and verification reports provided to Idaho Power include a verification of energy savings, costs, estimates of measure life, and any final recommendations.

#### *New Construction (Building Efficiency)*

The New Construction option enables customers in Idaho Power's Idaho and Oregon service areas to apply energy-efficient design features and technologies in new commercial or industrial construction, expansion, or major remodeling projects. New construction and major renovation project design and construction life is much longer than small retrofits and often encompasses multiple calendar years. Originated in 2004, the program currently offers a menu of measures and incentives for efficient lighting, cooling, building shell, controls, appliances, and refrigeration options. These measures may otherwise be lost opportunities for savings on customers' projects.

Twenty-four prescriptive measures are offered: interior lighting, exterior lighting, daylight photo controls, occupancy sensors, high-efficiency exit signs, efficient A/C and heat pump units, efficient variable refrigerant flow units, efficient chillers, air-side economizers, direct evaporative coolers, evaporative pre-coolers on air-cooled condensers, reflective roof treatment, energy-management control systems, guest room energy-management systems, HVAC variable-speed drives, kitchen hood variable-speed drives, onion/potato shed ventilation variable-speed drives, efficient laundry machines, ENERGY STAR® under-counter dishwashers, ENERGY STAR commercial dishwashers, refrigeration head-pressure controls, refrigeration floating-suction controls, efficient condensers, and smart power strips.

#### *Retrofits (Easy Upgrades)*

The Retrofits option is Idaho Power's prescriptive measure option for existing commercial and industrial facilities. This part of the program encourages commercial and industrial customers in Idaho and Oregon to implement energy efficiency upgrades by offering incentives on a defined list of measures. Eligible measures cover a variety of energy-saving opportunities in lighting, HVAC, building shell, variable-frequency drives (VFD), food-service equipment, and other commercial measures. Customers can also apply non-standard lighting incentives. A complete list of the measures offered through Retrofits (Easy Upgrades) is included in *Supplement 1: Cost-Effectiveness*.

## Program Activities

### *Custom Projects*

Incentive levels for the non-lighting projects remained the same in 2016 at 18 cents per kWh of first year savings with a 70-percent project cost cap on the incentive.

The Custom Projects option had another very successful year with a total of 196 projects, including 11 in Oregon, completed by 103 customers. However, related energy savings decreased in 2016 by 14 percent over 2015, from 55,186 MWh to 47,519 MWh. Idaho Power also received 248 new applications representing a potential of 61,240 MWh of savings on future projects.

Idaho Power made the following tariff changes in 2016: The required 100,000 kWh minimum savings was removed to allow for projects that may not meet that threshold to receive a Custom Projects incentive, such as Streamlined Custom Efficiency (SCE). The three-year term requirement was removed for the self-direct projects, which eliminates the need to file for tariff changes for every new three-year term.

Custom Projects may reach some level of saturation through program maturity, over 95 percent of the large-power service customers have participated in the program. With the high percentage of industrial customers who have taken advantage of the program, deeper energy savings may be challenging to achieve. The company is addressing this ongoing challenge in several ways by continuing to use multiple channels to reach customers and to encourage new energy-saving modifications. The company has expanded the cohort offerings, SCE, and expanded its ability to conduct energy audits through an expanded list of engineering firms.

Table 15 indicates the program's 2016 annual energy savings by primary project measures.

Table 15. 2016 Custom Projects annual energy savings by primary project measure

| Program Summary by Measure | Number of Projects | kWh Saved |
|---|---|---|
| Lighting | 117 | 9,386,277 |
| Refrigeration | 11 | 23,681,463 |
| HVAC | 6 | 4,839,312 |
| Compressed Air | 18 | 2,726,482 |
| Commissioning | 7 | 2,739,491 |
| Controls | 1 | 224,756 |
| Pump | 3 | 708,555 |
| VFD | 32 | 3,158,906 |
| Other | 1 | 53,629 |
| Total [a] | 196 | 47,518,871 |

[a] Does not include Green Motor Initiative project counts and savings.

Facility energy auditing, customer technical training, and education services are key components used to encourage customers to consider energy efficiency modifications. The Municipal Water Supply Optimization Cohort (MWSOC) and Wastewater Energy Efficiency Cohort (WWEEC) program offerings are also driving a significant number of new projects in addition to increasing vendor engagement from the SCE offering. The 2016 activities in the key components are described below.

**Facility Energy Auditing**

Idaho Power funds the cost of engineering services, up to $3,500, for conducting energy scoping audits to encourage its larger customers to adopt energy efficiency improvements. Currently, there are 11 different firms on contract to provide scoping audits and general energy efficiency engineering support services.

In 2016, Idaho Power consultants completed 25 scoping audits and two detailed audits on behalf of Idaho Power customers. These audits identified over 20,000 MWh of savings potential. Most of the customers engaged in these audits used the information to move forward with projects or expressed interest in moving forward in the near future.

**Program Education and Offerings**

Custom Projects engineers and the major customer representatives set up numerous visits with the large commercial and industrial customers in 2016. The visits ranged from commercial/industrial efficiency program training to a comprehensive targeted technical training sessions for a larger audience on potential energy-saving opportunities for different measure types, such as refrigeration, pumps and fans, compressed air, HVAC, lighting, etc. In addition to the eight comprehensive targeted technical training sessions that were held by Idaho Power, Custom Projects engineers also gave presentations on Idaho Power programs and offerings at a multi-industrial customer program training sessions, such as the Northwest Chapter of American Association of Airport Executives Airfield and Facilities Management Conference, the International Society of Healthcare Engineers (ISHE) Conference, the Energy Community Partnership Workshop facilitated by Mountain Home Air Force Base, and the Idaho Green Building and Energy Conference. In 2016, Custom Projects continued three offerings to increase the total program savings—WWEEC, MWSOC, and SCE. A new, fourth offering launched in November 2016—Continuous Energy Improvement (CEI) Cohort for Schools.

Wastewater Energy Efficiency Cohort

In January 2014, Custom Projects launched WWEEC, its third program offering since 2013, to increase the total program savings. WWEEC is a cohort training approach to low-cost or no-cost energy improvements. WWEEC is a two-year engagement with 11 Idaho Power service area municipalities and ended in 2016. WWEEC provided a series of five technical training workshops with a cohort training approach. In addition, WWEEC provided energy audits in conjunction with a qualified wastewater system expert and an energy management assessment conducted by a strategic energy management professional for each participating facility. Customers were able to immediately implement low-cost and no-cost energy efficiency improvements by actions as simple as turning off equipment or adjusting control points for systems. They also implemented many energy management principles, including forming an energy team, setting energy goals, and establishing energy policies in their organization for persistence of savings. Energy savings were tracked via Idaho Power-provided, third-party software using an energy model for each facility. WWEEC participants also completed several capital projects that received separate incentives from our Commercial and Industrial Energy Efficiency Program. Additionally, multiple pre-planning meetings were held with consultants and municipalities for upcoming new wastewater construction projects.

Due to involvement with our WWEEC, Custom Projects engineers also set up multiple program informational meetings with the area civil engineering firms specializing in water and wastewater designs to educate them on the Commercial and Industrial Energy Efficiency Program, audit process, energy efficiency opportunities, and available tools and resources. Presentations on Idaho Power offerings were given at a multi-industrial customer program training session in Boise, the annual Southwest Idaho Operators Section (SWIOS) Conference, the national annual Water Environment Federation Technical Exhibition and Conference (WEFTEC) in New Orleans, and Idaho Power had a booth at the Pacific Northwest Section American Water Works Association (PNWS-AWWA) regional conference.

Year-one incentives and savings totaled $57,559 and 2,561,177 kWh/year. In all cases, the incentive was capped at 70 percent of the eligible costs. Year-one incentives and savings were processed in 2016. Additionally, some WWEEC participants completed capital projects that were encouraged and discussed in the workshops and energy audits. These capital projects' savings are captured separately and not included in the above number. Year-two of the offering consisted of phone call check-ins with the participants and model data updates. Year-two incentives and savings will be processed in 2017.

Municipal Water Supply Optimization Cohort

In September 2015, Idaho Power held a recruiting/training session for municipal water supply operators and public works personnel garnering interest in a third Strategic Energy Management cohort—the MWSOC, similar to WWEEC but for clean water operators. The program officially launched in January 2016. The goal of the cohort is to equip water professionals with the skills necessary to identify and implement energy efficiency opportunities on their own, and to ensure that these energy and cost savings are maintained long term.

A series of three workshops were held in the Twin Falls area with representatives from the 15 participating organizations. Sessions included technical training, hands-on learning exercises to demonstrate simple low-cost and no-cost actions to diagnose problems and save energy, and peer-to-peer sharing of lessons learned as the classes progressed. MWSOC provided energy audits of the participants' facilities. Customers were able to immediately implement low-cost and no-cost energy efficiency improvements by actions as simple as changing pressure regulating valve (PRV) settings or well level adjustments. Participants had engineering support between each workshop, facilitated by an expert team of energy engineers with specific experience in optimizing water supply systems. Participants all received tools, such as a baseline hydraulic model (updated and modernized with the energy modules loaded), a mass balance for water, and an energy map showing locations of stored and lost energy, as well as the energy footprint of the various pumps within each system. A top down baseline energy model was constructed for each participant that uses electric data normalized for system operating data and weather. The baseline energy model will be used in conjunction with on-going actual energy, production and weather data to determine the energy savings for the offering.

Continuous Energy Improvement Cohort for Schools

In November 2016, Idaho Power held a recruiting/training session for school district personnel garnering interest in this cohort. Representatives from 19 school districts attended. The session introduced the

upcoming cohort whose goal is to equip district personnel with hands-on training and guidance to help get the most out of their systems while reducing energy consumption. Idaho Power and the company's consultants gave an overview what Continuous Energy Improvement is and how numerous low-cost or no-cost measures can be uncovered in schools. By 2016 year-end, 9 school districts have signed up for the cohort. The Cohort for Schools Kickoff Workshop is scheduled for late January 2017, in Boise with a final Report-out Workshop to be scheduled in December 2017. Energy savings for this offering are tracked with multi-variant regression models that are custom-built for each participating facility and based on historical utility data and current operations.

Streamlined Custom Efficiency

The SCE offering was initially started in 2013 and continues to keep vendor engagement high and provides custom incentives for small compressed air system improvements, fast-acting doors in cold-storage spaces, refrigeration controllers for walk-in coolers, and process-related VFDs. This offering targets projects that may have typically been too small to participate in the Custom Projects due to the resources required to adequately determine measure savings. Idaho Power contracted with a third party to manage SCE data collection and analysis for each project. In 2016, the SCE offering processed 42 projects, totaling 2,837,200 kWh per year of savings and $399,523 in incentives paid.

#### *New Construction*

The New Construction option completed 116 projects, the largest total number of projects completed in a calendar year, resulting in 12,393,249 kWh in annual energy savings in Idaho and Oregon. The total number of projects increased by over 43 percent from 81 projects in 2015.

Maintaining a consistent offering is important for large projects with long construction periods, though changes are made to enhance customers' options or to meet new code changes. Idaho Power ideally tries to keep the New Construction option consistent by making less frequent changes, approximately every other year. The option was modified in mid-2016 to include the addition of four new measures; evaporative pre-coolers on air-cooled condensers, kitchen hood variable-speed drives, onion/potato shed ventilation variable-speed drives, and smart-strip power strips.

Idaho Power contracted with ADM in 2015 to update the Technical Reference Manual (TRM) to address code changes that occurred January 1, 2015 in Idaho. The revised TRM provided updated savings for existing measures and savings for new measures that were added to the program. Minor modifications were also made to several existing measures to update requirements based on the code changes.

Thirty projects received the Professional Assistance Incentive, an incentive given to architects and/or engineers for supporting technical aspects and documentation of the project, in 2016 (equal to 10 percent of the participant's total incentive, up to a maximum amount of $2,500) compared to nine projects in 2015.

In 2016, Idaho Power continued its contract with GreenSteps to target the commercial real estate industry by continuing to support the Kilowatt Crackdown™ competition past participants. The original competition, which included benchmarking each building in ENERGY STAR® Portfolio Manager,

encouraged builders to implement low-cost and no-cost efficiency measures. Idaho Power also expanded engagement with participants through Strategic Energy Management (SEM). GreenSteps worked with 26 buildings in Boise and Ketchum, and six property management firms. A summary of the report is located in *Supplement 2: Evaluations.*

Idaho Power customer representatives visited 20 architectural and engineering firms in Boise, Meridian, Nampa, Hailey, Ketchum, Twin Falls, and Pocatello in 2016. Customer representatives visited with 100 professionals total to build relationships with the local design community, and to discuss Idaho Power's commercial and industrial energy efficiency programs.

#### *Retrofits*

The Retrofits option experienced increases in participation and energy savings in 2016. Some of the increase was attributed to the mid-June program change to adjust the screw-in LED incentive. The option received a noticeable number of projects with screw-in LED product before that change became effective. This also resulted in increased energy savings. Overall, Retrofits received more LED-only projects, which had a significant contribution to energy savings.

Several measure changes were implemented mid-year. The most notable changes were to adjust the screw-in LED incentive, to add the tube LEDs (TLED), and to add seven non-lighting measures to the incentive menu.

For the Retrofits option, Idaho Power facilitated eight workshops across the Idaho Power service area targeting contractors and large customers. The purpose of the workshops was to review option updates with market participants.

Idaho Power staff and contractors contacted over 195 trade allies to respond to inquiries, strengthen relationships, encourage participation, increase knowledge of the incentives, and receive feedback about the market, and individual experiences. This targeted outreach was to electrical contractors, electrical distributors, HVAC contractors, and food service equipment suppliers.

Idaho Power continued its contracts with Evergreen Consulting Group, LLC, Honeywell, Inc., and RM Energy Consulting to provide ongoing program support for lighting and non-lighting reviews and inspections as well as trade ally outreach.

