The RA Model utilizes the modeling platform Analytica®[4], an object-flow based modeling platform that is designed to visually show how different objects and parts of the model interrelate and flow throughout the modeling process. The model utilizes multidimensional tables and arrays to compute large, complex datasets in a relatively simple user interface. Energy Trust then deploys this cost-effective achievable potential exogenously to the RA model into an annual energy savings projection based on past program experience, knowledge of current and developing markets, and future codes and standards.

20-Year Forecast Detailed Methodology

Energy Trust's 20-year forecast for DSM savings follows six overarching steps from initial calculations to deployed energy savings, as shown in Figure 4. The first five steps in the varying shades of blue nodes - Data Collection and Measure Characterization to Cost-Effective Achievable Energy Efficiency Potential - are calculated within Energy Trust's RA Model. This results in the total cost-effective potential that is achievable over the 20-year forecast. The actual deployment of these savings (the acquisition percentage of the total potential each year, represented in the green node of the flow chart) is done exogenously of the RA model. The remainder of this section provides further detail on each of the steps shown below.

Figure 4 - Energy Trust's 20-Year DSM Forecast Determination Flow Chart

[4] http://www.lumina.com/why-analytica/what-is-analytica1/

1. Data Collection and Measure Characterization

The first step of the modeling process is to identify and characterize a list of measures to include in the model, as well as receive and format utility global inputs for use in the model. Energy Trust compiles a list of commercially available and emerging technology measures for residential, commercial, industrial and agricultural applications installed in new or existing structures. The list of measures is meant to reflect the full suite of measures offered by Energy Trust, plus a spectrum of emerging technologies.[5] Simultaneous to this effort, Energy Trust collects necessary data from the utility to run the model and scale the measure level savings to a given service territory (known as 'global inputs').

- ***Measure Level Inputs:***
  Once the measures to include in the model have been identified, they must be characterized to determine their savings potential and cost-effectiveness. The characterization inputs are determined through a combination of Energy Trust primary data analysis, regional secondary sources[6], and engineering analysis. There are over 30 measure level inputs that feed into the model, but on a high level, the inputs are put into the following categories:
  1. ***Measure Definition and Equipment Identification***: This is the definition of the efficient equipment and the baseline equipment it is replacing (e.g. a ductless mini-split heat pump replacing residential electric resistance space heat). A measure's replacement type is also determined in this step – Retrofit (RET), Replace on Burnout (ROB), or New Construction (NEW).
  2. ***Measure Savings***: the kWh or therms savings associated with an efficient measure calculated by comparing the baseline and efficient measure consumptions.
  3. ***Incremental Costs***: The incremental cost of an efficient measure over the baseline. The definition of incremental cost depends upon the replacement type of the measure. If a measure is a RET measure, the incremental cost of a measure is the full cost of the equipment and installation. If the measure is a ROB or NEW measure, the incremental cost of the measure is the difference between the cost of the efficient measure and the cost of the baseline measure.
  4. ***Market Data:*** Market data of a measure includes the density, saturation, and suitability of a measure. A density is the number of measure units that can be installed per scaling basis (e.g. the average number of showers per home for showerhead measures). The saturation is the average saturation of the density that is already efficient (e.g. 50% of the showers already have a low flow showerhead). Suitability of a measure is a percentage input to represent the percent of the density that the efficient measure is suitable to be installed in. These data inputs are all generally derived from regional market data sources such as NEEA's Residential and Commercial Building Stock Assessments (RBSA and CBSA).

---

[5] An emerging technology is defined as technology that is not yet commercially available but is in some stage of development with a reasonable chance of becoming commercially available within a 20-year timeframe. The model is capable of quantifying costs, potential, and risks associated with uncertain, but high-saving emerging technology measures. The savings from emerging technology measures are reduced by a risk-adjustment factor based on what stage of development the technology is in. The working concept is that the incremental risk-adjusted savings from emerging technology measures will result in a reasonable amount of savings over standard measures for those few technologies that eventually come to market without having to try and pick winners and losers.

[6] Secondary Regional Data sources include: The Northwest Power Planning Council (NWPPC), the Regional Technical Forum (the technical arm of the NWPPC), and market reports such as NEEA's Residential and Commercial Building Stock Assessments (RBSA and CBSA)

- ***Utility Global Inputs:***

  The RA Model requires several utility level inputs to create the DSM forecast. These inputs include:

  1. ***Customer and Load Forecasts***: These inputs are essential to scale the measure level savings to a utility service territory. For example, residential measures are characterized on a scaling basis 'per home', so the measure densities are calculated as the number of measures per home. The model then takes the number of homes that PGE serves currently and the forecasted number of homes to scale the measure level potential to their entire service territory.
  2. ***Customer Stock Demographics***: These data points are utility specific and identify the percentage of stock that utilize different heating fuels for both space heating and water heating. The RA Model uses these inputs to segment the total stocks to the stocks that are applicable to a measure (e.g. gas storage water heaters are only applicable to customers that have gas water heat).
  3. ***Utility Avoided Costs***[7]: Avoided costs are the net present value of avoided energy purchases and avoided system costs that result from energy efficiency savings represented as $s per kWh saved. These values are provided by PGE based generally upon the avoided costs generated by PGE as an outcome of their IRP modeling. Avoided costs are the primary 'benefit' of energy efficiency in the cost-effectiveness screen.

2. Calculate Technical Energy Efficiency Potential

Once measures have been characterized and utility data loaded into the model, the next step is to determine the technical potential of energy that could be saved. Technical potential is defined as the total potential of a measure in the service territory that could be achieved regardless of market barriers, representing the maximum potential energy savings available. The model calculates technical potential by multiplying the number of applicable units for a measure in the service territory by the measure's savings. The model determines the total number of applicable units for a measure utilizing several of the measure level and utility inputs referenced above:

Total applicable units =	*Measure Density * Baseline Saturation * Suitability Factor * Heat Fuel Multipliers (if applicable) * Total Utility Stock (e.g. # of homes)*
Technical Potential =	*Total Applicable Units * Measure Savings*

The measure level technical potential is then summed up to show the total technical potential across all sectors. This savings potential does not account for the various market barriers that will limit a 100 percent adoption rate.

3. Calculate Achievable Energy Efficiency Potential

Achievable potential is simply a reduction to the technical potential based on each measure's achievability assumption rate, to account for market barriers that prevent total adoption of all cost-effective measures. Historically the achievable potential was defined as 85 percent of the technical potential. The Northwest Power and Conservation Council (NWPCC) updated the achievability assumption for certain measures in the most recent power plan, and Energy Trust has aligned the

[7] Energy Trust uses a single electric blended avoided costs for its programs, measure development and benefit/cost metrics.

RA model with these assumptions. Many measures still have 85 percent achievability while market transformation and codes and standards are assumed to be closer to 100 percent achievability.

Achievable Potential =	*Technical Potential * achievability %*

4. Determine Cost-effectiveness of Measures using TRC Screen

The RA Model screens all DSM measures in every year of the forecast horizon using the Total Resource Cost (TRC) test, a benefit-cost ratio (BCR) that measures the cost-effectiveness of the investment being made in an efficiency measure. This test evaluates the total present value of benefits attributable to the measure divided by the total present value of all costs. A TRC test value equal to or greater than 1.0 means the value of benefits is equal to or exceeds the costs of the measure and is therefore cost-effective and contributes to the total amount of cost-effective potential. The TRC is expressed formulaically as follows:

TRC = Present Value of Benefits / Present Value of Costs

Where *the Present Value of Benefits* includes the sum of the following two components:

a) Avoided Costs: The present value of electricity saved over the life of the measure, as determined by the total kWh saved multiplied by PGE's avoided cost per kWh. The net present-value of these benefits is calculated based on the measure's expected lifespan using PGE's discount rate.
b) Non-energy benefits are also included when present and quantifiable by a reasonable and practical method (e.g. water savings from low-flow showerheads, operations and maintenance (O&M) cost reductions from advanced controls).

Where *the Present Value of Costs* includes:

a) Total participant incremental cost

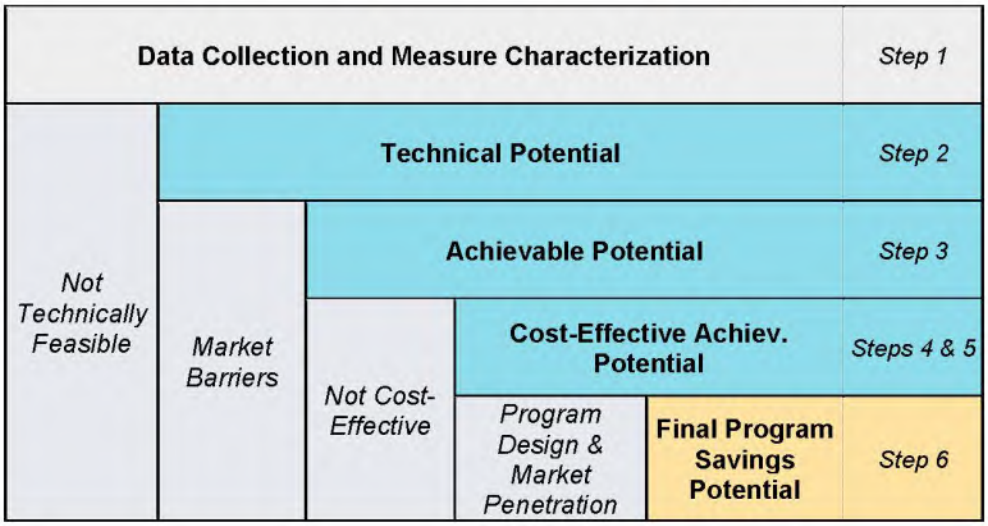
The cost-effectiveness screen is a critical component for Energy Trust modeling and program planning because Energy Trust is only allowed to incentivize cost-effective measures, unless an exception has been granted by the OPUC. Energy Trust is governed by policy directives to obtain all reasonably attainable cost-effective potential[8].

5. Quantify the Cost-Effective Achievable Energy Efficiency Potential

The RA Model's final output of potential is the quantified cost-effective achievable potential. If a measure passes the TRC test described above, then the *achievable savings* (designated percentage of technical potential) from this measure is included in the cost-effective achievable potential. If the measure does not pass the TRC test above, the measure is not included in the cost-effective achievable potential. However, the cost-effectiveness screen can be overridden for some measures under three specific conditions:

1) The OPUC has granted an exception to offer non-cost-effective measures under strict conditions or,

[8] As directed in OPUC docket UM-551 and 2017 ORS 757.054



2) When the measure isn't cost-effective using utility specific avoided costs, but the measure is cost-effective when using blended electric avoided costs for all of the electric utilities Energy Trust serves and is therefore offered by Energy Trust programs.

6. Deployment of Cost-Effective Achievable Energy Efficiency Potential

After the model determines the 20-year cost-effective achievable potential, Energy Trust develops a savings projection based on past program experience, knowledge of current and developing markets, and future codes and standards. The savings projection is a 20-year forecast of energy savings that is projected to result in a reduction of load on PGE's system. This savings forecast includes savings from program activity for existing measures and emerging technologies, expected savings from market transformation efforts that drive improvements in codes and standards.

Figure 5 below reiterates the types of potential shown in Figure 3, and how the steps described above and in Figure 4 fit together.

Figure 5 - The Progression to Program Savings Projections

Forecast Results

Forecast results will be shown in several different sections, as the RA model has different output capabilities that are applied to project energy savings potential in a variety of different views, including by segment, end use, and in supply curves. The final savings projection is provided by segment and program delivery type. The RA Model produces results by type of potential, as well as several other useful outputs, including a supply curve based on the levelized cost of energy efficiency measures. This section discusses the overall model results by potential type and provides an overview of the supply curve.

Forecasted Savings by Sector

Table 1 summarizes the technical, achievable, and cost-effective achievable potential for PGE's system in Oregon. The savings in the table represent the total 20-year cumulative energy savings potential identified in the RA Model for each of the three respective types of potential identified in Figure 3 and Figure 5, prior to deployment of the savings into the final savings projection.

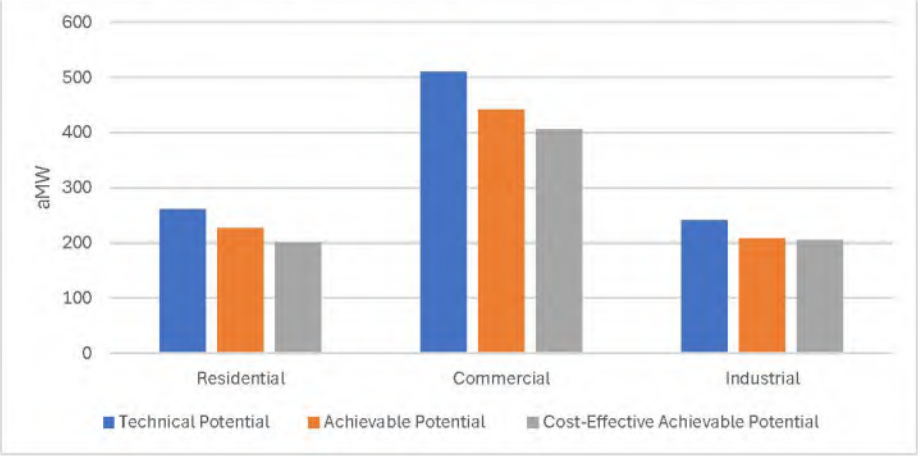


Table 1 - Summary of Cumulative Modeled Savings Potential - 2024–2043

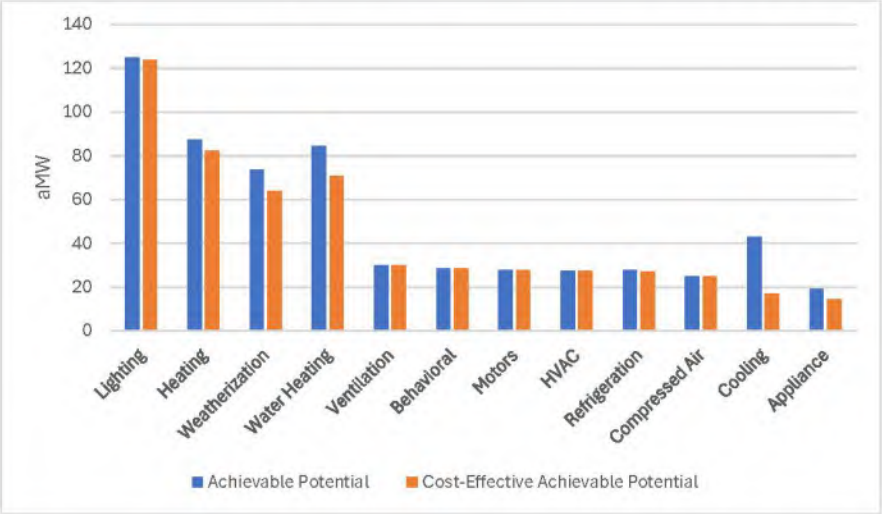
Sector	Technical Potential (aMW)	Achievable Potential (aMW)	Cost-Effective Achievable Potential (aMW)
Residential	261	226	202
Commercial	511	442	406
Industrial	241	209	206
Total	**1,012**	**876**	**813**

Figure 6 shows cumulative forecasted savings potential across the three sectors Energy Trust serves, as well as the type of potential identified in PGE's service territory.

The Commercial sector represents the largest source of efficiency potential within PGE's territory. 86% of the industrial technical potential is cost-effective, while the residential and commercial sectors cost-effective achievable potential are 77% and 80% of technical potential respectively.

Figure 6 - Savings Potential by Sector – Cumulative 2024–2043



Cost-Effective Achievable Savings by End-Use

Figure 7 below provides a breakdown of PGE's 20-year cost-effective DSM savings potential by major end use. Some potential that doesn't map to a single end-use is omitted from this figure such as general new construction whole building measures and custom industrial and large commercial measures.

Lighting, heating, weatherization and water heating are the end-uses with the largest energy savings potential in PGE territory. Most of the lighting and heating potential is cost effective while a lower share of weatherization, water heating and cooling past TRC test in the model.

Figure 7 – 20-year Cost-Effective Achievable Cumulative Potential by End Use

Contribution of Emerging Technologies

As mentioned earlier in this report, Energy Trust includes a suite of emerging technologies (ETs) in its model. The emerging technologies included in the model are listed in Table 2.

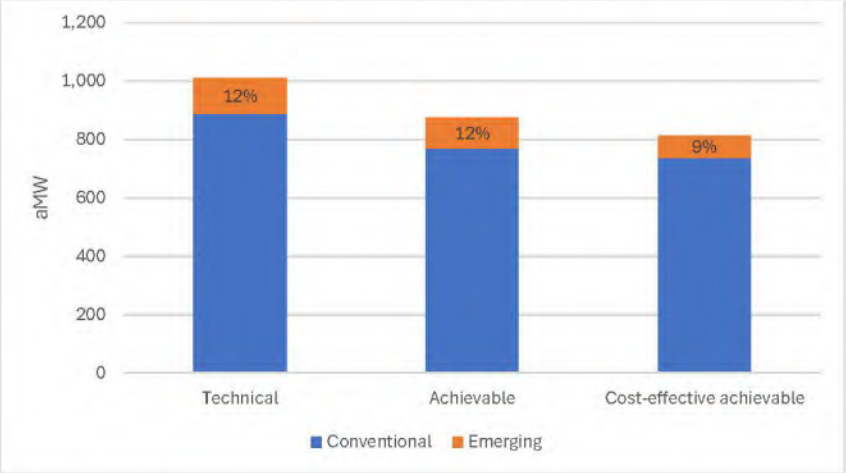
Table 2 - Emerging Technologies Included in the Model that are pertinent for PGE

Residential	Commercial	Industrial
• Window Attachments •Thin Triple Pane Windows • Advanced Insulation • Heat Pump Dryers • Split System CO2 Heat Pump Water Heater • Smart Line Voltage Thermostats	• Zero Net Energy Ready Construction • Hybrid Indirect-Direct Evaporative Cooler • Advanced Refrigeration Controls • Refrigeration Anti-Fogging Film • Advanced Window Technologies	• CO2 Refrigeration • Industrial Heat Pumps • Advanced Wall Insulation

Energy Trust recognizes that emerging technologies are inherently uncertain and utilizes a risk factor to hedge against that risk. The risk factor for each emerging technology is used to characterize the inherent uncertainty in the ability for ETs to produce reliable future savings. This risk factor was determined based on qualitative metrics of:

- Market risk

- Technical risk
- Data source risk



The framework for assigning the risk factor is shown in Table 3. Each ET was assessed within each risk category and a total weighted score was then calculated. Well-established and researched technologies have lower risk factors while nascent, unevaluated technologies (e.g., CO2 heat pump water heaters) have higher risk factors. This risk factor was then used as a multiplier of the incremental savings potential of the measure.

Table 3 - Emerging Technology Risk Factor Score Card

	ET Risk Factor				
Risk Category	10%	30%	50%	70%	90%
Market Risk (25% weighting)	**High Risk:** • Requires new/changed business model • Start-up, or small manufacturer • Significant changes to infrastructure • Requires training of contractors. Consumer acceptance barriers exist			**Low Risk:** • Trained contractors • Established business models • Already in U.S. Market • Manufacturer committed to commercialization	
Technical Risk (25% weighting)	**High Risk:** Prototype in first field tests. A single or unknown approach	Low volume manufacturer. Limited experience	New product with broad commercial appeal	Proven technology in different application or different region	**Low Risk:** Proven technology in target application. Multiple potentially viable approaches.
Data Source Risk (50% weighting)	**High Risk:** Based only on manufacturer claims	Manufacturer case studies	Engineering assessment or lab test	Third party case study (real world installation)	**Low Risk:** Evaluation results or multiple third-party case studies

Figure 8 below shows the amount of emerging technology savings within each type of DSM cumulative potential. While emerging technologies make up about 21% of the technical potential, once the cost-effectiveness screen is applied, the relative share of emerging technologies drops to about 13% of total cost-effective achievable potential. This is because many of these technologies are still in early stages of development and are quite expensive. Though Energy Trust includes factors to account for forecasted decreases in cost and increased savings from these technologies over time, some are still never cost-effective over the planning horizon or do not become cost-effective until later years.

Figure 8 – Cumulative Contribution of Emerging Technologies by Potential Type

Cost-Effective Override Effect

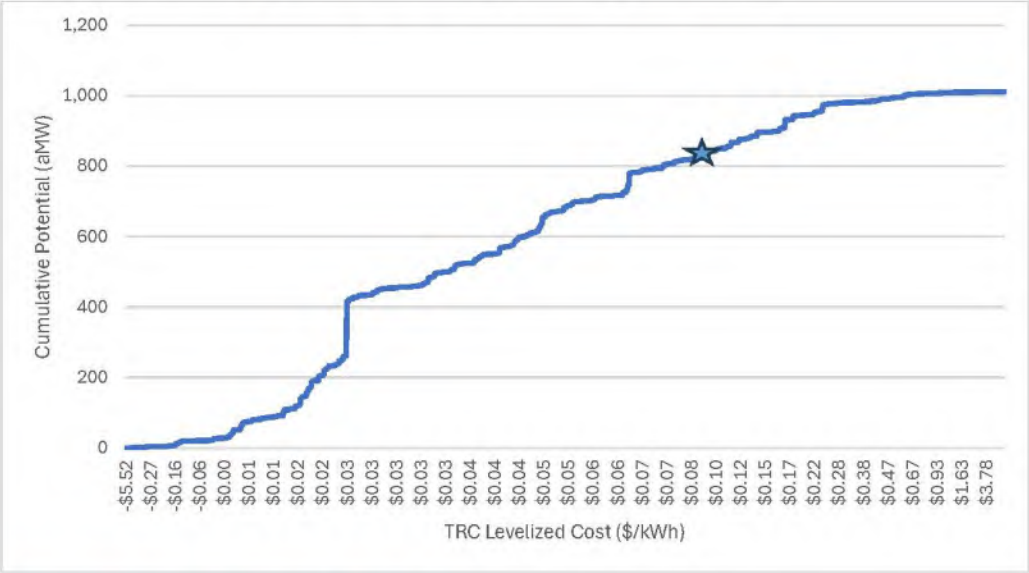
Table 4 shows the savings potential in the RA model that was added by employing the cost-effective override option. As discussed in the methodology section, the cost-effective override option forces non-cost-effective measures into the cost-effective potential results and is used when a measure meets one of the following three criteria:

1. A measure is offered under an OPUC exception.
2. When the measure isn't cost-effective using PGE-specific avoided costs but the measure is cost-effective when using blended electric avoided costs for all of the electric utilities Energy Trust serves and is therefore offered by Energy Trust programs.
3. The measure is not cost-effective in our model, but may appear cost-effective in program settings, where costs are combined with other measures or highly variable from project to project[9].

[9] Some measures can have high degrees of variations in savings and costs. If a measure is cost-effective in the RA model then all savings attributable to the measure are included. Conversely, if a measure is not cost-effective in the RA model then zero savings will be shown in the model. While costs are updated frequently to reflect changing markets there may be instances where some instances of installation are cost-effective and others are not. Many of these types of projects are screened individually for cost-effectiveness in Energy Trust's custom program offerings.

Table 4 - Cumulative Cost-Effective Potential (2024-2043) due to Cost-Effectiveness Override (aMW)

Sector	Total Cumulative Cost-Effective Potential With CE Override	Total Cumulative Cost-Effective Potential No CE Override	Difference
Residential	202	132	69
Commercial	406	406	-
Industrial	813	206	-
Total DSM:	**813**	**744**	**69**



In this IRP, 9% of the cost-effective potential identified by the model is due to the use of the cost-effective override for measures. This is a higher share than in previous IRPs and is attributable to the OPUC cost-effectiveness exception for manufactured homes early replacement (14 aMW of the 69 aMW shown in Table 4). This measure generates a lot of potential due to the stock of existing manufactured homes in PGE territory, however this measure receives a low ramp-rate in the deployment process to account for market barriers and qualification criteria of homes and not all potential is deployed. Measures under exception make up 7% of the cost-effective achievable potential without the override applied to manufactured homes early replacement.

Supply Curves and Levelized Cost Outputs

An additional output of the RA Model is a resource supply curve developed from the levelized cost of energy of each measure. The supply curve graphically depicts the total potential in average megawatts that could be saved at various costs for all measures. The levelized cost for each measure is determined by calculating the present value of the total incremental cost of the measure over its economic life, per kWh of energy savings ($/kWh saved). The levelized cost calculation starts with the customer's incremental cost of a given measure. The total cost is amortized over an estimated measure lifetime using the PGE's discount rate provided to Energy Trust. The annualized measure cost is then divided by the annual kWh savings. Some measures have negative levelized costs because non-energy benefits amortized over the life of the measure are greater than the total cost of the measure over the same period.

Figure 9 below shows the supply curve developed for this IRP that can be used for comparing demand-side and supply-side resources. The star on the graph shows roughly the cutoff where savings become non-cost-effective, although some savings above the star are included due to cost-effective override.

Figure 9 – Electric Supply Curve ($ per kWh saved)

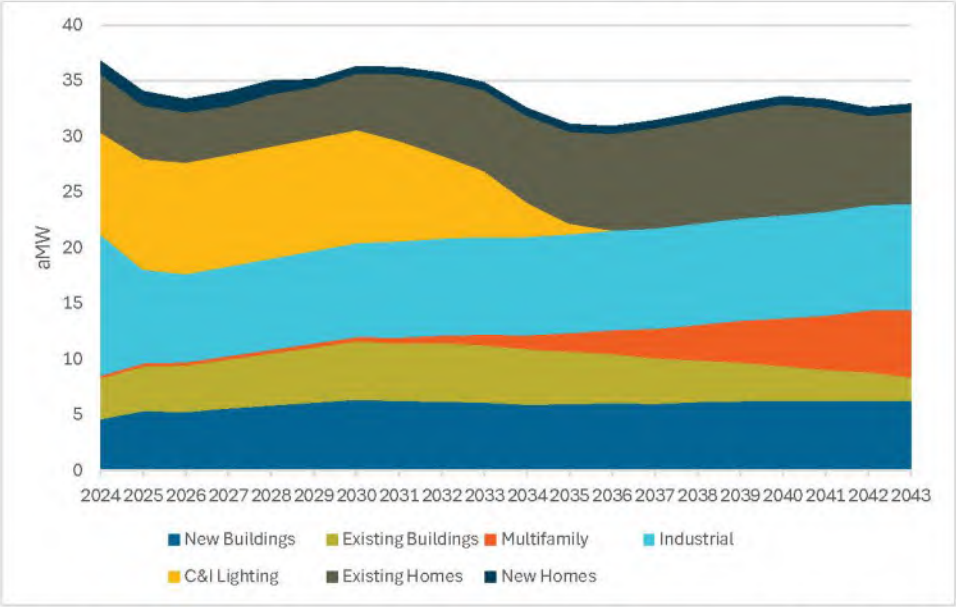
Deployed Results – Final Savings Projection

The results of the final savings projection show that PGE can save 171.7 aMW in the next five years from 2025 to 2029 and over 675 aMW by 2043. This represents a 16.5 percent cumulative load reduction by 2043[10] and is an average of 1.1 percent incremental annual load reduction. The cumulative final savings projection is shown in Table 5 compared to the technical, achievable and cost-effective achievable potential.

Table 5 - 20-Year Cumulative savings potential by type, including final savings projection (aMW)

Sector	Technical Potential	Achievable Potential	Cost-Effective Achievable Potential	Final Savings Projection[11]
Residential	261	226	202	151
Commercial	511	442	406	260
Industrial	241	209	206	203
Exogenous Savings[12]				62
Total	1,012	876	813	675

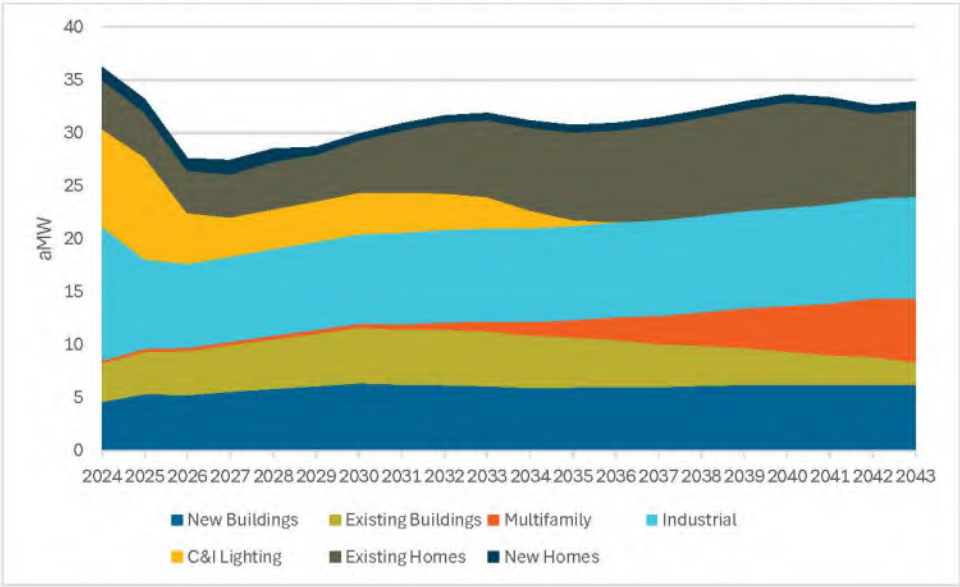
[10] Cumulative savings assumes customers will continue to purchase equipment of equal or higher efficiency equipment after the measure reaches the end of its useful life and therefore savings in this instance are assumed to persist in future years.
[11] The final savings projection includes market transformation lighting savings that will not be claimed by Energy Trust but are expected to come off PGE's system. These savings account for 44.7 aMW of the combined commercial and industrial final savings projections and 2.9 aMW of the residential final savings projection.
[12] Exogenous savings are calculated outside of the RA model and consist of commercial and residential prior codes, industrial large projects and residential electrification.



Energy Trust's general modeling principle is to deploy 100% of retrofit cost-effective achievable potential or ramp to 100% of cost-effective achievable potential for replacement and new construction measures consistent with Northwest Power and Conservation Council ramp rate methodology. However, certain measures have unique market barriers, uncertainties, or are early in their market adoption trajectory limiting their deployment. As such, the final deployed savings projections in Table 5 are a subset of the cost-effective achievable potential. This is most notable for the residential and commercial sectors which have a higher share of these measures where 100% deployment of cost-effective achievable potential is not feasible. There are several reasons why 100% acquisition is unrealistic, including:

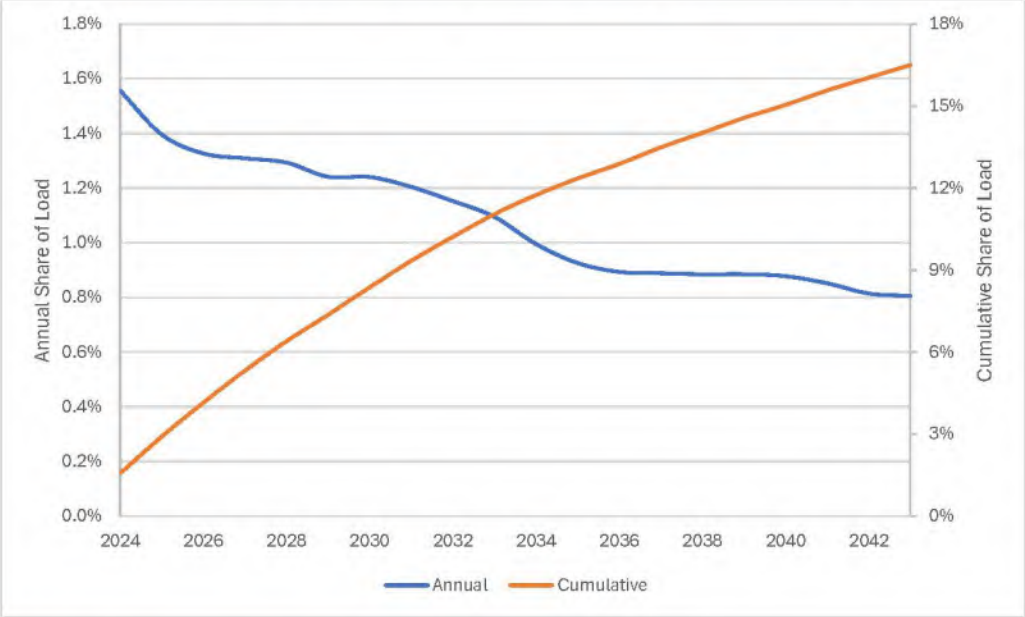
1) "Lost Opportunity Measures" – Measures that are meant to replace failed equipment (ROB) or new construction measures (NEW) are considered lost opportunity measures because programs have one opportunity to influence the installation of efficient equipment over code baseline when the existing equipment fails or when the new building is built. This is because these measures must be installed at that specific point in time, and if a program administrator misses the opportunity to influence the installation of more efficient equipment, the opportunity is lost until the equipment fails again. Energy Trust expects that most of these opportunities will be met in later years as efficient equipment becomes more readily adopted. However, in early years, the level of acquisition for these opportunities is smaller and ramps higher as time progresses.
2) "Hard to Reach Measures" – some measures that show high savings potential are notoriously hard to reach. These include multifamily and shell measures.
3) The nascent and uncertain nature of emerging technologies limit their market adoption in the forecast horizon similar to #2 above.
4) New, comprehensive measures added to the RA model including New Buildings Custom Data Center and New Homes Manufactured Home Early Replacement – Custom Data Center savings are subject to modeling uncertainty. Energy Trust modeled their adoption using program expertise and achievements from past projects and, given the magnitude of load forecast, make up a large share of the commercial sector step down in Table 5. Similarly, the Manufactured Home Early Replacement measure calculates potential for a large share of manufactured homes in PGE territory, however it is unrealistic that 100% of homes will turn over in the forecast period given its relatively high cost and labor (note this measure is under OPUC exception).

Exogenous savings are calculated outside of the RA model because they are generally accounted for in market characterization assumptions (prior codes) or their baseline is present in the utility load forecast (residential electrification). Energy Trust models prior codes using a forecast from NEEA. The inclusion of Residential Electrification is new for this round of modeling and was calculated as incremental lost opportunity savings above PGE's electrification forecast and were deployed consistent with similar lost opportunity measure adoption. Finally, Energy Trust exogenously adds industrial large projects because those savings are not characterized by the measures included in the RA model. In total exogenous savings total 62 aMW and make up 9% of the final savings projection.



The final savings projection of 675 aMW in Table 5 represents 20-years of efficiency savings. The annual shape of the deployed efficiency forecast is shown in Figure 10 below.

Figure 10 – Annual Deployed Final Savings Potential



As previously noted, the final savings projection depicted in Figure 10 above includes 47.5 aMW of market transformation lighting savings that energy trust will not claim. Figure 11 below shows the annual efficiency forecast of Energy Trust claimed savings.

Figure 11 – Annual Deployed Energy Trust Claimed Savings Potential

Finally, Figure 12 shows the annual and cumulative savings as a percentage of PGE's load forecast. Annually, the savings as a percentage of load varies from about 0.8% at its lowest to 1.6% at its highest, as represented on the *left* Y-axis of the graph and the blue line. Cumulatively, the savings as a percentage of load builds to 16.5% by 2043, shown on the right Y-axis and the gold line.