### Marketing Activities

Most marketing activities engaged in for the Commercial and Industrial Energy Efficiency Program can be found in the Marketing section of this report. Below are the 2016 activities specific to the option within the overall program.

#### *Custom Projects*

Idaho Power's Custom Projects option is unique from the company's other energy efficiency options by providing individualized energy efficiency solutions to a somewhat limited number of customers. Idaho Power's major customer representatives often act as the company's sales force. Marketing supports the major customer representatives by providing written program materials to help

them inform customers of the measures and benefits available to them. Idaho Power presented the Simplot Don Plant in Pocatello an incentive check for $197,335 toward energy efficiency upgrades to a pumping project.

#### *New Construction*

Idaho Power placed ads in the Idaho Association of General Contractors membership directory specific to the New Construction option. The New Construction brochure was also updated to include a list of current measures and provided to customers planning new construction and major renovation projects. Idaho Power alerted the media to its presentation of a cash incentive to Vallivue School District 139. During a board meeting, the School District accepted a check for more than $193,000 it had earned for adopting energy-efficient construction measures at two schools in Caldwell, Idaho.

#### *Retrofits*

Ads thanking contractors for their participation ran in numerous papers in December 2015, and continued in the *Business Insider, Southeast Idaho Business Journal, Idaho Business Review,* and *Business News* within the *Blackfoot Morning-News* in January 2016. Idaho Power also ran an ad promoting energy-efficient Retrofit incentives in the January Boise Chamber of Commerce newsletter.

### Cost-Effectiveness

#### *Custom Projects*

All projects submitted through the Custom Projects option must meet cost-effectiveness requirements, which include TRC, UC, and PCT tests from a project perspective. The program requires all costs related to the energy efficiency implementation and energy-savings calculations are gathered and submitted with the program application. Payback is calculated with and without incentives, along with the estimated dollar savings for installing energy efficiency measures. As a project progresses, any changes to the project are used to recalculate energy savings and incentives before the incentives are paid to the participant. To aid in gathering or verifying the data required to conduct cost-effectiveness and energy-savings calculations, third-party engineering firms are sometimes used via a scoping audit, detailed audit, or engineering measurement and verification services available under the Custom Projects option. Details for cost-effectiveness are in *Supplement 1: Cost-Effectiveness*.

#### *New Construction*

To calculate energy savings for the New Construction option, Idaho Power verifies the incremental efficiency of each measure over a code or standard practice installation baseline. Savings are calculated through two main methods. When available, savings are calculated using actual measurement parameters, including the efficiency of the installed measure compared to code-related efficiency. Another method for calculating savings is based on industry standard assumptions, when precise measurements are unavailable. Since the New Construction option is prescriptive and the measures are installed in new buildings, there are no baselines of previous measurable kWh usage in the building. Therefore, Idaho Power uses industry standard assumptions from the International Energy Conservation Code (IECC) to calculate the savings achieved over how the building would have used energy absent of efficiency measures.

New Construction incentives are based on a variety of methods depending on the measure type. Incentives are calculated mainly through a dollar-per-unit equation using square footage, tonnage, operating hours, or kW reduction.

To prepare for 2016 program changes, ADM, under contract with Idaho Power, updated the TRM for New Construction. The TRM, which provides savings and costs related to existing and new measures for the New Construction option, was updated to include the IECC 2012 baseline. These new savings were applied in 2016 when other program changes were implemented.

Based on the deemed savings value from the TRM, nearly all measures were cost-effective, with the exception of some air conditioning units and daylight photo controls. Idaho Power determined these measures met at least one of the cost-effectiveness exceptions outlined in OPUC Order No. 94-590. Idaho Power had received a cost-effectiveness exception on these measures when it filed changes to the program in 2014 under Advice No. 14-10. When Idaho Power filed Advice No. 16-08 for the combined commercial and industrial program, the company requested and received another cost-effectiveness exception for variant refrigerant flow (VRF) heat pumps.

Complete measure level details for cost-effectiveness can be found in *Supplement 1: Cost-Effectiveness*.

#### *Retrofits*

In 2016, Idaho Power used most of the same savings and assumptions as were used in 2015 for the Retrofits option. For all lighting measures, Idaho Power uses a lighting tool calculator developed by Evergreen Consulting, Group LLC. An initial analysis was conducted to see if the lighting measures shown in the tool were cost-effective based on the average input of watts and hours of operation, while the actual savings for each project are calculated based on specific information regarding the existing and replacement fixture. For most non-lighting measures, deemed savings from the TRM or RTF are used to calculate the cost-effectiveness. To prepare for 2016 program changes, ADM, under contract with Idaho Power, updated the TRM for the Retrofit option. The TRM which provides savings and costs related to existing and new measures for the Retrofit option. The TRM was updated to include the IECC 2012 baseline for several heating and cooling measures.

Several measures that are not cost-effective remain in the program. These measures include high-efficiency A/C units and heat pump units. After reviewing these measures, Idaho Power determined the measures met at least one of the cost-effectiveness exceptions outlined in OPUC Order No. 94-590. These cost-effectiveness exceptions were approved by the OPUC in Advice No 14-06 in 2014. When Idaho Power filed Advice No. 16-08 for the combined commercial and industrial program, the company requested and received another cost-effectiveness exception for VRF heat pumps.

Complete measure level details for cost-effectiveness can be found in *Supplement 1: Cost-Effectiveness*.

### Customer Satisfaction and Evaluations

Customer satisfaction with regards to the Commercial and Industrial Energy Efficiency Program is mentioned in the Commercial and Industrial sector overview. Activities that are specific to each component of the program are mentioned below.

#### *Custom Projects*

No specific activities were conducted in 2016.

#### *New Construction*

The New Construction option continued random installation verification on 10 percent of projects in 2016. The purpose of the verifications is to confirm program guidelines and requirements are adequate and ensure participants are able to provide accurate and precise information with regard to energy efficiency measure installations. The IDL completed on-site field verifications on 12 of the 116 projects, which encompass approximately 10 percent of the total completed projects in the program. Out of the 12 projects verified, only minor discrepancies were discovered. The minor discrepancies consist of the addition or subtraction of lighting fixtures compared to what was claimed on the application. Random project installation verification will continue in 2017.

In 2016, Idaho Power contracted with Leidos to conduct an impact evaluation of this option. The evaluation determined a high level of ex-post realization for option demand and energy savings at .99 and .98 respectively, as well as high realization at the measure level. The kWh confidence and precision ratios were 90 percent confidence at +/- 0.2 percent precision and 90 percent confidence at +/-4.8 percent for kW. In general, project documentation was adequate for verifying most measure impacts, and project data are recorded and tracked with high accuracy. Final reports are provided in *Supplement 2: Evaluation*.

#### *Retrofits*

In 2016, Idaho Power contracted with Leidos Engineering to perform an impact evaluation for the incentives paid in 2015 under the Retrofits option. The final report indicated that the option is well designed, well managed, and well implemented. The project documentation was adequate for verifying most measure impacts, and project data are recorded and tracked with high accuracy. The evaluation also determined a high level of ex-post realization for energy savings, as well as high realizations at the measure level. The 2015 kWh savings realization rate was 0.99 with 90 percent confidence at +/- 0.2 percent precision. Final reports are provided in *Supplement 2: Evaluation*.

### 2017 Program and Marketing Strategies

Future marketing for the overall Commercial and Industrial Energy Efficiency Program is described in the Marketing section of this report. Below are specific strategies that apply to the individual components of the program.

#### *Custom Projects*

Over the years, the Custom Projects option has achieved a high service-area penetration rate. As stated previously, over 95 percent of the large-power service customers have submitted applications for a project. Company staff is actively working to support these customers in new ways and find additional opportunities for cost-effective energy saving projects. Additional program offerings are currently under consideration for implementation in 2017.

Idaho Power will report the second year of energy savings and incentives for WWEEC in the *Demand-Side Management 2017 Annual Report*. Idaho Power will report the first year of energy

savings, and incentives in 2017 or early 2018 for the MWSOC offering. Activities and coaching will continue for the MWSOC participants and the report-out workshop will be held in 2017. The first year of the CEI Cohort for Schools will commence in January 2017. Three half-day workshops and a final report-out workshop will be held in 2017 along with monthly activities and frequent coaching. The SCE offering will continue in 2017, and new measures, processes, and other improvements will be evaluated to continuously improve the effectiveness of this offering.

Idaho Power will continue to provide site visits by Custom Projects engineers and energy scoping audits for project identification and energy-savings opportunities; measurement and verification of larger, complex projects; technical training for customers; and funding for detailed energy audits for larger, complex projects.

Custom Projects will continue to be marketed as part of Idaho Power's Commercial and Industrial Energy Efficiency Program.

#### *New Construction*

The following strategies are planned for 2017:

- Continue to perform random post-project verifications on a minimum of 10 percent of completed projects.
- Continue to sponsor technical training through the IDL to address the energy efficiency education needs of design professionals throughout the Idaho Power service area.
- Support organizations focused on promoting energy efficiency in commercial construction.
- Actively support the 2017 Idaho Energy and Green Building Conference as a member of the conference planning committee. Participate in planning the conference agenda and energy efficiency sessions.
- Continue to sponsor the BOMA symposium and offer energy efficiency training and support to the real estate market.
- Continue customer representative relationship building with local design professionals by targeting Idaho Power's Boise and Pocatello areas.

The New Construction option will continue to be marketed as part of Idaho Power's Commercial and Industrial Energy Efficiency Program.

#### *Retrofits*

Idaho Power will review and address the recommendations from the Leidos impact evaluation, and offer technical lighting classes to trade allies.

Retrofits will continue to be marketed as part of Idaho Power's Commercial and Industrial Energy Efficiency Program.

## *Flex Peak Program*

| | | 2016 | 2015 |
|---|---|---|---|
| **Participation and Savings** | | | |
| | Participants (sites) | 137 | 72 |
| | Energy Savings (kWh) | n/a | n/a |
| | Demand Reduction (MW) | 42 | 26 |
| **Program Costs by Funding Source** | | | |
| | Idaho Energy Efficiency Rider | $105,116 | $86,445 |
| | Oregon Energy Efficiency Rider | $247,897 | $219,654 |
| | Idaho Power Funds | $414,984 | $286,773 |
| | Total Program Costs—All Sources | $767,997 | $592,872 |
| **Program Levelized Costs** | | | |

| **Benefit/Cost Ratios** | | | |
| | Utility Benefit/Cost Ratio | n/a | n/a |
| | Total Resource Benefit/Cost Ratio | n/a | n/a |

### Description

The Flex Peak Program is a voluntary program available in Idaho and Oregon service areas. It's designed for Idaho Power's large commercial and industrial customers, with the objective to reduce the demand on Idaho Power's system during periods of extreme peak electricity use. By reducing demand on extreme system load days during summer months, the program reduces the amount of generation and transmission resources required to serve customers. Program participants earn a financial incentive for reducing load during peak electricity use: non-holiday weekdays, June 15 to August 15, between the hours 2:00 p.m. and 8:00 p.m. Reduction events may be called a maximum of 60 hours per season.

Customers with the ability to offer load reduction of at least 20 kW are eligible to enroll in the program. The 20-kW threshold allows a broad range of customers the ability to participate in the program. Participants receive notification of a load reduction event two hours prior to the start of the event, and events last between two to four hours.

The program originated in 2009 as the FlexPeak Management program managed by a third-party contractor. In 2015, Idaho Power took over full administration, and changed the name to Flex Peak Program. The IPUC issued Order No. 33292 on May 7, 2015, while the OPUC approved Advice No. 15-03 on May 1, 2015, authorizing Idaho Power to implement an internally managed Flex Peak Program (Schedule No. 82 in Idaho and Schedule No. 76 in Oregon), and to continue recovery of its demand response program costs in the previous manner.

## Program Activities

In 2016, 65 participants enrolled 137 sites in the program. Of those 137 sites, 67 were new—a 90-percent increase over 2015. Participants had a nominated load reduction of 34.2 MW in the first week of the program, which was the highest committed load reduction for the season. This weekly commitment, or nomination, was comprised of all 137 sites, 70 of which had participated in the 2015 season. The maximum realization rate during the season was 120 percent and the average for all three events combined was 98.8 percent. The realization rate is the percentage of load reduction achieved versus the amount of load reduction committed for an event. The highest hourly load reduction achieved was 41.5 MW during the July 26 event.

The first event was called on Thursday, June 30. Participants were notified at 2:00 p.m. of a four-hour event from 4:00 p.m. to 8:00 p.m. The total nomination for this event was 34.2 MW for each hour. The average load reduction was 32.8 MW, with the highest hourly load reduction of 34.8 MW from 6:00 p.m. to 7:00 p.m. The realization rate for this event was 96 percent.

A second event was called on Tuesday, July 26. Participants were notified at 2:00 p.m. of a four-hour event from 4:00 p.m. and 8:00 p.m. The total nomination for this event was 33.5 MW for each hour. The average load reduction was 40.3 MW, with the highest hourly load reduction of 41.5 MW from 4:00 p.m. to 5:00 p.m. The realization rate for this event was 120 percent.

The third event was called on Thursday, July 28. Participants were notified at 2:00 p.m. of a four-hour event from 4:00 p.m. to 8:00 p.m. The total nomination for this event was 33.9 MW. The average load reduction was 27 MW, with the highest hourly load reduction of 27.7 MW from 4:00 p.m. to 5:00 p.m. The realization rate for this event was 80 percent. Some larger sites underperformed or reduced participation because this was the second event in one week, therefore the realization rate was lower.