Figure 12 – Annual Forecasted Savings as a Percentage of Annual Load Forecast

Deployed Results – Peak Day Results

Ongoing regional emphasis on peak and capacity management and an OPUC docket focused on electric utility Distribution System Planning (OPUC docket UM 2005) has resulted in continued interest in the contribution energy efficiency can make to managing electric utility loads. Additionally, the OPUC has directed Energy Trust to report peak impacts in the appendices of our annual report beginning in 2017[13].

Peak hour factors are the percentage of annual energy savings that occur during peak hours over the course of a year. Energy Trust calculates peak demand factors using Equation 1, where load factors and coincidence factors being derived from the NWPCC library of load profiles.

Equation 1 – Calculation of Peak Factors from Load and Coincidence Factors

*Peak factor = (1 yr/8760) * Load Factor * Coincidence Factor*

Figure 11 below shows the annual, deployed peak day savings potential based upon the results of the 20-year forecast. Each measure analyzed is assigned a load shape and the appropriate peak factor is

[13] For the 2023 version of this report see Appendix 9 of Energy Trust's "*2023 Annual Report to the Oregon Public Utility Commission & Energy Trust Board of Directors*" available at https://www.energytrust.org/wp-content/uploads/2024/04/Energy-Trust-of-Oregon-2023-Annual-Report.pdf

applied to the annual savings to calculate the overall DSM contribution to peak day capacity. Cumulatively, this is equal to 1,980 MW[14], as shown in Table 6 below.

Figure 11 - Annual Deployed Peak Savings Contribution by Season

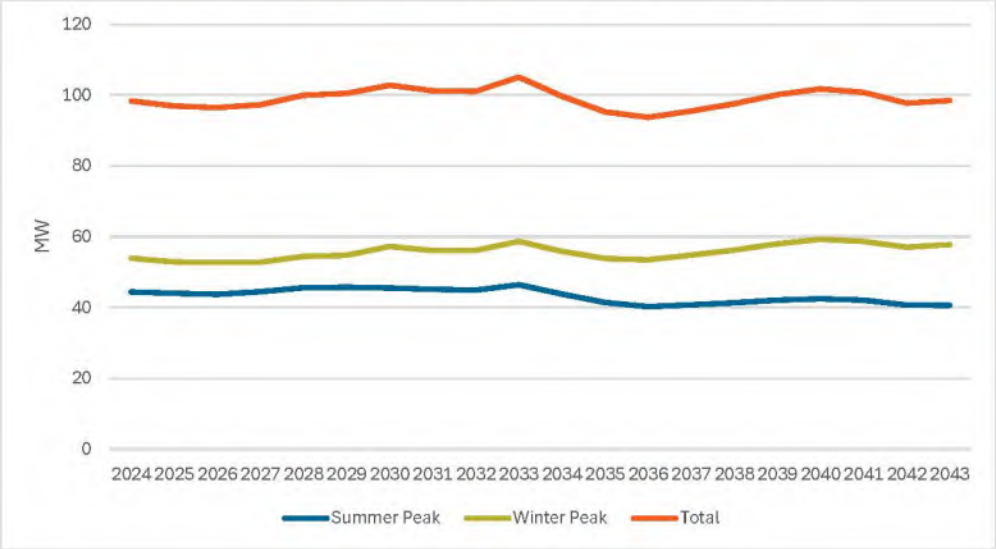


Table 6 - Cumulative Deployed Peak Savings Contribution by Sector

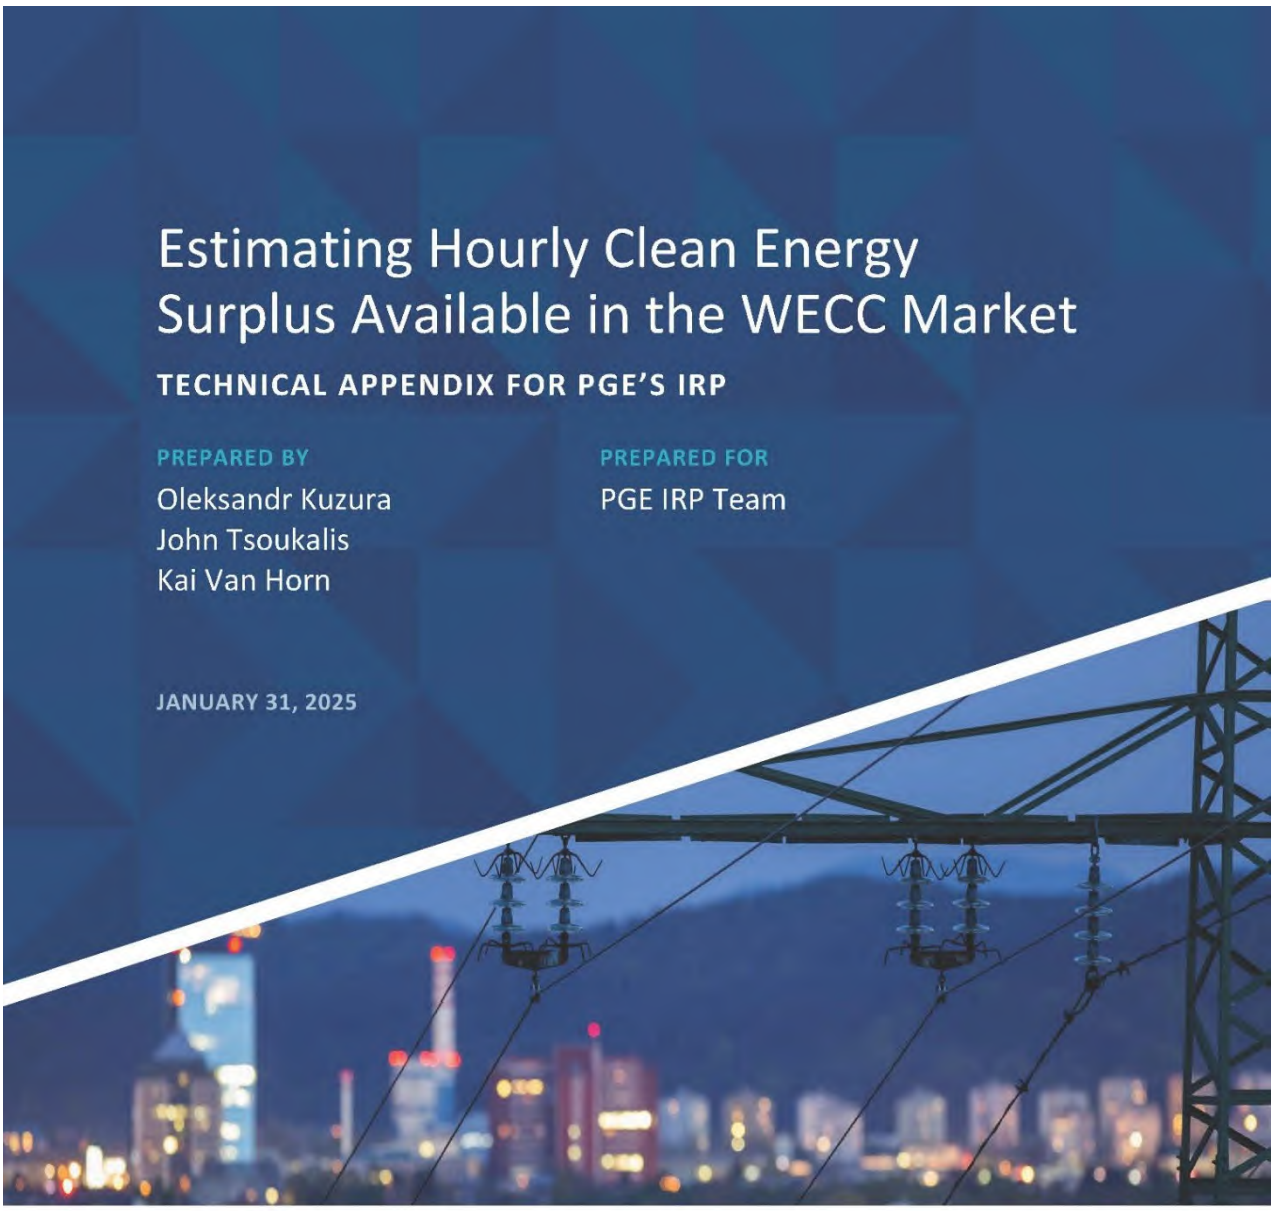
Sector	Cumulative Peak Savings (MW)	% of Overall Peak Savings
Residential	797	40%
Commercial	643	32%
Industrial	540	27%
Total	1,980	

Non-Cost-Effective Energy Efficiency

Starting in 2023, PGE requested that Energy Trust submit savings and levelized cost data from measures that did not pass the TRC cost-effectiveness screen in the Energy Trust RA model. This allows PGE to compare efficiency to supply side resources where the total resource cost of efficiency exceeds benefits calculated by utility submitted avoided costs. This modeling could highlight areas of value in addition to what is quantified in the UM 1893 avoided costs docket. This analysis is completed by PGE and the results are detailed in their IRP report. Summary values for the non-cost-effective efficiency submitted

[14] Peak results do not include energy savings from exogenous categories.



by Energy Trust are shown below in Table 7. For the 2025 IRP analysis, these savings total 75.1 aMW at a weighted average levelized cost[15] of $0.401/kWh.

Table 7 – 20-year Non-Cost-Effective Efficiency Potential

Sector	Non-Cost-Effective Achievable Potential (aMW)[16]	Weighted Average Levelized Cost ($/kWh)
Residential	32.6	$0.406
Commercial	40.1	$0.412
Industrial	2.4	$0.149
Total	75.1	$0.401

[15] This levelized cost represents the total resource cost, levelized over measure life ($/kWh) plus a 31% administrative cost adder.
[16] The values in this column do not exactly match the difference between Achievable Potential and Cost-Effective Achievable Potential in Table 5 for several reasons including substitution between competing measures, cost-effective override, and the timing of discretionary measures on the margin of cost-effectiveness.

I. Introduction And Background

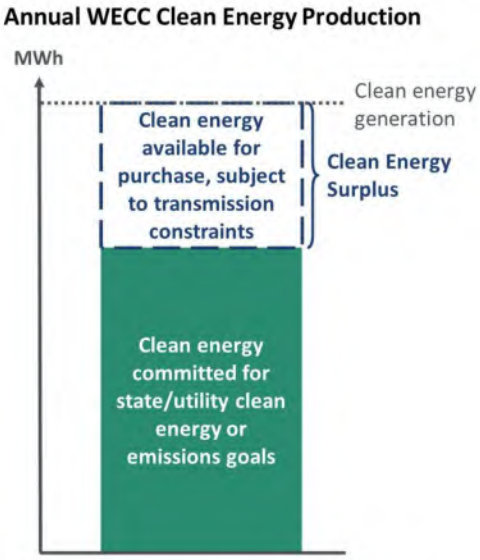
The Oregon Public Utility Commission (OPUC) directed Portland General Electric (PGE) to adopt hourly accounting of its clean energy position and the associated greenhouse gas (GHG) implications in its 2025 Clean Energy Plan (CEP) and Integrated Resource Plan (IRP) update. This directive was issued in Docket LC 80, in which OPUC Staff declined to acknowledge PGE's 2023 CEP due to concerns about PGE's ability to procure clean energy from the market. Specifically, PGE's portfolio was forecasted to be long on clean energy during shoulder seasons and short on clean energy during peak hours, matching regional supply trends across the Western Electricity Coordinating Council (WECC) territory. OPUC Staff and stakeholders raised concerns about PGE's assumption that clean energy would be equally available year-round, noting that supply could be limited at times and might also incur a premium cost to purchase.

The Brattle team (hereby "we") was engaged by PGE to address the OPUC's request to develop and implement an hourly accounting methodology for estimating the availability and cost of purchasing clean energy. Developing this methodology required answering the following questions:

- In each hour, how much clean energy is available after accounting for resources committed to other GHG reductions for non-PGE entities in the WECC?
- What, if any, is the cost premium associated with procuring surplus clean energy in a given hour? How does that cost premium vary with available supply?

We developed the Excel-based Clean Energy Surplus Model (CESM) to estimate the hourly WECC-wide market availability of clean energy deliverable to PGE and the potential cost premiums it may incur. The CESM uses hourly results from PGE's AURORA IRP simulations and a curve capturing the relationship between clean energy surpluses and potential purchase premiums to produce an hourly time series of clean energy deliverable to PGE and the potential associated premiums. The CESM outputs are then used in PGE's calculation of its resource plans' annual GHG impacts.

This appendix describes the CESM framework, including key assumptions, data inputs, outputs, strengths, and areas for future improvements. It is organized into five sections. Section 0 provides a detailed step-by-step explanation of the CESM's surplus calculation framework.



Section III details the CESM's premium calculation approach. Section IV summarizes the CESM's clean energy surplus and premium results for two AURORA simulations. Section V discusses the CESM's strengths and areas for potential future improvements.

II. Clean Energy Surplus Estimation Overview and Key Assumptions

Market purchases of clean energy could help offset PGE's emissions, but PGE's ability to access them depends on the WECC-wide clean energy supply, clean energy demand, and transmission available to PGE to import that energy. We define "clean energy surplus" (or "surplus") as the clean energy generated in the WECC beyond that which is needed to meet annual state-level clean energy requirements. Clean energy supply depends on the amount and types of generation resources available in each state and varies with regional and seasonal weather patterns and installed capacity. Clean energy demand depends on binding policy targets and voluntary goals set by states, municipalities, corporations, and other entities.[1] Transmission availability to PGE depends on the total transfer capability (TTC) over WECC transmission paths and the hourly utilization for regional trading. Figure 1 provides an illustration of the clean energy surplus as it relates to the overall availability of clean energy.

[1] We consider only binding state requirements in the CESM due to data availability constraints on voluntary targets.

FIGURE 1. ILLUSTRATIVE EXAMPLE OF CLEAN ENERGY SURPLUS

Using the CESM, we calculate hourly clean energy surpluses deliverable to PGE by:

1. Evaluating annual state-level clean energy surpluses or deficits,
2. Allocating annual regional surpluses or deficits to individual hours, and
3. Aggregating state-level results to the WECC-wide and regional levels,
4. Applying transmission constraints between PGE and the neighboring regions.

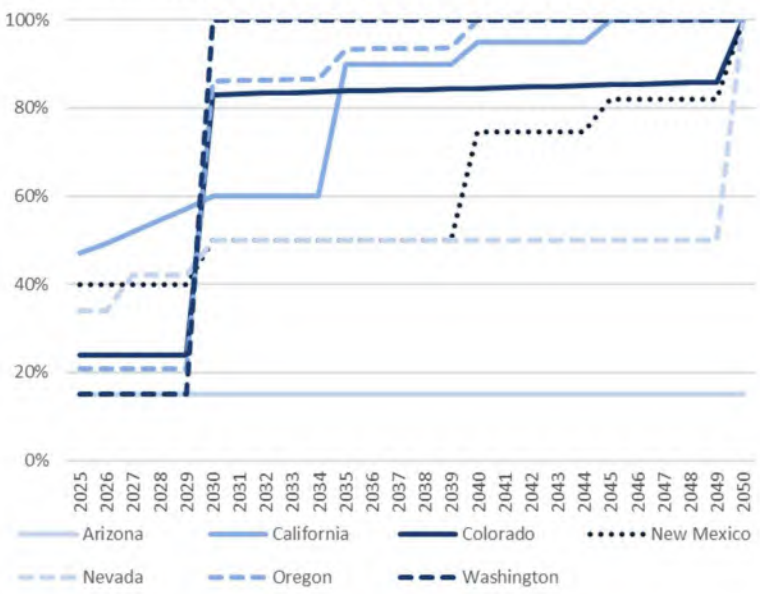
An overview of the CESM surplus calculation steps is given in Figure 2, with detailed descriptions of each step following.

FIGURE 2. SUMMARY OF CESM CLEAN ENERGY SURPLUS CALCULATION STEPS

1. Pre-Process and Aggregate Zonal AURORA Results to the State Level

PGE's IRP simulations in AURORA produce hourly load and generator dispatch results at a zonal level. The AURORA model divides the WECC into zones representing states, portions of states, and major transmission hubs as shown in Appendix C. In the CESM we assume states and transmission hubs with interconnected generation resources are the base geographic units to align with the geographic application of clean energy policy requirements. For utilities with multi-state service territories, generation and load are divided along state lines, consistent with the representation in the AURORA database.

We pre-process the AURORA results by aggregating sub-state results to the state level and combining all statewide generation into a single set of "clean" or "other" generation results. Appendix C contains a designation of resource types and a mapping of AURORA zones to states.



2. Calculate State-Level Annual Clean Energy Requirements

In the CESM, we assume only clean energy associated with legally binding state clean energy requirements is unavailable when calculating WECC-wide clean energy surplus. Voluntary targets from municipalities, corporations, and other entities have uncertain enforcement mechanisms. The CESM reflects additional demand from voluntary targets, such as corporate clean energy pledges or municipal clean energy programs through its calculation of purchase premiums described in Section III.

We calculate the total WECC-wide demand for clean energy by summing individual states' annual clean energy requirements. We calculate annual state-level clean energy requirements as the sum of each state's hourly electric demand multiplied by that state's percent-based clean energy requirement. State-level percent-based requirements are based on the LBNL's State Renewables Portfolio and Clean Electricity Standards database.[2] The CESM interpolates or extrapolates state-level targets set for specific years to derive annual clean energy targets for each of the PGE IRP study years, as needed. Figure 3 charts annual state-level targets included in the CESM, omitting data for states without policy targets.

[2] Lawrence Berkeley National Laboratory (LBNL). *U.S. State Renewables Portfolio & Clean Electricity Standards: 2023 Status Update*, 2023. Accessed online at https://emp.lbl.gov/publications/us-state-renewables-portfolio-clean.

FIGURE 3. STATE CLEAN ENERGY TARGETS INCLUDED IN THE CESM

3. Calculate State-Level Annual Clean Energy Surpluses or Deficits

The total volume of clean energy available to PGE for purchase depends on each state's annual clean energy generation surplus or deficit relative to its annual clean energy requirements. We assume that states prioritize meeting their annual clean energy requirements using in-state generation, and that any state-level clean energy generation in excess of state-level clean energy requirements would be available as surplus. On the other hand, any shortfalls in state-level clean energy generation relative to state-level targets reduce the total amount of clean energy surplus available WECC-wide, as we assume surpluses from other states fill requirement deficiencies before being offered to the market.

We calculate annual state-level clean energy surpluses or deficits as the difference between each state's annual clean energy policy targets and the total clean energy production that can be used to satisfy those requirements. In each hour, we assume that all clean energy generation up to a state's hourly load can be used to meet clean energy policy targets ("usable" clean energy). We assume that clean energy generation exceeding states' hourly loads would

be deemed surplus clean energy. We then calculate annual clean energy generation usable for meeting states' clean energy policy targets by summing usable clean energy generated across all hours of the year.

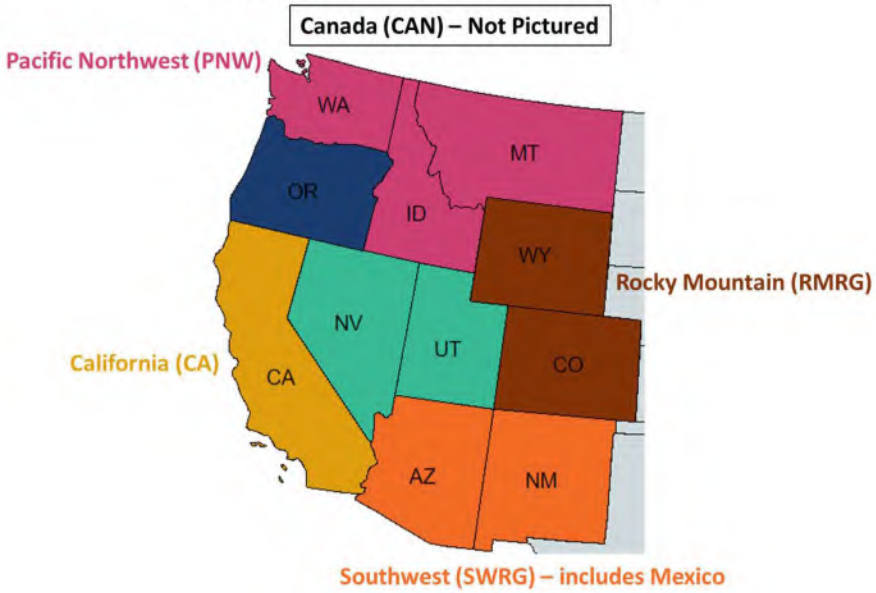
Next, we compare each state's annual usable clean energy generation to its annual clean energy targets. If a state's total annual clean energy generation is not enough to satisfy its annual clean energy requirements, that state is assumed to be in deficit and must rely on clean energy from other states to meet its targets. On the other hand, if a state's annual usable clean energy generation is greater than its annual clean energy requirements, that state is assumed to have an annual clean energy surplus.

4. Allocate State-Level Annual Surpluses or Deficits to Individual Hours

To calculate the hourly availability of clean energy WECC-wide and regionally, we next allocate states' gross annual clean energy surpluses or deficits to individual hours surplus availability. As a starting point, we assume that surpluses and deficits are proportional to hourly clean energy production and loads.

In the CESM we apply a heuristic to carry out this hourly allocation by assuming that states' surpluses or deficits are proportional to the difference between hourly clean energy production and demand. We implement this "proportional" approach in the CESM by deriving an annual surplus or deficit allocation factor.

For states with gross annual surplus clean energy production, we calculate the allocation factor as the difference between the state's total annual clean energy production and its total annual clean energy requirement. This factor is then applied to determine the portion of a state's hourly clean energy production that could be offered on the market. For example, a state with 100 MWh of annual clean energy production and 80 MWh of clean energy requirements would have an allocation factor of 20%. This means that the state can offer 20% of its annual clean energy production (20 MWh) and still have enough usable clean energy production to meet its annual clean energy targets (80 MWh). In an hour when the state produces 10 MWh of clean energy, it is assumed to offer 2 MWh on the market (20% of production in that hour) and keep 8 MWh (the remaining 80% of production in that hour) to count toward its own policy requirements.



For states with gross annual deficits of clean energy, we calculate the allocation factor as the difference between the state's annual clean energy target and the state's total annual clean energy production. This allocation factor is then used to determine quantity of clean energy procurement the state would seek to procure on the market in each hour. For example, if a state's annual clean energy policy target is 100 MWh and its local annual clean energy production is 60 MWh, then the state's allocation factor would be 40%. In an hour when the state's load is 10 MWh and its local clean energy production is 8 MWh, the state would seek an additional 0.8 MWh of clean energy (40% of 2 MWh) to contribute to filling its annual deficit.

5. Aggregate Hourly State-Level Results to Regional and WECC-Wide Level

We use the CESM to calculate the WECC-wide hourly surplus or deficit by summing the hourly surpluses and deficits of each state. The Oregon-West (OR-WE) AURORA zone contains PGE and is omitted from this calculation to represent PGE's view of the WECC market.

We aggregate state-level results into regions based on states' transmission connectivity to facilitate data validation and later application of deliverability constraints (Figure 4). Assuming sufficient transmission availability among states within each region, the CESM calculates hourly regional surpluses and deficits by summing the hourly surpluses and deficits of the region's member states. For example, the proportional allocation method may suggest that Wyoming could have 10 MWh of clean energy to offer on the market the same hour that Colorado could seek to procure 5 MWh of clean energy to fill its deficit. Since these states comprise the RMRG region, the CESM would indicate a 5 MWh clean energy surplus in the RMRG region in this hour.

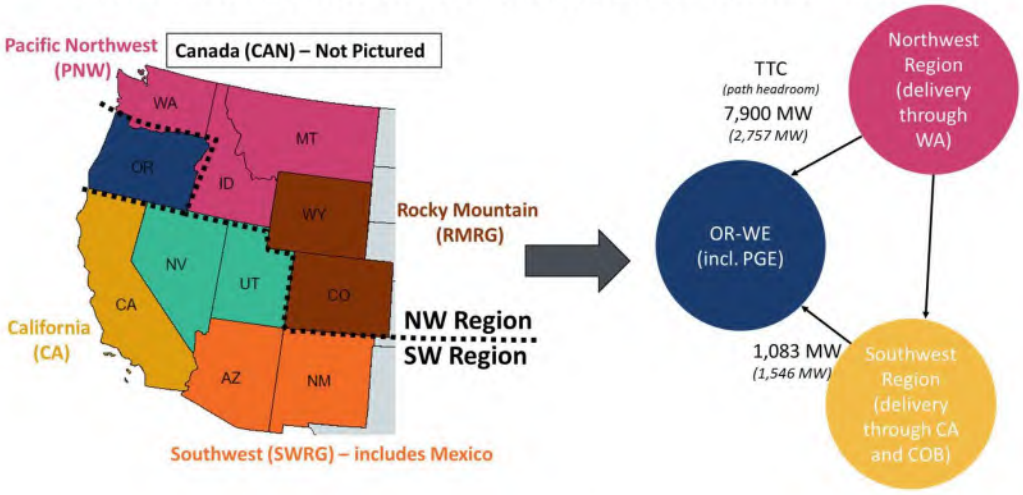


FIGURE 4. REGIONAL AGGREGATION IN THE CESM

6. Calculate Clean Energy Surplus Deliverable to PGE

We further limit the availability of clean energy surplus to PGE in the CESM based on available transmission headroom on the transmission paths connecting PGE to the rest of the system. To do so, we use the transmission path limits and power flow represented in the AURORA model between the OR-WE zone and the neighboring zones representing California, Washington, and the California-Oregon Border (COB) trading hub. For tractability in the CESM calculations, we aggregate the regions in Figure 4 into the Northwest and Southwest super-regions (Figure 5) and consider clean energy deliverability to PGE based on its transmission capacity and availability to these regions.

FIGURE 5. DIVISION OF WECC STATES INTO NORTHWEST AND SOUTHWEST REGIONS

We then calculate surplus *deliverable* to PGE in the Oregon-West zone in three steps:

1. **Balance Northwest and Southwest regional surpluses and deficits** by calculating the hourly surplus or deficit available in the Northwest and Southwest regions. This step uses a similar approach to that used for aggregating state-level results to the regional level as described in Step 5 above.

   In the CESM, we assume surplus transfers are unrestricted by transmission constraints within each super-region, except between the Rocky Mountain (RMRG) region and the rest of the Northwest. RMRG has a larger wind generation resource in Wyoming than it has transmission interconnectivity with the rest of the Northwest region. To reflect this in the CESM, we enforce a constraint between RMRG and the Pacific Northwest (PNW) region, balancing RMRG surpluses and deficits with the rest of the PNW. When RMRG surplus exceeds available headroom on the RMRG to PNW path, the rest of the RMRG surplus is assumed to be sent to the Southwest region. Any RMRG surplus beyond that which is deliverable to the Northwest and Southwest regions via available transmission headroom is assumed to be unavailable to PGE.

2. **Calculate available hourly transmission path headroom from the Northwest and Southwest regions to Oregon-West.** We calculate within the CESM the available headroom to Oregon-West based on the path ratings and hourly transmission utilization results from the AURORA model. For each transmission path, we calculate a net hourly flow by netting

out flows in the forward and reverse direction as defined in the AURORA inputs. To arrive at available headroom for the CESM, we then subtract the net flow from the path's TTC in each hour. In this initial version of the CESM, we assume no re-dispatch of storage or thermal resources to relieve congestion constraints or improve deliverability of clean energy to PGE at certain times of day. We calculate the total headroom from the Southwest region into OR-WE as the sum of the transmission headroom from California to OR-WE and from COB to OR-WE.

3. **Adjust Northwest and Southwest region surpluses for deliverability into OR-WE, accounting for transfers between the Northwest and Southwest regions**. We limit hourly transfers within the CESM from the Northwest and Southwest regions into OR-WE based on the hourly transmission headroom available into OR-WE. We additionally assume that surplus transfers can occur between the Northwest and Southwest regions as needed to ensure full utilization of transmission headroom into OR-WE. For example, if the Northwest region had 100 MWh of surplus but only 80 MW of transmission headroom available to OR-WE in some hour, then PGE could access only 80 MWh of surplus from the Northwest region in that hour. However, the CESM assumes those 20 MWh of surplus could be delivered to OR-WE via the Southwest region if there were enough transmission headroom available on the paths from the Northwest to the Southwest and from the Southwest to OR-WE.

III. Clean Energy Premium Estimation Approach

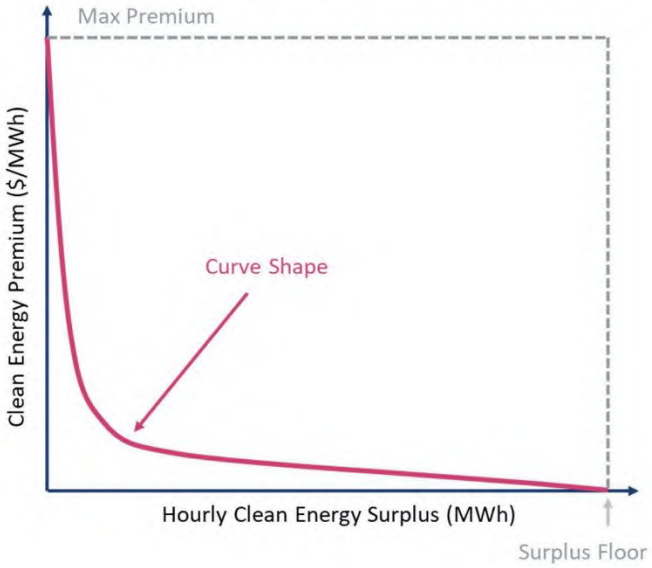
The CESM reflects an expectation that PGE may have to pay a premium to secure clean energy supplies when those supplies are relatively scarce.

We reflect this expectation in our calculations by estimating an hourly Clean Energy Premium, defined as the additional cost that PGE may have to pay beyond the energy price associated with the purchase of clean energy. Within the CESM we use a Clean Energy Premium Curve (CEPC) to translate hourly WECC-wide clean energy surpluses into hourly clean energy premiums. The CESM calculates the hourly Clean Energy Premium PGE may have to pay in three steps:

1. Create a WECC-wide CEPC for the simulation year

2. Calculate WECC-wide hourly Clean Energy Premiums
3. Implement PGE-specific Clean Energy Premium adjustments

Next, we discuss each of these steps in greater detail.



1. Create a WECC-Wide CEPC for the Simulation Year

The CEPC captures the impact of competition for scarce clean energy on the value of its clean energy attribute, broadly mimicking the price-quantity dynamics observed in other clean attribute markets. We define the CEPC separately for each model year using three parameters:

- **Curve shape** reflecting the relationship between the Clean Energy Premium and WECC-wide surplus quantity,
- **Max premium** related to the levelized cost of procuring clean energy from newly built capacity, in the case of PGE the cost of a new build wind resource, and
- **Surplus floor** threshold quantity above which the premium is assumed to be zero.

Figure 6 shows an illustrative CEPC with the above parameters labeled, followed by additional discussion of each parameter.

FIGURE 6. CLEAN ENERGY PREMIUM CURVE PARAMETRIZATION

CEPC Curve Shape Parameter

We model a negative exponential relationship between clean energy surplus and premium in the CESM, assuming clean energy attributes in the WECC would have similar price-quantity dynamics as renewable energy certificates (RECs) in other markets. Historical solar REC (sREC) auction outcomes from PJM states with liquid markets show an exponential relationship between trade volumes and clearing prices (Figure 7).[3] This relationship indicates that as the supply shrinks, buyers are willing to pay increasing premiums to secure clean attributes in the market. On the other hand, if there is ample supply, premiums settle at a relatively low baseline value. The negative exponential shape used in the CESM is a normalized version of the PJM sREC auction outcome graph shapes, tuned using outputs from the AURORA model.

[3] We relied on PJM sREC auction outcomes for the CESM due to a lack of available clean attribute market data in the WECC.

FIGURE 7. PJM SOLAR REC AUCTION PRICE-QUANTITY RELATIONSHIP BETWEEN 2010-2024

CEPC Max Premium Parameter

Based on guidance from PGE, we set the CEPC Max Premium parameter based on the cost of a new build wind resource, assuming that wind would be the source of incremental supply of clean energy beyond what is available from existing resources. We set the CEPC Max Premium to $15/MWh for the year 2030, reflecting a $10/MWh levelized cost of energy (LCOE) for a new wind resource earning the Production Tax Credit and a 1.5× scalar to reflect cost uncertainty not reflected in the LCOE. The LCOE value is based on the 2023 NREL ATB's calculation of the LCOE of a Class 4 onshore wind turbine using the moderate cost trajectory.[4]

CEPC Curve Floor Parameter

We set the Curve Floor parameter based on WECC-wide clean energy surpluses observed in the AURORA results when energy prices are below a certain threshold. Low energy prices indicate high enough clean energy production that there should be no premium associated with its procurement. This study used a $0/MWh threshold price, which indicates clean energy curtailments in the AURORA model. The Curve Floor parameter was set at the minimum WECC-wide surplus observed across all hours when the WECC-wide load-weighted average energy price was at or below the $0/MWh threshold.

2. Calculate WECC-Wide Hourly Clean Energy Premiums

We use the CESM process detailed in Steps 1 through 5 detailed in Section 0 above to calculate the total available WECC-wide surpluses in each hour. Since the premium does not depend on

[4] National Renewable Energy Laboratory. *2023 Annual Technology Baseline*. 2023. https://atb.nrel.gov/electricity/2023/land-based_wind.

how much of the available surplus is deliverable to PGE, we use the CEPC to calculate hourly WECC-wide premiums using the results of Step 5.

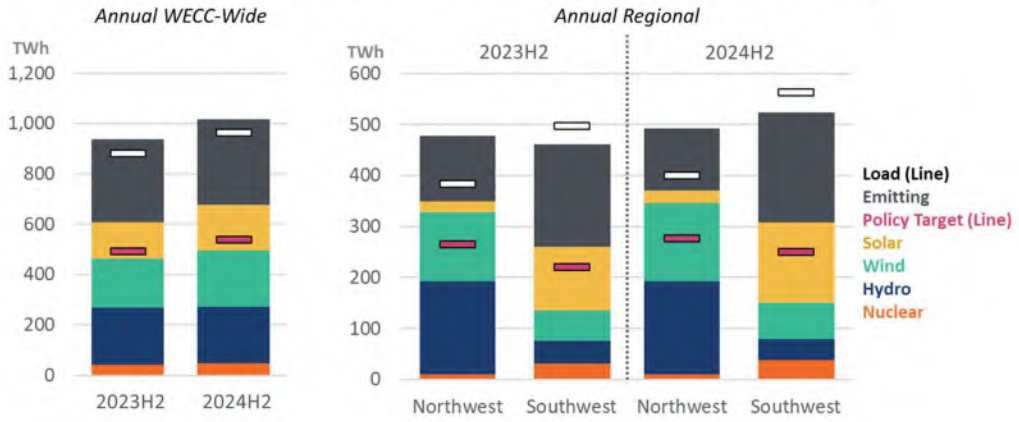
3. Implement PGE-Specific Premium Adjustments

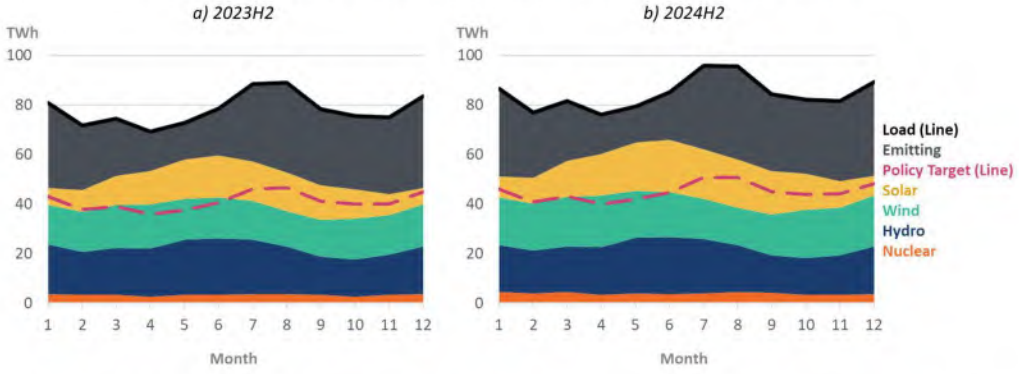
We divide each hour's WECC-wide premium by the capacity factor of a reference wind profile in that hour to capture the impact of wind availability on the cost of producing a MWh of clean energy in each hour. A key concern for PGE's CEP is whether to rely on market purchases or to procure new clean generation capacity. An owned or contracted resource seldom produces clean energy equal to its nameplate capacity. Thus, PGE may need more than a MW of clean generation nameplate capacity to produce a MWh of clean energy when needed. Dividing the hourly WECC-wide premium by the capacity factor of a reference wind output profile in that hour serves to make comparable the cost of procuring capacity or purchasing surplus on the market.

IV. Clean Energy Accounting Results

We evaluated potential clean energy surplus availability for the year 2030 based on AURORA model results from the 2023H2 and 2024H2 production cost model databases from Wood Mackenzie. The annual regional and WECC wide generation mix and load modeled in each set of AURORA inputs is given below in Figure 8, followed by the monthly WECC-wide generation mix and load in Figure 9. Both model databases show the WECC-wide and regional generation mixes as having high proportions of clean energy and an annual surplus. WECC-wide surpluses tend to concentrate in the spring months, when loads are low and clean energy generation is high. The Northwest region has higher surplus than the Southwest region, despite higher policy requirements, due to substantial wind and hydro penetration.

FIGURE 8. ANNUAL GENERATION ASSUMPTIONS IN THE AURORA MODEL





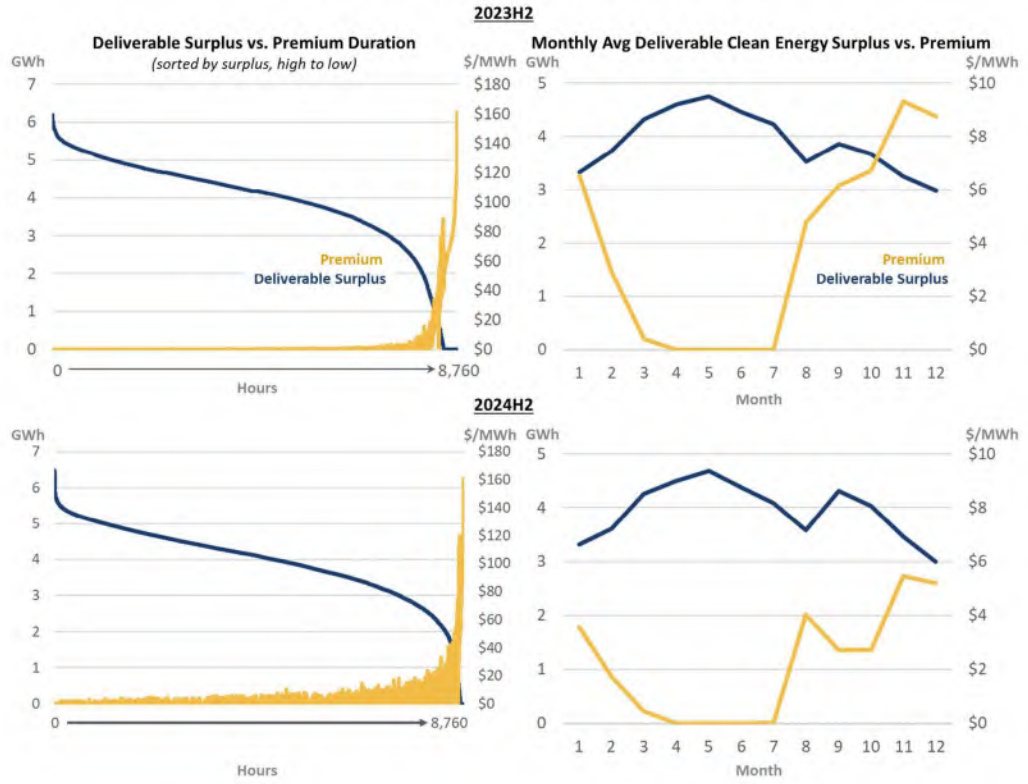


FIGURE 9. MONTHLY GENERATION ASSUMPTIONS IN THE AURORA MODEL

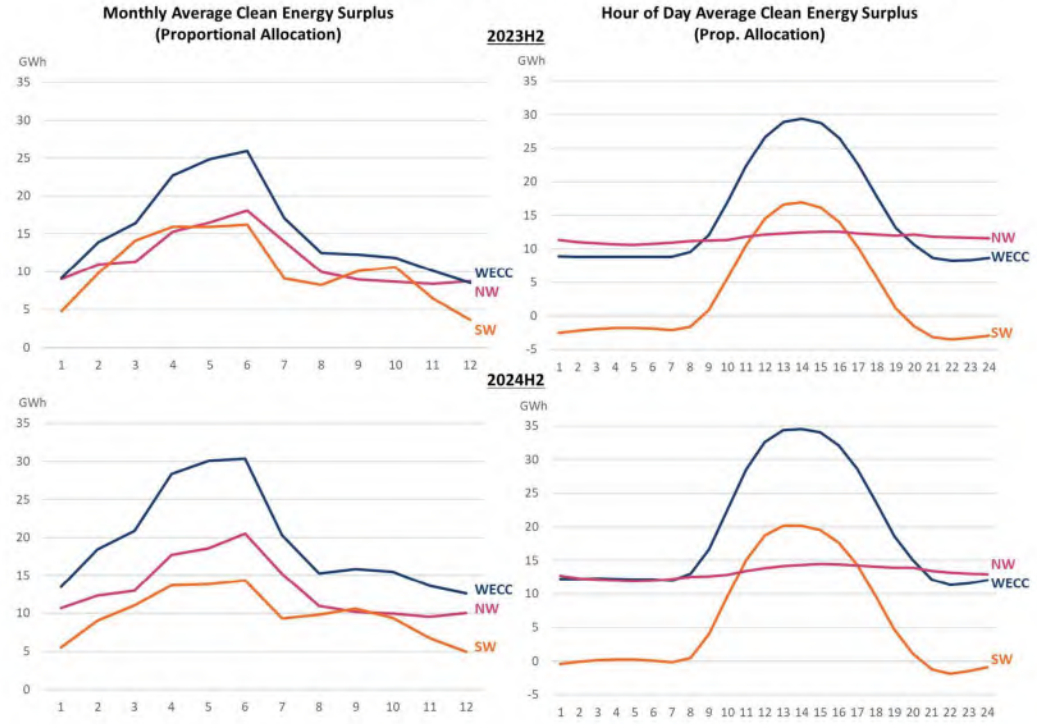

We find that deliverable surpluses are highest in the spring and early summer, roughly in line with the seasonality of clean generation. Premiums follow an inverse pattern and are highest in the winter, when surpluses are low, reflecting the price-quantity relationships defined in the CEPC. Figure 10 below plots the deliverable surpluses and premiums for both sets of AURORA data as a duration curve (left charts) and as average monthly values (right charts). The duration curves plot hourly surplus (blue line) and premium (yellow line) results arranged by surplus quantity in descending order. The monthly charts represent the simple average surplus and premium value for each month.

FIGURE 10. DELIVERABLE SURPLUS AND PREMIUM

We observe substantial variability in WECC-wide and regional surpluses across different months and hours of the day (Figure 11). The Northwest region's monthly clean energy generation patterns drive WECC-wide monthly clean energy surpluses because the Northwest region has a rich wind and hydro resource. On a daily scale, the Southwest region drives WECC-wide surplus patterns due to its large solar resource. In the right charts in Figure 11, the blue line (WECC-wide surplus) has a very similar shape to the orange line (Southwest average surplus), displaying a hump during solar generation hours. The pink line (Northwest average surplus) remains mostly flat across all hours of the day.

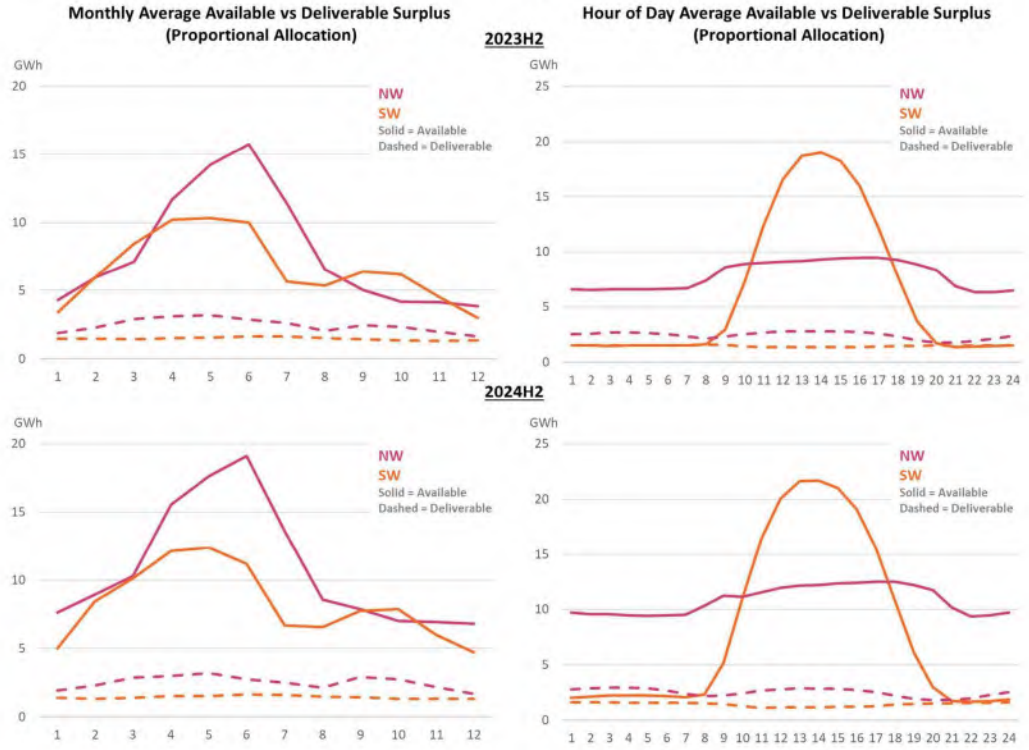

FIGURE 11. WECC-WIDE AND REGIONAL SURPLUSES[5] BY MONTH AND HOUR OF THE DAY

We found that deliverability constraints substantially curtail PGE's access to clean surplus. Figure 12 plots the available (solid line) and deliverable (dashed line) surplus for each region by month (left charts) and hour of day (right charts). PGE's deliverability constraints are most impactful during the springtime for Northwest surpluses and during the daytime for Southwest surpluses, with an overall impact of allowing just over 30% of available surplus to be delivered to PGE.

[5] Charts show average surplus quantities for hours when surpluses are available, before accounting for RMRG deliverability constraints and transfers between NW and SW regions. Aggregating to the WECC-wide level alters the timing and amounts of surpluses shown such that the NW and SW values may add to more than the WECC quantity.

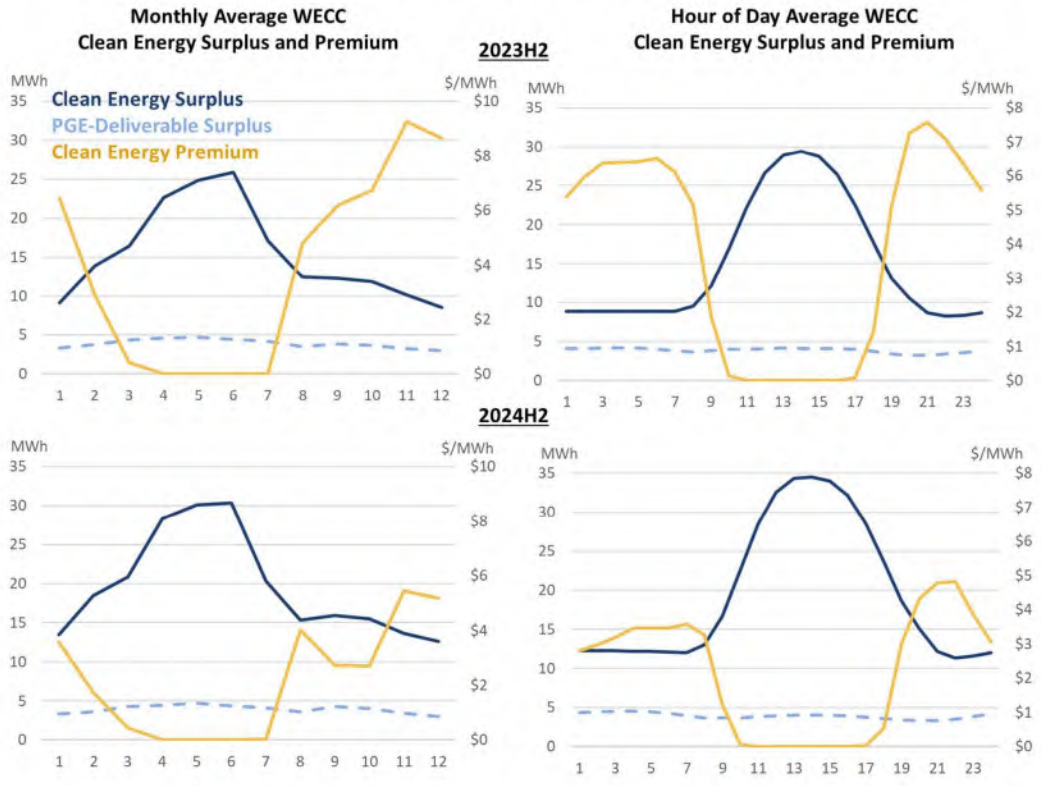

FIGURE 12. REGIONAL SURPLUS DELIVERABILITY RESULTS[6]

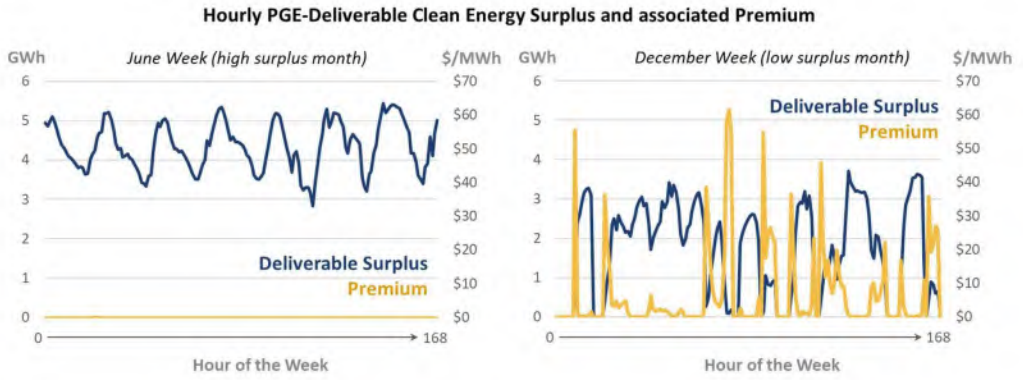
Hourly premium results are driven by WECC-wide surplus dynamics, reflecting the inverse relationship between surplus quantity and premium defined in the CEPC (Figure 13). Premium are based on WECC-wide surpluses and do not depend on deliverability to PGE. High WECC-wide surpluses in the spring and during the middle of the day drive down premiums during those periods.



6 Regional surpluses reflected in Figure 12 reflect surpluses deliverable from the respective regions. The solid lines indicate available surpluses after accounting for transfers from RMRG and between the NW and SW regions. The dotted lines indicate the regional surpluses deliverable to PGE.

FIGURE 13. WECC-WIDE AVAILABLE AND DELIVERABLE CLEAN ENERGY SURPLUS AND PREMIUM

We examined hourly CESM results to validate the annual, monthly, and hour-of-day trends observed above. Figure 14 plots hourly results for a week in June (left chart) and December (right chart) from the 2023H2 set of results. In June, when surpluses are high, there is no premium. In the December week, surpluses vary throughout the day, often falling to zero during evening hours with peak demand.

FIGURE 14. HOURLY CESM RESULTS

V. Framework Evaluation and Next Steps

The CESM provides a starting point for assessing the availability and cost of clean energy surplus in the WECC and deliverable to PGE.

The strengths of this hourly surplus accounting framework include:

- Broad capture of the fundamental dynamics that drive the availability and relative value of clean energy
- Simplicity in implementation with tunable parameters
- Internal consistency with the AURORA simulations that inform other areas of the PGE IRP analyses.
- Adaptability for studying multiple future outlook scenarios.

There are several areas in which the CESM can be improved:

- Add detail when applying deliverability constraints. The CESM currently includes deliverability constraints at the seams of the OR-WE AURORA zone containing PGE, assuming no transmission limitations in delivering surpluses to the seams from more distant entities. A future refinement could add constraints for calculating clean energy deliverability

to PGE's immediate neighbors and additionally to those neighbors' neighbors. We expect this improvement would reduce surplus deliverable to PGE.

- Refine the hourly surplus/deficit allocation approach. WECC entities may have various clean energy market participation strategies, including front-loading surplus procurements, concentrating purchases during times of abundant production, or attempting to maximize premium revenues. Alternate hourly allocation approaches can capture such behaviors, thereby altering the amount of surplus available to PGE. Adjustments to the allocation approach could increase or decrease the surplus available to PGE, depending on the specifics of the approach.
- Consideration of moving surplus within days or across days with storage. Our initial approach uses storage dispatch profiles as they are in Aurora results, but the WECC entities may dispatch storage resources to alter the amount of surplus available. We expect this improvement could modestly increase the surplus deliverable to PGE because the AURORA model already optimizes storage dispatch.
- Refine the approach to calculating state targets to account for varying clean energy eligibility requirements. We expect this refinement would have little to no impact on surplus deliverable to PGE because ineligible non-emitting energy can be traded to satisfy other states' requirements.
- Include the impacts of renewable forecast uncertainty. Deviations between day-ahead forecasts and real-time clean energy production would alter the quantity of available surplus and the utilization of transmission paths. We expect this refinement would have modest impacts on deliverable surplus quantities because renewable forecast errors are small compared to base production schedules and forecasting methods continue to improve.

Appendix A: Detailed List of Assumptions

General assumptions

- Each AURORA zone falls within a single state
  - Zones that are not labeled as belonging to specific states will be mapped based on proximity

- Clean energy surplus reflects availability after accounting for clean energy commitments to other states' policy goals
- Clean energy generated outside of PGE is only committed to state-legislated targets, not corporate or voluntary goals (i.e., those goals compete with PGE for clean energy surplus)
- Curtailed clean energy is assumed to be undeliverable and thus not considered part of the WECC-wide surplus
- Same set of resource types considered "clean" for all state RPS programs
- Transmission and deliverability constraints limit WECC-wide clean energy surplus only on a regional basis, if at all

Surplus estimation assumptions

- All clean energy policy targets increase linearly by year from 2024 until their mandated achievement year, with trajectories including interim targets
- All clean energy in excess of a balancing area's (BA's) load is counted as surplus
- If this results in an annual deficit relative to policy targets for the BA, then we assume that WECC-wide surpluses in other hours are reduced proportionally to return the BA to annual compliance
- Clean energy in states without policy targets is all counted as surplus
- There are no contributions to meeting annual policy targets from banked clean energy credits
- Surplus deliverability is not meaningfully impacted by sub-zonal transmission constraints
- Sufficient TTC exists between sub-zones of NW and SW deliverability regions to balance surpluses/deficits
- No shifting of surpluses between hours within a day (e.g., by using storage)

Premium estimation assumptions

- Premium price quantity dynamic resembles that of REC markets
- Maximum premium is representative levelized net cost of new wind build for PGE with hourly adjustments for wind availability
- Minimum premium is zero

- Surplus floor will be related to AURORA surplus quantities and energy prices
- Premium curve is static across the year

Appendix B: Table of Input Data Sources

CESM Input	Source
Generator state mappings	AURORA input
Generator type mapping	AURORA input
State RPS/CES targets	Brattle assumption based on public data from LBNL
Mapping of AURORA zones to states	Brattle team assumption
RPS unit type eligibility by program	Brattle team assumption
Transmission capacity from WECC zones to PGE/trading hubs	AURORA input
Hourly flow on transmission paths	AURORA results
Zonal hourly load	AURORA results
Hourly generation by unit	AURORA results
Zonal generator-weighted LMP	AURORA results
Annual market purchase premium floor and ceiling	Brattle assumption
Clean energy premium curve shape	Brattle assumption based on PJM REC auction outcomes

Appendix C: AURORA Modeled Zonal Topology And Resource Types

Figure 15 contains the zonal and transmission topology modeled in the AURORA database.

Appendix H Transmission planning and interconnection process

H.1FERC Order 1000 process

PGE coordinates its planning processes with other transmission providers through membership in NorthernGrid and the Western Electric Coordinating Council (WECC). PGE uses the NorthernGrid process for regional planning, coordination with adjacent regional groups and other planning entities for interregional planning, and development of proposals to WECC. Additional information is included in PGE's OATT Attachment K, in Transmission Planning Business Practice on OASIS, and on NorthernGrid's website at https://www.northerngrid.net.

H.2 FERC Order 1920 process

FERC Order No. 1920 reforms the regional transmission planning process by establishing a new 20-year, scenario-based Long-Term Regional Transmission Planning (LTRTP) process.[167] Three diverse and plausible scenarios must be studied, and these scenarios must be re-assessed and revised at least once every five years. Sensitivity analysis of uncertain operational outcomes during multiple concurrent and sustained generation and/or transmission outages due to an extreme weather event across a wide area must also be performed for each scenario. PGE's compliance with FERC Order No. 1920 will be primarily realized through modifications to the existing NorthernGrid regional transmission planning process to incorporate the new requirements established in FERC Order No. 1920.

The new long-term scenarios must be developed using a set of seven categories of factors. These categories of factors are like those used in integrated resource planning, including criteria such as federal, state, and tribal rules and regulations for resource mix, decarbonization, and electrification. Factor Category 3 specifically requires incorporating integrated resource plans into the scenario development. The requirement for these using these factor categories in scenario-based transmission planning closely aligns the long-term regional transmission planning process with the integrated resource planning process.

FERC Order No. 1920 also requires that transmission providers measure a set of seven benefits for each scenario to evaluate LTRTP facilities over a 20-year horizon starting from the in-service date of the facility. The seven benefits go beyond traditional reliability metrics in the existing transmission planning processes to address economic benefits for transmission projects that integrate cost-effective new resources, such as lowering production costs and mitigating congestion. This again speaks to the alignment with the requirements of FERC Order No. 1920 and the integrated resource planning process.

[167] FERC Order No. 1920, issued on May 13, 2024.

Additional requirements of FERC Order No. 1920 include development of selection criteria for facilities, re-evaluation of facilities due to changing policies or reliability criteria, use of grid-enhancing technologies, cost allocation, and more transparency into the local transmission planning, regional transmission planning, and interregional transmission planning processes.

PGE appreciates the strong partnership with the relevant state entities throughout the Order No. 1920 six-month state engagement period, which began November 1, 2024, and concludes November 1, 2025. The NorthernGrid transmission providers also commenced an open stakeholder engagement process to receive feedback on the new LTRTP in March 2025 per the new requirement issued in FERC Order No. 1920-A.[168] NorthernGrid will propose on compliance the start of the long-term regional transmission planning process, which will commence no later than two years after the filing date. The states in the NorthernGrid and WestConnect regional planning organizations requested and received a compliance extension at FERC to allow for more time for cost allocation discussions. All NorthernGrid FERC-jurisdictional transmission providers must complete their compliance filing by December 12, 2025. A second compliance filing for the new interregional transmission planning requirements is due February 12, 2026.

H.3 Local transmission planning process

H.3.1 Process overview

PGE's OATT is posted on its Open Access Same-time Information System (OASIS) at http://oasis.oati.com/PGE. Additional information regarding Transmission Planning is located in the Transmission Planning folder on PGE's OASIS.

The Local Transmission Plan (LTP) is prepared within the two-year process as defined in PGE's OATT Attachment K and summarized in **Table 39**. The LTP identifies the Transmission System facility additions required to reliably interconnect and transmit forecasted generation resources and serve the forecasted Network Customers' load, Native Load Customers' load, and Point-to-Point Transmission Customers' requirements, and also includes legacy, non-OATT agreements and rollover rights over a ten-year planning horizon. Additionally, the LTP typically incorporates the results of any stakeholder-requested economic congestion studies results that were performed.

Table 39. Local Transmission Planning Cadence

		Quarter	Tasks
Near Term	Even Years	1	Select Near Term base cases and gather load data
		2	Post Study Methodology on OASIS, select one Economic Study for evaluation
		3 & 4	Select Longer Term base cases, post draft Near Term Plan on OASIS, hold public meeting to solicit stakeholder comment

[168] FERC Order No. 1920-A, issued on November 21, 2024.

		Quarter	Tasks
		4	Incorporate stakeholder comments and post final Near Term plan on OASIS
Longer Term	Odd Years	5	Gather load data and accept Economic Study requests
		6	Select one Economic Study for evaluation
		7 & 8	Post draft Longer Term plan on OASIS, hold public meeting to solicit stakeholder comment
		8	Post final Longer Term plan on OASIS, submit final Longer Term Plan to stakeholders and owners of neighboring systems

PGE updates its Transmission Customers about activities and progress made under the Attachment K planning process during regularly scheduled customer meetings. Meeting announcements, agendas, and notes are posted in the Customer Meetings folder on PGE's OASIS. Meeting dates are posted on PGE's OASIS.

H.3.2 NERC planning standards (TPL-001)

PGE's Transmission System is designed to reliably supply projected customer demand and projected Firm Transmission Service. Studies are performed annually to evaluate where Transmission upgrades may be needed to meet the performance requirements established in the NERC TPL-001-5 Reliability Standard and the WECC TPL-001-WECC-CRT-3.2 Regional Criteria. Results from the annual TPL-001 process are made available via the Local Transmission Plan document, which is posted publicly on PGE's OASIS page.

The summer (June 1st through October 31st) and winter (November 1st through March 31st) load seasons are considered the most critical study seasons due to heavier peak loads and high power transfers over PGE's Transmission and Distribution System to its customers. However, the off-peak seasons have different regional flow patterns that can result in issues not seen during peak load times. PGE defines the seasons to align with Attachment I of the RC West.[169]

PGE maintains system models within its planning area for performing the studies required to complete the system assessment. These models use data that is provided in WECC base cases in accordance with the MOD-032 reliability standard. Electrical facilities modeled in the cases have established ratings, as defined in PGE's "Facility Ratings Methodology" document and in accordance with the FAC-014 reliability standard. A facility rating is determined based on the most limiting component in each transmission facility, in accordance with the FAC-008 reliability standard.

[169] RC West Southwest Power Pool BC Hydro, "RC Guidelines for Seasonal Assessment and Coordination Process," Attachment I, page 14, https://www.caiso.com/documents/rc0680.pdf.

Reactive power resources are modeled as made available in the WECC base cases. For PGE, reactive power resources include shunt capacitor banks available on the 230 kV, 115 kV, and 57 kV systems.

Studies are evaluated for the Near-Term Planning Horizon (years 1 through 5) and the Long-Term Planning Horizon (years 6 through 10) to ensure adequate capacity is available on PGE's transmission system. The load modeled in the studies is obtained from PGE's corporate forecast, reflecting a 1-in-20 demand level for peak summer and peak winter conditions. Known outages of generation or transmission facilities with durations of at least six months are appropriately represented in the system models. However, any significant outage is studied as a result of an N-1-1 contingency and is therefore analyzed for every major season and year that PGE studies as part of the TPL process. Transmission equipment is assumed to be out of service in the base case system models if there is no spare equipment or mitigation strategy for the loss of the equipment.

Studies in the Near Term – Two Year Planning Horizon and the Near Term – Five Year Planning Horizon are performed for peak summer, peak winter, and off-peak spring conditions. Sensitivity studies are performed for each of these cases by varying the study parameters to stress the system within a range of credible conditions that demonstrate a measurable change in performance. PGE adjusts the real and reactive forecasted load and the transfers on the paths into the Portland area on all sensitivity studies. For peak system sensitivity cases, the 1-in-20 load forecast.

The load levels used in the 2024 Local Transmission Plan are available on PGE's OASIS page.

The Bulk Electric System (BES) is evaluated for steady state and transient stability performance for planning events described in Table 1 of the NERC TPL-001-5.1 reliability standard. When system simulations indicate an inability of the systems to respond as prescribed in the NERC TPL-001-5.1 standard, PGE identifies projects and/or Corrective Action Plans which are needed to achieve the required system performance throughout the Planning Horizon.

H.3.2.1 Steady state studies

PGE performs steady-state studies for the Near-Term and Long-Term Transmission Planning Horizons. The studies consider all Contingency scenarios identified in Table 1 of the NERC TPL-001-5.1 reliability standard (Categories P0-P7) to determine if the BES meets performance requirements. PGE uses the criteria defined in the WECC TPL-001-WECC-CRT-3.2 document to establish acceptable System steady state voltage limits and post-Contingency voltage deviations. The WECC System Performance Criteria requires that the change in bus voltage percentage not exceed 8 percent for N-1 contingencies. Additionally, internal PGE performance criteria require that the change in bus voltage percentage not exceed 10 percent for N-2 and N-1-1 contingencies. These studies also assess the impact of Extreme Events on the System expected to produce severe System impacts.

The Contingency Analyses simulate the removal of all Elements that the Protection System and other automatic controls are expected to disconnect for each Contingency without Operator intervention. The analyses include the impact of the subsequent tripping of generators due to

voltage limitations and tripping of Transmission Elements where relay loadability limits are exceeded. Automatic controls simulated include phase-shifting transformers, load tap changing transformers, and switched capacitors and reactors.

Cascading, or the uncontrolled successive loss of System Elements triggered by a Disturbance that results in the inability of the Elements of the BES to regain a state of operating equilibrium is defined as a System instability. Cascading is not allowed to occur for any Contingency analysis. If the analysis of an Extreme Event concludes there is Cascading, an evaluation of possible actions designed to reduce the likelihood or mitigate the consequences and adverse impacts of the event(s) is completed.

H.3.2.2 Voltage stability studies

PGE's Transmission System is evaluated for voltage stability in accordance with the WECC established criteria.[170] These performance criteria are summarized in the table below. Any voltage stability result that violates the criteria listed below is defined as a System instability. Contingencies to PGE and adjacent utility equipment at 500 kV and 230 kV are evaluated. All planning events were screened or reviewed for voltage stability requirement per WECC Criterion WR5 by simulating P0 and P1 events at 105 percent of forecasted peak load and simulating P2-P7 events at 102.5 percent of forecasted peak load. This screening indicated all planning events met the reactive margin requirement with the implementation of their associated operating procedures, RAS, or Corrective Action Plans.

H.3.2.3 Transient stability studies

PGE evaluates the transient stability performance of the BES for select Contingencies to PGE and adjacent utility equipment at 500 kV, 230 kV, and 115 kV. The studies evaluate single line-to-ground and three-phase faults to these facilities, including generators, bus sections, breaker failure, and loss of a double-circuit Transmission line. Extreme events are studied for three-phase faults with Delayed Fault Clearing.

For all 500 kV and 230 kV breaker positions, PGE implements high-speed protection through two independent relay systems utilizing separate current transformers for each set of relays. For a fault directly affecting these facilities, normal clearing is achieved when the Protection System operates as designed and faults are cleared within four to six cycles.

PGE implements breaker-failure protection schemes for its 500 kV and 230 kV facilities, and the majority of 115 kV facilities. Delayed clearing occurs when a breaker fails to operate, and the breaker-failure scheme clears the fault. Facilities without delayed clearing are modeled as such in the Contingency definition.

The transient stability results are evaluated for compliance with the following NERC and WECC System performance requirements. The simulation durations are run to 20 seconds. All

[170] "Guide to WECC/NERC Planning Standards I.D: Voltage Support and Reactive Power," prepared by the Reactive Reserve Working Group (RRWG) and approved by the Technical Studies Subcommittee (TSS) on March 30, 2006. https://www.wecc.biz/_layouts/15/WopiFrame.aspx?sourcedoc=/Reliability/Voltage%20Stability%20Guide.pdf&action=default&DefaultItemOpen=1

oscillations that do not show positive damping within 20 seconds after the start of the studied event shall be deemed unstable.

H.3.2.4 Short circuit studies

Short circuit studies are performed annually addressing the Near-Term Planning Horizon. If the short circuit current interrupting duty on a circuit breaker exceeds 97 percent of its equipment rating, PGE identifies projects and/or Corrective Action Plans which are needed to achieve the required System performance throughout the Near- and Long-Term Planning Horizon.

H.4 Other relevant transmission planning standards

H.4.1 TPL-007

Transmission system planning requirements surrounding geomagnetic disturbances are addressed in NERC Standard TPL-007-4. Geomagnetic disturbances occur when high-energy emissions from the sun, known as coronal mass ejections, interact with the Earth's magnetic field. The resulting electromagnetic disturbances can propagate along long conductors, such as transmission lines, and have been known to cause power system damage in the past.[171]

TPL-007-4 requires that PGE:

- Maintain and report information on all Bulk Electric System transformers in its service territory
- Install a geomagnetic current sensor on at least one bulk transformer it its service territory
- Coordinate on a geomagnetic disturbance study with regional stakeholders every five years
- Address any thermal or reactive power exceedances identified in this study via a Corrective Action Plan.

Historically, PGE has not experienced significant system impacts from geomagnetic disturbances. This is due to a combination of the transmission topology in the area and the nature of the soil in the Willamette Valley. During a recent geomagnetic storm in May 2024, which was the highest recorded in nearly 20 years, there were negligible effects detected on PGE's system.

The related NERC Standard EOP-010-1 governs how PGE works with NASA and the Reliability Coordinator (RC West) to address geomagnetic disturbances in the operations horizon.

H.4.2 TPL-008 (in development)

On June 15, 2023, FERC issued FERC Order No. 896 that acknowledges the "challenges associated with planning for extreme heat and cold weather events, particularly those that occur during periods when the Bulk-Power System must meet unexpectedly high demand. Extreme heat and cold weather events, which can cause public safety and economic risks, have occurred

[171] See for example, Guillon, et.al., "A Colorful Blackout: The Havoc Caused by Auroral Electrojet Generated Magnetic Field Variations in 1989" IEEE, Nov 2016. https://ieeexplore.ieee.org/document/7592967.

with greater frequency in recent years and are projected to occur with even greater frequency in the future. As such, the impact of concurrent failures of Bulk-Power System generation and transmission equipment and the potential for cascading outages that may be caused by extreme heat and cold weather events should be studied and corrective actions should be identified and implemented."[172]

Part of the Order 896 effort involves the creation of a new NERC Standard, TPL-008-1, which currently in the drafting phase (as of August 2024). It is expected to be finalized in early 2025, with the various requirements having implementation dates of 12- to 60-month.