The Idaho Power CHQ building participated in the program again in 2016, and committed to reduce up to 200 kW of electrical demand during events—an increase from the 150 kWs nominated during the 2015 season. Unlike other program participants, Idaho Power does not receive any financial incentives for its participation. Idaho Power's CHQ participated in all three demand response events in 2016. The average reduction achieved by the facility across the three events was 348 kW, which exceeded the nominated amount. The maximum hourly reduction was 685 kW, achieved on July 28. Reductions were mostly obtained by turning off lights, adjusting chiller set points, decreasing fan speeds, and curtailing elevator use. Besides the benefit of experiencing firsthand what participants experience with the program, Idaho Power now has a quantifiable energy-reduction plan in place that can be executed when needed. Idaho Power will continue to look for opportunities to enroll more of its facilities in the program for future seasons.

## Marketing Activities

Idaho Power developed new program literature including a new program brochure. These were sent by direct-mail to encourage both past participants and new customers to enroll in 2016. Idaho Power launched an additional marketing campaign early in 2016 using customer representatives to recruit new participants. Customer representatives conducted field visits in early winter and followed up with

additional communication in early spring. This marketing campaign focused on identifying customer characteristics that make successful program participants based on load size, load shape, and type of operation. Customer representatives also communicated available incentive amounts based on customer load size.

The program's marketing campaign goals were expanded to increase the number and size diversity (in terms of nominated load reduction) of customers enrolled. By having a larger diversity of customer sizes enrolled, it was expected that the program would be less prone to volatility in its realization rate. The company also included an advertisement in the spring *Energy at Work* newsletter and published an article promoting the program in its commercial and industrial electronic newsletter, *Energy Insights*.

Idaho Power implemented an educational campaign with currently enrolled participants and potential participants to promote a variety of demand-reduction strategies. The goal was to refine the amount of nominated load reduction from each site to more realistically align with load reduction potential.

The Flex Peak Program was also marketed along with the Commercial and Industrial Energy Efficiency Program. Additional details can be found in the Marketing section of this report.

### Cost-Effectiveness

Idaho Power determines cost-effectiveness for it demand response program under the terms of IPUC Order No. 32923 and OPUC Order No. 13-482. Under the terms of the orders and the settlement, all of Idaho Power's demand response programs were cost-effective for 2016.

The Flex Peak Program was dispatched for 12 event hours and achieved a maximum reduction of 41.5 MW. The total cost of the program in 2016 was $767,997, had the Flex Peak Program been used for the full 60 hours, the cost would have been approximately $1,004,000.

In 2016, the cost of operating the three demand response programs was $9.47 million. Idaho Power estimates that if the three programs were dispatched for the full 60 hours, the total costs would have been approximately $12.87 million and would have remained cost-effective. A complete description of Idaho Power cost-effectiveness of its demand response programs is included in *Supplement 1: Cost-effectiveness.*

### Customer Satisfaction and Evaluations

Idaho Power conducted a post-season survey that was sent via email to all participants enrolled in the program. The survey was sent to 97 individuals representing 64 participating customer sites. Idaho Power received feedback from 34 individuals for a response rate of 35 percent. When customers were asked how satisfied they were with the Flex Peak Program, nearly 97 percent of respondents indicated they were "very satisfied" or "somewhat satisfied." When asked how likely they would be to re-enroll in the Flex Peak Program, 100 percent of respondents indicated they were likely to re-enroll next year with just over 91 percent indicating they were "very likely" to re-enroll. The complete details of the survey results are in *Supplement 2: Evaluation*, as is the *Flex Peak Program 2016 Report*.

Idaho Power contracted CLEAResult to conduct an impact evaluation of the 2016 Flex Peak Program. The goals of the impact evaluation were to determine the demand reduction (in MW) and realization rate for the three curtailment events during the program's June 15 through August 15, 2016 season.

The results of the analyses showed maximum demand reductions of 34.8, 41.5, and 27.7 MW, respectively, for the three events, and an average of 34.7 MW. The events achieved realization rates of 96.0 percent, 120 percent, and 80 percent, respectively, averaging 98.8 percent. These results are different than those listed in the CLEAResult report; these have been converted to generation-level reductions, while the CLEAResult report lists meter-level reductions.

The results of the impact evaluation show that Idaho Power's 2016 Flex Peak Program functioned as intended, and provided up to 42 MW to the electricity grid. A summary of the results is in *Supplement 2: Evaluation*.

## 2017 Program and Marketing Strategies

The company is exploring opportunities to improve the re-enrollment process for participants, and has filed a tariff advice with both the IPCU and OPUC to request that existing participants would be automatically enrolled each year without having to complete a new application and program agreement. Customers would still have the ability to change their nomination amounts and decline participation.

Recruitment efforts for the 2017 season will begin in the first quarter to encourage participation. Idaho Power will meet with existing participants during the winter/spring months to discuss past-season performance and upcoming season details.

For the upcoming season, Idaho Power plans to focus on retaining currently enrolled customers and to recruit new customers that show interest and are a good fit for the program. However, the company does not plan to actively market the program like it did in 2016 because the capacity from this past season remained around 35 MW, which comports with the desired program capacity set forth in the settlement agreement.

The company will continue to use its customer representatives to retain the currently enrolled sites and encourage new sites to participate. Flex Peak will also be marketed along with Idaho Power's Commercial and Industrial Energy Efficiency Program. See the Marketing section of this report for 2017 marketing strategies.

## Oregon Commercial Audits

| | 2016 | 2015 |
|---|---|---|
| **Participation and Savings** | | |
| Participants (a) | 7 | 17 |
| Energy Savings (kWh) | n/a | n/a |
| Demand Reduction (MW) | n/a | n/a |
| **Program Costs by Funding Source** | | |
| Idaho Energy Efficiency Rider | $0 | $0 |
| Oregon Energy Efficiency Rider | $7,717 | $4,251 |
| Idaho Power Funds | $0 | $0 |
| Total Program Costs—All Sources | $7,717 | $4,251 |
| **Program Levelized Costs** | | |
| Utility Levelized Cost ($/kWh) | n/a | n/a |
| Total Resource Levelized Cost ($/kWh) | n/a | n/a |
| **Benefit/Cost Ratios** | | |
| Utility Benefit/Cost Ratio | n/a | n/a |
| Total Resource Benefit/Cost Ratio | n/a | n/a |

### Description

The Oregon Commercial Audits identifies opportunities for commercial building owners to achieve energy savings. Initiated in 1983, this statutory required program (ORS 469.865) is offered under Oregon Tariff Schedule No. 82.

Through this program, Idaho Power provides free energy audits, evaluations, and educational products to customers. Energy audits provide the opportunity to discuss utility incentives available to customers who install qualifying energy efficiency measures. Business owners can make the decisions to change operating practices, or make capital improvements designed to use energy wisely.

### Program Activities

Seven customers requested audits. Of those audits, EnerTech Services, a third-party contractor, completed four, Idaho Power personnel completed two, and one customer received only the program-related booklet. No customers cancelled their audits. The costs were down in 2016 from 2015 because the third-party contractor performed only four audits.

Auditors inspected the building shell, HVAC equipment, lighting systems, and operating schedules, if available, and reviewed the customer's past billing data. Additionally, these visits provided a venue for auditors to discuss incorporating specific business operating practices for energy savings, and to distribute energy efficiency program information.

### Marketing Activities

Idaho Power sent out its annual mailing to 1,413 Oregon commercial customers in mid-September 2016 regarding the no-cost or low-cost energy audits, and the availability of Idaho Power's *Saving Energy Dollars* booklet.

### Cost-Effectiveness

As previously stated, the Oregon Commercial Audits program is a statutory program offered under Oregon Schedule 82, the Commercial Energy Conservation Services Program. Because the required parameters of the Oregon Commercial Audit program are specified in Oregon Schedule 82 and the company abides by these specifications, this program is deemed to be cost-effective. Idaho Power claims no energy savings from this program.

### Customer Satisfaction and Evaluations

Idaho Power conducted no customer satisfaction surveys or evaluations in 2016.

Historically, customers have been pleased with the audit process because the audits help identify energy-saving opportunities that may not be obvious to the business owner.

### 2017 Program and Marketing Strategies

The Oregon Commercial Audits program will continue to be an important avenue for Idaho Power to help customers identify energy-saving opportunities.

Idaho Power will continue to market the program through the annual customer notification.

This page left blank intentionally.

# Irrigation Sector Overview

The irrigation sector is comprised of agricultural customers operating water-pumping or water-delivery systems to irrigate agricultural crops or pasturage. End-use electrical equipment primarily consists of agricultural irrigation pumps and center pivots. The irrigation sector does not include water pumping for non-agricultural purposes, such as the irrigation of lawns, parks, cemeteries, golf courses, or domestic water supply.

In December 2016, the active and inactive irrigation service locations totaled 20,638 system-wide. This was an increase of 1.7 percent compared to 2015, primarily due to the addition of service locations for pumps and pivots to convert land previously furrow irrigated to sprinkler irrigation. Irrigation customers accounted for 1,948,079 MWh of energy usage in 2016, which was a decrease from 2015 of approximately 4.8 percent primarily due to variations in weather. This sector represented nearly 14 percent of Idaho Power's total electricity sales, and approximately 33 percent of July sales. Energy usage for this sector has not grown significantly in many years; however, there is substantial yearly variation in usage due primarily to the impact of weather on customer irrigation needs.

Idaho Power offers two programs to the irrigation sector:

1. Irrigation Efficiency Rewards, an energy efficiency program designed to encourage the replacement or improvement of inefficient systems and components

2. Irrigation Peak Rewards, a demand response program designed to provide a system peak resource

The Irrigation Efficiency Rewards program, including Green Motor Initiative, experienced increased annual savings, from 14,027 MWh in 2015 to 15,747 MWh in 2016. Annual savings were up in 2016 likely because several large projects were completed this year.

In 2016, the Irrigation Peak Rewards program was in its third full season of full operation after temporarily being suspended for the 2013 season. Idaho Power successfully recruited the majority of prior participants to continue their participation in 2016, with a small increase of 1.2 percent in eligible service points participating over 2015.

Table 16 summarizes the overall expenses and program performance for both the energy efficiency and demand response programs provided to irrigation customers.

Table 16. 2016 irrigation program summary

| Program | Participants | Total Cost | | Savings | |
|---|---|---|---|---|---|
| | | Utility | Resource | Annual Energy (kWh) | Peak Demand (MW) |
| **Demand Response** | | | | | |
| Irrigation Peak Rewards | 2,286 service points | $ 7,600,076 | $ 7,600,076 | n/a | 303 |
| **Total** | | **$ 7,600,076** | **$ 7,600,076** | **n/a** | **303** |
| **Energy Efficiency** | | | | | |
| Green Motors—Irrigation | 23 motor rewinds | | | 73,617 | |
| Irrigation Efficiency Rewards | 851 projects | $ 2,372,352 | $ 8,162,206 | 15,673,513 | |
| **Total** | | **$ 2,372,352** | **$ 8,162,206** | **15,747,130** | **303** |

**Note:** See Appendix 3 for notes on methodology and column definitions.

Each year, the company conducts a customer relationship survey. Overall, 56 percent of Idaho Power irrigation customers surveyed in 2016 for the Burke Customer Relationship Survey indicated Idaho Power was meeting or exceeding their needs in offering energy efficiency programs. Fifty-three percent of survey respondents indicated Idaho Power is meeting or exceeding their needs with information on how to use energy wisely and efficiently. Sixty-seven percent of respondents indicated Idaho Power is meeting or exceeding their needs with encouraging energy efficiency with its customers. Overall, 41 percent of the irrigation survey respondents indicated they have participated in at least one Idaho Power energy efficiency program. Of irrigation survey respondents who have participated in at least one Idaho Power energy efficiency program, 93 percent are “very” or “somewhat” satisfied with the program.

## Training and Education

Idaho Power continued to market its irrigation programs by varying the location of workshops and offering new presentations to irrigation customers. In 2016, Idaho Power provided eight workshops promoting the Irrigation Efficiency Rewards program. Approximately 200 customers attended workshops in Twin Falls, Emmett, McCall, Homedale, Mini-Cassia, Shoshone, American Falls, and Oxbow. The company displayed exhibits at regional agricultural trade shows, including the Eastern Idaho Agriculture Expo, Western Idaho Agriculture Expo, the Agri-Action Ag show and the Treasure Valley Irrigation Conference.

Idaho Power sends out *Irrigation News* to all irrigation customers in Idaho and Oregon. The newsletter focuses on the Idaho Power Irrigation topics. This newsletter provides an opportunity to increase awareness, and to promote our Irrigation programs.

## Field Staff Activities

Idaho Power’s agricultural representatives offer customer education, training, and irrigation-system assessments and audits across the service area. Agricultural representatives also engage agricultural irrigation equipment dealers in training sessions, with the goal to share expertise about energy-efficient system designs, and to bring awareness about the program. Agricultural representatives and the irrigation segment coordinator, a licensed agricultural engineer, participate in annual training to maintain

or obtain their Certified Irrigation Designer and Certified Agricultural Irrigation Specialist accreditation. This training allows Idaho Power to maintain its high level of expertise in the irrigation industry and is sponsored by the nationally based Irrigation Association.

## *Irrigation Efficiency Rewards*

| | 2016 | 2015 |
|---|---|---|
| **Participation and Savings** | | |
| Participants (projects) | 851 | 902 |
| Energy Savings (kWh)* | 15,747,130 | 14,027,411 |
| Demand Reduction (MW) | n/a | n/a |
| **Program Costs by Funding Source** | | |
| Idaho Energy Efficiency Rider | $1,672,328 | $1,714,399 |
| Oregon Energy Efficiency Rider | $634,101 | $61,295 |
| Idaho Power Funds | $65,923 | $60,018 |
| Total Program Costs—All Sources | $2,372,352 | $1,835,711 |
| **Program Levelized Costs** | | |
| Utility Levelized Cost ($/kWh) | $.018 | $0.016 |
| Total Resource Levelized Cost ($/kWh) | $.063 | $0.085 |
| **Benefit/Cost Ratios** | | |
| Utility Benefit/Cost Ratio | 4.95 | 6.00 |
| Total Resource Benefit/Cost Ratio | 3.21 | 3.84 |

*2016 total includes 73,617 kWh of energy savings from 23 Green Motors projects.