While the standard is not yet finalized, in general, it will require Transmission Planning entities such as PGE to:

- Coordinate on the development of extreme weather base cases for both cold winter and hot summer conditions
- Model and simulate the ability of the transmission system to respond to transmission outage scenarios (i.e. contingencies) during these extreme weather events
- Develop Corrective Action Plans for any scenarios that do not meet the established acceptance criteria in the standard

The goal of this standard is to ensure that the transmission system remains robust to future extreme weather conditions.

H.4.3 FERC Order No. 2023

FERC Order No. 2023 reforms the large generator interconnection process to make it more efficient by moving to a first-ready, first-served cluster study process.[173] The new process consists of a 150-day Cluster Study (or Cluster Restudy) and a 90-day or 180-day Facilities Study. New financial and readiness requirements, including increased deposits, increased site control, and significant withdrawal penalties are aimed to reduce the number of speculative interconnection requests entering the queue and, as a result, minimize the number of withdrawals from the interconnection queue, which typically result in restudies, lengthening the interconnection study process. These improvements provide more certainty that the new resources identified in the integrated resource planning process can be energized when they are needed, minimizing delays in the interconnection study process.

Information available to prospective interconnection customers is improved with the publishing of an interconnection heatmap, which will be updated at the end of every cluster study or cluster restudy. This heat map can be utilized in the integrated resource planning process to identify on-system locations with existing capacity for new renewable resources.

New advancements were added to FERC Order No. 2023 to allow more flexibility and timeliness improvements for interconnecting new resources. First, multiple customers at the same site with the same Point of Interconnection (POI) can submit a single interconnection request. This

[172] N. Am. Elec. Reliability Corp., 183 FERC ¶ 61,191 (2023) (FERC Order), Final Rule.
[173] FERC Order No. 2023, issued on November 6, 2023.

streamlines jointly owned interconnection projects because multiple owners do not need to submit individual requests. Second, Surplus Interconnection Service can be requested for a project with a signed large generator interconnection agreement – the project no longer must be in commercial operation. This allows for more co-location of different renewable resources behind a single POI to move faster, not waiting for the energization of the first resource to be able to apply for the subsequent resource. Finally, FERC Order No. 2023 requires transmission providers to evaluate alternative transmission technologies for each identified network upgrade. These alternative transmission technologies traditionally can be constructed and energized before traditional solutions, often at a lower cost. All these improvements provide even more certainty to the interconnection process timeline for use in the integrated resource planning process.

To continue alignment with state-jurisdictional and FERC-jurisdictional large generator interconnection processes, the QF-LGIP was amended to conform with the cluster study process. This is beneficial for QF projects, as these projects will be subject to the same cost allocation and sharing as the FERC-jurisdictional projects, potentially reducing costs by spreading across more projects. The OPUC approved PGE's filing with an effective date of January 7, 2025.

PGE began the Transitional Cluster Study on January 6, 2025 to study projects in the serial queue as of May 26, 2024, which was 30 days after PGE submitted its compliance filing to FERC. There are no QF-LGIP projects in the Transitional Cluster Study, as none were in the interconnection queue as of May 26, 2024. The first Cluster Study Request Window for when new large generation projects can request interconnection will open January 1, 2026.

H.4.4 Miscellaneous

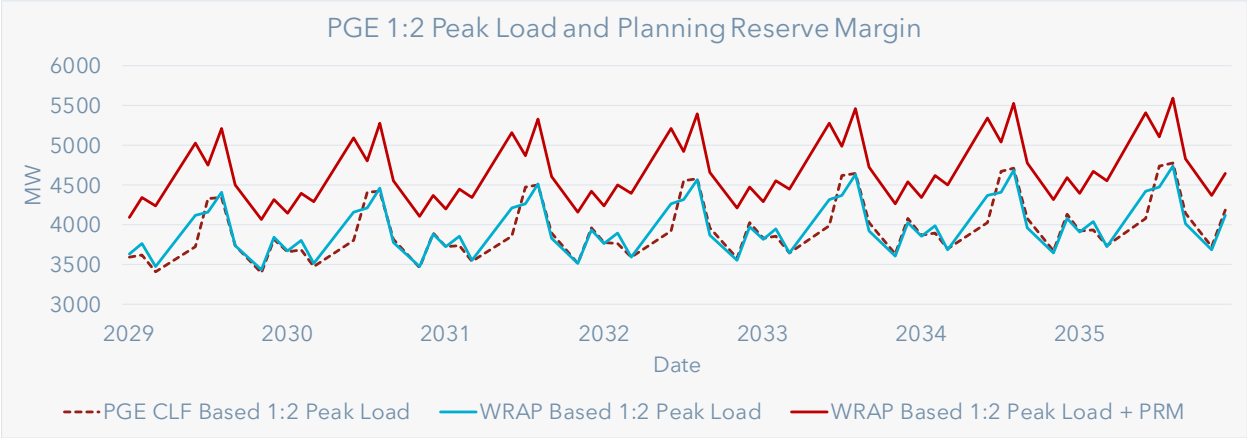
In addition to the transmission planning specific standards, there are a number of additional NERC standards in which transmission planning is involved. These include:

- Establishing requirements for generation requesting to interconnect to the Bulk Electric System (FAC-001)
- Establishing a study process for generation interconnection (FAC-002)
- Vegetation management practices near transmission lines (FAC-003)
- Development of detailed generator models, including real and reactive power capabilities (MOD-025), exciter models (MOD-026), and governor and turbine models (MOD-027)
- Coordination of transmission base case development (MOD-032) (Note: PGE and neighboring utilities coordinate this process through the Western Power Pool and the Western Electricity Coordinating Council)
- Validation of transmission base cases for both steady-state and transient stability, utilizing recorded historical events (MOD-33)

- Development of Underfrequency Load Shedding (PRC-006) and Undervoltage Load Shedding (PRC-010) schemes to maintain system stability during extreme transient events.

These related study efforts help ensure that the future state of the transmission system is modeled accurately and that planners can make the best long-term decisions regarding necessary upgrades to reliably maintain the grid.

Appendix I Inputs for state RA requirements portfolio



PGE used demand and supply assessment methods from the Western Resource Adequacy Program (WRAP) to analyze the adequacy of PGE's system across the IRP planning horizon. These methods provide the primary metrics needed to derive capacity need and ELCCs for portfolio modeling based on State RA Requirements, which currently rely on WRAP methodology. WRAP metrics for Summer 2026 and Winter 2025-2026 in the MID-C subregion, and WRAP's 2025 qualifying capacity contribution (QCC) estimates for PGE resources are the primary inputs for this exercise.[174,175]

I.1 WRAP based load forecast

PGE estimated load requirements using WRAP methodology for seasonal peak load forecasts plus the WRAP estimated PRM required to achieve a 1 event in 10 years adequacy metric. 5-years of historical PGE load data was used to estimate 1:2 peak load for summer (May-September) and winter (November-March) months as described in WRAP Business Practice Manual (BPM) - 103 – Participant Forward Showing Capacity Requirements.[176] A PGE specific annual growth rate of 1.2 percent was used to scale peak loads across the planning horizon.[177] This growth rate was estimated using PGE's May 2024 load forecast. WRAP's month specific PRM was applied to the resulting load forecast to arrive at estimated load requirement by month.[178] **Figure 94** shows the resulting load forecast for a portion of the planning horizon with and without the PRM. For comparison the median of maximum peak monthly load from the PGE's May 2024 Corporate Load Forecast (CLF) is show. The figure shows there is close alignment in estimated 1:2 peak loads from PGE estimates and WRAP based estimates. There is a divergence in the month of June due to a heavier weighting of the 2021 heat dome event as only 5 years of historical load data are used in the WRAP based estimates.

[174] WRAP Metrics for Summer 2026
[175] WRAP Metrics for Winter 2025-2026
[176] WRAP BPM 103
[177] WRAP's established growth rate is 1.1%, as defined in WRAP BPM-103. 1.1% was defined through and informal survey process, as described in the WRAP's Detailed Design Document – March 2023. Rather than use the establish growth rate for this exercise, PGE elected to estimate a growth rate specific its system.
[178] Preliminary values published 3-31-2024 used for winter season months.

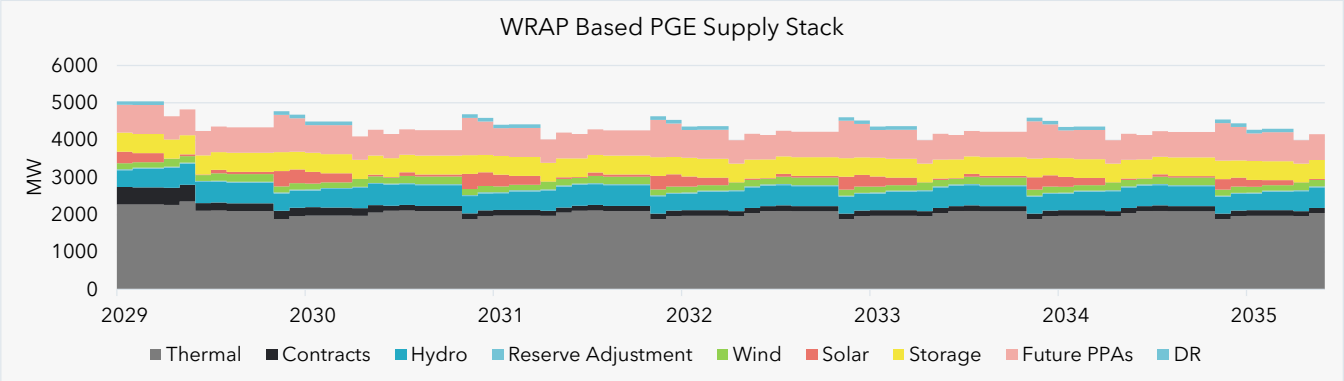


Figure 94. WRAP Based PGE 1:2 Peak Load and Planning Reserve Margin

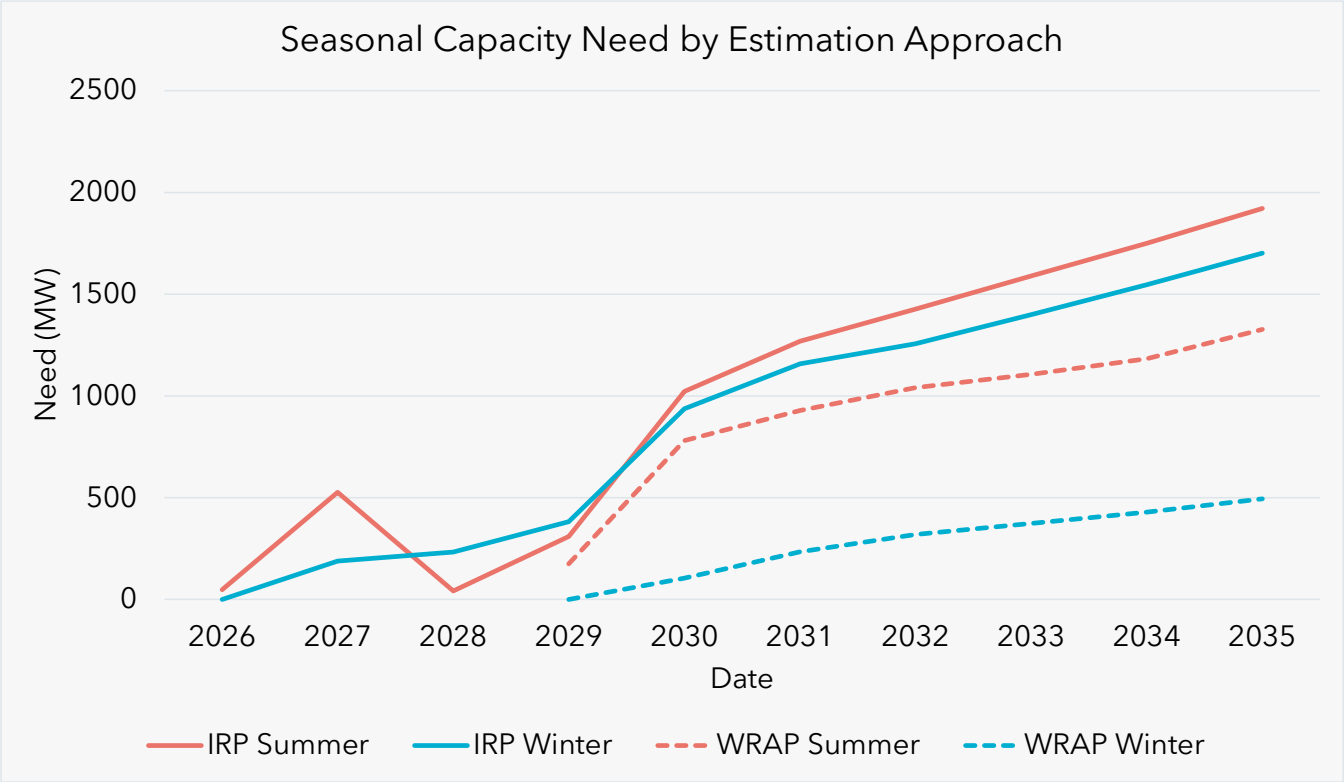
I.2 WRAP based supply forecast

The company used WRAP provided estimates of resource specific QCC values to estimate the capacity contribution of existing PGE resources in each month of the WRAP summer and winter seasons. WRAP's Winter 25-26 Forward showing (FS) and Summer 2026 FS qualifying capacity values were used capacity assumptions across the planning horizon. Exits and entry from the supply stack were assumed in accordance with assumptions used for resource adequacy modeling in Sequoia. For example, exits were assumed based on known contract expiration dates for the related resources or structured agreements and 2023 RFP Proxy resources were assumed to enter the supply stack in January 2028. **Figure 95** displays the supply assumptions that resulted from this WRAP based forecast.

Figure 95. WRAP Based PGE Supply Stack



I.3 WRAP based capacity need

Capacity need was calculated using the difference between WRAP based forecasts of load requirements and supply, as detailed above. **Figure 96** shows the resulting capacity need as compared to the IRP derived capacity need values as estimated in Sequoia. 2030 capacity need

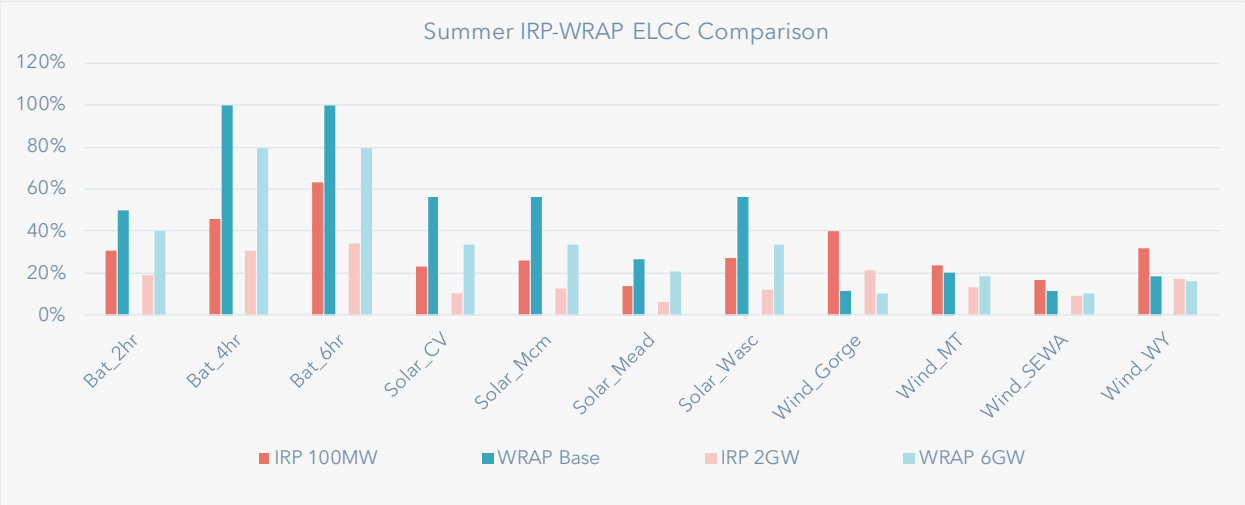
is approximately 250 MW less in Summer and 830 MW less in Winter using the WRAP based methods, compared against the IRP estimates from Sequoia.

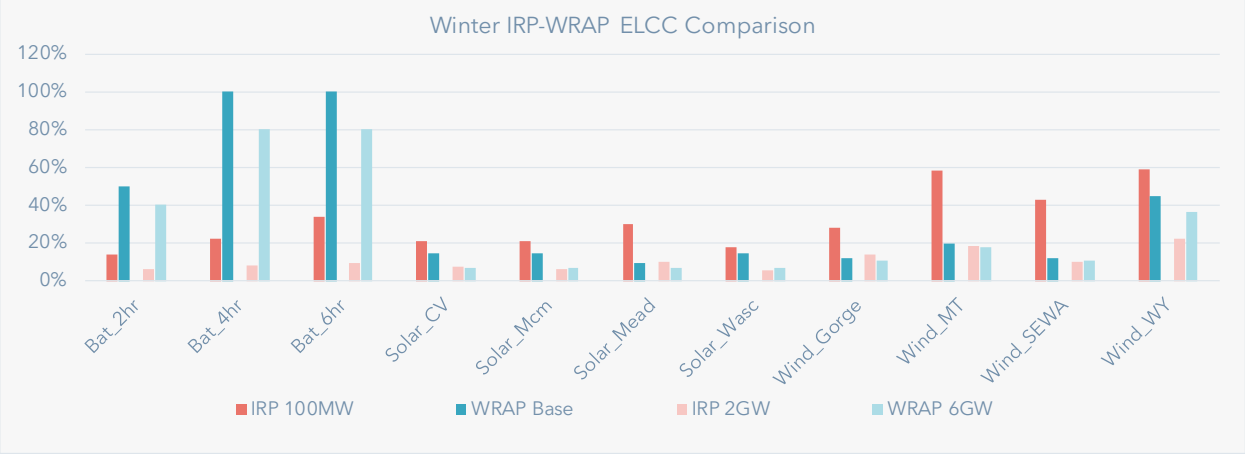
Figure 96. Seasonal Capacity Need by Estimation Approach

I.4 WRAP based ELCCs

PGE used ELCC estimates from WRAP's summer 2025 and winter 2025-2026 adequacy assessment for the valuation of Proxy Resources in portfolio expansion modeling. The company elected ELCC values from the +6 GW entry scenarios provided by WRAP. **Figure 97** shows a comparison of WRAP based ELCCs for the base system and +6 GW scenarios against ELCCs estimated in Sequoia for 100 MW and 2000 MW tranches. In general, summer WRAP ELCCs for storage and solar resources are significantly greater than IRP estimates for resources within the same WRAP zones. Wind resources show less divergence between the two estimation approaches, save for Gorge Wind, which has a predominantly summer generation profile.

Figure 97. Summer IRP-WRAP ELCC Comparison





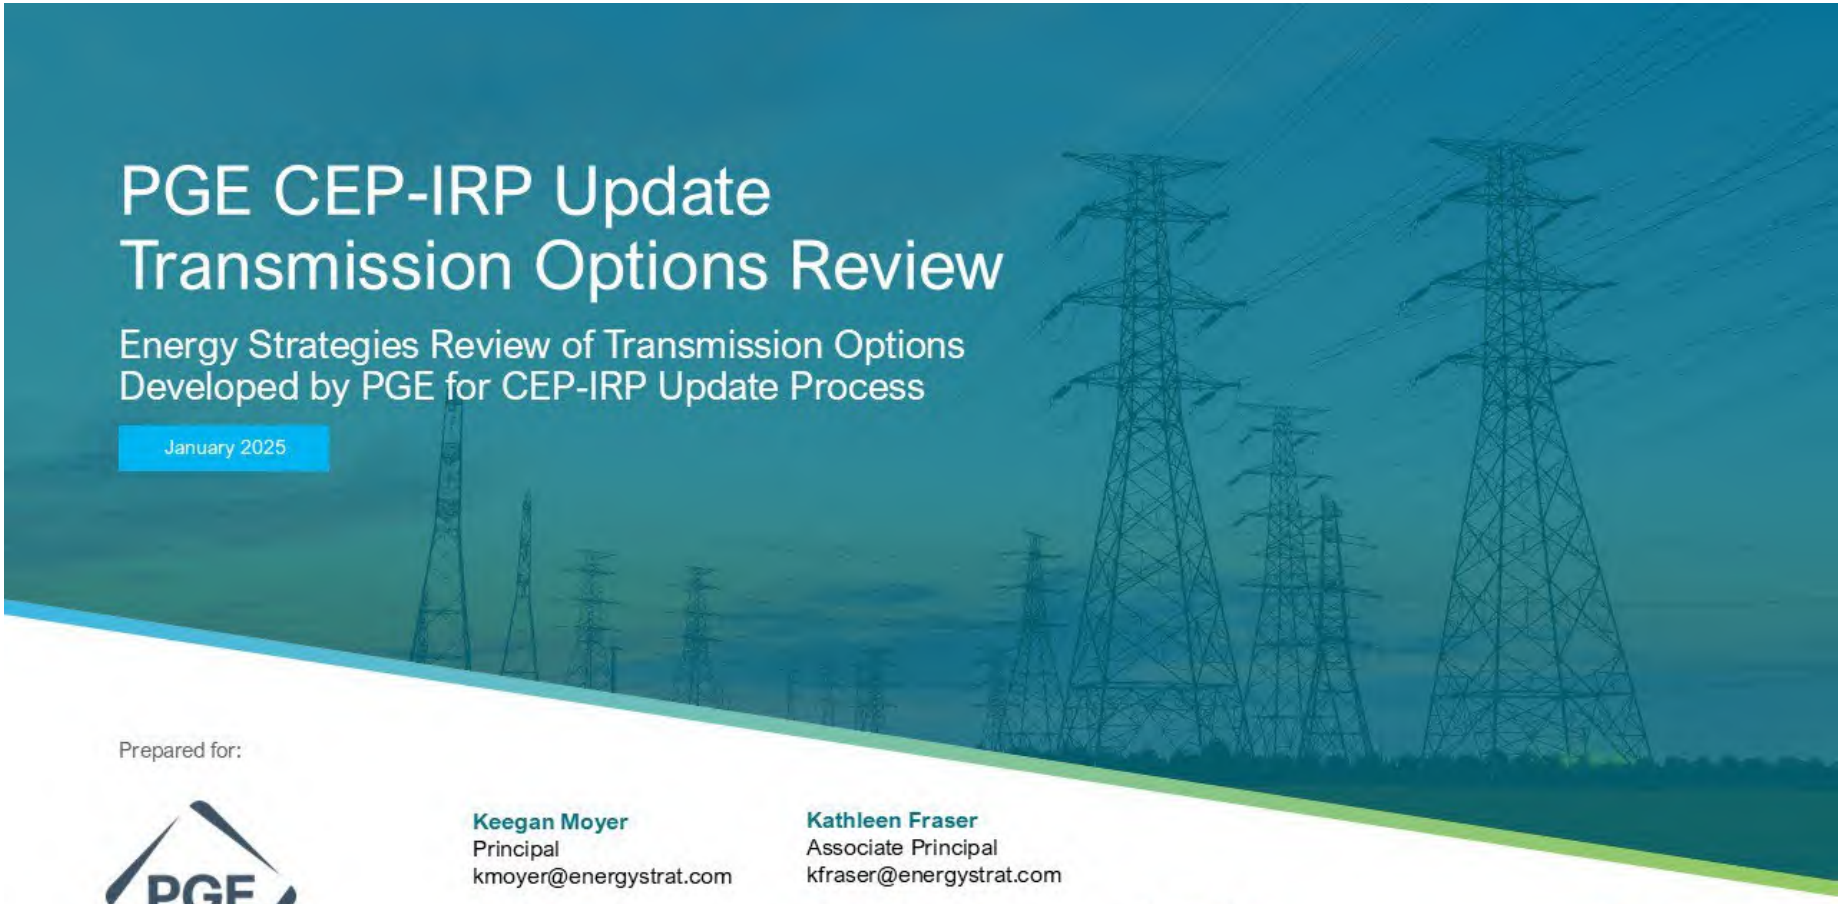


Figure 98 shows a similar comparison for the winter season. Winter WRAP ELCCs for storage resources continue to be significantly greater than IRP estimates for similar storage resources, while IRP estimates of solar and wind resources are greater.

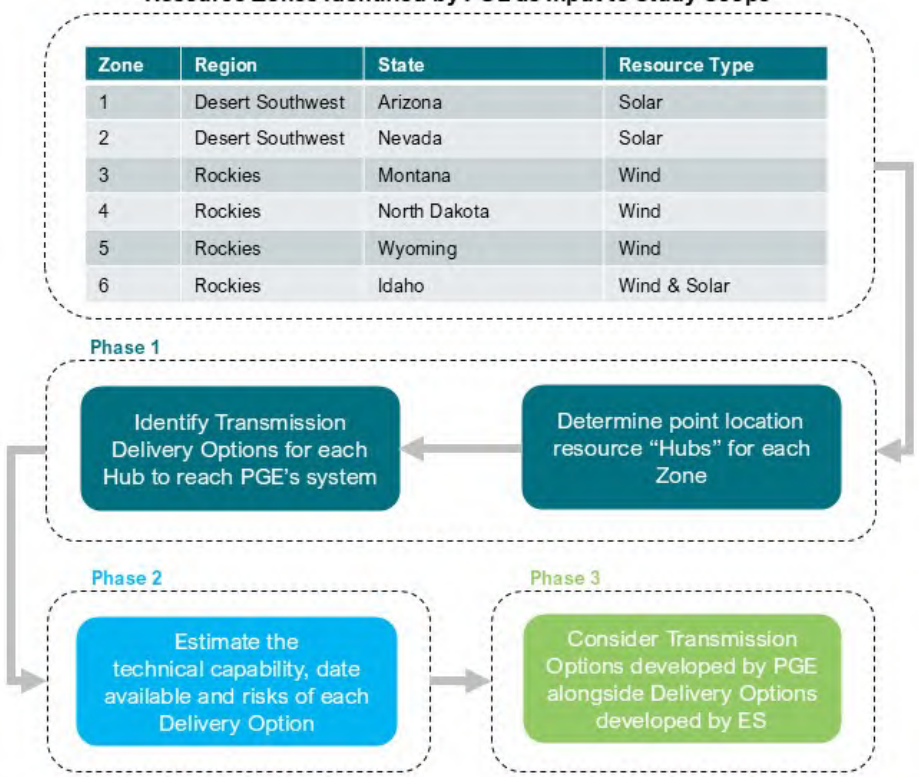
Figure 98. Winter IRP-WRAP ELCC Comparison

For PGE's Proxy Resources without a direct overlap with WRAP ELCCs, the following assumptions were made: North Dakota Wind assigned ELCC values for WRAP Region 4 (Colorado and Wyoming), Batteries greater than 6-hour duration assigned WRAP ELCCs for 4-hour batteries, hybrids assigned the sum of WRAP based solar and 4-hr battery ELCCs, while other smaller resources (e.g., EE, DERs, CBREs) maintained ELCCs as estimated in Sequoia.

Appendix J Transmission options study



ENERGY STRATEGIES

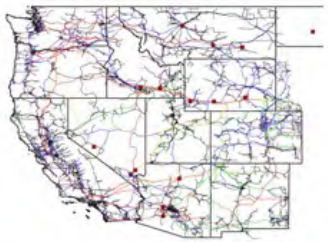
Work Scope

- **Portland General Electric (PGE) engaged Energy Strategies (ES) to identify and evaluate transmission strategies to access remote resources.**
  - Designed to help PGE evaluate options to efficiently meet load and policy requirements in its Clean Energy Plan and Integrated Resource Plan (CEP-IRP).
- **The study consists of three phases:**
  1. **Identify Transmission Delivery Options** for six Resource Zones, considering:
     - Existing transmission system (e.g., Available Transfer Capacity (ATC))
     - Known or previously proposed transmission upgrades
     - New transmission upgrades
  2. **Characterize technical and risk profiles** of each feasible delivery option.
  3. **Review Transmission Options** developed by PGE and propose alternatives based on assessment.

Resource Zones Identified by PGE as Input to Study Scope

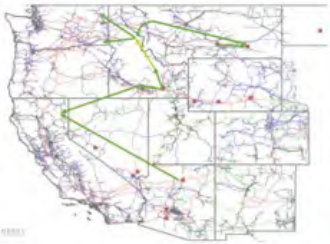
Zone	Region	State	Resource Type
1	Desert Southwest	Arizona	Solar
2	Desert Southwest	Nevada	Solar
3	Rockies	Montana	Wind
4	Rockies	North Dakota	Wind
5	Rockies	Wyoming	Wind
6	Rockies	Idaho	Wind & Solar

PGE | IRP Regional Transmission Study



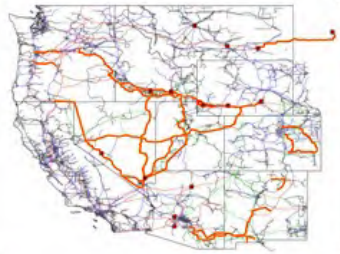
ENERGY STRATEGIES

Transmission Delivery Options Development Methodology & Results



1 Resource Zones identified by PGE

Zone	State and Resource(s)
1	Arizona Solar
2	Nevada Solar
3	Montana Wind
4	North Dakota Wind
5	Wyoming Wind
6	Idaho Wind & Solar



2 Establish Resource Hubs

3 Review ATC Postings on OASIS

4 Include Likely Transmission Upgrades

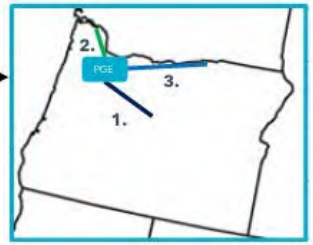
Interim selection of Transmission Delivery Options by Energy Strategies:

State and Resource	Description	Capacity (MW)	Date Available
Arizona Solar	APS ATC + NVE Expansion + existing NWACI + PGE Rights	183	~2035-2040
	APS Upgrade + NVE Expansion + existing NWACI + PGE Rights	550	2040+
Nevada Solar	NVE Expansion + updated NWACI + Bethel Round Butte	~600	~2035-2040
	SWIP N + Gateway West 8 + B2H + new BPA TSRs	400	~2035-2040
Montana Wind	Existing PGE Rights after Colstrip retired	270	2030
	PGE rights + new BPA & possibly NWMT TSRs	~1000	~2035-2040
North Dakota Wind	North Plains Connector + PGE rights + new BPA + NWMT TSRs	~1000	~2035-2040
Wyoming Wind	Gateway West & B2H + new BPA TSRs	400	~2035-2040
Idaho Wind & Solar	Gateway West & B2H + new BPA TSRs	400	~2035-2040
	New Hemingway -> Grizzly line + Bethel Round Butte	~1000	2040+

Highlighted Transmission Options Correspond to PGE Transmission Options from prior IRP roundtables

3

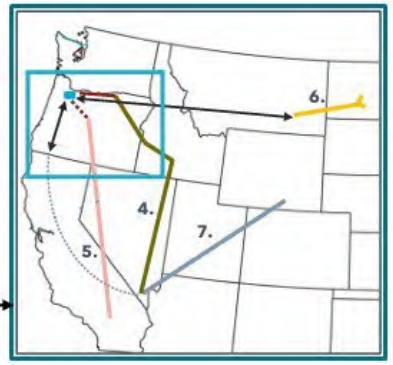
PGE | IRP Regional Transmission Study



ENERGY STRATEGIES

Review of PGE's Transmission Options from Prior Roundtables

- **Energy Strategies work scope included a review of Transmission Options developed by PGE:**
  - At the direction of the Oregon Public Utility Commission (PUC), PGE to update 2023 CEP-IRP Transmission Options.
  - As part of the CEP-IRP Update process and monthly public roundtables, PGE has developed 7 Transmission Options and asked Energy Strategies to review these options as a part of its broader work scope:
    1. **Are these options appropriate to meet the PUC's direction?**
    2. **What are the risks for each?**
    3. **Of the transmission alternatives identified by Energy Strategies, do any serve as viable alternatives?**



Seven Transmission Options Identified in PGE CEP-IRP Roundtables

1. Bethel-Round Butte
2. Trojan-Harborton
3. Cascade Renewable Transmission Project
4. SWIP N + Gateway West 8 + B2H
5. Western Bounty
6. North Plains Connector
7. TransWest Express

Oregon/PNW specific transmission options

As the ES work scope did not consider stand alone intra-Oregon transmission, we will provide comments but cannot propose alternatives at this time.

Remote resource transmission options

With the consideration of remote resource zones in the ES scope, we assess the viability of these transmission options and propose alternatives as needed.

4

ENERGY STRATEGIES

Overview of Findings from Review of PGE Transmission Options

Resource Area	PGE Transmission Option	ES Alternatives to Consider	Recommendation
North Dakota (Wind)	**North Plains Connector**	No alternatives recommended	• With PGE's Colstrip rights and NWMT + BPA TSRs, North Plains Connector is the best option. • Based on development status and need for downstream upgrades, recommend first available date no sooner than 2035 (perhaps later).
Wyoming (Wind)	**TransWest Express + CAISO**	Gateway West & B2H	• There is significant policy and pricing risk to using TransWest Express, without providing firm transmission access. • Using Gateway West may require upgrades to existing lines to increase transfer capacity.
Nevada (Solar)	**Western Bounty**	Greenlink and PGE's Rights + Upgrades	• Western Bounty likely too early in development to reach service before mid- to late-2030s. • Combining NVE's Greenlink with PGE's rights and upgrades provides a lower risk alternative to consider.
Nevada (Solar)	**SWIP N + Gateway West 8 + B2H**	No alternatives recommended	• This transmission option represents a strong option but would require additional TSRs on the BPA introducing timing risk.

- **Resource areas evaluated by ES not captured by PGE transmission options:**
  - Arizona
  - Idaho
  - Montana
- **Resource areas and transmission options in PGE CEP/IRP Roundtables outside ES scope:**
  - OR/WA/BPA
    - Bethel – Round Butte
    - Trojan – Harborton
    - Cascades Renewable Transmission
  - CAISO

PGE | IRP Regional Transmission Study

ENERGY STRATEGIES

"Evolving Grid" Status Improves Transmission Service-Driven Upgrades, but Significant Uncertainty Remains

- **BPA's Evolving Grid initiative prioritizes significant transmission projects that are critical to meet regional needs in the PNW.**
  - Initiative supports upgrades that will improve resource deliverability in the coming decade, attempting to address cyclical nature of TSRs triggering recurring upgrades in TSEP cycles and eventually dropping out.
  - Evolving Grid is designed to provide an actionable path forward primarily for projects that were identified in BPA's 2021, 2022 and 2023 TSEP processes and relate to specific TSRs.
- **Despite this step, BPA has not yet committed to constructing these projects and many still have several years of scoping, design and NEPA milestones prior to a BPA decision to fund and construct.**
  - In-service dates for EVG 1 projects: ~2026-2032.
  - In-service dates for EVG 2 projects: not announced, but possibly mid-late 2030s.
- **Conclusion for this work: Evolving Grid 1.0 projects create capacity that is likely "already spoken for" by existing TSRs (and generation projects PGE is likely aware of via RFPs) and Evolving Grid 2.0 projects have too many uncertainties to forecast impact at this time.**
  - Therefore, for this study we assume generic "new BPA TSRs" are needed for service on or through BPA to reach PGE and recommend continued monitoring of both sets of Evolving Grid projects.