### Description

Initiated in 2003, the Irrigation Efficiency Rewards program encourages energy-efficient equipment use and design in irrigation systems. Qualified irrigators in Idaho Power's Idaho and Oregon service areas can receive financial incentives and reduce their electricity usage through participation in the program. Two options help meet the needs for major or minor changes to new or existing systems: Custom Incentive and Menu Incentive.

#### *Custom Incentive Option*

The Custom Incentive Option addresses extensive retrofits or installation of an efficient new system.

New Systems: For a new system, the incentive is based on installation of a system Idaho Power determines to be more energy efficient than standard. Water source changes to an existing system are treated as a new system. The incentive is 25 cents per annual kWh saved, not to exceed 10 percent of the project cost.

Existing Systems: For existing system upgrades, the incentive is 25 cents per annual kWh saved or $450 per kW demand reduction, whichever is greater. The incentive is limited to 75 percent of the total project cost.

The qualifying energy efficiency measures include any hardware changes that result in a reduction of the potential kWh use of an irrigation system.

Idaho Power reviews, analyzes, and makes recommendations on each project. All project information is reviewed for each completed project before final payment. Prior usage history, actual invoices, and, in most situations, post-usage demand data are used to verify savings and incentives.

#### *Menu Incentive Option*

The Menu Incentive Option covers a significant portion of the costs of repairing and replacing specific components that help the irrigation system use less energy. This option is designed for systems where small maintenance upgrades provide energy savings from 11 separate measures. These measures are as follows:

- New flow-control type nozzles
- New nozzles for impact, rotating, or fixed-head sprinklers
- New or rebuilt impact or rotating type sprinklers
- New or rebuilt wheel-line levelers
- New complete low-pressure pivot package
- New drains for pivots or wheel-lines
- New riser caps and gaskets for hand-lines, wheel-lines, and portable mainlines
- New wheel-line hubs
- New pivot gooseneck and drop tube
- Leaky pipe repair
- New center pivot base boot gasket

Payments are calculated on predetermined average kWh savings per component.

### Program Activities

Of the 851 irrigation efficiency projects completed in 2016, 728 were associated with the Menu Incentive Option, providing an estimated 10,357 MWh of energy savings and 2.02 MW of demand reduction. The Custom Incentive Option had 123 projects, of which 65 were new irrigation systems and 58 were on existing systems. This option provided 5,316 MWh of energy savings and 2.03 MW of demand reduction for the year.

### Marketing Activities

In addition to training and education mentioned in the overview section, Idaho Power agricultural representatives targeted visits with a selected number of customers who had not participated in the program to increase customer education. Idaho Power maintained a database of irrigation dealers and vendors for direct-mail communication. Irrigation dealers and vendors are a key component to the successful marketing of the program. Therefore, Idaho Power's face-to-face interactions and direct-mailings containing the most up-to-date program information, brochures, and dealer-specific meetings ensured correct program promotion.

In 2016, the company sent a copy of *Irrigation News* to all irrigation customers in Idaho and Oregon. The August 2016 newsletter focused on the Irrigation Efficiency Rewards program: why read dates are important and summary bill options. This newsletter provides an opportunity to increase transparency, and to promote the Irrigation Efficiency Rewards program.

Idaho Power also placed numerous ads in print agricultural publications including the *Argus Observer*, *Gem State Producer*, *Capital Press, Power County Press,* and *Potato Grower Magazine;* updated and distributed the program brochure; and used radio advertising during Agri-Action and FFA week.

## Cost-Effectiveness

Idaho Power calculates cost-effectiveness using different savings and benefits assumptions and measurements under the Custom Incentive Option and the Menu Incentive Option of Irrigation Efficiency Rewards.

Each application under the Custom Incentive Option received by Idaho Power undergoes an assessment to estimate the energy savings that will be achieved through a customer's participation in the program. On existing system upgrades, Idaho Power calculates the savings of a project by determining what changes are being made and comparing it to the service point's previous five years of electricity usage history on a case-by-case basis. On new system installations, the company uses standard practices as the baseline and determines the efficiency of the applicant's proposed project. Based on the specific equipment to be installed, the company calculates the estimated post-installation energy consumption of the system. The company verifies the completion of the system design through aerial photographs, maps, and field visits to ensure the irrigation system is installed and used in the manner the applicant's documentation describes.

Each application under the Menu Incentive Option received by Idaho Power also undergoes an assessment to ensure deemed savings are appropriate and reasonable. Payments are calculated on a prescribed basis by measure. In some cases, the energy-savings estimates in the Menu Incentive Option are adjusted downward from deemed RTF savings to better reflect known information on how the components are actually being used. For example, a half-circle rotation center pivot will only save half as much energy per sprinkler head as a full-circle rotation center pivot. All deemed savings are based on seasonal operating hour assumptions by region. If a system's usage history indicates it has lower operating hours than the assumptions, like the example above, the deemed savings are adjusted.

Based on the deemed savings from the RTF, all the measures offered under the Menu Incentive Option are cost-effective. Complete measure-level details for cost-effectiveness can be found in *Supplement 1: Cost-Effectiveness*.

## Customer Satisfaction and Evaluations

Idaho Power conducted no customer satisfaction surveys for this program.

In 2016, Idaho Power contracted with Leidos to conduct an impact and process evaluation of this program. The evaluation team conducted 46 desk reviews; 30 for a stratified sample of Menu Option

projects and 16 for a stratified sample of Custom Option projects. The team also completed site visits for 11 custom incentive projects.

The findings of the impact evaluation indicate a realization rate of 98 percent, with a relative precision of +/- 2.4 percent overall at 90 percent confidence, on the ex-post kWh savings for both the Menu Option and the Custom Option savings combined. The realization rate on the ex-post kW impacts was 97 percent for the Menu Option and 75 percent for the Custom Option, respectively. The overall combined realization rate for the program demand savings was 90 percent with a relative precision of +/-3.3 percent at 90 percent confidence. The realization rate is the percent comparison of the expected savings or load reduction to the realized savings or load reduction.

The process evaluation indicated that the program is well designed, well managed and well implemented. A summary of the results is in *Supplement 2: Evaluation*.

### 2017 Program and Marketing Strategies

Marketing plans for 2017 include conducting six to eight customer-based irrigation workshops. Additionally, Idaho Power will continue to participate in four regional agricultural trade shows. Idaho Power will work closely with customers who have participated in the Irrigation Efficiency Rewards program, and continue to take photos for program promotion highlighting efficient irrigation system designs.

Idaho Power will continue to promote the program in agriculturally focused editions of newspapers and magazines, and to provide valuable information in its *Irrigation News* newsletter.

## *Irrigation Peak Rewards*

| | | 2016 | 2015 |
|---|---|---|---|
| **Participation and Savings** | | | |

| | Total Resource Benefit/Cost Ratio | n/a | n/a |

### Description

Idaho Power's Irrigation Peak Rewards program is a voluntary program available only to Idaho and Oregon agricultural irrigation customers with metered service locations that have participated in the past. Initiated in 2004, the purpose of the program is to minimize or delay the need to build new supply-side resources. By reducing demand on the most extreme load days in the most extreme summer conditions, the Irrigation Peak Rewards program can reduce the amount of generation and transmission resources Idaho Power needs to build.

The program pays irrigation customers a financial incentive to interrupt the operation of specified irrigation pumps with the use of one or more load control devices. Historically, the Irrigation Peak Rewards program provides approximately 300 MW of load reduction during the program season of June 15 through August 15, which is nearly 9 percent of Idaho Power's all-time system peak.

The program offers two interruption options: an Automatic Dispatch Option and a Manual Dispatch Option. To participate in the Automatic Dispatch Option, either an advanced metering infrastructure (AMI) or a cellular control device is attached to the customer's electrical panel that allows Idaho Power to remotely control the pumps. To participate in the Manual Dispatch Option, Idaho Power must determine that the service location cannot take advantage of the current installation and communication technology, or the service point offers at least 1,000 cumulative horse power (hp). These customers must nominate a particular amount of kW reduction by June 1 of the program year.

For either interruption option, load control events could occur up to four hours per day, up to 15 hours per week, but no more than 60 hours per season. Customers will experience at least three events per season between 1:00 p.m. and 9:00 p.m. on weekdays and Saturday.

The incentive structure consists of fixed and variable payments. The fixed incentive is paid to those who participate during each of the first three events. A variable incentive is paid to those who participate in subsequent events. Customers who participate from 5:00 p.m. until 9:00 p.m. can receive a higher variable incentive.

Program rules allow customers the ability to opt out of dispatch events up to five times per service point. The first three opt outs each incur a penalty of $5 per kW, while the remaining two each incur a penalty of $1 per kW based on the current month's billing kW. The opt-out penalty may be prorated to correspond with the dates of program operation, and are accomplished through manual bill adjustments. The penalties will never exceed the amount of the incentive that would have been paid with full participation.

### Program Activities

Idaho Power filed a request in December 2015 to modify the existing Irrigation Peak Rewards program to allow the company to use more of its AMI technology for load control as well as to allow greater flexibility for some customers to participate in the Manual Dispatch Option. After approval in Idaho and Oregon in February 2016, Idaho Power decided not to renew the contract with program provider, EnerNOC/M2M Communications.

Idaho Power enrolled 2,286 service points in the program in 2016, an increase of 1 percent over 2015. The enrolled service points accounted for approximately 82 percent of the eligible service points (where there is a load control device installed). The incentive rate remained the same in 2016. The customer's incentive is a demand credit of $5.00/kW and an energy credit of $0.0076/kWh applied to the monthly bills for the period of June 15 through August 15. The demand credit is calculated by multiplying the monthly billing kW by the demand-related incentive amount. The energy credit is calculated by multiplying the monthly billing kWh usage by the energy-related incentive amount. Credits were prorated for periods when reading/billing cycles did not align with the program season dates from June 15 to August 15. The incentive structure also includes a "variable" payment for more than three events of $0.148/event kWh, with an increased variable credit of $0.198/event kWh for service points that voluntarily participate in the "extended" 9 p.m. interruption period.

The three load control events occurred June 29, July 27, and July 29, 2016 with the highest load reduction occurring on June 29, providing an estimated 316.9 MW at the generation level.

### Marketing Activities

Idaho Power used workshops, trade shows, and direct-mailings to encourage past participants to re-enroll in the program. See the Irrigation Sector Overview section. The company updated an informational flyer to increase appeal and readability by using a brochure format. Idaho Power mailed the new brochure, program enrollment application, and program agreement, to all eligible participants in February 2016.

## Cost-Effectiveness

Idaho Power determines cost-effectiveness for it demand response program under the terms of IPUC Order No. 32923 and OPUC Order No. 13-482. Under the terms of the orders and the settlement, all of Idaho Power's demand response programs were cost-effective for 2016.

The Irrigation Peak Rewards program was dispatched for 12 event hours and achieved a maximum demand reduction of 302.7 MW. The total expense for 2016 was $7,600,075 and would have been approximately $10.8 million if the program was fully used for 60 hours.

In 2016, the cost of operating the three demand response programs was $9.47 million. Idaho Power estimates that if the three programs were dispatched for the full 60 hours, the total costs would have been approximately $12.87 million and would have remained cost-effective. A complete description of Idaho Power cost-effectiveness of its demand response programs is included in *Supplement 1: Cost-Effectiveness.*

## Customer Satisfaction and Evaluations

On the June 29 event, the program experienced two unexpected problems. The AMI signal to the load control device was not able to process all of the necessary commands because the communication settings were incorrect. The issue was discovered near the beginning of the event, and was corrected within two hours of the event starting time. Additionally, the EnerNOC/M2M device notification process did not work as intended, consequently not all of the participants were notified. EnerNOC/M2M corrected the issue, and it did not happen in subsequent events.

Each year, Idaho Power produces an internal annual report for the Irrigation Peak Rewards program. This report includes a load-reduction analysis, cost-effectiveness information, and program changes. A copy is included in *Supplement 2: Evaluation.*

In 2016, Idaho Power conducted a potential realization rate analysis and, as in past years, that potential event date has a large influence on the expected realization rate. Table 18 shows the season in two-week blocks and the potential realization rate associated with each. The rate drops off significantly in August due to a higher percentage of pumps turned off during the baseline period. The 2016 counterfactual realization rate peaked the last two weeks of June. The analysis determined that the highest realization rate of 76.9 percent occurred June 29. A further breakdown of the load reduction for each event by is shown in Table 17.

Table 17. Irrigation Peak Rewards program load reduction for each 2016 event by program option

| Event | Automatic Dispatch Option (MW) | Manual Dispatch Option (MW) | Total Load (MW) |
|---|---|---|---|
| June 29 | 233,589 | 69,171 | 302,760 |
| July 27 | 177,685 | 66,911 | 244,569 |
| July 29 | 185,180 | 64,096 | 249,275 |

Table 18. Irrigation Peak Rewards 2016 potential realization rate

| 2016 Season Timeframe | Average Potential Realization Rate |
|---|---|
| June 15–June 30 | 68.82% |
| July 1–July 15 | 62.42% |
| July 16–July 31 | 58.89% |
| August 1– August 15 | 55.66% |

## 2017 Program and Marketing Strategies

The company is in the process of exchanging all of the EnerNOC/M2M communication devices with load control units that work with its AMI meters or company designed cell phone-controlled devices. Once the exchanges are complete, the program will no longer use EnerNOC/M2M to provide services for the program. This change out of devices is expected to reduce overall program costs and potentially reduce the complexity of coordinating communications and load control commands.

Idaho Power will continue to recruit past participants in this program for the 2017 irrigation season. The company will conduct six to eight workshops throughout its service area to familiarize customers with the program details and eligibility requirements. Each eligible customer will be sent a comprehensive packet containing an informational brochure, sign-up worksheet, and contract agreement encouraging their participation. Idaho Power agricultural representatives will continue one-on-one customer contact to inform and encourage program participation.

This page left blank intentionally.

# OTHER PROGRAMS AND ACTIVITIES

Idaho Power recognizes the value of energy efficiency awareness and education to create behavioral change to help customers use energy wisely. The goal of other programs and activities is to promote energy efficiency programs, projects, and behavior in customers. These awareness efforts increase customer demand for, and satisfaction with, Idaho Power's programs and activities. These activities include customer outreach, marketing, research, project development, and education programs. This category includes the Residential Energy Efficiency Education Initiative, Easy Savings Program, Commercial Education, and Educational Distributions.

## Building-Code Improvement

Since 2005, the State of Idaho has been adopting a state-specific version of the IECC. The Idaho Building Code Board convened another Energy Code Collaborative in late 2015 in an effort to address implementation of the new series of building-related codes.

The Idaho Building Code Board requested the collaborative review of the 2015 codes and suggested recommendations to the board regarding adoption of codes. The first meeting occurred on December 2, 2015 and three subsequent meetings occurred in 2016.

Idaho Power participated and offered support in those collaborative meetings, which was attended by members of the building industry, local building officials, code development officials, and other interested stakeholders. The Energy Code Collaborative is an ongoing effort in which Idaho Power will continue to participate. Additional meetings will be scheduled in 2017.

## Energy Efficiency Advisory Group

Formed in 2002, EEAG provides input on enhancing existing DSM programs and on implementing energy efficiency programs. Currently, EEAG consists of 13 members from Idaho Power's service area and the Northwest. Members represent a cross-section of customers from the residential, industrial, commercial, and irrigation sectors, as well as representatives from low-income households, environmental organizations, state agencies, public utility commissions, and Idaho Power. EEAG meetings are generally open to the public and attract a diverse audience. Idaho Power appreciates the input from the group, and acknowledges the commitment of time and resources the individual members give to participate in EEAG meetings and activities.

EEAG met four times in 2016: February 18, May 5, August 30, and November 3. Additionally, EEAG held two conference calls on February 16 and November 28. During these meetings, Idaho Power discussed and requested feedback on new program ideas and new measure proposals, marketing methods, and specific measure details; provided a status of the Idaho and Oregon Rider funding and expenses; gave an update of ongoing programs and projects; and supplied general information on DSM issues and other important issues occurring in the region. Idaho Power relies on input from EEAG to provide a customer and public-interest view of energy efficiency and demand

response programs and expenses. A summary of each meeting and phone call is below; the complete notes from the 2016 EEAG meetings are included in *Supplement 2: Evaluation*.

February 16, 2016: EEAG members participated in a confidential conference call to discuss the *2015 Flex Peak Program One-Time Report*. This report was submitted to the IPUC by May 7, 2016, and compares the current Flex Peak Program to the prior program managed by EnerNOC.

February 18, 2016: Darrel Anderson, President and CEO of Idaho Power, addressed the group and thanked members of EEAG for their time and guidance throughout the years. He commented that Idaho Power has benefited by having the EEAG as a resource that brings new thoughts and ideas about energy efficiency. CLEAResult presented results of the demand response program evaluations. Idaho Power sought feedback from the group on two programs: See ya later, refrigerator® and the Multifamily Direct Install project (Multifamily Energy Savings Program). The group supported continuing See ya later, refrigerator® in 2016, and provided good ideas for other measures that could be included in the Multifamily Direct Install project. Idaho Power also discussed its website redesign; spring 2016 residential energy efficiency ad campaign tactics, including a new customer pledge; and results from an em**powered** community survey to gauge customers' interest in making energy-saving improvements to their homes.

May 5, 2016: Idaho Power demonstrated its myAccount web tool, and handed out an abridged home assessment form for the group to fill out. The Energy Savings Pledge (later named the Smart-saver Pledge) was discussed and EEAG was asked for feedback on behavioral change options that could be included in the pledge. The group provided several options that pledge participants could choose from. Idaho Power presented its Program Planning Update, and asked EEAG for feedback on a couple of new residential ideas it is researching. The group suggested Idaho Power continues the Multifamily Direct Install project and continues to look for ways to encourage the installation of DHPs into new multi-family housing units if they appear to be cost-effective. The history of the Idaho and Oregon Rider was presented to the group and included the financial history for both Idaho and Oregon balances since their inception. Idaho Power provided EEAG with results from the spring residential energy efficiency ad campaign, further discussed plans for the Smart-saver Pledge, and reviewed Idaho Power's social media channels and specific energy efficiency posts and ads on each channel.

August 30, 2016: EEAG member and CSHQA president, Kent Hanway, hosted this meeting at the CSHQA office on Broad Street in Boise. Along with a presentation of the building's energy efficiency measures, EEAG members and guest were given a tour of the building. A presentation covering 2017 preliminary cost-effectiveness provided a summary of all programs and how anticipated changes may impact programs for 2017. Idaho Power updated the group on activities related to customer alerts and home energy reports, and presented the results of an analysis conducted by the company to quantify the estimated value of deferral of transmission and distribution investments that could occur as a result of energy-efficiency efforts. Idaho Power discussed results from an em**powered** community survey about the spring residential energy efficiency ad campaign, plans for the fall ad campaign, and 2017 marketing efforts.

November 3, 2016: EEAG members were given an update on the development of a home energy report pilot to be deployed in 2017. EEAG was asked for feedback on target audience type for these reports. The Commercial Program Performance presentation highlighted energy savings and participation and feedback was requested from EEAG regarding some possible changes to the Flex Peak Program for 2017. Idaho Power provided an update about its various surveys and how they impact marketing, shared results from the fall residential energy efficiency ad campaign and Smart-saver Pledge, discussed plans for new Commercial and Industrial Energy Efficiency Program ads, and shared some new initiatives and successes from 2016. The company presented the non-cost-effective aspects of the Home Improvement Program and advised EEAG of the company's plan no longer offer the program.

November 28, 2016: A conference call was held to discuss Idaho Power's recommendations to decrease the collection percentage of the Rider.

## Green Motors Initiative

Idaho Power participates in the Green Motors Practices Group's (GMPG) Green Motors Initiative (GMI). Under the GMI, service center personnel are trained and certified to repair and rewind motors in an effort to improve reliability and efficiency. If a rewind returns a motor to its original efficiency, the process is called a "Green Rewind." By rewinding a motor under this initiative, customers may save up to 40 percent when compared to buying a new motor. The GMI is available to Idaho Power's agricultural, commercial, and industrial customers.

Twenty-one service centers in Idaho Power's service area have the training and equipment to participate in the GMI, and perform an estimated 1,200 Green Rewinds annually. Of the 21 service centers, currently nine have signed on as GMPG members. The GMPG will work to expand the number of service centers participating in the GMI, leading to market transformation and an expected kWh savings in southern Idaho and eastern Oregon.

Under the initiative, Idaho Power pays service centers $2 per hp for each National Electrical Manufacturers Association (NEMA)-rated motor up to 5,000 hp that received a verified Green Rewind. Half of that incentive is passed on to customers as a credit on their rewind invoice. The GMPG requires all member service centers to sign and adhere to the GMPG Annual Member Commitment Quality Assurance agreement. The GMPG is responsible for verifying quality assurance.

In 2016, a total of 37 motors were rewound under the GMI. Table 19 provides a breakdown of energy savings and the number of motors by customer segment.

Table 19. 2016 Green Motor Initiative savings, by sector and state

| Sector | State | Number of Motors | Sum of kWh Savings |
|---|---|---|---|
| Irrigation | ID | 22 | 72,871 |
| | OR | 1 | 746 |
| **Irrigation Total** | | **23** | **73,617** |
| Commercial and Industrial | ID | 12 | 50,955 |
| | OR | 2 | 72,745 |
| **Commercial and Industrial Total** | | **14** | **123,700** |
| **Grand Total** | | **37** | **197,317** |

## Idaho Power's Internal Energy-Efficiency Commitment

Idaho Power continues to upgrade the company's substation buildings across its service area. Focus for 2017 will be to provide energy-efficient heating and cooling, and to develop a plan to replace all T-12 lighting with LED fixtures in substation buildings.

Renovation projects continued at CHQ in downtown Boise in 2016. The company remodeled the eighth floor, and exchanged the old T-12 parabolic lighting fixtures with T-8 lighting. Remodels continue to incorporate energy efficiency measures, such as lower partitions, lighting retrofits, and automated lighting controls. In 2017, Idaho Power plans to remodel the ninth floor of the CHQ.

Also in 2106, the new Twin Falls Operation Center was constructed to replace the 1951-built center used to house the South-East Region operations staff. The design incorporates LED lighting, energy-efficient heating and cooling by way of a VRF design, and lighting control that includes daylight harvesting to reduce power consumption. The building also features a rooftop solar array to offset the amount of energy the building uses from the grid.

In 2016, Idaho Power redesigned the HVAC delivery system for the Maintenance and Electrical Shops; construction on these projects is planned for 2018. Idaho Power estimates that with these improvements the shops may reduce their usage by 300,000 kWh in coming years.

Idaho Power continued its major sustainability initiative by installing more electric vehicle (EV) charging stations at the company's EV Workplace Charging Center at CHQ and at several operations centers. The company continues to provide a variety of models of EV charging stations to promote awareness, use, and information dissemination about EVs. More employees now have the opportunity to charge their EV while at work. In addition to adding more EVs to the Idaho Power fleet, employees' personal use of EVs will further promote the financial and environmental benefits of EVs.

Idaho Power's internal energy efficiency projects and initiatives are funded by non-rider funds.

## Local Energy Efficiency Funds

The purpose of LEEF is to provide modest funding for short-term projects and activities that do not fit within other categories of energy efficiency programs, but still provide energy savings or a defined benefit to the promotion of energy-efficient behaviors or activities.

Idaho Power received two applications for LEEF in 2016. Both applications were reviewed and found to be standard practice, and not appropriate for LEEF. A residential program specialist followed up with these applicants, and directed them to the residential energy efficiency resources found on Idaho Power's website. One project involved replacing all lighting in the applicant's house with LED lighting. The other project involved replacing single-pane windows with new, more energy-efficient windows.

## Market Transformation

Market transformation is an effort to change the existing market for energy efficiency goods and services by engaging and influencing large national companies to manufacture or supply more energy-efficient equipment. Market transformation can also attempt to identify barriers and opportunities to increase the market adoption of efficiency. Idaho Power achieves market transformation savings primarily through its participation in the NEEA.

### *Northwest Energy Efficiency Alliance*

Idaho Power has been a funding member of NEEA since its inception in 1997. NEEA's role in this process is to look to the future to find emerging opportunities and to create a path forward to make those opportunities a reality in the region.

NEEA's current, five-year funding cycle began 2015. In this cycle the 2015 to 2019 NEEA business plan is forecast to obtain 145 average megawatt (aMW) of regional energy savings at a cost savings of about $3 million over the next five years to Idaho Power customers as compared to the previous five-year business plan. The NEEA plan also offered some optional programs and activities to prevent overlap of activities when local utilities have the capability to provide the same services at a lower cost or more effectively.

Idaho Power participates in all of NEEA's committees and workgroups including representation on the Regional Portfolio Advisory Committee and the Board of Directors. In 2016, Idaho Power continued to help with the implementation of the Commercial and Industrial Lighting Regional Market Plan.

NEEA performs several MPERs on various energy efficiency efforts each year. In addition to the MPERs, NEEA provides market-research reports, through third-party contractors, for energy efficiency initiatives throughout the Pacific Northwest. Copies of these reports are included on the CD accompanying *Supplement 2: Evaluation* and on NEEA's website under Market Effects Evaluation.

## NEEA Marketing

As stated in Idaho Power's agreement with NEEA for the 2015 to 2019 funding cycle: "Idaho Power will fund, create, and deliver specific market transformation activities for all initiatives that are relevant for the Idaho Power service area." In 2016, these activities included educating residential customers on heat pump technology and heat pump water heaters, and promoting reduced wattage T-8 lightbulbs to business customers.

Idaho Power placed an article about heat pump technology and included heat pump water heaters as an example in its summer *Energy Efficiency Guide*. The company also issued a *News Briefs* article titled *New, More-Efficient Heat Pump Water Heater!* on heat pump water heaters to media April 25, and promoted the products on social media and in the October issue of *Connections.*

To promote reduced wattage lightbulb replacement, Idaho Power published an article in its fall *Energy @Work* newsletter, placed a promo pod linking to a newly developed flyer (PDF) on the company's Retrofits web page, and wrote an article that was included in BOMA's member email in November.

## Residential NEEA Activities

Idaho Power participates in the Residential Advisory Committee, Efficient Homes Workgroup, the Manufactured Homes Interest Group, the Retail Products Platform (RPP) Initiative, the DHP research project, the Smart Water Heat Initiative (previously known as the HPWH Initiative), Efficient Homes Workgroup, the Super Efficient Dryers Workgroup, the Northwest Regional Strategic Market Plan for Consumer Products group, and Northwest Regional Retail Collaborative. During 2016, NEEA combined the Efficient Homes Workgroup and the Manufactured Homes Interest Group and renamed it the Better Built NW Workgroup.

NEEA provides Better Built NW builder and contractor training, manages the regional-homes database, develops regional marketing campaigns, and coordinates energy-efficient new construction activities with utilities in Idaho, Montana, Oregon, and Washington.

In 2016, NEEA completed the sun setting of their ENERGY STAR® Homes Northwest program. All single-family and multi-family builders seeking ENERGY STAR certification must now go through the national EPA ENERGY STAR Homes program. NEEA will continue oversight of a regional database for utilities to access ENERY STAR Home certifications for incentive payments and will continue working towards the creation of a single-family Residential Performance Path program to offer utilities flexibility in program design and the opportunity to capture all above building code savings on residential new construction projects.