Evolving Grid 1.0

1	Cross Cascades North Upgrades • Schultz-Raver 500 kV Line Upgrade • Paul 500 kV Substation Upgrade • Olympia 230 kV Substation Upgrade
2	Big Eddy-Chemawa 230/500 kV Line Upgrade

ENERGY STRATEGIES

PGE Transmission Options Review – Overview of Contents

1. **PGE Transmission Options to access remote resources:**
   - SWIP N + Gateway West 8 + B2H
   - Western Bounty
   - North Plains Connector
   - TransWest Express Transmission Project

2. **Appendix: PGE Transmission Options specific to Oregon/PNW:**
   1. Bethel – Round Butte 500kV Upgrade
   2. Trojan – Harborton Upgrade
   3. Cascades Renewable Transmission Project

ENERGY STRATEGIES

SWIP N + Gateway West 8 + B2H

Details from PGE's CEP-IRP Update Roundtable:

- *This option entails PGE purchasing access on five transmission lines leading to the desert southwest:*
  1. *Boardman to Hemingway (B2H)*
  2. *Gateway West segment E8*
  3. *Southwest Intertie Project (SWIP) – North*
  4. *One Nevada Transmission Line (ON Line)*
  5. *Desert Link*
- *This is achievable by **2027** (line COD). However, this option would require additional access across BPA's system, which is plausibly expected by **2032** (IRP COD).*
- *Up to **600 MW** of Nevada solar is modeled to be enabled through this option.*

SWIP N + Gateway West 8 + B2H:

- **Energy Strategies' conclusions:**
  - SWIP N + Gateway West 8 + B2H is a viable transmission option to access Nevada generation – it involves transactions with three transmission providers: 1. NVE, 2. PacifiCorp or Idaho Power, and 3. BPA.
  - Up to 400 MW of Nevada solar can be accessed, with unallocated transmission capacity on B2H as the limiting segment (see details on next slide).
  - Boardman (Longhorn) to PGE requires additional TSRs on the BPA system.
  - Earliest Date: 2035-2040, with greatest timing risk related to receiving additional TSRs on BPA system and availability of capacity on B2H.

ENERGY STRATEGIES

SWIP N + Gateway West 8 + B2H: Details

- **Energy Strategies' determination of rights on each segment:**

Segment	Description	Rights MW	Est. Date Available
NVE	ATC from Greenlink projects (Southsys to Northsys)	~550 (1)	2029
SWIP North	Utilizing DOE's northbound entitlements	500 (2)	2027 COD
Gateway West E8	Utilizing forecasted available transmission	600 (3)	2028 COD
B2H	Use currently unallocated 218MW of PAC rights and 182MW of IPCo rights	400 (4)	2026 COD
Longhorn to PGE	New BPA TSRs – see prior slides	400	2035-2040
	Rights and Date Available entire path:	**400**	**2035-2040**

SWIP N + Gateway West 8 + B2H:

(1) ATC from OASIS Postings, Southsys to Northsys, 550MW represents minimum during 2029-2033 period (Expansion entails Greenlink West, Greenlink North).
(2) For SWIP-North, CAISO and the DOE hold a combined 1072.5 MW of entitlements in the northbound direction. We assume that PGE could request and acquire up to 500 MW (equal to DOE's entitlements) (sources: here and here).
(3) Gateway West Segment E8 will have a transfer capacity of 2000 MW. Energy Strategies assumes PGE can request and receive 600 MW of capacity (source: PacifiCorp here).
(4) From IPCO for B2H (CPCN documents filed by IPCO here and here).

Western Bounty

Details from PGE's CEP-IRP Update Roundtable:

- *The Western Bounty Transmission System is a proposed 3000 MW HVDC line that could connect southern California to the Grizzly substation*
- *The projected commercial operation date (COD) is **2033***
- *Up to **3000 MW** of Nevada solar is modeled to be enabled through this option*
- *This option would provide access to the SP-15 market hub*
- *Additional BPA upgrades would be required for this option to reach PGE*

Western Bounty

- **Energy Strategies' conclusions:**
  - Western Bounty early in its development cycle and unlikely to materialize before mid- to late-2030s based on historical transmission development rates.
    - Development started in 2023 with the Interregional Transmission Project (ITP) joint evaluation process only starting in 2024. Project is early stage.
  - The scope, timing and available capacity of necessary BPA upgrades would likely limit PGE's 3000 MW of proposed solar access to a smaller amount – we do not recommend assuming 3000 MW of availability.
  - As an alternative, NVE's Greenlink expansion that increases ATC on their system, together with PGE's rights on the Northwestern AC Intertie (NWACI) and the Bethel – Round Butte upgrade, could be utilized to access resources within a similar proposed timeframe (details provided on next slide).

ENERGY STRATEGIES

Western Bounty Alternative: NVE Expansion and PGE rights

- **NVE Greenlink expansion and PGE's rights and projects as an alternative to Western Bounty for access to southwest solar:**
  - With NVE's Greenlink expansion, Southsys to Northsys capacity increases, creating additional ATC which PGE can utilize.
  - Pros:
    - Less risk in terms of parties involved and permitting timelines: NVE taking lead on "Greenlink 3" (Fort Churchill -> Captain Jack).
    - The expected route for Greenlink 3 roughly falls within the "Mountain – Northwest" National Interest Electric Transmission Corridor meaning any environmental review process under NEPA could be expedited as part of DOE's National Transmission Needs Study.
  - Cons:
    - Available capacity is less than considered with Western Bounty, however the 3000 MW envisioned capacity on Western Bounty would be limited by BPA upgrades.
- **Conclusion: Less risk and same desired timeframe and capacity potential as Western Bounty.**

Greenlink vs. Western Bounty:

ID	Element	Description	Rights MW	Est. Date Available
1	NVE	ATC from Greenlink projects (Southsys to Northsys)	~550 (1)	2029
2	Greenlink 3	Fort Churchill -> Captain Jack (early stage proposed by NVE)	725 (2)	2035-2040
3	Captain Jack -> Grizzly	Planned contractual updates to allow intra-region scheduling on the Northwest AC Intertie (NWACI) and use PGE's existing rights.	627 (3)	2029
4	Bethel – Round Butte Upgrade	TTC depends on configuration but not limiting segment in path	~3000 (4)	2032
		Rights and Date Available entire path:	**627**	**2035-2040**

(1) ATC from OASIS Postings, Southsys to Northsys, 550MW represents minimum during 2029-2033 period (Expansion entails Greenlink West, Greenlink North).
(2) NVE IRP Filing on initial study work related to Fort Churchill -> Captain Jack (Greenlink 3) (sources: here and here)
(3) Data from PGE.
(4) Data from PGE.

North Plains Connector

Details from PGE's CEP-IRP Update Roundtable:

- *This project is a 412-mile HVDC transmission line to be constructed with endpoints near Bismarck, North Dakota and Colstrip, Montana.*
- *PGE currently has **270 MW** of rights from Colstrip to PGE.*
- *If nothing changes between now and 2032, only a combined 270 MW NPC will be available for model selection.*
- *However, the company has submitted TSRs for an additional 720 MW across both BPA's and NorthWestern's systems.*
- *Up to 3000 MW of North Dakota wind is modeled to be enabled through this option, subject to the constraints mentioned above.*
- *Additionally, this option would provide access to the MISO Resource Zone 1 market.*
- *This option's COD is expected by **2032**.*

North Plains Connector:

- **Energy Strategies' conclusions:**
  - With PGE's existing rights from Colstrip, this project represents the best option to access North Dakota wind.
  - However, the timing to receive requested BPA and NWMT TSRs, as well as early stage of project development, are not consistent with a 2032 availability - we suggest a late 2030s timeframe may be more appropriate given historical greenfield transmission development timelines.
  - As already noted above, the actual MW capacity of access will be limited by PGE rights from Colstrip and pending TSRs.

PGE | IRP Regional Transmission Study

ENERGY STRATEGIES

TransWest Express Transmission Project

Details from PGE's CEP-IRP Update Roundtable:

- *This project is a two-part line that connects near Sinclair, WY and near Boulder City, NV:*
  - *Near Sinclair, WY to near Delta, UT: 3000 MW DC*
  - *Near Delta, UT to near Boulder City, NV: 1500 MW AC*
- *This option is being structured as a gen-tie through CAISO, which PGE can access using its rights at the California-Oregon Border (COB) trading hub.*
  - *This line could add up to approximately 3,000 MW of transmission access, however PGE's COB rights limit access to 600 MW of Wyoming Wind.*
  - *No other market access benefits assumed.*
- *The anticipated COD for this option is 2027 and would not require any additional transmission expansion.*

TransWest Express Transmission Project:

- **Energy Strategies' conclusions:**
  - PGE would need to be a subscriber on TWE and deliver to Eldorado; then make a market purchase at California Oregon Border (COB) which may be subject to paying CAISO transmission access charge (TAC).
    - This strategy would also be subject to basis risk between Eldorado and COB (or require a developer to carry this risk).
    - Would also likely need to ensure the transaction was designated as a high priority wheel-through.
    - This results in potentially high cost of transmission to access WY wind.
  - Other factors to consider include CAISO LSEs obtaining all TWE capacity (for reliability/clean energy needs), lack of ability to document delivery to PGE given lack of firm service, significant policy risk and dependence on CAISO market rules.
  - An alternative using Gateway West and B2H may be viable but has risks in timing and availability of capacity.

14

ENERGY STRATEGIES

TransWest Express Alternative: Utilizing Gateway

- **Utilizing the Gateway buildout as an alternative to TransWest Express for access to Wyoming wind:**
  - Pros:
    - Provides access to Wyoming wind on a firm basis while avoiding the policy and pricing risks that would be associated with CAISO market transactions.
  - Cons:
    - Puts PGE in competition with PAC and IPCo and would require timely granting of TSRs on all systems.
- **Conclusions: Neither TransWest Express nor the Gateway alternative are ideal options**
  - PGE may be unable to secure affordable transmission access to Wyoming wind on a firm basis in the 2030s.

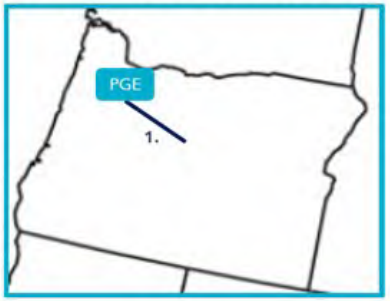
Gateway West vs. Transwest Express:

ID	Element	Description	Rights MW	Est. Date Available
1	Gateway West: Anticline -> Populus	Completing construction of Gateway West segment D-3	400 (1)	2031
2	Gateway West: Populus -> Hemingway	Completing construction of Gateway West segment E	400 (1)	2036
3	B2H	Use currently unallocated 218MW of PAC rights and 182MW of IPCo rights	400 (2)	2026 COD
4	Longhorn to PGE	New BPA TSRs.	400	2035-2040
		Rights and Date Available entire path:	**400**	**2035-2040**

(1) Gateway West segment E8 will have a transfer capacity of 2000 MW. Energy Strategies assumes PGE can apply for 400 MW of capacity (source: PacifiCorp here).
(2) (2) From IPCO for B2H (sources: IPCO here and here).

Appendix: Review of PGE Oregon/PNW Specific Transmission Options

PGE | IRP Regional Transmission Study



ENERGY STRATEGIES

Bethel – Round Butte 500kV Upgrade

Details from PGE's CEP-IRP Update Roundtable:

- *The Bethel-Round Butte reconductoring would increase the capacity on the existing line.*
- *The line is 98 miles, running from the Bethel substation (near Salem) to the Round-Butte substation.*
- *The projected commercial operation date (COD) is **2032** and will not require any other transmission expansion for PGE to access these benefits.*
- *Rebuilding the line from 230 kV to 500 kV will increase capacity.*
- *This could support an increase of **2,385-4,770 MW** increase in 'BPA' resources (off-system resources in the PNW region), depending on specification and subsequent path rating processes.*
- *This option provides market access to the California-Oregon border.*

Bethel – Round Butte 500kV Upgrade:

- **Energy Strategies' conclusions:**
  - As noted in the PGE 2023 CEP/IRP this upgrade is a "no regrets" option and facilitates significant access to queued resources.
  - However, depending on the reconductoring configuration chosen, the total transfer capacity is likely to reach only 3000 MW.

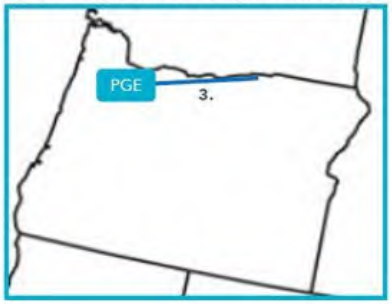
ENERGY STRATEGIES

Trojan – Harborton Upgrade

Details from PGE's CEP-IRP Update Roundtable:

- Approximately 34 miles long, running between PGE's Trojan and Harborton substations, paralleling two existing lines in service since the 1970s.
- PGE currently owns the additional unused ROW necessary for the project and has since the 1970s.
- The projected commercial operation date (COD) is **2032** and will not require any other transmission expansion for PGE to access these benefits.
- This transmission project will enable **800 MW** from BPA's generation resources, subject to cooperative study and agreement with other South of Allston path owners, BPA and PacifiCorp.

Trojan – Harborton Upgrade:



- **Energy Strategies' conclusions:**
  - With the importance of South of Allston and the control over right of way and facilities PGE possesses which are necessary to complete this upgrade, completing Trojan – Harborton upgrades appears "no regrets" similar to the Bethel – Round Butte upgrade.
  - In addition to the mentioned need to coordinate with other South of Allston path owners, timing of benefits from this upgrade is not certain:
    - Realizing the 800MW of BPA generation resources seemingly requires receipt of TSRs PGE has applied for on the BPA system and likely date to receive these TSRs is closer to 2035 than the proposed 2032 COD of this upgrade option.

Cascade Renewable Transmission Project

Details from PGE's CEP-IRP Update Roundtable:

- This project involves an electric transmission cable bundle, buried entirely underground and underwater, along with two converter stations located next to existing substations.
- This travels approximately 100 miles, primarily beneath the Columbia River, from the Big Eddy substation to the Harborton substation.
- The projected commercial operation date (COD) is **2032** and will require additional BPA and PGE transmission expansion for PGE to access these benefits.
- This is modeled to enable the transfer of **1,100 MW** of 'BPA' resources (off-system resources in the PNW region).
- PGE is not currently participating in this project, but involvement may be possible if selected as part of PGE's preferred portfolio.

Cascade Renewable Transmission Project:

- **Energy Strategies' conclusions:**
  - The point of delivery at Harborton makes PGE well-positioned to realize benefits from access to BPA resources.
  - The timing for 1260 MW of solar + storage projects in BPA's Queue at Big Eddy as well as the Cascade Renewable Transmission Project's own queue position (all seeking interconnection/energization in 2029) seems aggressive given the early stage of development for this project.
    - With the challenges to work in the Columbia River, especially from a permitting perspective, late 2030s more likely as a time for project COD.

2024 Environmental, Social and Governance Report

Advancing toward a clean energy future

About this report

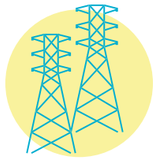
This report outlines Portland General Electric's (PGEs) commitment to advancing environmental, social and governance values core to our business through responsible practices.

We disclose data under the Edison Electric Institute (EEI) ESG Quantitative Template, Sustainability Accounting Standards Board (SASB) and Task Force on Climate-Related Financial Disclosures (TCFD) to provide stakeholders information about how we identify, measure and manage the subset of environmental, social and governance topics that most directly impact long-term enterprise value. The inclusion of information in this report should not be interpreted as characterization regarding the materiality or financial impact of that information.

About Portland General Electric

Portland General Electric is a fully integrated energy company that generates, transmits and distributes electricity, serving roughly half of Oregon's population and nearly two-thirds of its commercial and industrial activity.

CORPORATE STRATEGIC IMPERATIVES



Decarbonize

Reduce greenhouse gas emissions associated with electricity served to retail customers by at least 80% by 2030 and 100% by 2040.

Electrify

Increase beneficial electricity use to capture the benefits of new technologies while building an increasingly clean, flexible and reliable grid.

Perform

Improve efficiency, safety and system and equipment reliability while maintaining affordable energy service and growing earnings per share 5% to 7% annually.

"At the heart of Portland General Electric's work is an enduring commitment to our responsibility to provide safe, reliable and affordable energy to every customer and community we serve."

Letter from our President and CEO

At the heart of Portland General Electric's work is an enduring commitment to our responsibility to provide safe, reliable and affordable energy to every customer and community we serve.

Today, our company works at the intersection of important changes in society from the onshoring of manufacturing to the transition to clean energy and the risk of extreme weather events, especially wildfires. The decisions we make and the results we achieve help shape the future of the Pacific Northwest and the country.

As the energy industry experiences rapid change, aligning our core values with our business practices is essential to earning and maintaining the trust of customers and stakeholders. When we ground our business strategy in our values, we can better identify and mitigate the risks of a changing climate, prioritize investments in safety, resilience and reliability for customers, and innovate to deliver affordable electricity.

PGE made sustained progress toward our clean energy goals in 2024. The carbon intensity of the power supply declined to 0.27 MTCO2e per MWh in 2024, despite load growth on our system. Of the energy our company generated and procured in 2024, 45% came from clean, non-carbon emitting sources, a 7% compounded growth rate in our non-emitting resource mix since 2020, building on our commitment to reach net-zero carbon emissions by 2040.

New renewable energy resources from the Clearwater Wind Energy Center and battery storage systems brought increased availability and reliability to our energy mix. These systems, along with the rest of PGE's technology and infrastructure, work together to provide reliable, clean energy even when the wind doesn't blow and the sun doesn't shine.

In 2024, PGE strengthened our commitment to environmental stewardship. As Oregonians, we care deeply about the natural beauty and natural resources that make our state one of the best places to live. In everything we do, we strive to protect those resources for the benefit of all. Our salmon restoration projects, youth engagement programs and clean energy job internships all serve to protect resources and engage future generations.

I am very proud of the work we are doing to create an inclusive environment within our company. Grounded in our company's Guiding Behaviors, over the last ten years, we have seen a 9% increase in the number of women at PGE and a 38% increase in women in leadership. The number of Black, Indigenous and People of Color in our company grew by 39% overall and 110% in leadership.

PGE employees are also active members of the community in which we live and work, with PGE employees and retirees completing 22,957 volunteer hours during the year. The company contributed $5.5 million to charity though corporate contributions, the PGE Foundation, current and retired employee contributions and our company match program. Contributing to economic growth and community development in our service area remains an important part of PGE's culture.

Portland General Electric remains deeply committed to being responsible stewards of Oregon's vital resources. It will take all of us, working together and guided by our shared values, to power a prosperous, clean and vibrant future.

Maria Pope
President and CEO, PGE

"As PGE grows and evolves to meet some of the most pressing challenges of our time, our environmental, social and governance strategy aligned with our core values will continue to guide us to shared success."

Letter from our Vice President, Policy and Resource Planning

At PGE, we pride ourselves on providing excellent service and being effective stewards of our resources. For more than 130 years, we've been a trusted partner to the communities we serve. Our commitment to customers, to environmental stewardship, to employees and their communities, to ethical conduct, transparency and sound governance has never wavered. We anchor our business decisions in these commitments, informed by the best available science and technology, to ensure reliable, affordable electricity service for the communities we serve.

PGE's holistic approach reflects our company's core values of service, accountability, affordability and sustainability and balances environmental, social and governance goals with our core mission to power Oregon's economy and communities. This is underscored by our commitment to deliver long-term results for our stakeholders, including our customers, shareholders and communities.

In recent years, PGE has aggressively pursued Federal grant and tax credit opportunities to lower costs while growing the Company's renewable energy portfolio. We developed programs and technologies that help customers manage their energy use, pursued capital raises through green financing, and attracted and retained a dedicated, talented and diverse workforce.

In 2024, we continued our commitment to delivering shared success through responsible business practices across all operational areas.

Since 2021, the year PGE first committed to an ambitious 80% emissions reduction target for 2030, PGE and its customers have committed to adding the equivalent of more than 2,900+ MW of new clean energy resources to the grid, including energy efficiency, rooftop solar and flexible demand response programs.

The new Clearwater Wind Energy Center increased our total wind generation to more than 1,000 MW a day — enough to power all our residential customers on wind energy alone — a milestone that we've hit repeatedly since Clearwater began operating. New, utility-scale battery systems including Constable, Sundial and Coffee Creek brought 292 MW of energy storage capacity to the grid in 2024, increasing the reliability of PGE's renewable energy portfolio.

Our environmental stewardship programs saw continued improvement as well. At PGE's hydro facilities, working with our partners, strong environmental stewardship increased fish returns by 185% on the Clackamas River and 510% on the Deschutes River compared to our 10-year average. At the Round Butte Dam, we measured 733 steelhead upstream of the facility, the largest fish return at this site since construction.

From our first hydroelectric project on the Willamette River in 1889 — the site of the nation's first long-distance power transmission — to our state-of-the art salmon restoration programs delivering record breaking returns along the Deschutes and Clackamas rivers in 2024, we deploy business solutions that deliver lasting value for customers, communities, employees and shareholders.

As PGE grows and evolves to meet some of the most pressing challenges of our time, our environmental, social and governance strategy aligned with our core values will continue to guide us to shared success.

Kristen Sheeran, PhD
Vice President, Policy and Resource Planning, PGE

PGE's wind farm, Wheatridge

Our focus areas and priorities

Our purpose is to power the advancement of society. Customers count on us to power their lives with safe, reliable and affordable energy, as they have for more than 130 years. We energize lives, strengthen communities, support sustainable livelihoods and deliver clean energy solutions that advance economic, social and environmental progress.

As our business continues to grow and evolve to meet some of the most pressing challenges of our time, we are committed to a long-term planning and decision-making approach that aligns with our key focus areas.

Affordability

- We work to keep prices as low as possible for customers.
- Design innovative customer programs and solutions to promote energy savings.
- Leverage all available tax credits, incentives and public funding to reduce costs for customers.

Reliability

- Enhance the reliability and resiliency of the grid to withstand extreme weather and growing peak customer demand, facilitate electrification and integrate renewable and distributed energy resources.
- Maintain a comprehensive risk management program, including data security, cybersecurity, physical security, wildfire and climate-related risks.

Decarbonization

- Transition from fossil fuel generation to non-emitting energy and capacity resources to support customers' climate and clean energy goals by 2040.
- Achieve net zero emissions across all of our operations by 2040.

Community

- Provide excellent electricity service to the customers and communities we serve.
- Attract and develop a talented and diverse workforce.
- Support local communities through partnerships, philanthropy, employee giving and volunteerism.

These focus areas closely align with several of the United Nations Sustainable Development Goals (SDGs) — a set of 17 interlinked global goals aimed at achieving peace and prosperity for people and the planet.

We primarily focus on five U.N. SDGs that most directly align with our values and upon which we believe we can create the greatest impact.

A decade of progress

KEY MOMENTS AND DISCLOSURE TIMELINE

We have a solid track record of performance — but we are continuously evolving our ambition and efforts to match the most pressing environmental and social equity challenges of our time.

2014

- Completed **Tucannon Wind farm**

2015

- Achieved **15% Renewable Portfolio Standard** requirement
- **First year of reporting for sustainability progress**

2016

- Collaborated on the passage of Oregon Clean Electricity and Coal Transition Plan law, **doubling the state's RPS standard to 50%,** while requiring PGE to remove coal from PGE's energy mix by 2030

2019

- Launched **Smart Grid Test Bed**
- **Added SASB Framework and EEI ESG Quantitative Sustainability Template to Sustainability Report**

2019

- PGE and NextEra Energy Resources announced development of **Wheatridge Renewable Energy Facility,** the nation's first major energy facility co-locating wind, solar and battery storage

2020

- Permanently shuttered Boardman Generating Station, **eliminating coal generation** in Oregon
- **First stand-alone ESG Report published, including disclosures aligned with the TCFD framework**

2021

- Placed **$150 million** in green bonds following recent closing on $650 million sustainability-linked revolving credit facility

2021

- Collaborated with Oregon lawmakers and stakeholders to pass one of the nation's **most ambitious emissions reduction targets** in the power sector (HB 2021)

2021

- First U.S. utility to sign **The Climate Pledge** committing to net zero emissions by 2040, 10 years ahead of the Paris Accords Goal

2021

- **PGE Board of Directors expands ESG oversight by amending Nominating and Corporate Governance Committee charter to include oversight of sustainability and ESG matters**

2022

- **Issued green bonds** to finance or refinance investments in assets and projects that advance our sustainability goals

2022

- Issued the Company's first **Human Rights Policy Statement**
- **Began reporting on progress toward U.N. SDGs**

2023

- Filed inaugural **Clean Energy Plan**

2023

- **311 MW** Clearwater wind energy facility began generating test energy in 2023 (and came fully online in 2024)

2023

- In collaboration with other parties, awarded over **$300 million** in federal grant funding for projects to support the clean energy economy

2023

- Announced procurement of three battery storage projects totaling **475 MW** — the largest single procurement by a U.S. utility outside the state of California

2023

- Executed, renewed and extended cooperative agreements for more than **500 MW of hydropower** from regional public utility districts

2024

- Produced a record output of **more than 1 gigawatt of wind energy**

2024

- PGE customer actions resulted in the **largest electricity demand shift in company history of 109 MW** during multi-day heat wave

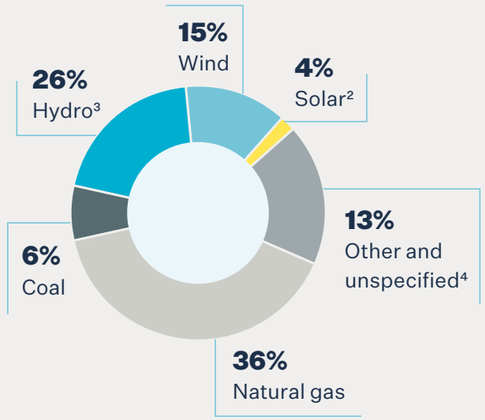
2024

- Achieved **supplier diversity target of 18%**

2024

- **15 years** of No. 1 ranking from the U.S. Department of Energy's National Renewable Energy Laboratory for the largest participation of customers in a renewable energy program among U.S. electric utilities

2024



- PGE and its customers have committed to adding nearly **3 gigawatts of clean energy since 2021** (see Clean energy additions graphic)

PGE's 2024 resources and emissions at a glance

RESOURCE MIX FOR PGE'S TOTAL SYSTEM LOAD[1]

Retail and wholesale

45%
NON-EMITTING

1. Percentages above represent 2024 resource mix from PGE's total system load, inclusive of wholesale volumes. The percentage of 2024 retail load, excluding wholesale sales, served by non-emitting resources is 40%. Refer to the appendix for additional information.
2. Represents owned and contracted solar resources, does not include the 264,826 MWh of customer owned rooftop resources.
3. Hydro amounts include purchases from Bonneville Power Administration, which may have an immaterial amount of emissions associated with them, per ODEQ rules.
4. Unspecified is purchased power for which a specific generating resource is not defined and could be any of the generation types (e.g., wind, hydro, gas).

ROOFTOP SOLAR GENERATION

Customer-sited rooftop solar generation provided 264,826 MWh of non-emitting energy in our service territory.

PGE was the first utility in the U.S. to sign The Climate Pledge

THE CLIMATE PLEDGE

There are currently

539 signatories[1]

across 60 industries and 45 countries who have signed The Climate Pledge

2024 EMISSIONS FOR POWER SERVED TO OREGON CUSTOMERS

5.90
million metric tons of CO_2e

GHG emissions from power served to Oregon customers[1]

0.28
metric tons of CO_2e per MWh

GHG intensity for power served to Oregon customers[1]

1. These figures are preliminary and based on generated and purchased energy associated with serving retail customers within the state of Oregon, as required by the Oregon Department of Environmental Quality (ODEQ). Some or all of the renewable energy attributes associated with PGE's Basic Service Mix may be sold, claimed or not acquired.

PGE HAS AMBITIOUS TARGETS TO REDUCE GHG EMISSIONS FROM POWER SERVED TO RETAIL CUSTOMERS WITHIN THE STATE OF OREGON

Baseline (2010-2012 average emissions)	8.1 $MMTCO_2e$
80% reduction from baseline by 2030	1.62 $MMTCO_2e$
90% reduction from baseline by 2035	0.81 $MMTCO_2e$
100% reduction from baseline by 2040	0 $MMTCO_2e$

Scope 1[2]

6.41 million metric tons of CO_2e

Scope 1 emissions includes all of PGE's direct emissions, made up of fuel burned by thermal generating resources, fuel burned by PGE's vehicle fleet and natural gas used at PGE's office facilities.

Scope 2[2]

0.04 million metric tons of CO_2e

Scope 2 emissions are emissions related to transmission and distribution line loss and emissions associated with power purchased from a third party that is consumed by PGE.

Scope 3[2]

2.06 million metric tons of CO_2e

Scope 3 emissions include the generation of purchased electricity then sold to end users. Reporting and data collection capabilities are still being developed for other Scope 3 sources of emissions.

2. Scope 1, 2 and 3 accounting reflects a company's carbon footprint across all corporate operations. PGE's Scope 1, 2 and 3 accounting includes emissions, above and beyond those associated with power served to Oregon customers.

NET ZERO EMISSIONS TARGET

We have set a goal to achieve net zero emissions across our operations by 2040, which will require reducing PGE's Scope 1, 2 and 3 emissions. Our targets align with The Climate Pledge, which implements decarbonization timelines in accordance with the U.N. Paris Agreement.

North Fork Reservoir on the Clackamas River

Resilient energy ecosystem

As Oregon's largest electricity provider, PGE has significant responsibilities to lower carbon emissions, steward critical habitats, protect air and water quality and minimize environmental impacts in the places we serve and call home.

At PGE, we are committed to a future in which all customers, communities and employees can thrive. Our decisions about how we provide electricity impact environmental health, safety and the quality of life today and for future generations. We base those decisions on the best available science, industry-leading knowledge and experience, risk-informed decision-making practices, data-driven analysis of alternatives and above all else, our privilege and obligation to serve Oregonians with reliable electricity at the lowest possible price.

We are confronting the impacts of climate change and extreme weather across our service territory and in the places where we generate, transact and transmit power. Wildfire risk, droughts, extreme storms and record temperature events place some utility assets at risk and pose significant challenges for grid operations, power supply planning and utility management. Some communities we serve – including Black, Indigenous and People of Color (BIPOC), low-income and rural communities – are often disproportionately burdened by climate change and extreme weather and less prepared to withstand its impacts.

By collaborating with customers and communities, PGE aims to mitigate the disruptive impacts of climate change on Oregon's electricity system and protect Oregon's land, water and habitats, while making proactive investments in grid resilience, modernization, electrification and decarbonization.

A changing power supply

Our power supply is steadily decarbonizing to meet the needs of customers today and into the future.

PGE meets the growing energy demands of customers with a diverse mix of generation facilities owned in whole or in part, or through contract. Today, our generation portfolio consists of seven hydroelectric facilities, five natural gas facilities, three wind facilities, one combined wind/solar/battery facility and a partial ownership stake in an out-of-state coal facility. PGE previously announced the acquisition of 475 MW of new battery storage projects, of which 275 MW achieved commercial operations in December 2024 with the remaining 200 MW scheduled for service in mid-2025.

Customer-sited resources, including rooftop solar, batteries and standby generation play an increasingly critical role in our resource portfolio. For example, customer-sited rooftop solar generation contributed an additional 264,826 MWh of non-emitting energy in PGE service territory in 2024.

We manage the output of our own power plants in conjunction with available power supplies on the wholesale market to deliver power to customers at the lowest possible price. We actively coordinate with transmission providers like the Bonneville Power Administration and other utilities and energy suppliers across the region, to secure transmission access and additional power on contract for customers. We also own major transmission rights to the Pacific Intertie and participate in the California Independent System Operator's (CAISO) Energy Imbalance Market (EIM) and the soon-to-be established Extended Day-Ahead Market (EDAM). These options provide additional flexibility to buy and sell power and to access a more diverse and increasingly clean mix of generating resources.

In 2024, PGE made strong progress toward advancing a resource mix for our total system load that is increasingly clean. The percentage of total load comprised by non-emitting resources grew from 35% in 2023 to 45% in 2024. As a result, the carbon intensity of the power supply declined to 0.27 MMTCO2e per MWh in 2024, despite load growth on our system.

3,500+ MWS OF GENERATION CAPACITY

CENTRAL OREGON
- Pelton
- Round Butte

EASTERN OREGON
- Biglow Canyon
- Carty
- Coyote Springs
- Wheatridge

MONTANA
- Clearwater
- Colstrip

EASTERN WASHINGTON
- Tucannon River Wind Farm

- Coal
- Gas
- Hydro
- Wind
- Combined wind, solar, and battery
- Service territory

While natural gas remains the largest component of our generating mix and provides much-needed capacity to meet resource adequacy and reliability requirements — hydropower, wind and utility-scale solar continue to grow on our system, in addition to customer-sited renewable energy resources like rooftop solar. Wind output alone grew by 56%, reaching record breaking levels of wind generation on our system in 2024 primarily due to the addition of the Clearwater Wind facility in Montana. Not only does this facility have a high energy output rate, but it also generates power when other wind resources closer to home in Oregon and Washington are less productive. This exemplifies the importance of resource diversity in our portfolio – and is a critical decarbonization strategy.

Unspecified emissions are reported when the underlying source of generation for energy we purchase from the market, including from CAISO's Energy Imbalance Market, is unknown or not otherwise specified in a contract. Following best practice and ODEQ rules, we assign an emissions rate to unspecified purchases in recognition that the power pool in Western states still includes fossil fuel generation. Throughout 2024, PGE reduced emissions from unspecified sources, from 16% of our retail resource mix in 2023 to 14% in 2024. As Western states decarbonize and energy markets such as CAISO adopt more precise mechanisms for tracking and reporting the carbon content of resources dispatched and allocated through energy markets, emissions associated with unspecified purchases should continue to decline in our system.

PGE recently concluded the largest open-application request for proposal (RFP) for clean energy resources to augment our portfolio to date and we anticipate returning to the market with another RFP in 2025. This and subsequent RFPs will be necessary to meet customers' energy needs and PGE's emissions targets. PGE's steady progress in procuring clean energy and investing in grid-edge technologies and customer programs will reduce reliance on fossil fuels and drive a cleaner resource mix in future years.

MORE ENERGY, FEWER EMISSIONS

0.27 **metric tons of CO2e per MWh is the GHG intensity for PGE's power supply**

Carbon intensity is an indicator of how clean PGE's electricity is. It is measured as carbon emissions per megawatt hour of energy produced for PGE's total system load. Monitoring and assessing the carbon intensity of our generation portfolio is important because it provides insights into how well PGE is doing to decarbonize, even when its total electricity load is increasing.

As reported on page 11, the carbon intensity for PGE's retail load is 0.28 MMTCO2e.