In 2016, NEEA formed the Super Efficient Dryers Initiative to support the acceleration of heat pump dryers into the market and Idaho Power participated in the workgroup. The initiative focuses on influencing manufacturer product development and executing strategies to overcome the barriers of this new technology. Barriers include a high incremental cost, limited consumer awareness, and product availability. The initiative offers incentives to reduce the retail price. A second goal of the initiative is

lab and field-testing to better understand how heat pump dryers perform in real-world conditions, evaluate consumer preferences, and gather data to support RTF provisional energy savings.

Idaho Power participated in RETAC which met quarterly to review the emerging technology pipeline for BPA, NEEA, and the Northwest Power and Conservation Council (NWPCC) Seventh Power Plan. RETAC is developing a regional database to increase coordination among the utilities to identify and track emerging technologies; plan and conduct research; and develop, implement, and assess pilots and field demonstrations.

Idaho Power continued participation in the RBSA. The purpose of the RBSA is to determine common attributes of residential homes, and develop a profile of the existing residential buildings in the Northwest.

### Commercial and Industrial NEEA Activities

NEEA continued to provide support for commercial and industrial energy efficiency activities in Idaho in 2016, which included partial funding of the IDL for trainings and additional tasks.

The Idaho Building Code Board requested the Idaho Code Collaborative review the 2015 codes and make a recommendation to the board on adoption. NEEA facilitated the Code Collaborative meetings and Idaho Power participated.

NEEA facilitated regional webinars for the Commercial Code Enhancement (CCE) initiative for new construction to discuss how utilities can effectively align code changes and utility programs. NEEA is using the code collaborative in Idaho and Montana as examples of success for other regions.

NEEA facilitated the conference planning committee and, along with Idaho Power, supported the 2016 Idaho Energy and Green Building Conference held in Boise on November 1 and 2, 2016. Idaho Power had two active members on the conference planning committee.

NEEA's work on SEM in the commercial and industrial sectors continued in 2016. The primary focus in 2016 was to consolidate all of the SEM templates, guidelines, and documents into the new SEM Hub website.

NEEA's work with the Refrigerating Engineers & Technicians Association (RETA) on the RETA certified refrigeration energy specialist (CRES) certification process continued in 2016. A new CRES contractor was hired in 2016 to work with RETA marketing of the RETA CRES certification, improving the RETA CRES training materials, and improving the RETA CRES practice exams.

Idaho Power kept abreast on NEEA's initiatives in the commercial lighting arena via periodic conference calls and in-person meetings. Idaho Power continued participation as a member of the NEEA Commercial Lighting Program Manager Work Group.

The Reduced Wattage Lamp Replacement (RWLR) initiative achieved some success in 2016, especially in Idaho. NEEA worked with 20 branches across five electrical distributor organizations in Idaho Power's service area, with new distributors added to the initiative in 2016. Preliminary data shows

the 2016 market penetration of reduced wattage T-8 lightbulb in the company's service area is between 30 to33 percent, which is higher than the average 22 percent penetration across all four Pacific Northwest states. Overall, linear fluorescent lightbulb sales continue to decline at roughly 10 percent per year. Market sales of linear LEDs are increasing, which is having an impact on the RWLR initiative; however, NEEA estimates 2017 will continue to see good participation from distributors in reduced wattage T-8 sales.

In 2016, the NEEA Top-Tier Trade Ally (TTTA) training was renamed NXT Level. Ultimately, the plan is to offer lighting trade allies throughout the region the opportunity for multi-tiered training, each level building on the one before, over the next few years. NEEA rolled out Level 1 on-line training to the Idaho Power service area June 2016. Level 1 is geared toward more seasoned trade allies. In October, the company's first trade ally completed the course and received the Level 1 designation. Several other trade allies in the Idaho Power service area are in process of taking the course.

Idaho Power continued participation in the Regional Strategic Market Planning Collaborative for commercial and industrial lighting. The collaborative formed in 2015 to create regional strategic market plans in four market segments. Commercial and industrial lighting was the first segment of focus because it was identified as the collaborative's top priority. Idaho Power is represented on a steering committee formed to monitor and oversee the progress of the regional commercial and industrial lighting plan.

The NEEA Existing Building Renewal (EBR) pilot project in Boise, which began in 2013 and phased through 2016, saw no significant results in 2016. The project has not resulted in any Idaho Power incentive applications.

NEEA completed several assessment studies related to irrigated agriculture to support their scanning activities. Idaho Power has kept apprised of these activities, and has reviewed each of these assessments. Copies of the reports are included on the CD accompanying *Supplement 2: Evaluation* and on NEEA's website under NEEA Market Effects Evaluations.

### NEEA Funding

In 2016, Idaho Power began the second year of the 2015 to 2019 *Regional Energy Efficiency Initiative Agreement* with NEEA. Per this agreement, Idaho Power is committed to fund NEEA based on a quarterly estimate of expenses up to the five-year total direct funding amount of $16.5 million in support of NEEA's implementation of market transformation programs in Idaho Power's service area. Of this amount in 2016, 100 percent was funded through the Idaho and Oregon Riders.

In 2016, Idaho Power paid $2,676,387 to NEEA. The Idaho jurisdictional allocation of the payments was $2,542,567, while $133,820 was paid for the Oregon jurisdiction. Other expenses associated with Idaho Power's participation in NEEA activities, such as administration and travel, were paid from Idaho and Oregon Riders.

Final NEEA savings for 2016 will be released in June 2017. Preliminary estimates reported by NEEA for 2016 indicate Idaho Power's share of regional market transformation MWh savings for 2016 is

24,616 MWh. These savings are reported in two categories; codes- and standards-related savings of 20,060 MWh and non-codes and standards related savings of 4,556 MWh.

In the *Demand-Side Management 2015 Annual Report*, preliminary funding share estimated savings reported were 21,900 MWh. The revised estimate included in this report for 2015 final funding share NEEA savings is 23,039 MWh. These saving include savings from code-related initiatives as well as non-code-related initiatives. Idaho Power relies on NEEA to report the energy savings and other benefits of NEEA's regional portfolio of initiatives. For further information about NEEA, visit their website at neea.org.

## Program Planning Group

In 2014, Idaho Power convened an internal PPG to explore new opportunities to expand current DSM programs and offerings. The group consisted of residential program specialists, commercial and industrial engineers, energy efficiency analysts, marketing specialists, energy efficiency program leaders, and the research and analysis leader. The PPG does not perform program execution. Instead, the group's role is to determine if a measure has energy-saving potential, has market adoption potential, and is potentially cost-effective.

Throughout 2016, the group met regularly to explore new ideas to promote energy efficiency including evaluating new potential programs and measures. Idaho Power incorporated five new ideas from the PPG into the overall portfolio of residential program offerings: 1) mailing energy efficiency kits, 2) initiating a multi-family direct-install project, 3) installing smart thermostats, and 4) distributing clothes drying racks for educational purposes. The first three offerings will continue to be available in 2017. Idaho Power will evaluate the drying rack offering for its long-term viability.

In the commercial sector, the company began the school cohort. In November 2016, Idaho Power recruited school districts to establish a structured energy program where each district will have an individualized initiative and develop a program to implement energy efficiency measures and behaviors at their schools.

Three other PPG ideas were presented to EEAG and are being considered for implementation in 2017: 1) Home Energy Reports, mailed to customers to inform them of their energy use and how it compares to others; 2) an on-line marketplace for customers to review and purchase energy-efficient appliances; and 3) installation of a thermostatic shower valve to reduce hot water use. Each of these measures has an element of behavior change.

Idaho Power will continue to use the PPG to review, evaluate, and deliver new energy efficiency offerings in 2017 and beyond.

## Regional Technical Forum

The RTF is a technical advisory committee to the NWPCC, established in 1999 to develop standards to verify and evaluate energy efficiency savings. Since 2004, Idaho Power has supported the RTF by

providing annual financial support, regularly attending monthly meetings, participating in sub-committees, and sharing research and data beneficial to the forum's efforts.

The forum is made up of both voting members and corresponding members from investor-owned and public utilities, consultant firms, advocacy groups, Energy Trust of Oregon, and BPA, all with varied expertise in engineering, evaluation, statistics, and program administration. The RTF advises the NWPCC during the development and implementation of the regional power plan in regards to the following listed in the RTF charter:

- Developing and maintaining a readily accessible list of eligible conservation resources, including the estimated lifetime costs and savings associated with those resources and the estimated regional power system value associated with those savings.
- Establishing a process for updating the list of eligible conservation resources as technology and standard practices change, and an appeals process through which utilities, trade allies, and customers can demonstrate that different savings and value estimates should apply.
- Developing a set of protocols by which the savings and system value of conservation resources should be estimated with a process for applying the protocols to existing or new measures.
- Assisting the Council in assessing: 1) the current performance, cost and availability of new conservation technologies and measures; 2) technology development trends; and 3) the effect of these trends on the future performance, cost and availability of new conservation resources.
- Tracking regional progress toward the achievement of the region's conservation targets by collecting and reporting on regional research findings and energy savings annually.

When possible, Idaho Power uses the savings estimates, measure protocols, and supporting work documents provided by the RTF, and when the work products are applicable to the Idaho climate zones and load characteristics. In 2016, Idaho Power staff participated in all RTF meetings as a voting member and the RTF Policy Advisory Committee.

During 2016, RTF impacted measure changes include savings tier additions to DHPs, updates to multi-family weatherization and new construction measures, updates to low-flow showerhead savings, and the addition of connected or "smart" thermostats as a supported RTF measure. All implementations of changes were accounted for in planning and budgeting for 2017. Idaho Power considered the multi-family weatherization measure updates when it decided to sunset the Home Improvement Program. A complete list of RTF decisions in 2016 can be accessed at rtf.nwcouncil.org.

## Residential Energy Efficiency Education Initiative

Idaho Power recognizes the value of general energy efficiency awareness and education in creating behavioral change and customer demand for, and satisfaction with, its programs. The Residential Energy Efficiency Education Initiative (REEEI) promotes energy efficiency to the residential sector. The company achieves this by creating and delivering educational materials and programs that result in

wise and informed choices regarding energy use and increase Idaho Power's energy efficiency program participation.

REEEI continued to produce semiannual *Energy Efficiency Guide*s in 2016. Idaho Power distributed these guides primarily via insertion in local newspapers and at events across Idaho Power's service area. The *Winter Energy Efficiency Guide* was published and distributed by 16 newspapers in Idaho Power's service area the week of January 26, in accordance with the new distribution plan outlined in 2015. The *Boise Weekly* also inserted the guide, increasing circulation by 30,000, which focused on ways to find the truth about energy-saving claims, seven ways to improve a home's energy efficiency, ventilation and lighting for optimum health and efficiency, and tips for hiring a home improvement contractor. The information was applicable to all residential customers, but the design was adapted and enhanced for particular usefulness and appeal to the senior population. Idaho Power included a story from the guide in the January *News Briefs* and promoted it that month on KPVI during the energy efficiency news segment.

The *Summer Energy Efficiency Guide* was delivered nearly 222,000 homes the week of July 24, 2016. This guide focused on saving energy as a family and highlighted why Idaho Power promotes energy efficiency, energy-saving computer settings, behavior change, smart technology, and making saving energy fun for the whole family. The guide also featured a mini home assessment so customers could gauge how energy efficient their behaviors were.

The release of the summer guide received public relations support through numerous communication channels, including an item in Idaho Power's weekly *News Briefs* email to all media in the Idaho Power service area on July 18 and 25, promotion on KTVB and KPVI in the July energy efficiency news segments, on Idaho Power's social media accounts, and using banner ads and native ads on the Idaho Statesman website. A banner ad appears as a traditional advertisement; a native ad is formatted as an on-line news article, with several paragraphs of text, but is, in fact, paid media. The native ad includes a disclaimer that reads "Advertisement."

In 2016, the company distributed over 6,000 guides, including issues from past years, at energy efficiency presentations and events, which continued to reinforce the overall value of these guides. On its website, Idaho Power provides a link to the most current seasonal guide, and to a list of historical guides.

REEEI distributed energy efficiency messages through a variety of other communication methods during 2016. Idaho Power increased customer awareness of energy-saving ideas via continued distribution of the third printing of the 96-page booklet *30 Simple Things You Can Do to Save Energy*, a joint publishing project between Idaho Power and The Earthworks Group. In 2016, the program distributed 2,595 English and 480 Spanish copies directly to customers. This was accomplished via community events and local libraries; by customer representatives during in-home visits; by participating contractors in the Home Improvement Program, Energy House Calls program, H&CE Program, and Fridge and Freezer Recycling Program; through direct web requests; and in response to inquiries received by Idaho Power's Customer Service Center. Agency partners also used the books to educate clients about Energy Efficiency. Additionally, more than 34,000 customers had an opportunity

to request the booklet and/or the most recent *Energy Efficiency Guide* when they ordered their ESK online.

Idaho Power continues to recognize that educated employees are effective advocates for energy efficiency and Idaho Power's energy efficiency programs. Idaho Power customer relations and energy-efficiency staff reached out to each of Idaho Power's geographical regions and the Customer Service Center to speak with customer representatives and other employees to discuss educational initiatives and answer questions about the company's energy efficiency programs.

The Kill A Watt™ Meter Program remained active in 2016. Idaho Power's Customer Service Center and field staff continued to encourage customers to learn about the energy used by specific appliances and activities within their homes by visiting a local library to check out a Kill A Watt meter. The Kill A Watt meters were mentioned on live television studio news programs on KTVB and KPVI in Idaho Power's monthly energy efficiency segments.

As in previous years, Idaho Power continued to strengthen the energy education partnership with secondary school educators through continued participation on the Idaho Science, Technology, Engineering and Mathematics (iSTEM) Steering Committee. In 2016, 16 teachers completed the four-day, two-credit professional development seminar, Energy for Future Citizens, facilitated by Idaho Power and co-sponsored by Intermountain Gas and the Idaho National Laboratory (INL). Among other things, participating teachers received a classroom kit containing Kill A Watt meters and other tools to facilitate student learning related to energy efficiency and wise energy use.