PERCENTAGE OF RESOURCES MIX FROM NON-EMITTING RESOURCES

45% 2024 (actual)

45-50% 2025 (projected)

75-80% 2030 (targeted)

PGE'S HISTORY OF CLIMATE LEADERSHIP

In 2010, PGE negotiated the early closure of the 30-year-old Boardman Generation Station coal plant in Oregon, the state's only coal-fired facility and one of the youngest plants in the nation to retire due to air quality concerns. The plant ceased operations in 2020 and today that site may become the location for solar and storage or emerging green hydrogen technology through PGE's participation in the Department of Energy (DOE) funded Pacific Northwest Hydrogen Hub consortium. In 2016, PGE helped pass Oregon's landmark Coal to Clean bill, establishing a firm timeline for ending coal service for Oregon electricity customers. PGE continues to pursue an exit from Colstrip that balances reliable and affordable outcomes for customers, while also complying with Oregon state law to no longer serve retail customers with coal generated energy.

BEFORE: Boardman Generation Station

AFTER: Demolition of Boardman stack

Climate commitments and emissions

Customers drive our commitments to clean energy, carbon reduction and sustainability.

PGE customers include some of the world's most sophisticated corporate renewable energy buyers and local municipalities with ambitious climate action plans that call for transitioning to cleaner energy and lowering emissions. Portland, Beaverton, Multnomah County, Hillsboro, Salem and many other municipalities have developed climate action plans that encourage us to find new and innovative ways to reduce the carbon intensity of the electricity we serve, while also supporting their electrification efforts, fostering economic development and modernizing the grid to enhance resilience to extreme weather.

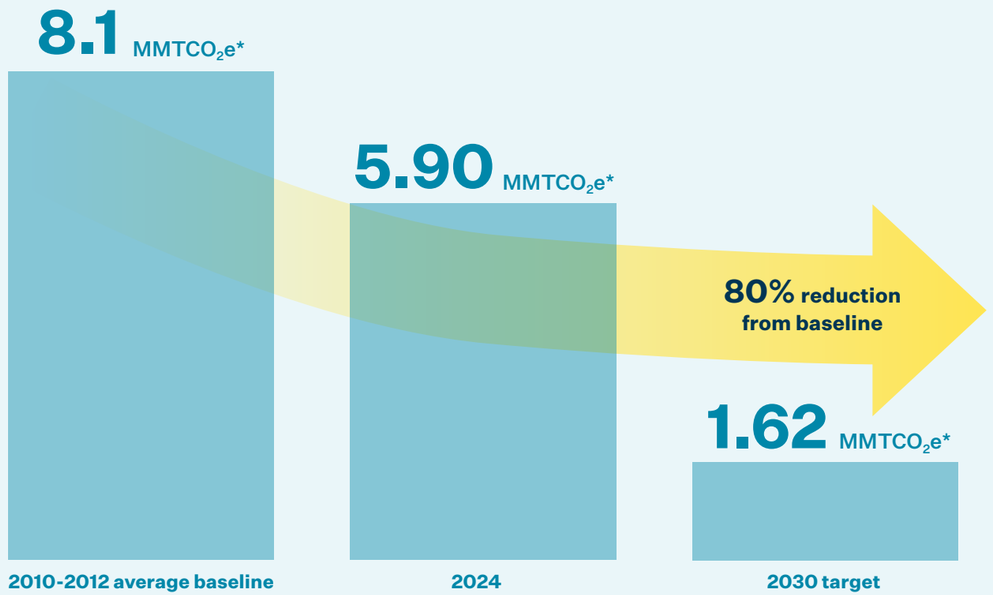
Many companies in PGE's service territory have publicly adopted ambitious clean energy or emissions goals, including Oregon Health and Science University, Nike, Intel, STACK Infrastructure, Daimler and others. As large electricity buyers, they look to PGE to support their decarbonization efforts.

PGE supports customers' climate and sustainability goals by decarbonizing the electricity supply and offering innovative voluntary programs that enable customers to go further and faster. We offer programs for large businesses, cities and counties that match their electricity needs with new renewable energy facilities in our region. We also offer convenient options for small business and residential customers to support clean energy development by purchasing renewable energy certificates from energy generation throughout the U.S.

Because of customers' strong preferences for clean energy, PGE has embraced very ambitious targets for decarbonization.

In 2021, PGE became the first utility in North America to sign The Climate Pledge to achieve net zero emissions across company operations (Scope 1, 2 and 3 emissions) by 2040, ten years ahead of the United Nations' Paris Agreement. PGE then collaborated with state lawmakers and stakeholders to pass Oregon's 100% Clean Electricity Law (HB 2021) to establish emissions targets for electric utilities in Oregon. These targets apply to emissions associated with power served to Oregon retail customers and include an 80% reduction in emissions below an average 2010-2012 baseline, 90% reduction by 2030 and a 100% reduction by 2040.

PGE is actively exploring the process of third-party certification of our emissions targets, including the Science Based Target Initiative and other efforts underway by the power sector to develop a science-based target.



For the 15th straight year, the U.S. Department of Energy's National Renewable Energy Laboratory ranked PGE the first of any U.S. electric utility for customer participation in renewable energy programs.*

**NREL did not release rankings in 2011.*

PGE is more than one-third of the way toward the emission reductions needed to meet its 2030 emissions target

** Emissions associated with power served to Oregon customers.*

Emissions reporting

PGE has been a mandatory reporter of greenhouse gas emissions for all facilities to state regulators since 2010. Compliance with state emission targets is based on that reporting, which is also subject to third-party verification. Year-to-year variation in emissions is expected primarily due to fluctuations in temperature and hydro, wind and solar generation.

At the close of 2024, PGE disclosed a 27% reduction in baseline emissions from power served to Oregon retail customers. Emissions associated with power served to Oregon customers in 2024 equated to approximately 5.90 million metric tons of CO_2e. This is a 10% decrease in retail emissions reported in 2023, largely driven by additional hydropower and the addition of the Clearwater Wind facility.

PGE also discloses material quantities of emissions from all power generation (retail and wholesale) and company operations as Scope 1, 2 and 3 sources of emissions. Scope 1 includes PGE's direct emissions, primarily from fuel burned by our thermal generating fleet and fuels used in PGE's vehicle fleet and buildings.

Scope 2 for an electric utility is relatively small and associated with transmission and distribution system line losses, and any electricity PGE purchases from third parties for our facilities.

Scope 3 is where PGE reports emissions associated with the power purchased for customers. As noted above, PGE regularly turns to the market to supplement generating resources to meet customers' energy needs reliably and affordably. PGE currently reports Scope 3 emissions from purchased power.

Like most utilities, PGE's emissions are driven by the fossil fuels combusted to generate power, accounting for more than 99% of our currently reported Scope 1, 2 and 3 emissions. This is why emissions reporting, emissions targets and clean energy strategies are largely focused on decarbonizing our power supply, either through generation or purchased power. PGE is actively planning and executing strategies for a balanced transition from thermal generation to increasingly cleaner generation sources while providing reliable energy service that can affordably meet customers' energy needs.

PGE's Clean Energy Plan

Mitigating customer price impacts and maintaining system reliability are core priorities as PGE decarbonizes its power supply.

In 2023, PGE published its combined Clean Energy Plan and Integrated Resource Plan, a twenty-year roadmap for meeting customer energy needs at the lowest possible costs while transitioning from fossil fuel generation. We demonstrated a path toward the 80% emissions reduction target in 2030 that involves resources and technologies that are economically and technically feasible in the region today. No single technology right now can replace the role of natural gas generation in the electric power system. Clean energy of all types — including customer rooftop generation, community-scale microgrids that combine batteries and solar, utility-scale wind, solar and batteries — energy efficiency and demand response programs and customer dispatchable standby generation will all be needed to replace the energy and backstop capacity that natural gas currently provides.

As we look ahead to deeper decarbonization targets in 2035 and beyond, PGE anticipates the need for access to a broader geographic diversity of resources and technologies to replace fossil fuels on the grid. This will require solutions to current regional transmission constraints and adopting future non-emitting technologies as they become cost-effective. This could include green hydrogen, offshore wind, nuclear, long-duration storage and carbon capture and storage.

CLEAN ENERGY ADDITIONS*

Achieving emissions reduction requires steadily adding renewable energy, battery storage, energy efficiency and demand response to our portfolio, so we can reliably and affordably reduce fossil fuel generation.

Since PGE implemented its emission targets in 2021, PGE and its customers have committed to adding 2,900+ MW of clean energy.

Clean energy additions since 2021

Wind
- Clearwater 2024: 311 MW

Utility scale solar
- Wheatridge Solar 2022: 50 MW
- Patchwayit Solar** 2023: 162 MW
- Tower Solar** 2026: 120 MW
- Daybreak Solar** 2026: 138 MW
- Bakeoven Solar** 2026: 60 MW

Batteries
- Wheatridge Battery 2022: 30 MW
- Constable 2024: 75 MW
- Sundial 2024: 200 MW
- Coffee Creek 2024: 17 MW
- Seaside 2025: 200 MW
- Other BESS facilities: 8 MW

Small-scale solar
- Community Solar & QFs: 96 MW
- Rooftop Solar: 172 MW

Hydro contracts
- Mid-C PPA 2023 (2024-2025): 76 MW
- Mid-C PPA 2023 (2024-2026): 434 MW
- Douglas PUD 2024 (2026-2030): 79 MW

Customer programs
- Energy Efficiency***: 122 aMW
- Demand Response****: 603 MW

Next steps:

PGE received Commission acknowledgement to pursue over 1,600 MWs of renewable energy and storage from its 2023 All-Source RFP final short list.

PGE will solicit the market through RFPs for renewable energy resources and storage, starting again in 2025.

PGE is executing on plans to shift up to 25% of peak energy demand through distributed resources and customer programs coordinated through our virtual power plant.

** Through ownership, PPA, contract or customer participation in programs.*
*** Procured by customers through Green Future Impact program.*
**** Preliminary numbers as provided by ETO. Numbers are subject to change from this report to the final filed report, which will occur later in the year.*
***** Cumulative capacity deployed in summer and winter seasons over time period. Total DR capacity in Summer 2024 is 105 MW.*

FUTURE STATE TECHNOLOGIES

DISPATCHABLE ENERGY:
Reliance on wind, solar and short-duration storage exposes portfolios to energy shortfalls and reliance on thermal generation until more non-emitting dispatchable generation is a reality for our region.

Advanced nuclear

Both small modular reactors and advanced nuclear reactors offer potential emissions-free power in the future. The designs' modular construction lowers costs and reduces risks, though siting in Oregon is currently prohibited.

Enhanced geothermal

Enhanced geothermal has not yet been successfully demonstrated in the Northwest, but the technical potential for geothermal remains.

Carbon capture storage (CCS)

CCS technology is the beneficiary of substantial tax credits in the Inflation Reduction Act. Compression, storage and mineralization in the Northwest basalt geology is claimed to resolve the long-term CO2 escape risks.

LONG DURATION STORAGE:
Without dispatchable carbon sources, PGE will require additional renewables paired with long-duration energy storage resources to meet load.

Green hydrogen

Electrolysis allows for surplus renewable energy to be stored as green hydrogen in 100+ mile pressurized pipelines to allow for carbon free electricity generation through combustion.

Iron-air energy storage

Iron-air stationary battery storage has the potential to allow for non-flammable, low-energy density and low-cost per unit MWh long-duration energy storage.

Compressed air

Advanced compressed air energy (A-CESC) is a long-term energy storage technology which has renewed commercial interest.

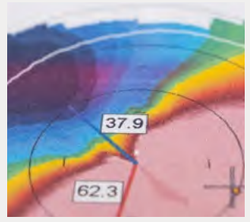
Balancing affordability, reliability and decarbonization

This is a period of dynamic change for PGE and the power sector at large. We're experiencing an increase in energy demand driven by electrification and rapid growth in demand as a result of advancements like artificial intelligence (AI), expansion of data centers and growth of technology manufacturing. Climate variability is changing how our customers use energy, resulting in record-high winter and summer system peaks and changes in regional power flows that impact power operations and transmission planning. Utilities across the entire western grid are decarbonizing, contributing to energy storage and capacity scarcity, while facing increasing demand on the region's existing transmission and siting availability for new renewables. Power cost volatility, inflation, wildfire mitigation, investments in grid safety and stability and integration of new clean energy technologies are exerting upward pressures on customer prices. We're deploying technologies to help customers reduce energy expenditures and minimize disruptions. Wireless sensors and centrally controlled automated switches help isolate disruptions and more rapidly reroute power, preventing or shortening disruptions. During outages, these technologies help us share timely, accurate information with customers by notifying them when their power goes out and providing updates through digital and mobile channels.

GRID ENHANCING TECHNOLOGIES

The clean energy grid of the future will require new transmission capacity to transport clean electricity to where customers live and work. PGE is prioritizing new grid enhancing technologies (GET), including hardware and software solutions such as advanced conductors, dynamic line ratings, power flow controllers and topology optimization, where applicable, to increase the capacity of our existing transmission infrastructure and minimize disruptions to landscapes or communities from building new transmission infrastructure.

Advanced conductors



Dynamic line ratings

Power flow controllers

Topology optimization

Customer collaboration

Customers play a critical role in decarbonization as they electrify vehicles, homes and businesses and generate and store their own power.

Currently, 24% of PGE's residential households participate in voluntary programs to shift energy use, including Peak Time Rebates, Smart Thermostats program, and Time of Day pricing. These programs not only save customers money on their bills, but also provide critical capacity to our system, especially when the grid needs it most. In addition, our residential and business customers are rapidly adopting electric vehicles and installing rooftop solar systems, batteries and standby generation.

Programs that allow customers to manage their own energy use as well as generate and store their own power are possible due to an increasingly sophisticated bidirectional grid. We are deploying a distributed energy resource management system (DERMS) to provide real-time visibility into distributed energy resources and to better serve customers using a two-way flow of energy safely and reliably.

At our state-of-the-art Integrated Operations Center, PGE orchestrates these customer-sited resources so they can function as a Virtual Power Plant (VPP), providing energy and resiliency to the grid for the benefit of all customers. A VPP can help customers shift their energy consumption from traditional peak times, reducing their energy costs and avoiding the need for emitting resources. We also work with electric vehicle (EV) drivers to shift charging usage through our EV Smart Charging program.

To help reduce the costs of new clean technologies and resources, we are leveraging federal, state and local funding currently available and guiding customers toward incentives for electric vehicles, heat pumps, energy efficiency, weatherization, solar panels and storage.

RECORD-SETTING CUSTOMER COLLABORATION IN TIMES OF HIGH DEMAND

Climate change-induced extreme whether is contributing to temperatures with higher peaks and lower troughs, as well as greater volatility. By 2030, we aim to serve growing energy needs by partnering with customers to offset up to 25% of peak demand by using distributed resources and flexible load orchestrated through our virtual power plant.

PGE customer actions resulted in the largest electricity demand shift in company history during a multiday heat wave in July 2024. Coupled with PGE's ongoing system upgrades and preparedness efforts, customers' collective energy conservation actions supported reliable power delivery and grid stability during a time of extremely high power demand.

Customer actions reduced electricity demand by nearly 109 MW during peak demand hours on Monday, July 8 and 100 MW on Tuesday, July 9; that is enough electricity to power over 90,000 homes for a four-hour period.

CUSTOMERS MADE THE DIFFERENCE DURING A SUMMER HEAT WAVE

A changing Western grid

Organized markets and regional collaboration help expand our resource footprint and are critical tools for managing costs and reliability.

Just as we work with customers, we also collaborate with energy producers across the West to support the region's decarbonization efforts. This collaboration also helps address transmission constraints and clean resource availability.

The western grid is rapidly evolving and the generation mix continues to change as coal plants are decommissioned and more renewables and storage come online. The region's transmission system is aging and needs to be expanded to accommodate increasing demand and changing climate patterns. According to a recent North American Electric Reliability Corporation (NERC) study, extreme demand during heat events strains resources and the transmission network because the region has insufficient operating reserves.

Western Power Pool's Western Transmission Expansion Coalition (WestTEC) initiative is working to address the lack of transmission across the western interconnection. WestTEC is unique due to the unprecedented regional partner engagement, including states and tribes, and will produce an actionable transmission study incorporating a 10-year look and a scenario-based 20-year analysis.

Organized market expansion across the West facilitates regional decarbonization, lowering costs, accelerating renewable integration, improving operational efficiencies and reducing the need for real-time flexible reserves. PGE was one of the early participants in the Western Energy Imbalance Market (WEIM), a decision that has significantly reduced power costs for customers from what they otherwise would have been and enhanced our system reliability during extreme weather events. PGE is committed to participation in EDAM organized by CAISO. PGE is also a leader in the development of the Western Resource Adequacy Program (WRAP), operated by the Western Power Pool. PGE is currently active in the non-binding phase of this first-of-its-kind resource adequacy program that includes both forward-showing and operational components.

Reducing emissions across sectors

While the Clean Energy Plan focuses on decarbonizing the electricity supply, our broader commitment to net zero leads us to find ways to lower emissions and across other areas of our business, while supporting our customers in their efforts to electrify their vehicles, homes and buildings. Reducing diesel and gasoline purchases for PGE's fleets and reducing energy use in PGE's buildings and facilities reduces our operational costs. Similarly, our customers may reduce expenditures on their total energy purchases by switching to electric vehicles, implementing energy efficiency measures, switching from gas to electric appliances, or more directly managing their energy use through demand response programs.

Transportation electrification

The transportation sector is the single largest contributor to Oregon's total greenhouse gas emissions and the state is actively supporting vehicle electrification efforts through vehicle incentives and development of charging infrastructure. Oregon has joined other West Coast states in prohibiting new retail sales of internal combustion engine vehicles by 2035. As internal combustion engines are phased out, PGE is anticipating rapid adoption and expansion of electric vehicles in the service area.

In 2024, programs and strategies in place to support vehicle electrification include:

- **Residential EV Smart Charging:** This program offers customers rebates for Level 2 chargers and bill credits to encourage vehicle charging during times when energy demand and prices are lower.
- **Public charging:** The Municipal Charging Collaboration Program aims to improve charging availability for customers and identify how pole and curbside chargers can create greater access, especially for those in underserved communities.
- **Business and multi-family make-ready solutions:** This program expands commercial installation of public or semi-public EV charging, including multifamily locations, workplaces, retail locations, destination centers, schools and houses of worship.
- **Fleet Partner program:** This program helps businesses and municipalities transition their fleets by taking out the guesswork of fleet transition, providing cost analysis, preliminary design, construction and other support services from start to finish.

Drive Change Fund

Using funds made available from the Oregon Clean Fuels Programs, PGE awarded local organizations $4.8 million to expand access to transportation electrification. We also awarded $6.5 million to electrify school buses in eight districts through the Electric School Bus Fund.

Fleet electrification

At PGE, we are electrifying our own vehicle fleet to reduce fuel and maintenance costs, improve local air quality and advance our broader net zero goal for 2040. We've electrified 18% of the total fleet, up from 15% last year.

Our efforts to decarbonize our fleets reflect emerging technological changes in the fleet space and utilize technologies beyond electrification that can contribute to emissions reduction. For example, we have implemented a new telematics solution, Geotab, that offers real-time transparency into the fleet's performance and reducing fossil fuel use. We also utilize R99 renewable diesel in our fleet, a high-efficiency fuel with lower CO_2 emissions.

Oregon is the
6th largest
retail market for EVs in the nation.

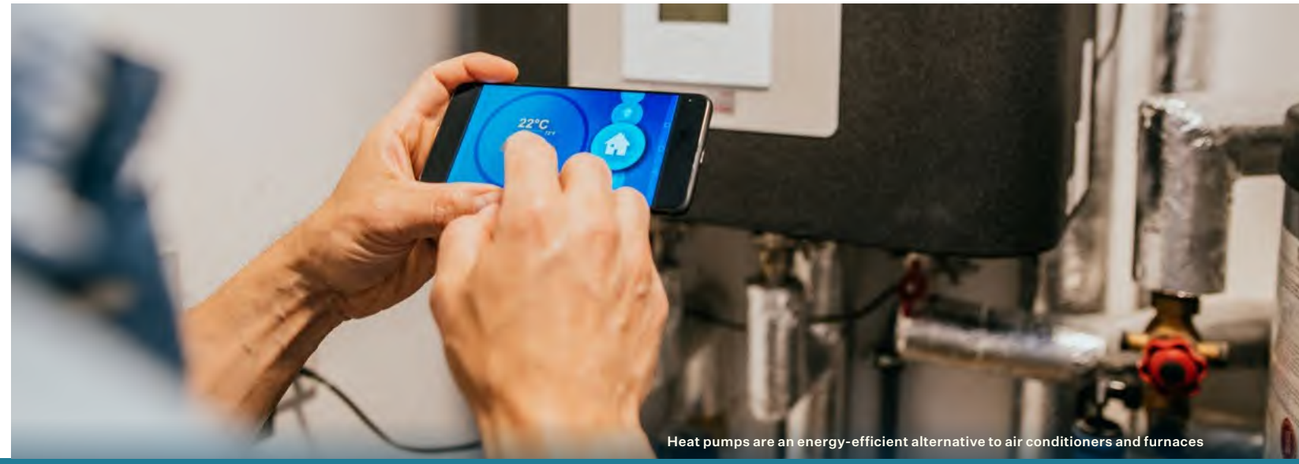
Added
43
EVs to our fleet in 2024

Electrified
30%
of our Class 1 vehicles

An electric Chevrolet Silverado added to our fleet in 2024



Building electrification

PGE engages broadly with home builders to promote energy efficiency and the use of efficient electric appliances, such as heat pumps and induction cooktops. Oregon has a statewide goal of installing 500,000 new heat pumps by 2030. PGE is doing our part to support the achievement of that goal by marketing to our customers the varied benefits of heat pumps and promoting their use via incentives offered through the Energy Trust of Oregon. Within PGE's Smart Grid Test Bed, PGE is offering incentives for new homes built with heat pumps and flexible load technologies. In addition, to help support building new efficient electric homes, PGE recently increased its line extension allowance to home builders. Lastly, to help inform the appliance and vehicle choices made by our customers, PGE supports and participates in local home and vehicle electrification fairs where customers can learn about PGE programs and the latest in building electrification technologies.

Facilities

PGE is committed to reducing environmental impacts in the buildings we own and we explore ways to conserve energy to support a reduction in demand on the grid and reduce overhead costs for our corporate electricity use. Methods employed include improving insulation to reduce heating and cooling demands, reduced water usage for landscaping and rooftop solar on six properties.

Our corporate headquarters' ongoing operations and maintenance also meet the rigorous sustainability standards of LEED for Existing Buildings Operations and Maintenance rating system, which was certified at the Gold level in 2015. Using this experience, two locations were built to LEED Gold standards.

Heat pumps are an energy-efficient alternative to air conditioners and furnaces

PGE manages Balancing Rocks Overlook, along with the U.S. Forest Service in the Deschutes National Forest

Selective Water Withdrawal on the Deschutes River

Kokanee swimming upstream in the Deschutes River

How we care for the environment

Oregon's natural beauty inspires us to operate in ways that preserve and enhance ecosystems, generate less waste and recycle as much material as possible. As a steward of over 11,000 acres of land in Oregon, we are committed to caring for natural habitats and creating conditions that are safe, restorative and resilient to wildfire.

PGE manages
11,000+ acres
of wildlife habitat

PGE also has a robust environmental management system (EMS) to fulfill compliance obligations, manage environmental issues and address environmental risks and opportunities. The core objectives of the EMS are establishing compliance with laws and regulations, providing training to employees with environmental responsibilities, minimizing environmental risk and being prepared for unplanned events such as spills or releases.

Modernizing our hydropower plants

Hydroelectric facilities have powered the region and the nation with reliable, emissions-free electricity for over a century, making them PGE's oldest assets to address climate change. As we add more intermittent resources like wind and solar to the grid, hydro provides flexible emissions-free power that can be quickly dispatched to customers when needed or stored for later use. Our hydropower projects play a key role in our efforts to decarbonize Oregon's electricity supply and we operate and maintain them to the highest environmental standards.

Oak Grove Powerhouse

OAK GROVE POWERHOUSE CELEBRATES 100 YEARS OF CLEAN ENERGY PRODUCTION

100 years ago, the Oak Grove Powerhouse on the Clackamas River helped electrify Oregon, providing power for homes and businesses as the Portland area developed into the metropolitan center it is today. Over the course of a century, the facility weathered floods and fires, booms and busts in the economy and the transformation of the Pacific Northwest. Oak Grove's legacy and enduring importance in PGE's generation fleet highlight the value of hydropower to Oregon communities and clean energy landscape for years to come.

Deschutes River Basin

In the Deschutes River Basin, we work with the Confederated Tribes of the Warm Springs (CTWS) Reservation of Oregon with whom we co-own the Pelton Round Butte hydro facility to provide enough clean, emissions-free hydropower to power more than 127,000 homes. At the same time, we're advancing an ambitious, long-term initiative to restore native salmon and steelhead runs to a fully reconnected Deschutes River Basin. Restoring these runs includes aiding the downstream migration of juvenile fish, as well as the upstream return of adults, which spawn in their historic habitat upstream of Lake Billy Chinook.

While we have not yet reached our long-term goals for self-sustaining, harvestable runs of salmon and steelhead, we are seeing incremental progress and science suggests we're on the right track. Results to-date include:

- **Juvenile collection:** Each year we collect between 38,000 and 490,000 juvenile fish at the Selective Water Withdrawal – our fish collection facility. Changes to hatchery practices and operations have improved our ability to capture these young fish.
- **Spawning in the wild:** Chinook, sockeye and steelhead now have access to 250 miles of their historic habitat that were blocked for nearly 50 years. Adult fish returning from the ocean have been located spawning near Bowman Dam on the Crooked River, in Whychus Creek at Camp Polk and upstream of Camp Sherman on the Metolius River.
- **Record returns:** Fish returns have increased by 501% on the Deschutes River across our 10-year average. In 2022, more than 700 adult spring Chinook salmon were released above Round Butte Dam – the highest number since the reintroduction effort began in 2010. These fish were observed spawning in nature and their offspring passed through our collection facility in 2024 on their way to the ocean, starting the cycle over again. During the first six months of the 2024-2025 steelhead run, we passed a record 733 steelhead upstream of Round Butte Dam, including 528 reintroduction program fish that came through our facilities as juveniles - the largest steelhead return since dams were completed on the Deschutes River in the 1960s. The improved returns are likely a result of better ocean conditions, as well as changes we've implemented over time in response to science.

Of the 2,500 hydropower projects in the U.S., only 200 are certified by the Low Impact Hydropower Institute (LIHI) for their environmental excellence. Pelton Round Butte was first LIHI certified in 2007 and was recertified in 2023. This certification affirms that we're generating power in a way that respects Oregon's aquatic, terrestrial, cultural and recreation resources.

The Pelton Round Butte project continues to be managed collaboratively by PGE and CTWS with oversight from local, state, federal, and non-governmental organizations. For example, the Pelton Round Butte Fish Committee meets bimonthly to oversee the Licensees' development and implementation of study plans, reports, facility designs and operating and implementation plans that affect aquatic ecosystems. In addition, the Fish Committee has developed a Reintroduction Roadmap and Water Quality Graphic to help visualize ongoing efforts for reintroduction and water quality. All of this helps to make sure that we are on the path to restoring a healthy Deschutes basin – both upstream and downstream of the dams.

In 2024, PGE's environmental team and CTWS hosted the 30th annual Pelton Round Butte Fisheries Workshop. Since the 1990s, when PGE and CTWS first started hosting the workshop, fish habitat in the upper Deschutes Basin has improved. Whychus Creek (an important tributary to the Deschutes) has more water flowing through it, several key partner organizations have formed to protect and restore habitat in the river and PGE and the Tribes have contributed $28 million to fish and water conservation.

On top of these habitat enhancements, salmon and steelhead are now spawning and reproducing upstream of Round Butte Dam – something that hadn't happened since before the hydropower complex was constructed in the 1960s.

Ospreys are one of several avian species that benefit from PGE's Avian Protection Plan

Northern red-legged frog

Clackamas River Basin

Since building our first fish ladder in 1907, we've been innovating to protect, enhance and study fish populations in the Clackamas River Basin, where we operate four hydropower facilities. Since 2006, PGE has spent more than $200 million to modernize and improve passage systems on the Clackamas River which salmon and steelhead use to migrate past the dams. We've also updated our fish ladder at River Mill Dam to accommodate Pacific lamprey, an important but often-overlooked fish species in the Pacific Northwest. Our work is guided by a federal license and partnerships with non-profit organizations and local, state and federal agencies who work together to protect and restore the Clackamas.

Led by a dedicated team of biologists, we've built safe and effective fish passage systems near the dams and collaborated with partners to restore habitat throughout the river basin. Our success shows in the growing number of wild fish migrating up and down the Clackamas and in positive shifts in fish behavior, including:

- **Higher survival rates:** PGE is on the way to meeting our 97% passage goal as early measurements show fish are migrating downstream past PGE dams quickly and safely.
- **Earlier upstream migration:** Spring Chinook are traveling past the dams a month earlier, reaching headwater streams when water temperatures are cooler and healthier for fish.
- **Record returns:** Fish returns have increased by 185% on the Clackamas River across our 10-year average.In 2023, the PGE team at Westside Hydro on the Clackamas River successfully passed more than 25,000 adult salmon and steelhead upstream of North Fork Dam. This success, along with several other fish return records broken in 2023, is a testament to the power of collaboration with partners in the Clackamas River Basin over the past 18 years to modernize and improve fish passage systems.

Avian Protection Plan

In addition to our efforts to protect aquatic life, we are always looking for opportunities to make facilities, power poles and other utility equipment safer for birds. Our companywide Avian Protection Plan has been incorporated into our design and construction standards for all new poles and replaced electrical infrastructure.

These actions include:

- Training employees on bird protection issues and procedures.
- Tracking bird and nest issues to minimize impacts in high-risk areas and building nesting platforms to reduce pole-top nesting and outages.
- In 2024, 8,208 poles and 4,544 transformers were added or replaced with ones that feature avian-safe protective covers or design features.
- Collaborating with the U.S. Fish and Wildlife Service and the Avian Power Line Interaction Committee on strategies that reduce bird and power interactions.

Habitat restoration at Harborton

PGE continues transforming Harborton — a property we have owned for 80 years — into a haven for native plants and wildlife. In 2020, PGE completed a major restoration project at this 53-acre site along the Willamette River in Northwest Portland's industrial corridor, one of the most important breeding grounds for northern red-legged frogs and a prime rest area for migrating juvenile salmon. In 2024, wildlife surveys continued to find an increased abundance of use, documenting juvenile salmonids, several mammals, over 60 species of birds and over 700 northern red-legged frog egg masses.

To support wildlife habitat gains, invasive reed canary grass and other plant species are being aggressively replaced with native species. PGE is currently in discussions with the City of Portland and local organizations on additional improvements for red-legged frogs as part of the proposed Harborton Reliability Project to enhance transmission capacity.

Brownfield redevelopment at Seaside Battery Project

PGE, in collaboration with Eolian, is finishing construction of a 200 MW battery storage farm on the former Time Oil property, in Portland, Oregon. Time Oil was a major petroleum terminal during World War II, serving the needs of the nearby Kaiser Shipyards. The property was recently cleaned up and listed on the EPA's national inventory of Brownfield sites. PGE is repurposing the site for an extensive new battery storage site, bringing renewed functionality and infrastructure into the greater Portland Harbor area.

Water management

Protecting natural resources, including water resources, continues to be a priority. PGE's operational facilities are located in basins with low baseline water stress, with the exception of our two wind farms, both of which are located in basins rated as medium-high baseline water stress. However, wind farms as a form of electric generation are not major water consumers.

Our PGE-led and PGE-partnership projects in these watersheds focus on basin-wide water conservation measures to increase in-river flows that are critical for habitat improvement and fisheries restoration goals.

Waste management

We have rigorous protocols to minimize waste generation, foster efficient use of resources and prioritize responsible disposal. We emphasize recycling and reuse wherever feasible. In instances where waste cannot be recycled, we employ practices to treat and dispose of waste in an environmentally friendly manner.

Our waste handling and disposal procedure provides guidelines to all personnel for maintaining environmental compliance related to waste, outlining responsibilities and procedures for hazardous, universal, electronic and other types of waste.

Creating a space in nature for all

In addition to managing resources and restoring habitat, we provide recreational opportunities so that Oregon residents and visitors can enjoy the natural beauty of our state and its history. Customer surveys for 2024 show that 97% of respondents who made reservations at PGE-managed parks and recreation sites were satisfied with their experience. Additionally, 68% of respondents report being PGE electricity customers. PGE is also committed to protecting archaeological sites and historic buildings located on the lands we operate.

PGE's 28 parks and recreation sites across nearly 3,600 acres host over

491,000

visitors annually.

Children reading TRACK Trail brochures at Timber Park

In 2024, PGE's Timber Park in Estacada celebrated the launch of a new TRACK Trail designed to provide an engaging environmental scavenger hunt experience for young children and their families, encouraging them to embrace the outdoors.

Children enjoying Project Zero's comic book at a community event

Thriving communities

The well-being of employees and the communities we serve is foundational to PGE's long-term success.

We never lose sight of our core purpose of powering Oregon homes and businesses and the vital role employees play in delivering affordable, reliable, safe and increasingly clean electricity to Oregon's communities. We recognize that employees and their families live, work and play in the communities we serve. We secure our shared future by aligning our business practices and values to deliver lasting benefits for communities and team members.

PGE is committed to advancing a clean energy future that is inclusive of the needs of all customers. This means prioritizing energy affordability and providing customers with the tools and resources they need to manage energy use and costs and building a diverse workforce that is reflective of the communities we serve. It requires that we proactively engage with communities to better understand their needs and expectations for the clean energy transition and meaningfully invest in communities through employee volunteerism and giving. Our ongoing commitment to a positive and empowered workplace culture creates a stronger workforce and a more resilient company, able to serve communities with integrity and impact.

Serving communities

Energy affordability is at the forefront of all decision-making at PGE.

We acknowledge our role in delivering an essential service that is foundational to the well-being and vitality of society. Affordability and access remain at the forefront of PGE's commitment to serving customers, as we balance multiple imperatives to serve society's growing need for electricity, decarbonize our power supply and enhance system reliability in the face of increasingly extreme weather events. Our focus on affordability drives us to continuously innovate by reducing costs and simplifying processes as we launch new technologies and tools to deliver exceptional electricity service for customers.

We take a holistic approach to affordability that includes prudent planning and decision-making to manage system costs. We maximize the use of public funds, including grants, tax credits and incentives to mitigate costs of key energy projects and programs. We also provide bill discounts and assistance to support our most vulnerable customers and innovative tools and programs to help all customers manage their energy use and costs. Our goal is to serve electricity at the lowest possible cost, reduce customer energy burdens and find solutions to the challenges our most vulnerable customers face accessing energy assistance and incentives and implementing energy-saving measures.

PGE continues to collaborate with federal, state and local entities to support customers and reduce energy burdens. This includes our long-standing relationship with Energy Trust of Oregon (ETO) supporting programs and incentives for energy efficiency, energy conservation in schools and low-income affordable housing, no-cost weatherization and rooftop solar. In 2024, PGE established a multiyear planning approach and co-deployment framework, in partnership with ETO, to provide a more accessible and seamless experience for customers to manage their energy use though combined ETO and PGE services.

We also continued expansion of our Income-Qualified Bill Discount program (IQBD), which provides bill discounts to income-qualified recipients, adding two new income-based discount tiers and offering larger discounts to the most heavily burdened households. Additionally, we continue to work with Oregon Department of Housing and Community Services, Oregon Department of Energy and community action agencies to administer a variety of assistance and resources for customers in need.