Idaho Power continued to engage customers in energy efficiency discussions at many community events throughout Idaho Power's service area. In February, Idaho Power participated in the Smart Women, Smart Money conference for the second year and educated nearly 2,000 women about the benefits of energy-efficient choices and LED lighting. In February, March, April, and May Idaho Power participated in the Twin Falls Home and Garden Show, the College of Southern Idaho's Sustainability Show, the Centennial Ribbon Cutting at the Twin Falls Visitor Center, Platt's Super Tool Day, Pocatello's Spring Home Show and the Portneuf Valley Community Environmental Fair—actively promoting wise energy use and participation in energy efficiency programs while distributing over 16,000 LED lightbulbs at these specific events.

In September 2016, Idaho Power participated in the FitOne Expo in Boise, Idaho. The event continued to be important to the initiative due to the size of the audience and because Idaho Power's prior participation confirmed the demographics of attendees appear to align with the company's residential energy efficiency target audience. In 2016, Idaho Power staff at the event once again focused attendee attention on the benefits of LED lighting technology, distributed LED lightbulbs, and promoted participation in the ESK program.

Idaho Power further increased its energy efficiency presence in the community by providing energy efficiency and program information through 92 outreach activities, including events, presentations, trainings, and other activities. In addition, Idaho Power customer representatives delivered 189 presentations to local organizations addressing energy efficiency programs and wise

energy use. In 2016, Idaho Power's Community Education team provided 91 presentations on *The Power to Make a Difference* to 2,350 students and 53 classroom presentations on *Saving a World Full of Energy* to 1,411 students. The community education representatives and other staff also completed 14 senior citizen presentations on energy efficiency programs and shared information about saving energy to 592 senior citizens in the company's service area. Additionally, Idaho Power's energy efficiency program managers responded with detailed answers to 364 customer questions about energy efficiency and related topics received via Idaho Power's website.

As part of National Energy Awareness Month in October, Idaho Power held its sixth annual student art contest in the Idaho Power service area, bringing energy education into the classroom and inspiring students and families to think more about energy. This year, the contest set a new record with more than 2,239 entries representing all regions. The contest, which featured "Ways to Save Energy" as one of the highlighted categories, was promoted in a late September *News Briefs* and results were publicized in *Connections*. Regional and overall winning students and their teachers were recognized.

The Residential Energy Efficiency Education Initiative continued to provide energy efficiency tips in response to media inquiries and in support of Idaho Power's *#TipTuesday* posts. In addition to supplying information for various Idaho Power publications, such as the *News Scans* weekly employee newsletter, the *Connections* customer newsletter, and Idaho Power's Facebook page, energy efficiency tips, and content was provided for weekly *News Briefs* and monthly KTVB (Boise) and KPVI (Pocatello) live news segments.

The initiative completed the program design phase of the ESK program and implemented the new program. Each kit was shipped with a mini-home assessment to cross-market other energy efficiency programs, promote the use of myAccount and help families learn about other energy-saving behavior changes. Savings and expenses have been reported under Educational Distributions.

The initiative continued to coordinate LED lightbulb distributions aimed at getting the newest lighting technology into customer hands along with customer education and answers to their common questions. At events and presentations, company staff distributed over 24,900 LEDs in custom packaging that highlighted the advantages of energy-efficient lighting and encouraged participation in Idaho Power's myAccount on-line portal. LED lightbulbs were mentioned on nine of the news segments on KTVB and KPVI. The energy savings resulting from this effort and from the SEEK for the school year 2015 to 2016, are reported in the Educational Distributions program section of this report.

In 2016, the initiative implemented the Drying Rack Pilot Project—a behavioral change program with the goal of helping customers reduce their automatic clothes dryer use by 25 percent or more. Educational messages to support the behavior change were delivered to customers at the point of enrollment, when drying racks were picked up and during the project period. Additional information about the project can be found in the Educational Distributions program in this report.

In the fall, the initiative conducted a survey with the em**powered** community to learn more about customers' shower behaviors—in particular, details around how they warm up the water prior to taking a shower. Information from the survey may be used to improve potential future offerings such as the

addition of a thermostatic shower valve as an educational distribution option. A copy of the survey can be found in *Supplement 2: Evaluation*.

The initiative's 2017 goals are to increase program participation and promote education and energy saving ideas that result in energy-efficient, conservation-oriented behaviors and choices. In addition to producing and distributing educational materials, the initiative will continue to manage the company's Educational Distributions program responsible for distributing educational measures that have associated savings. Examples of activities conducted under Educational Distributions include LED lighting education, distribution of LED lightbulbs to customers, the SEEK program, the Drying Rack Project and the ESK program. In addition to these activities, the initiative plans to implement a home energy report pilot project.

The initiative will continue to work with the PPG to explore additional behavioral program opportunities that may include distribution of thermostatic shower valves, increased promotion of myAccount, or a pilot program to test other behavioral messages.

## Evaluation and Best Practices Review

In 2016, the company contracted with Leidos to perform a process evaluation and best practices review of the REEEI. Leidos found that REEEI is comprised of 23 different activities, efforts and elements that educate, inform, and persuade residential electric customers to install energy-efficient measures and to take other actions that decrease energy use. They also found the initiative both investigates and engages in various behavioral change strategies.

Leidos also found Idaho Power has a comprehensive presence on both traditional and social media channels. The 23 initiative elements reach over 415,000 customers in a variety of ways ranging from: 1) in-person contacts and presentations, courtesy of five community educational and approximately 20 customer representatives in the field daily; 2) newsletters, guides, mailers, conventional broadcasting, social media; and 3) gamification reward systems, sponsorships, educational materials and training.

Interviews with Idaho Power staff and initiative efforts indicate a strong focus on driving customers to use the myAccount on-line portal located on the company website, where customers check on energy use via near real-time smart-meters, billing and account information with links to tools, rebates and other resources that aid in understanding their energy use and reduction strategies. Daily customer logins to myAccount have steadily increased over the last four and a half years, from 2,000 logins in mid-2012, to about 5,000 in late-2016. Moreover, the number of myAccount registrations per month is also increasing, from 2,000 to4,000 accounts per month in 2010 through 2011, up to 3,000 to 5,000 per month more recently.

Idaho Power is marketing energy-savings programs and activities by linking them to home improvement, money savings, comfort, and other NEBs to capture interest in energy efficiency and move it to top-of-mind. Surveys conducted with external program managers, subject-matter experts, and Idaho Power staff rated their customers' non-energy motivational drivers on a 10-point scale.

"Saving money" was rated highest (9.4), followed by improved comfort (9.1), health and safety (7.6), and being/feeling "green" and reducing environmental impacts (7.3).

External program managers, subject-matter experts, and Idaho Power staff rated marketing channels that involve person-to-person interaction and active learning environments higher than more passive, informal channels, to reach and educate customers. On a 10-point scale, situations where strong in-group social identity exists were rated most effective/useful (8.0), followed by on-line customer utility accounts (7.7), universities and college settings (7.6), public or community events, on-line energy dashboards and smart or real-time meters (all 7.3).

Leidos estimates conservatively that Idaho Power staff conducted over 590 in-person (or webinar) outreach activities, training sessions and events recorded in the Outreach Tracker database (from early 2012 to mid-2016) with an average attendance of 8091 people per event.

The SEEK and *The Power to Make a Difference* presentation (given by Idaho Power staff 124 times to 3,359 students in 2015) are also features of REEEI. Both received numerous positive comments from customers and build strong customer-utility relations. "The children always express that they tried everything included [in the kits] with their parents or family members. The adults express they are happy to have the free materials especially the lightbulbs and showerheads…teachers cannot thank us enough for this program!" Eighteen high school teachers participated in a three-day professional development seminar (facilitated by iSTEM) that empowered teachers with information and classroom tools to teach students to think critically about energy, including; the science of energy, energy generation and sources, wise energy use and social impacts.

A literature review of best practices regarding energy education programs was performed and indicated there are four basic types of behavioral change programs and strategies: 1) informational programs, 2) socially interactive approaches, 3) education and training, and 4) a stacked approach. Leidos states the four types of behavioral change strategies are well represented in the breadth of REEEI elements described in the final report.

The final report can be found in *Supplement 2: Evaluation.*

## University of Idaho Integrated Design Lab

Idaho Power is a founding supporter of the IDL. The IDL is dedicated to the development of high-performance, energy-efficient buildings in the Intermountain West. Idaho Power has worked with the IDL since its inception in 2004 to educate the public about how energy-efficient business practices benefit the business and the customer. In 2016, Idaho Power entered into an agreement with the IDL to perform the following tasks and services.

### *Foundational Services*

The goal of this task was to provide energy efficiency technical assistance and project-based training to building industry professionals and customers. When the IDL receives requests for their involvement in

building projects, the projects are categorized into one of three types. Phase I projects are simple requests that can be addressed with minimal IDL time. Phase II projects are more complex requests that require more involvement and resources from the lab. Phase III projects are significantly more complex and must be co-funded by the customer.

In 2016, the IDL provided technical assistance on a total of 38 projects in the Idaho Power service area. There were 32 Phase I projects, five Phase II projects, and one Phase III project. An additional three projects, currently in early stages, and the full scope of work is yet to be determined. Overall, 44 percent of the projects were on new buildings, 38 percent were on existing buildings and 18 percent were not building specific. The report is located in the IDL section of *Supplement 2: Evaluation*.

## Lunch & Learn

The goal of the Lunch & Learn task was to educate architects, engineers, and other design and construction professionals about energy efficiency topics through a series of educational lunch sessions.

In 2016, the IDL scheduled 20 technical training lunches in Boise, and Ketchum. The trainings were coordinated directly with architecture and engineering firms and organizations; a total of 161 architects, engineers, interior designers, project managers, and others attended.

Eighteen lunches were offered in Boise, and two in Ketchum. The topics of the lunches (and number of each) were: The Classroom of the Future: A DOE project (1); New Design Recommendations for Exterior Lighting (1); Case Study—Daimler Truck North America (1); Passive House Standard for Multifamily Projects (1); Life Sciences Building Path to High-Performance Design and Construction (1); Integrated Design Principles (1); Daylight Performance Metrics for Human Health, Productivity, and Satisfaction (1); Cold Feet: Managing Controls and Condensation with Simulating Radiant Slab Cooling (1); Daylight in Buildings: Schematic Design Methods (1); Radiant Heating and Cooling Design Considerations (1); Benchmarking and Energy Goal Setting (1); Integrated Design Case Studies (2); Hybrid Ground Source Heat Pump (2); and Daylight in Buildings: Getting the Details Right (5). The report is located in the IDL section of *Supplement 2: Evaluation*.

## Building Simulation Users Group

The goal of this task was to facilitate the Idaho BSUG, which is designed to improve the energy efficiency-related simulation skills of local design and engineering professionals.

In 2016, six monthly BSUG sessions were hosted by IDL. The sessions were attended by 73 professionals in person and were made available remotely, attended by 48 professionals. Evaluation forms were completed by attendees for each session. On a scale of 1 to 5, with 5 being “excellent” and 1 being “poor,” analyzing results from the first six questions, the average session rating was 4.34 for 2016. For the final question “The content of the presentation was…” on a scale of 1 to 5, with 1 being “too basic,” 3 being “just right,” and 5 being “too advanced,” the average session rating was 3.15 for 2016.

Each presentation was archived on the BSUG 2.0 website along with general BSUG-related content. The BSUG 2.0 site logged 994 page views with 234 specific to Idaho users in 2016. The report is located in the IDL section of *Supplement 2: Evaluation*.

## New Construction (Building Efficiency) Verification

The goal of this task was to continue random installation verification of over 10 percent of New Construction program participants who received incentives. This consisted of conducting a full review of documentation and complete on-site inspections to validate whether noted systems and components had been installed. The purpose of this verification was to confirm program guidelines and requirements were adequately facilitating participants to provide accurate and precise information with regard to energy efficiency measure installations.

This task also included the review of all daylight photo-control incentives to verify site conditions and improve the quality of design and installation.

The IDL completed on-site field verifications for the New Construction program as summarized in the New Construction Customer Satisfaction and Evaluations section presented earlier in this report. The verification report is located in the IDL section of *Supplement 2: Evaluation*.

## Tool Loan Library

The TLL gives customers access to equipment that enables them to measure and monitor energy consumption on various systems within their operation. The goal of this task was to operate and maintain measurement equipment, including a web-based equipment tool loan-tracking system, and to provide technical training on how each tool is intended to be used.

The inventory of the TLL now consists of over 900 individual pieces of equipment. In 2016, two new tools and eight manuals were added to the library. Additionally, 25 tools were calibrated in 2016. The tools and manuals are available for customers, engineers, architects, and contractors in Idaho Power's service area to borrow at no cost to aid in the evaluation of energy efficiency projects and equipment they are considering.

There were 49 tool loan requests in 2016, which included a total of 206 tools loaned. The tools were loaned to 30 unique customers, including engineering firms, equipment representatives, educational institutions, industrial plants, and office/commercial facilities. The report is located in the IDL section of *Supplement 2: Evaluation*.

## Building Metrics Labeling

The goal of this task was to continue the support and promotion of the Building Metrics Labeling (BML) sheet, a graphical display of four building metrics on a single sheet that was developed in a task that began in 2012. The metrics displayed are Energy Use Intensity, ENERGY STAR® score, Walk Score®, and Space Daylit Area. The purpose of the BML sheet is to increase awareness of building energy use and to promote energy efficiency during the sale or lease of commercial properties. The final version of the BML tool became available for public use in early 2014.

The IDL continued support and maintenance of the sheet in 2016. The tool was discussed and/or flyers were distributed at twenty Lunch & Learn presentations to architecture or engineering firms and organizations, multiple Central Addition Planning meetings hosted by the USGBC, six BSUG events, and during calls or visits to five building owners within the Central Addition (LIV District). One-on-one support was also available if requested, but no requests were made in 2016. The report is located in the IDL section of *Supplement 2: Evaluation*.

## Heat Pump Calculator/Climate Design Tools

This task was a continuation of work done in a task that began in 2013 and continued through 2016. The goal of the original task was to develop an Excel-based heat pump analysis tool to calculate energy use and savings based on site-specific variables for commercial buildings. Previously, IDL identified a lack of sophisticated heat pump energy-use calculators available with the capability of comparing the energy use of heat pumps in commercial buildings against other technologies in a quick, simple fashion.

The calculator has been updated to reflect feedback from validation testing, including an improved user interface and the ability to integrate Typical Meteorological Year, version three (TMY3) weather files for locations where that data is available. A few years ago, the IDL completed a set of Climate Design Tools intended to inform sustainable design and calculate the impacts of five innovative types of systems: earth tubes, passive heating, cross ventilation, stack ventilation, and night flush ventilation/thermal mass. In 2015, the IDL integrated three of the five climate design tools into the Heat Pump Calculator. This unification produced a single platform life-cycle analysis tool for several energy efficiency measures not currently well-supported with other tools in the industry.

The work in 2016 included the unification of two additional climate design tools to the calculator and the addition of seven unique weather files for sites around Idaho. The report for this task is located in the IDL section of *Supplement 2: Evaluation*.

## Daylight Training

New in 2016, this task involved advance preparation work to provide daylight training sessions for local professionals in 2017. The training will enhance knowledge of, and appreciation for, daylight, and keep professionals informed of the latest advances in daylighting technologies.

The 2016 preparation included recommissioning lighting controls in the IDL, gathering of installed lighting controls manuals, writing a protocol for demonstration, and reviewing new lighting control technologies. A market-needs assessment was performed in the third quarter of 2016 to determine the need for a daylight training class, as well as to help develop the curriculum. Initial marketing began in November 2016 for the 2017 sessions. The report for this task is located in the IDL section of *Supplement 2: Evaluation*.

## 2017 IDL Strategies

In 2017, the IDL will continue or expand work on the Foundational Services, Lunch & Learn sessions, BSUG, Building Efficiency Verifications, TLL, Heat Pump Calculator, and Daylight Training tasks. IDL will also provide work on one new task in 2017, an Absorption Chiller Feasibility Study.

# REGULATORY OVERVIEW

Idaho Power believes there are three essential components of an effective regulatory model for DSM: 1) the timely recovery of DSM program costs, 2) the removal of financial disincentives, and 3) the availability of financial incentives. By working with its stakeholders and regulators through negotiations and filings, Idaho Power seeks to move DSM regulatory treatment toward achieving all of these goals.

## Timely Recovery of DSM Program Costs: Energy Efficiency Rider and Prudence Determination of Expenditures

Since 2002, Idaho Power has recovered most of its DSM program costs through the Rider with the intended result of providing a more timely recovery of DSM expenditures. In addition, since January 1, 2012, Idaho demand response program incentives expenses have been included in base rates and tracked in the annual PCA mechanism.

### *Annual DSM Expense Review Filing and Order No. 33583*

On March 15, 2016, Idaho Power filed Case No. IPC-E-16-03 with the IPUC requesting an order finding the company had prudently incurred $35,196,964 in DSM expenses in 2015, including $28,495,701 in Rider expenses and $6,701,263 in demand response program incentives. The filing included three reports: *Demand-Side Management 2015 Annual Report*, *Supplement 1: Cost-Effectiveness*, and *Supplement 2: Evaluation*. Due to previous IPUC decisions in Order Nos. 32667, 32690, and 32953 to defer Idaho Power's request to deem prudent the increases in the company's Rider-funded labor-related expenses for 2011and 2012, Idaho Power did not request a prudence determination for labor-related expenses of $441,856 in the 2015 filing. The 2015 labor-related expenses of $441,856 bring the cumulative balance of increases in Rider-funded labor-related expenses that have not yet received a prudence determination to $1,313,407 through 2015. Idaho Power plans to request a prudence determination on these amounts in its 2016 DSM prudence request.

In Order No. 33583, dated September 14, 2016, the IPUC deemed $35,196,964 as prudently incurred.

Since 2012, the company has experienced a mismatch in Rider funding levels compared to expenditures in that the Rider has been collecting more than the company has been spending on its DSM efforts. As part of Order No. 33583, the IPUC directed Idaho Power to work with staff and other stakeholders to examine an adjustment to the Rider percentage and to submit a proposal for revising the Rider percentage to the commission no later than December 30, 2016.

Following collaboration with the parties to the case (staff, Industrial Customers of Idaho Power [ICIP] and Idaho Conservation League [ICL]) and a conference call with EEAG, on December 22, 2016, Idaho Power filed an application in Case No. IPC-E-16-33 requesting an order approving: 1) a decrease to the Rider collection percentage from 4 to 3.75 percent of base rate revenues, effective March 1, 2017; 2) a $13 million refund of previously collected Rider funds to be included in the 2017/2018 PCA effective June 1, 2017, and 3) the elimination of the annual transfer of $4 million of Rider funds through

the PCA. The annual transfer of $4 million of Rider funds through the PCA is more fully described in the following paragraph.

### *Energy Efficiency Rider-Funds Transfer*

On April 15, 2016, Idaho Power filed the annual PCA Case No. IPC-E-16-08 with the IPUC. As part of that case, the company proposed that the commission approve a transfer of $3,970,036 from the Rider to customers as a credit, or reduction, in the 2016/2017 PCA on customers' bills. In Order No. 33526, the commission approved the transfer. This transfer is needed to maintain the revenue neutrality associated with the June 2014 update to the normalized level of net power supply expense included in base rates approved by Order No. 33000.

## Removal of Financial Disincentives: Fixed-Cost Adjustment

To address the removal of financial disincentives, Idaho Power has in place a fixed-cost adjustment (FCA) mechanism in Idaho. Under the FCA, rates for Idaho residential and small general-service customers are adjusted annually up or down to recover or refund the difference between the fixed costs authorized by the IPUC in the most recent general rate case and the fixed costs Idaho Power received the previous year through actual energy sales. This mechanism removes the financial disincentive that exists when Idaho Power promotes energy efficiency programs designed to reduce customer usage. The FCA addresses, for residential and small general-service customers, the percentage of fixed costs that are recovered through their volumetric energy charges.

On May 27, 2016, the IPUC issued Order No. 33527 approving the company's request to implement FCA rates beginning June 1, 2016, for the 2015 fixed-cost deferrals. The overall rate adjustment was a 2.2 percent increase for residential and small general-service customers to collect a combined $28 million. This adjustment was an increase of $11 million from the previous year's FCA. Residential customers pay an FCA of 0.5416 cents per kWh, while small general-service customers pay an FCA of 0.6875 cents per kWh. The rate will be in place until May 31, 2017.

## Promotion of Energy Efficiency through Electricity Rate Design

Idaho Power believes rates offered to customers should reflect their cost of service to provide cost-based price signals, and encourage the wise and efficient use of energy.

Since 2012, Idaho Power has offered a Time-of-Day (TOD) Pilot pricing plan to residential customers in Idaho. The overall goal of this TOD pricing plan is to use the AMI system to offer customers a choice of pricing plans while providing them with tools to manage their energy use, to provide the company with the opportunity to further study the effects of a time-variant rate on customers' use, and to help shape the company's future communication efforts. The plan provides participants the opportunity to shift their usage from higher-priced, on-peak time periods to lower-priced, off-peak time periods and possibly lower their bills. As of the end of 2016, approximately 1,300 Idaho customers were TOD plan participants. A description of this plan is at Idaho Power's website (idahopower.com/TOD).

# GLOSSARY OF ACRONYMS

A/C—Air Conditioning/Air Conditioners
ADM—ADM Associates, Inc.
Ads—Advertisement
AEG—Applied Energy Group
AMI—Advanced Metering Infrastructure
aMW—Average Megawatt
ARCA—Appliance Recycling Center of America
ASHRAE—American Society of Heating, Refrigeration, and Air Conditioning Engineers
B/C—Benefit/Cost
BCA—Building Contractors Association
BCASEI—Building Contractors Association of Southeast Idaho
BCASWI—Building Contractors Association of Southwestern Idaho
BML—Building Metrics Labeling
BOMA—Building Owners and Managers Association
BOP—Builder Option Package
BPA—Bonneville Power Administration
BPI—Building Performance Institute
BSUG—Building Simulation Users Group
CAP—Community Action Partnership
CAPAI—Community Action Partnership Association of Idaho, Inc.
CAZ—Combustion Appliance Zone
CCE—Commercial Code Enhancement
CCOA—Aging, Weatherization and Human Services
CCNO—Community Connection of Northeast Oregon, Inc.
CEI—Continuous Energy Improvement
CEL—Cost-Effective Limit
CFL—Compact Fluorescent Lamp/Lightbulb
CFM—Cubic Feet per Minute
CHQ—Corporate Headquarters (Idaho Power)
CINA—Community in Action
CLEAResult—CLEAResult Consulting, Inc.
COP—Coefficient of Performance
CR&EE—Customer Relations and Energy Efficiency
CRES—Certified Refrigeration Energy Specialist
DHP—Ductless Heat Pump
DOE—Department of Energy
DSM—Demand-Side Management
EA5—EA5 Energy Audit Program
EBR—Existing Building Renewal
ECM—Electronically Commutated Motors

EEAG—Energy Efficiency Advisory Group
EICAP—Eastern Idaho Community Action Partnership
EL ADA—El Ada Community Action Partnership
EM&V—Evaluation, Measurement, and Verification
EPA—Environmental Protection Agency
ESK—Energy-Savings Kit
EV—Electric Vehicle
FCA—Fixed-Cost Adjustment
$ft^2$—Square Feet
$ft^3$—Cubic Feet
GIS—Geographic Information System
GMI—Green Motors Initiative
GMPG—Green Motors Practice Group
gpm—Gallons per Minute
H&CE—Heating & Cooling Efficiency Program
HP—Hewlett Packard
hp—Horsepower
HPS—Home Performance Specialist
HPWH—Heat Pump Water Heater
HSPF—Heating Seasonal Performance Factor
HUD—Housing and Urban Development
HVAC—Heating, Ventilation, and Air Conditioning
IBCA—Idaho Building Contractors Association
IBOA—International Building Operators Association
ICIP—Industrial Customers of Idaho Power
ICL—Idaho Conservation League

| Energy Efficiency Direct Program Overhead | | 293,039 | 293,039 | | | | | |
| **Total Program Direct Expense** | | **$ 40,499,570** | **$ 70,984,603** | **170,792,152** | **378** | | | |
| Indirect Program Expenses | | 2,263,893 | | | | | | |
| **Total DSM Expense** | | **$ 42,763,464** | | | | | | |

[a] Levelized Costs are based on financial inputs from Idaho Power's 2013 IRP, and calculations include line-loss adjusted energy savings.

[b] The Total Utility Cost is the cost incurred by Idaho Power to implement and manage a DSM program.

[c] The Total Resource Cost is the total expenditures for a DSM program from the point of view of Idaho Power and its customers as a whole.

[d] Demand response program reductions are reported with 9.7-percent peak loss assumptions.

[1] Peak demand is the peak performance of the program during summer 2016.

[2] Savings are preliminary estimates provided by NEEA. Final savings for 2016 will be provided by NEEA May 2017.

## **Appendix 4.** Historical DSM expense and performance, 2002–2016

## **Appendix 4.** Historical DSM expense and performance, 2002–2016 (continued)

| Program/Year | Participants | Total Costs | | Savings and Demand Reductions | | | Measure Life (Years) | Levelized Costs [a] | | Program Life Benefit/Cost Ratios [b] | |
|---|---|---|---|---|---|---|---|---|---|---|---|
| | | Utility Cost [c] | Resource Cost [d] | Annual Energy (kWh) | Average Energy [e] (aMW) | Peak Demand [f] (MW) | | Total Utility ($/kWh) | Total Resource ($/kWh) | Utility | Total Resource |
| **Total Expenses** | | | | | | | | | | | |
| 2013 | | $ 26,841,378 | | | | | | | | | |
| 2014 | | 36,713,333 | | | | | | | | | |
| 2015 | | 39,040,935 | | | | | | | | | |
| 2016 | | 42,763,464 | | | | | | | | | |
| **Total 2002–2016** | | **$ 385,228,330** | | | | | | | | | |

[a] Levelized Costs are based on financial inputs from Idaho Power's *2013 Integrated Resource Plan* and calculations include line loss adjusted energy savings.

[b] Program life benefit/cost ratios are provided for active programs only.

[c] The Total Utility Cost is all cost incurred by Idaho Power to implement and manage a DSM program.

[d] The Total Resource Cost is the total expenditures for a DSM program from the point of view of Idaho Power and its customers as a whole.

[e] Average Demand = Annual Energy/8,760 annual hours.

[f] Peak Demand is reported for programs that directly reduce load or measure demand reductions during summer peak season. Peak demand reduction for demand response programs is reported at the generation level assuming 13 percent peak line losses.

[1] Savings are preliminary funder share estimates. Final results will be provided by NEEA in May 2017.

## **Appendix 5.** 2016 DSM program activity by state jurisdiction

| Program | Idaho Participants | Idaho Utility Costs | Idaho Demand Reduction/ Annual Energy Savings (MW) | Oregon Participants | Oregon Utility Costs [a] | Oregon Demand Reduction/ Annual Energy Savings(MW) |
|---|---|---|---|---|---|---|
| **Demand Response** | | | | | | |
| A/C Cool Credit | 27,947 homes | $ 1,061,450 | 33 | 368 homes | $ 41,845 | 0.4 |
| Flex Peak Program | 128 sites | 520,088 | 29 | 9 sites | 247,909 | 13 |
| Irrigation Peak Rewards | 2,236 service points | 7,378,725 | 295 | 50 service points | 221,351 | 7 |