In 2024, PGE conducted an Energy Burden Assessment, prepared by Empower Dataworks, to gain further insight into the energy burden needs of residential customers and assess our progress in meeting customer needs.

This assessment found that our IQBD program is operating effectively and following energy assistance best practices.

PGE will utilize insights gleaned from this assessment to continuously improve affordability program design, evaluate the performance of energy assistance programs and develop targeted marketing and outreach strategies.

Regardless of a customer's income, PGE provides several programs and options for flexibility and bill management. PGE is here to help customers manage their energy use and guide the adoption of energy saving tools and technologies.

PGE HAS PARTICIPATED IN CLEAN ENERGY GRANT PROJECTS TOTALING MORE THAN $2 BILLION

Grant Partnerships

- Bethel Round Butte with the Confederated Tribes of Warm Springs
- Grid Edge Devices
- North Plains Connector Transmission
- Hydrogen Hub
- Department of Labor (Critical Sector Jobs)

Direct Grant Support

Nearly $470 Million

Negotiation
$152M

Active Application
$ 1.2M

Execution
$315M

1. PGE has participated in federal clean energy grant programs totaling more than $2 billion, including nearly $470 million in direct grants for PGE.

CUSTOMER TOOLS AND PROGRAMS TO MANAGE ENERGY COSTS

Rebates and incentives for electrification, energy efficiency and weatherization help customers reduce energy costs.

Residential and community solar combined with battery programs can reduce customer costs and provide additional grid value.

Income-Qualified Bill Discount program lowers prices for nearly 90,000 enrolled households.

PGE+ takes the guesswork out of getting the right electrical appliance or equipment for customers' homes.

Energy management programs: Smart Thermostat, Time of Day pricing, EV Smart Charging, Peak Time Rebates and Equal Pay

Community engagement and impact

The success of PGE programs and services relies upon engaged and informed customers.

Our work as an electric utility is dynamic and complex. Successfully engaging diverse customers and communities requires intentionality in communicating our core values of equity, transparency and environmental stewardship, creating inclusive forums for public input and investing in community partnerships. PGE's Community Engagement and Community Impact teams lead our strategies with communities as we continue to explore new ways to engage with and learn from the communities we serve.

Community engagement

PGE is committed to engaging in various ways to meet the diverse needs of the communities we serve. Our Community Benefits and Impacts Advisory Group (CBIAG) is the centerpiece of our efforts to develop more equitable strategies for our shared energy future in partnership with environmental justice communities. To protect the safety and well-being of communities in high fire risks areas, PGE collaborates with public safety partners and local governments to increase community awareness and education about wildfire preparedness. PGE also hosts public forums for sharing information and gathering input on infrastructure improvements in communities.

Engaging with area Tribes

We respect and embrace the integral role of Tribes as sovereign governments, economic drivers, political influencers and nation-builders in our collective journey toward a clean energy future. PGE also co-owns the Pelton Round Butte hydroelectric facility with the Confederated Tribes of the Warm Springs.

Tribes have been stewards of lands in which we now work since time immemorial. We have worked closely with Tribal governments, businesses, elders, employees and organizations for many years, providing Tribal leaders, along with other members of the community, an opportunity to engage meaningfully with PGE. As part of these valued relationships, we also seek to raise awareness of historic barriers and address Tribal equity issues with Tribal leaders and other members of the community. PGE's Strategic Tribal Engagement Plan (STEP) provides an enterprise-wide framework for our teams to develop and maintain successful Tribal partnerships.

PGE celebrates Bethel Round Butte grant with the Confederated Tribes of Warm Springs

TRIBAL PARTNERSHIP

The Confederated Tribes of Warm Springs are the co-owners of the Pelton-Round Butte hydroelectric facility and the recipients of a $250 million grant from the Department of Energy to partner with PGE on upgrading the 230 kV Bethel-Round Butte transmission line — a critical artery in the region's transmission system.

PGE volunteers at We Believe in Portland event

Community impact

PGE is deeply rooted in the communities we serve and where we operate facilities and produce power. PGE is dedicated to uplifting and supporting those communities through charitable giving, volunteerism and partnerships. In 2024, PGE and the PGE Foundation surpassed $4.2 million in charitable giving, guided by a strategic investment strategy focusing on education, economic development, workforce readiness and environmental stewardship.

PGE Foundation

The PGE Foundation, a private 501(c)(3) endowed foundation created in 1997, is committed to strengthening economic prosperity by investing in education, creative learning and career pathways that help people build the knowledge and skills they need to reach their full potential. Grants are awarded through a competitive evaluation process and approved by a board of directors made up of PGE officers and senior leaders. 40% of the PGE Foundation board and staff identify as BIPOC, reflecting the diversity of the communities we serve.

In 2024, the PGE Foundation granted $1.6 million to organizations that empower Oregonians to achieve personal and community prosperity through investments in education, career development and creative expression. 64% of grant dollars supported communities of color and 38% invested in culturally-specific, BIPOC-led organizations. 16% of total giving supported organizations in rural areas of Oregon where PGE operates.

The PGE Foundation was the primary funder of the PGE Project Zero green jobs internship program, which received the 2024 Edison Electric Institute Corporate Citizenship Award. Project Zero engages students and young adults in learning about clean energy and sustainability through stewardship and internship programs. The Project Zero green jobs program will now transition to Portland Opportunities Industrialization Center in 2025, with continued financial support from PGE Foundation.

PGE's commitment to customers includes supporting organizations that help communities build resilience and thrive. The PGE Foundation granted $25,000 to the Portland Central City Taskforce to help restore the livability, economic and cultural vitality of Portland's Central City – also home to PGE's corporate headquarters. Following severe weather events in January 2024 that impacted PGE's service area, the PGE Foundation donated $50,000 to several local organizations that provided vital emergency services and resources, including warming shelters, food and water distribution and emergency response coordination.

"As Oregonians, we value the expertise of community partners, prioritizing areas of shared value that reflect the mutual interests of the community and PGE."
– Kregg Arntson, Executive Director, PGE Foundation

GIVING BACK TO COMMUNITIES

$5.5M total company charitable giving from corporate contributions, PGE Foundation, current and retired employees and company match.

55 scholarships through the PGE Foundation and PGE Director Scholarship program focused on access to higher education for students of color, women and students with demonstrated financial need.

22,957 volunteer hours completed by employees and retirees.

66% employee participation in charitable giving and/or volunteerism

Powering community partnerships

Engaging the next generation in learning about climate science and clean energy is at the heart of our corporate partnership strategy, reflecting our values as an Oregon company committed to education access, environmental stewardship and economic equity. In 2024, PGE contributed $1.6 million to support community-based nonprofits across our service area, including a significant investment in a new five-year partnership agreement with Oregon Museum of Science and Industry (OMSI), Oregon's signature destination for experiential science learning and a trusted source of science and climate information for the communities we serve.

PGE has a decades-long history of partnership with OMSI, having once donated the property where OMSI sits and serving on the OMSI Board of Trustees. PGE is the exclusive Energy Sector Partner of OMSI's new Nancy Stueber Natural Sciences Hall opening in 2026 with a focus on climate and clean energy and more than 1 million visitors anticipated per year. To support science learning across Oregon, PGE is also collaborating with OMSI to enhance their existing statewide education outreach programs on energy topics with hands-on classroom activities and take-home projects. One example is through the OMSI Lab embedded in Tamarack Elementary School, where students can explore STEM applications related to clean energy engineering.

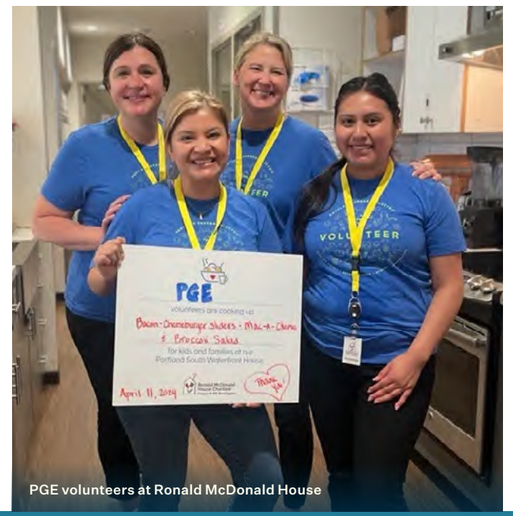
PGE corporate partnerships in 2024 included support for culturally-specific organizations and events, including El Grito, Fiesta Mexicana, Self-Enhancement, Inc., Skanner Foundation MLK Day, the White Lotus Foundation and PRIDE NW. It also included more than $49,000 to support organizations and events in more rural areas where PGE has power generating assets. Other corporate partners in 2024 included Adopt One Block - We Believe in Portland, Friends of Trees, Oregon Zoo, Portland Winter Light Festival, and SOLVE amongst others.

PGE volunteering with HOPE Dementia Support

PGE and OMSI have a longstanding partnership

PGE volunteers and a newly-planted tree at a Friends of Trees event

Employee giving and volunteerism



In 2024, almost two thirds of employees participated in the matching gift program, well above the national average of ~10%. On average, PGE employees and retirees contribute to 1,200 organizations and schools through the employee giving program, including organizations in 97 cities all across Oregon.

PGE's matching gift program provides 100% match up to $2,000 per employee for eligible contributions. Employee-driven contributions must meet anti-discrimination and IRS eligibility requirements. In 2024, PGE updated its matching gift eligibility parameters and risk controls to ensure alignment with PGE values.

Spring Into Action is a month-long volunteering campaign that amplifies employees' commitment to giving back. This year, we saw more than a 50% increase in participation, with over 500 employee volunteers contributing to volunteer events that involved planting native trees, city cleanups, park and beach cleanups, food donations and student education. Employees volunteered for over 2,200 hours, exceeding our goal of 1,500 hours for the volunteering campaign. Additionally, PGE employees regularly volunteer in classrooms and lead hands-on activities. These opportunities focus on connecting science, technology, engineering and mathematic (STEM) concepts to real-world applications, exposing students to career opportunities that help them envision future possibilities and understand how they might positively impact their communities and the planet.

PGE volunteers at Ronald McDonald House

Workforce development

Providing equitable access to the breadth of opportunities available within the clean energy sector is a core value in how PGE approaches the clean energy transition. This is embedded in how we support supplier diversity and labor standards on PGE projects, implement Community Benefit Plans through federal grant funding and lead the Oregon Clean Energy Workforce Coalition.

In 2024, PGE spent
$228M with diverse suppliers.

This represents 18.3% of total spend with diverse-owned suppliers in 2024,
achieving our 18% target.

Supplier diversity and Responsible Contractor Policy

In 2024, PGE continued our efforts to build more robust supplier diversity practices and labor standards. This included an updated RFP evaluation template to provide preference points for diverse suppliers and subcontracting and union contractor utilization. PGE also updated its Responsible Contractor Policy in coordination with labor unions to advance high road labor standards including the payment of prevailing wage and apprenticeship utilization.

Embedding equity in community engagement and outreach continues to be a pivotal process in driving inclusive procurement. We encourage employees to identify small and diverse suppliers when looking for goods and services, construction and professional services. Through the PGE Foundation, we are also assisting underrepresented and diverse vendors in establishing themselves through supporting entrepreneurship, business development and economic opportunities. We encourage any supplier with whom we spend over $250,000 with to provide quarterly information about their diversity practices and empower our suppliers to promote diversity and inclusion in their planning when contracting outside services. We continued to evaluate our supplier diversity efforts and seek opportunities to grow and evolve the program.

Apprenticeship

Our apprenticeship program offers rigorous training and competitive pay, preparing students of all ages and backgrounds to become journeyman lineworkers and other trade workers. The program provides a well-defined wage increase schedule, support from established employees and the local union chapter and consistent progress monitoring to facilitate success at the entry level and beyond. As with all PGE roles, we work to recruit a diverse pool of candidates.

Clean Energy Workforce Coalition

PGE convened the Oregon Clean Energy Workforce Coalition in 2022. It includes representatives from nearly 100 organizations across industry, labor unions, government, employers, education, nonprofits and community-based organizations (CBOs). The Oregon Clean Energy Workforce Coalition continued to grow in 2024 by intentionally recruiting and prioritizing culturally specific CBOs and Tribes to incorporate the voices and needs of all workers within decision-making processes. The coalition will be launching statewide listening sessions in partnership with local CBOs and Tribes to better inform program development and identify barriers to participation. Our efforts will guide existing and future program pilots aimed at training and placing workers in Oregon's clean energy economy.

Community benefits planning

PGE believes in strategically investing in and creating opportunities that benefit traditionally underrepresented groups who often experience the most detrimental impacts of climate change. We are actively pursuing support for such initiatives.

A key component of PGE's federal grant implementation is the Community Benefits Plan (CBP), which details how awardees will use funds to deploy essential clean energy infrastructure in ways that provide opportunities to underserved populations. Over the next several years, PGE's CBP implementation will include developing a clean energy K-12 curriculum in collaboration with educators, a workforce training program for Tribal members, partnerships with pre-apprenticeship programs in construction trades and an energy mentorship program.

Valuing and supporting our employees' well-being

We understand that when communities and our employees thrive, so do we.

As a large employer in Oregon, PGE recognizes that our commitment to the community begins with how we treat employees. Our employees are the cornerstone of our success. The investments we make in our people multiply outwards to benefit the workforce and enrich communities.

We encourage work-life integration and overall physical, emotional and financial well-being. Our benefits help provide the support employees' need to be their best selves as they serve customers and communities in our region. We're proud to offer these valuable advantages: competitive salary, medical, dental and vision insurance, a company incentive program for non-represented employees, ongoing training opportunities, mentorship and professional development programs, paid vacation, retirement savings with company match, education assistance, volunteer opportunities and flexible work options.

All employees have access to paid time off to care for ill or injured family members through PGE time-off programs and through the Paid Leave Oregon program. Non-represented employees are also provided with six weeks of paid parental leave to bond with new children through birth, legal adoption, or foster care. This program runs concurrently with state and federal job-protected leave, Paid Leave Oregon, or other state paid leave programs, which are available to all employees. We also recognize that the process of finding caregiving and educational services can be difficult. To help, employees have access to a free premium-level membership with a vendor to help locate services such as nannies, back-up care, elder care, pet sitters and tutoring services.

Physical and emotional well-being

PGE's employee wellness program, myWellness, provides the benefits and resources needed for PGE employees to power their day. Our health plans offer a variety of wellness perks and programs to support well-being, including free apps and fitness classes, health coaching and discounts on gym memberships and meal delivery services. Many PGE locations have on-site exercise equipment or fitness facilities for employee use. For non-represented and represented employees at Carty, Coyote and Port Westward, the Personify Health program offers tools and programs to keep our employee's wellness goals top of mind. Employees have access to on-demand classes including cardio, strength, yoga, meditation and sleep and new this year, access to a rigorous weight management program. Each fall, we offer convenient on-site flu shots to help protect employees during flu season so they don't have to take time away from their busy schedules to get vaccinated. In addition to programs to support physical health, employees' mental and emotional health are supported through PGE's Employee Assistance Program (EAP) provided by Canopy. Employees can access 10 free counseling sessions through Canopy and other work-life balance support, including webinars, free legal consultation, ID theft services, life coaching and other family support services.

Financial well-being

Another key feature of PGE's wellness program is supporting employees' financial well-being. Our programs have empowered employees to make informed financial decisions and receive support via multi-channel approaches through a comprehensive range of services and resources, including financial education seminars, personalized financial counseling and access to retirement planning tools. Canopy, our EAP, also provides free, unlimited financial coaching, financial wellness webinars and budgeting tools. Meeting employees and their families wherever they are in their financial journey is paramount to PGE's success as we strive toward our strategic goals.

Employee culture and engagement

PGE checks in with employees regularly to ask about our culture and their levels of engagement. Our employee engagement survey is an opportunity for employees to share how PGE can help them feel inspired and energized to do great things and how we can sustain a company culture we are all proud to be a part of. In 2024, our average engagement score was 70.5. Along with engagement survey data, we also look closely at exit interviews and other feedback to understand how workplace experiences affect our collective ability to give our very best.

Understanding the level of inclusion employees feel is a priority for us. In 2024, we added a fourth question to our engagement survey as part of the inclusion index: "I feel a sense of belonging at PGE," "Our team has a climate in which diverse perspectives are valued," "I feel free to speak up without fear of negative consequences" and "Everyone at PGE has an equal opportunity to succeed."

Guiding Behaviors

Our Guiding Behaviors have been central to our company for more than 25 years. While business conditions, customer needs and corporate strategies evolve, our values are long-held and enduring. Our Guiding Behaviors are foundational and provide a single set of expectations for how we work together to be more customer-centric, purpose-driven and results-oriented. Our culture defines not just how we get work done — it shapes our treatment of each other, our approach to safety and our experiences as employees at PGE.

Career development

PGE is committed to supporting the career development goals and long-term success of employees. We provide guidance, resources and frameworks for development, including regular performance appraisals for employees, allowing them to remain adaptable and proficient in a constantly evolving business landscape.

GUIDED BY OUR SHARED GOALS AND ASPIRATIONS, WE ARE INTENTIONALLY SHAPING OUR CULTURE TO BE:

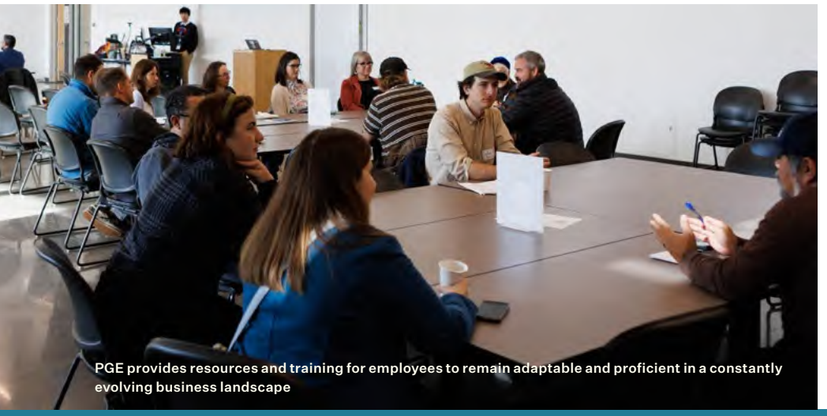
Customer-centric:
Customers and their current and future needs are at the forefront of all that we do. We actively look for ways to improve customers' experience with PGE.

Purpose-driven:
Our commitment to decarbonization and to serving customers and the community with affordable, clean, reliable power is understood and shared across employees.

Results-oriented:
We are outcome-focused, hold ourselves and each other accountable and work as a team to build and align processes that achieve results.

Good Energy Happy Hour bringing together women in the utility industry

Learning opportunities



PGE offers a variety of in-person and online learning opportunities to enhance both technical and essential skills. All employees can access LinkedIn Learning and the Career Development guide, which provide curated learning opportunities on high-priority topics. An average of 7.7 hours of required learning per employee was completed during the 2024 learning cycle. We partner with educational institutions such as Portland State University and the Western Energy Institute to develop or deliver joint training to support programs for staff. We offer skill-building workshops including Electric Utility Fundamentals + Insights, Project Management Basics, Presenting Data Visually and Crafting Strategic Visual Stories. We evaluate the effectiveness of learning solutions through surveys and performance changes. The results of this evaluation influence further development of our learning solutions.

Tuition assistance

PGE supports continuing education and professional development by providing tuition assistance and financial incentives for relevant courses and degrees.

Job rotations

Employees can participate in job rotations within PGE to foster cross-functional skills. Rotation programs allow PGE to develop and retain talent by providing opportunities for employees to gain valuable experience working in different roles and areas of the company while more effectively deploying talent to meet business needs and reduce disruptions caused by talent gaps. Rotations can help close critical skill gaps and improve employee performance while helping prepare employees for their next role. Rotations also support our employees' desire to have more internal development opportunities.

PGE provides resources and training for employees to remain adaptable and proficient in a constantly evolving business landscape

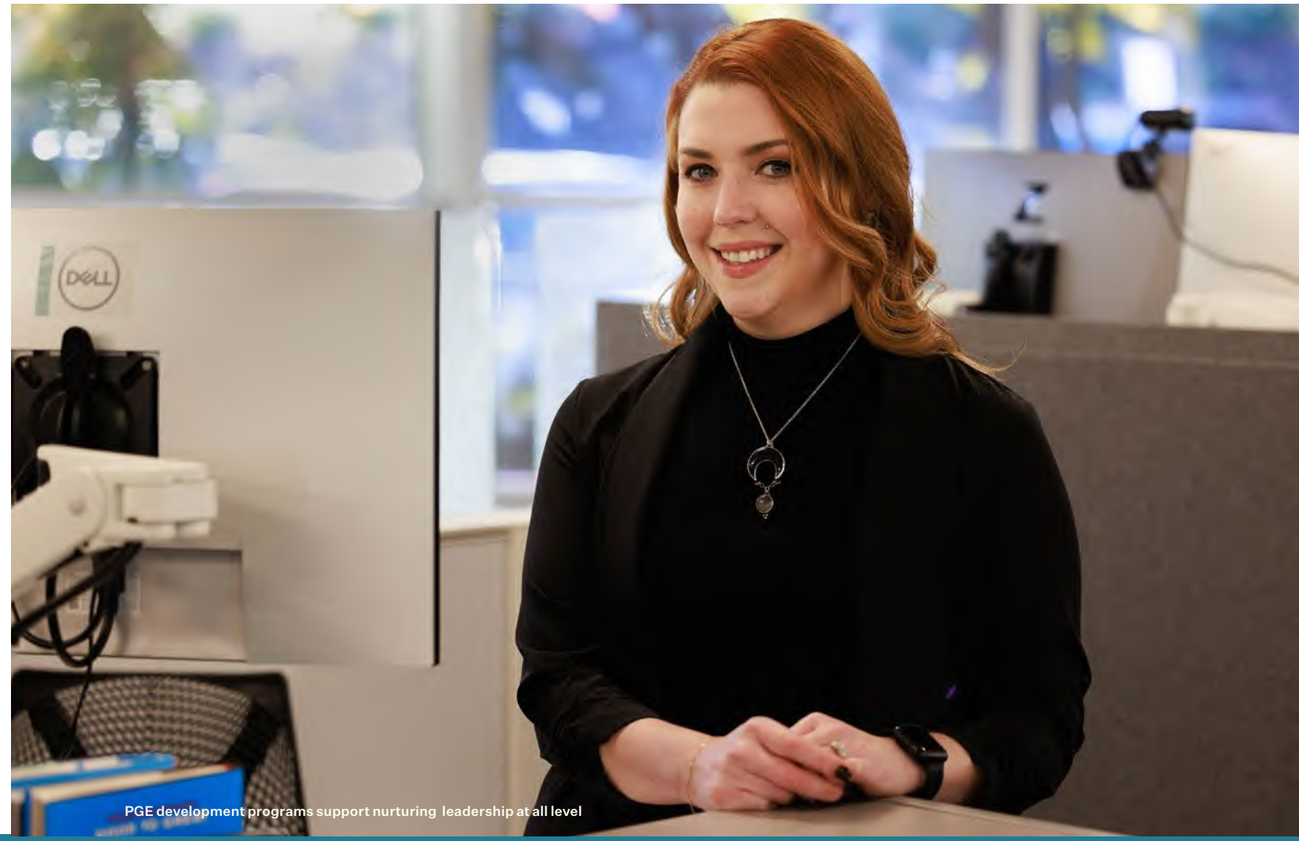
CAREER MOBILITY

13%

of employees were **promoted** in 2024

Leadership development

We nurture leadership at all levels. Our development initiatives aim to identify, nurture and promote organizational leadership potential. We continue to strengthen our leadership pipeline with our programs for high potential leaders with the Enterprise Transformation Leadership and Leadership Excellence programs, co-created with Korn Ferry. These cohort-based programs elevate capabilities and create an always-learning mindset for our leadership bench. PGE also offers the Leadership Effectiveness Acceleration Program (LEAP) to achieve stronger outcomes and engagement by cultivating exceptional leadership. In a competitive talent market, LEAP helps PGE attract and retain top performers by investing in their development, while growing leaders who create environments that inspire people to bring their best. Our leadership programs combine experiential learning, executive coaching, peer-to-peer feedback, mentoring and interactive dialogues with senior leaders and market experts.



Our Workforce Planning department works with business leaders to forecast hiring needs and identify the skill sets needed now and for the future. Through a variety of community partnerships, we continue to expand our talent pipeline and provide living wage jobs here at PGE.

We hold a monthly manager discussion series on relevant topics to increase our leaders' capability and business acumen. These 90-minute sessions create a productive arena for honest conversations, along with a platform to share unique experiences and connect with other leaders.

We also offer leadership development courses targeted to historically underrepresented groups. The development programs, Accelerate and Illuminate, are geared toward expanding leadership diversity and creating new career pathways for women and BIPOC employees.

We've had **149 graduates of Accelerate and Illuminate** since 2019.

This resulted in **71 promotions** and **39% promotions** to management.

PGE development programs support nurturing leadership at all level

Workplace leadership

Our commitment to diversity is an expression of our values and a business priority that makes us stronger as a company. All employees are expected to do their part by embracing others' varied backgrounds, qualities, skills, perspectives and cultures and being willing to talk, listen and learn. We are committed to ensuring a positive work environment where everyone is treated with dignity and respect. We have five commitment areas:

- Recruitment and development
- Leadership diversity
- Awareness, education and training
- Partners and suppliers
- Customer and community engagement

Recruitment and development

We're committed to being a green employer of choice with a workforce that reflects Oregon's increasingly diverse population. Increasing representation and inclusivity at all levels of our organization is a top priority. 44% of hires were female and 29% of hires were BIPOC in 2024. For leadership hiring, 36% were female and 14% were BIPOC.

In 2022, we started a semi-annual Count Me In campaign to promote self-identification. This helps us understand the makeup of our workforce and enables us to create more intentional programs for our employees that allow them to feel seen and heard.

We also perform annual pay equity studies to ensure pay decisions are applied fairly and consistently throughout our workforce.

Leadership diversity

Equity in leadership is crucial, which is why we're growing the diversity of our board of directors and officer team. While we are making steady progress from year to year in almost every workforce demographic category, we also recognize that more can and must be done.

Awareness, education and training

Education is fundamental to building an equitable workplace culture. PGE strives to provide learning opportunities that support employees where they are at. Sessions are designed to offer safe spaces to build skills around self-identity and cultural competence. By offering the opportunity to explore perspectives and discuss experiences in specific communities, we foster greater understanding and positive change in the workplace.

In addition to these optional learnings, all employees complete several required learning modules annually, including PGE's Code of Business Ethics and Conduct training and Harassment and Bullying Prevention, which focus on treating others with dignity and respect.

WORKFORCE DEMOGRAPHICS

Black, Indigenous and People of Color in leadership

BIPOC 26%
White 74%

110% increase since 2014

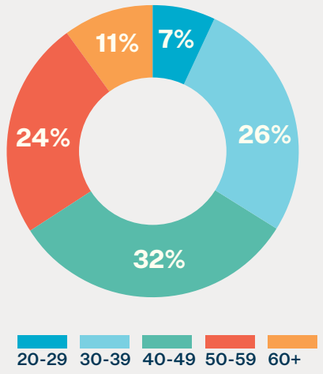
Gender representation in leadership

Women 37%
Men 63%

38% increase since 2014

Black, Indigenous and People of Color

BIPOC 25%
White 75%



39% increase since 2014

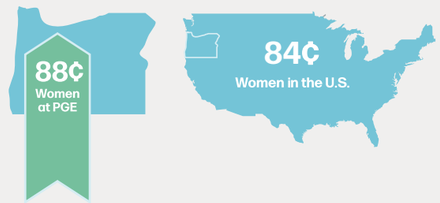
Gender

Women 34%
Men 66%

9% increase since 2014

Age demographics of PGE employees:

PAY EQUITY AT PGE



PGE has achieved equal pay for equal work

BIPOC: Black, Indigenous and People of Color

PGE employees in the same role, with comparable work experience at the same work location, continue to earn a near-perfect dollar-for-dollar pay.

PGE is continuing to shrink the gender pay gap

The gender pay gap is a measure that compares the average pay for women relative to the average pay for men, regardless of factors that determine compensation. At PGE, the gender pay gap is $0.88, which is better than the national average of $0.84[1].

1. Per the Pew Research Center.

PGE'S BUSINESS RESOURCE GROUPS:

- **Asian and Pacific Cultures BRG (APCBRG)**
- **Advocate Broaden Lead Enlighten BRG (ABLE BRG)**
- **Black BRG (BBRG)**
- **Lesbian, Gay, Bisexual, Transgender plus others (LGBT+ BRG)**
- **Latin American BRG (LABRG)**
- **Military Veterans BRG (MVBRG)**
- **Native American BRG (NABRG)**
- **Women's BRG (WBRG)**

PGE's Business Resource Groups (BRGs) also support education and awareness, company business objectives, strengthen our leadership pipeline, enhance employee engagement and build cultural affinity. Participation in these various groups is open to all PGE employees, regardless of how they identify.

Each BRG has an executive mentor from our officer team to guide, represent and support the group. These pairings provide the BRGs a direct avenue of communication with officers, which fosters opportunities to network and develop relationships with executive leadership and enhance recognition of their contributions. In tandem, the officers gain insight into the challenges faced by marginalized employees and access to a wellspring of ideas to improve employee experience. Annually, our Board of Directors actively engages in learning events with our BRGs, aimed at fostering and enhancing business acumen.

Partners and suppliers

We are dedicated to expanding our procurement from diverse small business suppliers, with a strategic focus on amplifying opportunities for minority-, women-, and veteran-owned enterprises. For more information on our supplier diversity commitment, see page 35.

Customer and community engagement

A strong community is the foundation for a prosperous future. Promoting affordability and access remains at the forefront of PGE's commitment to serving customers and our CBIAG is the centerpiece of our efforts to develop more equitable engagement strategies. We also support communities through the PGE Foundation, charitable giving, volunteerism and community partnerships. For more information, see pages 32-34.

PGE crew repairing distribution lines

Governance

Sound corporate governance practices bring lasting value to all our stakeholders.

As our business continues to grow and evolve to address some of the most pressing issues of the time, high standards for corporate governance guide decision making to deliver outcomes for customers, shareholders, employees and communities. We seek solutions that manage costs for customers, foster a resilient and reliable grid, enhance financial performance, reduce environmental impacts, protect the health, safety and well-being of PGE employees and benefit communities.

Our success in achieving these goals depends on our ability to earn and maintain the respect and trust of customers, stakeholders and the communities we serve. To do this, we must hold ourselves to the highest ethical standards. Our work to transparently align our business practices with our core values helps PGE mitigate significant risks to our business. We take a holistic approach that balances a commitment to environmental, social and governance goals with our core mission to supply reliable, affordable electricity service to Oregon.

We believe that good governance is the foundation for consistent, long-term value creation — it allows us to be prepared to address key issues while providing a framework that reflects our values of service, accountability, innovation, sustainability and affordability.

Governance

The Board of Directors

Our Board of Directors is elected annually by our shareholders. The Board receives high levels of support, with over 99% of shareholders voting in 2024 and directors receiving over 99% support on average.

In 2024, our governance practices earned the highest score from proxy advisory firm ISS, a score we have held for 12 consecutive years.

We follow established best practices for Board governance, including implementing maximum tenure and retirement age, ongoing director education and annual Board and director evaluations. These practices are consistent with shareholders' and voting advisory firms' guidelines and we review them annually. The Board annually evaluates committee assignments and periodically moves directors to new committees or into committee leadership positions. These practices allow us to maintain the depth of knowledge required to provide effective oversight of a complex business, while also providing for fresh perspectives.

The directors bring diverse perspectives — as large commercial customers, residents of the Pacific Northwest, experts in customer experience, policy and governance experts and skilled utility operators — which promote an understanding of customers' and stakeholders' needs. In addition, the Board annually identifies the expertise required to allow the Board to efficiently and properly carry out its fiduciary responsibilities. These regular assessments help the Board respond to changes in the industry by identifying potential new expertise that should be brought to the Board.

For 2025, the Board determined that the following areas of expertise are critical for providing effective oversight:

- Finance and Accounting
- Industrial and Utility Operations
- Technology, Cybersecurity and Information Security
- Innovation and transformation
- Environment and Sustainability
- Regulatory and Public Policy
- Human Capital Management and Culture
- Infrastructure Development
- Risk Management and Compliance
- Strategic Planning, Business Development and/or M&A
- Senior Executive Leadership
- Corporate Governance
- Customer Experience

Each of these areas is well-covered by our current Board members. For more information about the expertise of our Board members, see our Proxy Statement.

In 2024, the Board engaged a consulting firm to provide an independent view of its practices and culture. This assessment assisted the Board with prioritizing 2025 work to focus on the highest impact items. It also helped open new channels to create effective communication across the Board, committees and management.

The Role of the Board

Oversight of strategy
The Board's primary responsibility is to oversee the company's long-term strategy. To do that, the Board holds an annual strategy meeting that is separate from the quarterly board meetings. Topics at the meeting include industry and national trends and information about the company's forecasts and evolving customer needs. Past strategy meetings have included nationally recognized speakers on topics like cybersecurity, climate change and infrastructure development and visits to customer or company sites. The Board measures progress and assesses strategy at subsequent meetings to evaluate whether strategic changes are needed in a rapidly changing environment.

Oversight of succession and workforce development
Workforce development and succession planning are essential to building a resilient, future-ready organization. By investing in employees' growth and cultivating internal talent, organizations create a skilled, knowledgeable workforce that can respond more effectively to customer needs and deliver higher-quality service. They also make sure that high-potential employees are prepared to step into key roles, preserving institutional knowledge and ensuring continuity.

The Board believes CEO succession planning is one of its most important responsibilities. In accordance with our Corporate Governance Guidelines, the Board actively oversees CEO and senior management succession planning and talent development to create a strong pipeline of internal candidates ready to assume executive roles. To provide further insight into our internal talent pool, the Board also identifies opportunities for directors to engage with potential senior management successors. At least annually, the Board reviews succession plans for senior management, including a review of possible internal candidates' qualifications and development plans.

MEET OUR 2025 BOARD OF DIRECTORS

Our nine-member Board is comprised of PGE CEO Maria Pope and eight independent directors.

The Compensation, Culture and Talent Committee is primarily responsible for overseeing our workforce development and leadership succession programs. The Compensation, Culture and Talent Committee also regularly engages with management on a broad range of human capital management topics, such as pay equity, strategic workforce planning, employee engagement, performance management and employee well-being programs.

Oversight of financial management
Through the Audit and Risk Committee, the Board plays a critical governance role by ensuring that our financial reporting is accurate and reliable, overseeing our risk management program and overseeing the independent and internal auditors. In 2024, the Audit and Risk Committee membership included two audit committee financial experts as defined by the SEC. The Committee directed improved reporting on SOX controls and internal audit results, allowing the Committee to gain better insight into internal controls. The Committee also has regular executive sessions with the company's independent auditor to hear their perspectives on the company's financial reporting.

The Finance and Operations Committee of the Board provides oversight of capital budgeting and how capital spending is prioritized and access to capital markets and liquidity.

Oversight of sustainability
Oversight of sustainability is woven across all of the Board's committees. The Board's strategic responsibility includes overseeing actions to address risks and opportunities related to climate change and the company's decarbonization strategy. The Nominating, Governance and Sustainability Committee provides guidance to programs related to sustainability, including reviewing progress toward our decarbonization goals and community and political engagement. The Audit and Risk Committee has oversight of ESG disclosures and the company's risk management programs. The Compensation, Culture and Talent Committee has oversight of talent management and compensation plan metrics. The Finance and Operations Committee approves capital budgets, oversees safety and operations and key performance indicators related to financing structures.

PGE crews making repairs at Zig Zag

Risk management and mitigation

Effective risk management is essential to an organization's stability and resilience. At PGE, we use data and modeling to understand risk. We evaluate risks across a wide range of potential consequences, such as safety, impact to customers, environmental, reliability, financial and compliance. Using a consistent evaluation methodology, we can calculate risk values and evaluate mitigations to reduce these values.

We invest millions of dollars each year in maintaining and developing our infrastructure to provide reliable service to customers. Our governance programs work to make sure that PGE's investments are made responsibly and are aligned with corporate priorities to mitigate risk and continue building value for customers and shareholders. Capital projects are vetted through internal governance that requires increased scrutiny and higher levels of approval as the cost of the project increases. Employees with relevant expertise make sure that the reviews focus on long-term strategy and maximize value and are ultimately reviewed and approved by executive officers, the Finance and Operations Committee and the Board.

Enterprise risk management

Our enterprise risk management program reports directly to the company's Executive Risk Committee (ERC), which is responsible for reviewing key enterprise risks and current and planned mitigation actions. The ERC reports to the Audit and Risk Committee of the Board and reviews our top risks at least once every twelve months. The Audit and Risk Committee also has special oversight of market and credit risk associated with energy trading activities and receives detailed reports quarterly.

Climate change

At PGE, we recognize climate change impacts how we serve customers, our assets and communities. We are actively adapting to these risks by strengthening infrastructure to better withstand extreme weather. In addition, we are collaborating with communities to enhance system resiliency. We're also accelerating investments in renewable and non-emitting backup energy capacity and refining our forecasting models to account for changing climate patterns and energy needs. Details can be found in our Clean Energy Plan and Integrated Resource Plan, Distribution System Plan and Wildfire Mitigation Plan.

Wildfire risk management

We understand that the risk wildfire poses to customers, employees and our environment in terms of safety, financial, property and ecosystem damage is significant and growing. We take our ongoing wildfire risk mitigation efforts seriously. Our key objectives are to mitigate the potential of electric infrastructure contributing to wildfires, protect our utility assets and minimize the impact of mitigation measures on customers. During fire season, we closely monitor mitigation efforts to safeguard system performance, train employees on wildfire related safety practices and PSPS procedures and engage customers in fire season readiness.

Our Wildfire Steering Committee (WSC) is comprised of key executives, under the oversight of the Board of Directors. The WSC provides oversight and strategic direction on operational, policy (legal and regulatory) and financial activities related to wildfire risk management. Our Wildfire Mitigation team plans and implements the Wildfire Mitigation Program, which includes developing our Wildfire Mitigation Plan (WMP). The WMP is filed annually with the Oregon Public Utilities Commission. The 2025 WMP details PGE's plan for enhancing situational awareness, system hardening, conducting thorough inspections and managing vegetation, among other mitigation measures. It includes PGE's commitment to spend $53 to $56 million in operations and maintenance costs and $56 to $78 million on system improvements to strengthen our ability to protect customers, our assets and communities. With increased investments planned through 2027, the WMP focuses on hardening our system to reduce wildfire risks to mitigate impacts on customers. To date, we have developed tools and implemented advanced technologies designed to anticipate and respond

PGE EXECUTES A DATA-DRIVEN, HOLISTIC WILDFIRE RISK REDUCTION PLAN

to high-fire risk conditions, including:

- 37 AI-driven wildfire cameras covering 100% of high-risk zones and remote generation assets
- 85 weather stations that provide real-time data
- Early fault detection sensors that identify issues before they cause outages or ignitions
- Refined risk modeling accuracy
- Patrolled and cleared over 1,000 line-miles through our advanced risk reduction vegetation management.

In 2024, we completed approximately 16,500 probable hazard mitigations in high fire risk zones. We also patrolled and trimmed over 5,300 line-miles across our service territory.

We govern this work through the Executive Risk Committee, Wildfire Steering Committee and a dedicated Wildfire Mitigation team focused on wildfire risk; we regularly report to the Board on progress against our WMP. We include metrics on grid hardening, ignition prevention inspections and corrections, line-miles of vegetation cleared and reported ignitions.

While we take our responsibilities seriously, we recognize we can't do it alone. Successful wildfire mitigation requires coordination and collaboration with multiple organizations to advance mitigation efforts. These organizations include local and state emergency managers, the U.S. Forest Service, the Bureau of Land Management, the Oregon Department of Forestry, Indigenous Tribes, fire districts and other emergency responders.

AI-driven wildfire cameras in Mt. Hood National Forest

AI-DRIVEN WILDFIRE CAMERAS

AI-driven wildfire cameras allow PGE, in collaboration with fire and Tribal agencies, to gain quicker visibility and improve response times to protect our assets. During the Hawn Creek fire, first responders received notification of the incident almost two hours ahead of traditional means, allowing the Oregon Department of Forestry to monitor the fire and activate response.

Innovation and solutions

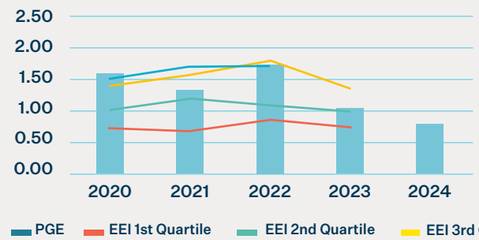
Innovation allows PGE to evaluate viable technologies that support PGE's vision for a non-emitting, reliable and resilient grid. Governance enables us to move quickly on assessing new technologies that improve the customer experience and enhance reliability while putting appropriate guardrails on investments. In addition to internal governance on innovation spending, executive officers report to the Board quarterly on investments made and lessons learned by exploring new technology.

The company's executive team identified the following focus areas that are used to evaluate and prioritize innovation projects:

- Decarbonization at scale
- Strengthen grid performance
- Execute business enhancements
- Realize transportation electrification and load flexibility.

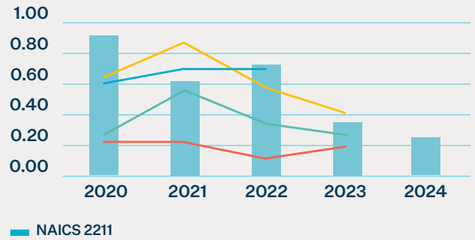
We also encourage leveraging innovation in safe ways. For example, our AI policy is designed to help users harness the power of AI while raising awareness of the risks of AI use, including safeguarding information and privacy.

Safety and emergency preparedness



2024 SAFETY DATA

The introduction of the industrial injury prevention specialist and the injury management program has aided in significant continued improvement of PGE's safety metrics:



0.79 Annual OSHA Recordable Rate
a 64% decrease over the past 5 years

0.26 Lost Time Incident Rate
a 66% decrease over the past 5 years

OSHA Recordable Incident Rate

Lost Time Incident Rate (LTIR)

PGE EEI 1st Quartile EEI 2nd Quartile EEI 3rd Quartile NAICS 2211

The rate of OSHA recordable incidents (also known as the total recordable incident rate) per 100 workers over a set period of time.

The rate of incidents leading to an employee being unable to work for a minimum of one day per 100 workers over a set period of time.

PGE vs. EEI Companies: Group 3 (utilities with 2000-3999 employees)

Safety

Safety is a long-standing priority at PGE. Our dedication to safety is reflected in rigorous training programs, continuous risk assessments and clear communication. We empower employees to uphold high standards in every interaction. We are focused on preventing workplace injuries through pre-emptive interaction and coaching. We have deployed a comprehensive program for injury prevention and management, driver and vehicle safety and increasing supervisors in the field to evaluate working conditions and practices. PGE has also hired an Industrial Injury Prevention Specialist — a mid-level medical provider who is a certified athletic trainer with industrial occupational specialization. The intent is to connect with employees and provide education and guidance on injury prevention and self-care and guidance on minor injuries, allowing employees to return safely to full function. This service has helped drive improvements in one of PGE's most pervasive safety challenges, which is soft-tissue injuries when field employees perform more physically demanding work in variable environments.

To uphold our commitment to safety, we have upgraded the employee health and safety management system to be more user-friendly and better enable employees to report incidents, manage tasks and access critical safety information. Enhanced features and improved data accuracy help managers make informed decisions, track compliance and implement safety measures proactively and swiftly.

Emergency preparedness

PGE proactively plans for unforeseen events, from natural disasters to system outages, enabling us to minimize disruptions and maintain critical services when customers need them most.

Preparing for an emergency requires a comprehensive plan and a local team trained and ready to execute. The 2023 Push Partner Point of Distribution project was a full-scale exercise involving 20 players from various departments at PGE, designed to evaluate our readiness for a large-scale public health emergency, such as biological terrorism. In partnership with the Cities Readiness Initiative Push Partner program, we introduced this exercise in real-time to a group of over 100 employees. This hands-on drill helped us update processes, documentation and training to increase effectiveness in an emergency. This readiness protects employees and reassures customers that they can rely on the Company's ability to respond swiftly and effectively, even in challenging situations.

View from the West Hills across Portland to Mt Hood

Transparency across our business practices

We strive to meet the highest standards of excellence in our work and reporting; our commitment to transparency helps us achieve that goal. Visibility into how we run our business automatically results in accountability, not just to stakeholders but to each other.

Public policy and political advocacy

Public policy can significantly impact our company and stakeholders, so we participate in the political process through regular and constructive engagement with government officials and policymakers, by making contributions to candidates and organizations and by encouraging political engagement by our employees. We collaborate with organizations like the Edison Electrical Institute on national energy policy issues. Our advocacy is focused on supporting customer growth objectives, investing in infrastructure, decarbonization and reducing wildfire risk.

PGE is committed to complying with all laws and regulations governing political activities and engaging in the political process ethically and transparently. All political activities, including contributions, are conducted or made in full compliance with the law and our Political Engagement Policy.

Contributions are approved by the officer responsible for government affairs or by our President and CEO. Any exceptions to the Political Engagement Policy require approval from our General Counsel.

We publish an annual report detailing corporate-funded contributions and expenditures to promote transparency. The Nominating, Governance and Sustainability Committee of the Board reviews this report, along with our Political Engagement Policy and any exceptions, annually. The committee collaborates with management each year to align our political lobbying and contributions with our strategic priorities.

Oregon State Capitol

Ethics and compliance

At PGE, acting with integrity and accountability is fundamental to how we operate and we hold our employees, leadership and board to high standards.

Our Ethics and Compliance programs are designed to reinforce transparency, responsibility and ethical business practices across the company. The cornerstone of this program is our Code of Business Ethics and Conduct (Code), adopted by the Board and upheld by all directors, officers and employees. The Code addresses many areas of workplace conduct, including conflicts of interest, unfair or unethical use of corporate opportunities, protection of confidential information and legal and regulatory compliance. All existing employees are required to affirm adherence to the Code through biennial refresher training. Our CEO, CFO and Controller must also abide by the specialized Code of Ethics for Chief Executive and Senior Financial Officers.

Anti-corruption training is provided to all employees, with additional specialized training for leaders, procurement teams and those who work with government officials. Employees are expected to act in PGE's best interests, avoid conflicts of interest and refrain from exchanging gifts that could influence or appear to influence business decisions. All employees are prohibited from engaging in any form of corruption, including making or accepting improper payments or other forms of compensation. We have stated policies for disclosing any potential, perceived or actual conflicts and clear processes for requesting approval for certain gifts, meals or entertainment.

The Audit and Risk Committee of the Board of Directors receives quarterly updates from our Ethics and Compliance departments on key compliance metrics and internal investigations related to employee conduct.

Employees are expected to report any violations of the law, our ethics codes or company policies. Employees may use a variety of internal channels to make their reports, including their manager, HR Business Partner, the Ethics team, or directly to the Chief Legal and Compliance Officer. We also offer the option to report anonymously through the EthicsPoint hotline, which NAVEX, a trusted third-party whistleblowing hotline service operates. The Audit and Risk Committee has also adopted procedures for receiving and addressing whistleblower concerns regarding accounting practices, internal controls and auditing matters.

Additional information on our ethics and compliance policies and commitments can be found on our website:

- Human Rights Policy Statement
- Sustainability Policy
- Supplier Code of Conduct
- Code of Business Ethics and Conduct
- Safety Policy
- Political Engagement Policy

*Additional information on our financials and governance can be found in our Proxy and Annual Report.

ESG data tables

In this section, we disclose data under the Edison Electric Institute (EEI) ESG Quantitative Template, Sustainability Accounting Standards Board (SASB) and Task Force on Climate-Related Financial Disclosures (TCFD). We also provide additional key ESG metrics.

Governance
Governance and business performance data is available in our 2024 10-K, 2024 Annual Report and 2025 Proxy statement.

NOTES

(1) Value calculated using data provided by PGE per Oregon Department of Environmental Quality, Investor-owned Utility GHG protocols. Value cannot be used directly with Generation Fleet emissions as it is based on total energy served to retail customers, including power purchased from other sources.

(2) Electric vehicles as defined by the Edison Electric Institute.

(3) Information presented is based on data reported to Oregon DEQ in PGE's Investor Owned Utility GHG Report. Percentages represent the portion of power delivered to PGE customers in Oregon.

(4) Hydro includes power purchased from Bonneville Power Administration (BPA).

(5) "Other" fuels may include biomass, biomass gases, landfill gas or other fuel types, including certain emissions-free sources that do not meet DEQ requirements to qualify as "specified purchases." PGE presumes the resources are not emissions-free.

(6) Data based on voluntary employee reporting.

(7) Electric department only, excludes station use.

(A) These amounts have been restated from the prior year ESG report as a result of finalizing review and third-party verification procedures with the Oregon Department of Environmental Quality.

(B) These amounts are preliminary and could vary from those filed with ODEQ. Refer to footnote 3 under the EEI template for additional details related to this metric.

2024
Sustainability Accounting Standards Board (SASB) Report

THIS YEAR MARKS PORTLAND GENERAL ELECTRIC'S FIFTH YEAR MAPPING OUR DISCLOSURES TO THE SASB STANDARD FOR ELECTRIC UTILITIES & POWER GENERATORS. OUR RESPONSES REFLECT 2024 PERFORMANCE AS OF 12/31/2024.

Topic	Data Request	PGE Response
Greenhouse gas emissions and energy resource planning	(1) Gross global Scope 1 emissions, percentage covered under (2) Emissions-limiting regulations (3) Emissions-reporting regulations	(1) Total $MTCO_2e$ from Scope 1 activities: 6,412,964. Refer to the Notes for a breakout by activity. (2) 99.9% of our Scope 1 emissions relate to our thermal generating resources, which are covered in the State of Oregon emissions-limiting regulations. (3) 99.9% of our Scope 1 emissions relate to our thermal generating resources, which are covered in the State of Oregon emissions-reporting regulations. Notes: (1) The reported Scope 1 emissions are from PGE's thermal generating resources, fuel burned by PGE's fleet, SF6 and natural gas used at PGE's office facilities. Thermal generating resources make up 6,404,517* $MTCO_2e$, vehicle fleet fuel burned equates to 6,656, SF6 equates to 1,233 and natural gas used equates to 558. Emissions associated with R99 diesel fuel not included within Scope 1 are 2,651 $MTCO_2e$. Emissions associated with fleet fuel burned include estimates related to the vehicle type in order to assign an emission factor. Given the emission factors for vehicle types are materially consistent, this does not materially impact emissions reported. *This is a preliminary number that is subject to change following regulatory agency review and approval of submittals.
	Greenhouse gas (GHG) emissions associated with power deliveries	5,895,803 $MTCO_2e$* PGE is required to report emissions associated with power delivered to retail customers in Oregon to the Oregon Department of Environmental Quality (ODEQ) on an annual basis. Refer to the link for publicly available historical information. PGE follows ODEQ's Greenhouse Gas Reporting guidelines when calculating this number. This includes the use of ODEQ specific emission factors, removing power sold to end users outside of Oregon, and proportionally adjusting retail sales for wholesale sales in order to arrive at the total amount of MWhs sold to Oregon customers. This amount represents anthropogenic emissions only. 2024 biogenic emissions were 75,820 $MTCO_2e$. Greenhouse Gas Emissions Reported to ODEQ *To calculate 2024 emissions associated with power deliveries to retail customers in Oregon, PGE used ODEQ 2023 emission factors for purchased power and estimated emission factors for generated power as ODEQ 2024 emission factors are not yet available. This is a preliminary number and could vary from those filed with ODEQ.
Greenhouse gas emissions and energy resource planning *(continued)*	Discussion of long-term and short-term strategy or plan to manage Scope 1 emissions, emissions reduction targets and an analysis of performance against those targets	Oregon has some of the most ambitious clean electricity targets in the country—achieving at least an 80% reduction in greenhouse gas (GHG) emissions associated with the power served to customers by 2030, a 90% reduction by 2035 and a 100% reduction by 2040. The baseline for these reductions is based on the annual average of 2010, 2011 and 2012 emissions as reported to the ODEQ. PGE is more than one-third of the way toward the emission reductions needed to meet its 2030 target. For more information about PGE's emissions progress, see page 11 of the 2024 ESG Report. PGE's transition plan to a clean energy future is outlined in its Clean Energy Plan, which is embedded in our strategy to meet Oregon's House Bill 2021 emissions targets. The plan prioritizes investments in renewable energy resources, transportation electrification, and advanced grid technologies. In 2024, 77% of PGE's retail emissions come from PGE-owned generating assets that are covered in Scope 1 reporting. Achieving emissions reduction requires steadily adding renewable energy, battery storage, energy efficiency and demand response to our portfolio, so we can reliably and affordably reduce fossil fuel generation. Since implementing its emissions targets in 2021 PGE and its customers have committed to 2,900+ MW of clean energy. Recent additions to this portfolio include 475 MW of new battery storage projects, with 275 MW achieving commercial operations in December 2024 and the remaining 200 MW scheduled for service in mid-2025. Of the 275 MW in service, PGE owns 75 MW and procures the remaining 200 MW under a 20-year storage capacity agreement. The portfolio also includes PGE procurement of 311 MW of energy from the Clearwater Wind facility which began generating power in January 2024. PGE owns 208 megawatts of the project and procures the remaining 103 megawatts under a purchase power agreement (PPA). Resources required to meet the remaining 2030 need and further progress toward our emission reduction goals are anticipated to be procured through future acquisition processes, including, but not limited to, the 2021, 2023 and 2025 All-Source RFP and future RFPs. For more information about PGE's resource additions to meet its emission targets, see page 18 of the 2024 ESG Report.

Topic	Data Request	PGE Response
Air quality	Air emissions of the following pollutants: (1) NOx (excluding N_2O) (2) SOx (3) Particulate matter (PM_{10}) (4) Lead (Pb) (5) Mercury (Hg) Percentage of each in or near areas of dense population	(1), (2), (5): Refer to section 6 of the EEI template for these metrics. PGE 2024 EEI ESG Report PM_{10} — Pb 479 MT — 0.048 MT Percentage near a dense population NOx — 36.7% SOx — 4.1% PM10 — 56.1% Pb — 1.5% Hg — 14.4%
Water management	(1) Total water withdrawn (2) Total water consumed, percentage of each in regions with High or Extremely High Baseline Water Stress Percentage of each in regions with High or Extremely High Baseline Water Stress	(1) 23,209 thousand cubic meters (2) 22,490 thousand cubic meters consumptive, 719 thousand cubic meters non-consumptive N/A; PGE operations are not in High or Extremely High Baseline Water Stress areas Note: Water withdrawal and consumption data is associated with PGE thermal generating facilities only, and does not include nominal water use (e.g., drinking water) for which data was not readily available.
	Number of incidents of non-compliance associated with water quality permits, standards and regulations	None
	Description of water management risks and discussion of strategies and practices to mitigate those risks	Efficient use of natural resources–including water resources–continues to be a priority. PGE's operational facilities are located in basins with low or low-medium baseline water stress per the World Resources Institute (WRI) Aqueduct Water Risk Atlas. PGE's thermal generation assets, which rely on water access, are located in basins that are classified as low baseline water stress. PGE operates three hydropower generation systems licensed by the Federal Energy Resource Commission (FERC): Pelton Round Butte Hydroelectric Project (Deschutes River), Clackamas River Hydroelectric Project (Clackamas River and tributaries), and Willamette Falls Hydroelectric Project (Willamette River). License conditions (e.g., specific flow requirements based on seasonal natural resource needs) were developed in partnership with natural resource agencies and environmental stakeholders and support our objectives of healthy native fisheries (e.g., salmon and steelhead) and long-term sustainability for wildlife and water quality in the basins where we operate. Our efforts include significant PGE-led and PGE-partnership projects in the watersheds of our hydropower facilities focused on basin-wide water conservation efforts to increase in-river flows that are critical for habitat improvement and fisheries' restoration goals.

Topic	Data Request	PGE Response
Coal ash management	Amount of coal combustion residuals (CCR) generated, percentage recycled	112,406 MT of CCR generated from operations, 0.0% recycled. These values represent PGE's 20% share of Colstrip.
	Description of coal combustion products (CCPs) management policies and procedures for active and inactive operations	PGE does not have any active coal combustion product operations, and the State of Oregon has not developed a Coal Combustion Residual (CCR) permit program for EPA approval; therefore, the one CCR landfill that PGE operated for the Boardman Coal Plant completed closure on August 21, 2021, in accordance with the requirements of the Closure Plan developed per 40 CFR 257.102(b). Inspection of the closed CCR landfill occurs annually and PGE monitors groundwater per the requirements of 40 CFR 257.93 and 40 CFR 257.94. On April 25, 2024, the EPA released final regulations pertaining to electric generation facilities, including Disposal of Coal Combustion Residuals (CCR) from Electric Utilities – Legacy CCR Surface Impoundments. This rule builds on 2015 regulations, which apply to active power plants that dispose of coal combustion residuals in surface impoundments or landfills, by regulating inactive surface impoundments at inactive power plants, as well as CCR management units at both active and inactive power plants. PGE has assessed the potential impact of these regulatory changes and believes they will not have a material impact on the Company's current Asset Retirement Obligations. PGE does have 20% share of Colstrip, and the majority owner manages the CCP program following state and federal regulations.
Energy affordability	Average retail electric rate for: (1) Residential (2) Commercial (3) Industrial customers	 (1) 18.05 cents/kWh (2) 13.77 cents/kWh (3) 8.61 cents/kWh
	Number of residential customer electric disconnections for nonpayment, percentage reconnected within 30 days	Total number of residential disconnections: 35,324 Number of residential disconnections reconnected within 30 days: 30,720 As a percentage of total: 86.97%
	Discussion of impact of external factors on customer affordability of electricity, including the economic conditions of the service territory	Together with policymakers and regulators we are working to keep affordability at the forefront of clean energy transition discussions. Careful planning and policy design can reduce the costs of an emissions-free economy. Despite efforts to keep electricity broadly affordable, we recognize that some customers need more help. We support our customers by connecting them with bill assistance funding and discount programs, energy efficiency and weatherization, arrearage forgiveness, flexible payment options and advocating for public sector funding. Per the passage of the Energy Affordability Act (Oregon House Bill 2475) that authorizes the Public Utility Commission of Oregon to consider differential energy burden and other inequities of affordability in rates, PGE offers income-qualified customers a new program that provides a 15-60% discount on their energy use. This program is the first of its kind for large, investor-owned utilities in Oregon and is designed to result in a meaningful reduction in energy bills for income-qualified customers, alleviating hardship and providing easier, more affordable access to reliable power. To date, PGE has enrolled nearly 90,000 households in the program. For more information about PGE's energy affordability efforts, see page 30 of the PGE's 2024 ESG Report.

	Customer electricity savings from efficiency measures, by market	37.8 aMW were saved from PGE's Energy Efficiency Measures in 2024. In 1999, the Oregon Legislative Assembly adopted Senate Bill 1149 which directed Oregon's two largest investor-owned electric utilities, Portland General Electric (PGE) and Pacific Power, to collect three percent of their revenues for a public purpose charge (PPC). In 2002, the Energy Trust of Oregon (ETO), an independent non-profit organization overseen by OPUC, was created to administer the PPC funds received from the OPUC and to incent new cost-effective energy conservation, new market transformation efforts, above-market costs of new renewable energy resources and new low-income weatherization. Since then, the ETO has helped PGE customers save energy and money by providing information, assistance and cash incentives for energy efficient upgrades and renewable energy systems. In support of this mission, the OPUC directs PGE to provide ETO with a limited set of information about large and commercial industrial customers, including customer name, service address and whether the customer is applying self-direct credits against its energy-efficiency and renewable public purpose charge during each billing period. In 2021, the Oregon Legislative Assembly adopted House Bill 3141 which directs ETO to, with public utilities, jointly develop public utility-specific budgets, action plans and agreements that detail the entity's public utility- specific planned activities, resources and technologies. The legislation also expands the scope and allocation of new renewable energy sources to include distribution system connected technologies (DSCT) and require that 25 percent be used for activities, resources and technologies that serve low and moderate income customers, including for technologies that do not have above-market costs. In 2022, PGE implemented HB 3141 by codifying a Budget Coordination Memorandum with the Energy Trust of Oregon which established an annual process for development of utility specific action plans and staff work groups. The 2023 utility specific action plan includes, among other activities, coordinated capacity building for community partners, pairing of PGE income qualified bill discounts (QBD) with no/low-cost heat pump incentives, and advancement of two non-wires solution proposals to address equity needs and grid constraints. 2024 was an excellent year with continued, steady customer demand growth for heat pumps and other home energy efficient products. PGE's partnership with ETO has exceeded the annual goal by 35% with 37.8 aMW saved and the annual IRP goal by 32%. *These numbers are preliminary numbers as provided by the ETO. Numbers are subject to change from this report to the final filed report, which will occur later in the year.

Topic	Data Request	PGE Response
Nuclear safety and emergency management	Total number of nuclear power units, broken down by results of most recent independent safety review	N/A Note: The NRC regulates the licensing and decommissioning of nuclear power plants, including PGE's Trojan nuclear power plant, which was closed in 1993. The NRC approved the 2003 transfer of nuclear spent fuel from a spent pool to a separately licensed dry cask storage facility that will continue to house the fuel on the former plant site until a United States Department of Energy (USDOE) facility is available. Radiological decommissioning of the plant site was completed in 2004 under an NRC-approved plan, with the plant's operating license terminated in 2005. Spent fuel storage activities will continue to be subject to NRC regulation until all nuclear fuel is removed from the site and radiological decommissioning of the storage facility is completed. 2024 Form 10-K
	Description of efforts to manage nuclear safety and emergency preparedness	PGE permanently ceased commercial operation of the Trojan nuclear power plant in January 1993. Since then, the plant has been dismantled as part of the decommissioning process and all nuclear fuel has been placed in long-term, dry storage as of September 2003. Trojan's nuclear fuel is stored in robust canisters which are encapsulated in vertical concrete casks that provide structural protection, radiation shielding and sufficient passive cooling to maintain the safety of the fuel. Based on this robust design and extensive analysis of hazards, there are no operations or credible accidents that result in a release of radioactive material from the canisters. As an owner of special nuclear material, PGE is licensed by the Nuclear Regulatory Commission for fuel storage. In 2019, following an extensive review of PGE's proposed Aging Management Program, the Nuclear Regulatory Commission granted an extension of PGE's license to store fuel an additional 40 years to 2059. Nuclear safety is the highest priority for the Trojan staff, and its nuclear safety culture is assessed and monitored by an Independent Spent Fuel Storage Installation (ISFSI) Safety Review Committee, which advises the Corporate Executive Responsible for Trojan on all matters related to the safe storage of spent fuel. The Trojan organization operates in compliance with a Quality Assurance Plan under which operations and security functions are regularly audited. Trojan Spent Fuel Storage

Grid resiliency	Number of incidents of non-compliance with physical or cybersecurity standards or regulations	Portland General Electric Company is subject to mandatory physical and cybersecurity standards adopted by the North American Electric Reliability Corporation (NERC). Our practice is to self-report all identified instances of actual or potential noncompliance with the NERC physical and cybersecurity standards, regardless of severity. In 2024, PGE had five instances of actual or potential noncompliance filed with the Western Electricity Coordinating Council (WECC), the Regional Entity responsible for NERC compliance monitoring and enforcement in the Western Interconnection. All five of the instances were identified by PGE and self-reported. One instance has already received a Compliance Exception disposition from WECC. Four instances are under review by WECC's Risk and Enforcement staff.
	(1) System Average Interruption Duration Index (SAIDI) (2) System Average Interruption Frequency Index (SAIFI) (3) Customer Average Interruption Duration Index (CAIDI), inclusive of major event days	(1) 757 minutes (2) 1.18 events (3) 642 minutes PGE experienced a total of 6 Major Event Days in 2024. The most significant impact was a storm event in January 2024 which resulted in 5 Major Events Days, approximately 400,000 customer impacted, and 14 days of disruption to PGE operations. PGE also experienced 1 Major Event Day in December 2024.

Task Force on Climate-Related Financial Disclosures (TCFD)

PGE IS COMMITTED TO PROVIDING OUR STAKEHOLDERS WITH TRANSPARENCY AROUND OUR SUSTAINABILITY PRACTICES AND HOW WE ARE ADDRESSING CLIMATE-RELATED ISSUES. A SUMMARY OF OUR RESPONSE TO THE TASK FORCE ON CLIMATE-RELATED FINANCIAL DISCLOSURES (TCFD) FOLLOWS. ADDITIONAL INFORMATION CAN BE FOUND THROUGHOUT THIS REPORT, IN OUR ANNUAL REPORT ON FORM 10-K AND AT THE VARIOUS RESOURCES LINKED BELOW.

Topic	Data Request	PGE Response
Governance Disclose the organization's governance around climate-related risks and opportunities.	Describe the board's oversight of climate-related risks and opportunities.	The Board of Directors provides strategic oversight of PGE's operations and governance, supporting alignment with its mission and overseeing and advising management on PGE's strategic imperatives to decarbonize, electrify and perform, and creating value for shareholders, customers, and stakeholders. Responsibility for environmental, social, and governance (ESG) performance—including climate-related risks and opportunities—is integrated into PGE's policies and governance principles. Through the "Sustainability and ESG Governance Framework," the company aligns sustainable practices with business goals fostering transparency around ESG-related risks and opportunities. The Board and its committees oversee significant strategic, operational, financial, reputational, and ESG risks. This includes active review of the company's enterprise risk management (ERM) program to monitor and address strategic and emerging risks, including those related to climate change. The Board evaluates whether management has implemented effective systems to identify, assess, and manage material risks across areas such as cybersecurity, environmental, financial, legal, and regulatory risks. Regular reporting from management keeps the Board informed of risks and mitigation efforts, including those arising from climate-related events like wildfires and ice storms. The Board also oversees the impact of legislation and regulation on PGE's clean and renewable energy and transportation electrification strategies, supporting alignment with local, state, and federal goals. At least annually, the Board and the Finance and Operations Committee review corporate goals and approve capital budgets to prioritize system resilience, customer-focused programs, and investments tied to key ESG metrics. The Board has established four standing committees to assist the Board with its oversight responsibilities each of which plays a specific role in monitoring and addressing climate-related risks and opportunities. **Audit and Risk Committee** The Audit and Risk Committee assists the Board in overseeing the company's Enterprise Risk Management Program (ERM), which includes the identification, evaluation, and mitigation of material environmental risks, including climate-related risks. The committee receives quarterly reports from management on the activities and findings of the risk management program, including risks related to financial reporting, internal controls, and ESG disclosures. The Audit and Risk Committee oversees controls and metrics for ESG performance, including those addressing climate-related risks, are robust and reliable.

Topic	Data Request	PGE Response
Governance Disclose the organization's governance around climate-related risks and opportunities. *(continued)*	Describe the board's oversight of climate-related risks and opportunities.	**Nominating, Governance, and Sustainability Committee** The Nominating, Governance, and Sustainability Committee oversees the company's ESG strategy, policies, and progress, with a specific focus on climate change, sustainability, and environmental issues. This committee evaluates risks and opportunities associated with the company's governance and sustainability initiatives, monitoring progress against emissions and clean energy goals and targets related to climate change. Additionally, the committee reviews and guides the development of policies that support the company's decarbonization strategy. **Finance and Operations Committee** The Finance Committee oversees the company's financial and capital planning to support its climate-related objectives, as well as overseeing the company's operations, technology investments and emergency preparedness response plans. This includes overseeing the alignment of capital budgets with strategic goals. The committee reviews financing arrangements tied to ESG key performance indicators and assesses potential financial risks that could impact the company's ability to achieve its climate-related goals. **Compensation, Culture, and Talent Committee** The Compensation, Culture, and Talent Committee oversees compensation plan metrics, including long-term incentive (LTI) goals related to decarbonization, as well as human capital management programs and outcomes. Starting in 2019, PGE incorporated emission reduction metrics as part of a long-term incentive (LTI) awards program to encourage the planning and execution of actions that drive progress toward the decarbonization of PGE's resource portfolio. PGE's LTI awards granted to executives and other key employees includes a performance metric related to achievement of the Company's strategic goals surrounding clean energy. This metric is used to create incentive to reduce carbon potential in the Company's energy supply portfolio in support of Oregon's GHG emission reduction goals. The metric is to be measured based on average megawatts of forecast energy from carbon-free resources, Oregon Renewable Portfolios Standard-qualifying resources, and low-carbon emitting (i.e., greater than or equal to 95% carbon-free) systems of resources added to the Company's energy supply portfolio during the performance period. The committee also monitors talent management, human capital disclosures, and workforce health and safety, aligning with the company's ESG and strategic objectives. For more detailed descriptions, please refer to the committee charters available on PGE's Corporate Governance website.
	Describe management's role in assessing and managing climate-related risks and opportunities.	The executive team is responsible for developing and executing strategies that address PGE's climate-related risks and opportunities, including efforts to decarbonize, electrify, and improve performance. Regular updates are provided to the board on the progress of these strategies, including achievements toward emissions reduction and clean energy goals, the status of key climate-related initiatives, and emerging risks such as wildfire and other climate impacts. Management is responsible for day-to-day management of identifying and mitigating climate-related risks and pursuing climate-related opportunities. To promote consistency and comprehensiveness in its approach, PGE established a management-level Sustainability and Environmental, Social and Governance Steering Management Committee (S&ESG) to oversee the execution of climate-related strategies. The committee reports to the Strategy Executive Steering Committee and meets on an as-needed basis, with plans to meet at least annually beginning in 2025. Co-chaired by the Controller and the Vice President of Policy and Resource Planning, the committee includes senior leaders from various departments such as Environmental Services, Finance, Supply Chain, and Human Resources. This cross-functional group drives alignment across the organization, actively managing and integrating both climate-related risks and opportunities into business operations. The committee also provides governance and oversight, supporting PGE's efforts to manage climate risks, capitalize on opportunities and comply with relevant standards and regulations. In addition to the S&ESG Management Steering Committee, PGE's enterprise risk management program reports directly to the Company's Executive Risk Committee (ERC), which is responsible for reviewing key enterprise risks and current and planned mitigation actions, including climate-related risks. The ERC reports to the Audit and Risk Committee of the Board, who is responsible for assisting the Board in overseeing the Company's enterprise risk management program and reviews top risks at least once every twelve months. The Audit and Risk Committee also has special oversight of market and credit risk associated with energy trading activities and receives detailed reports on a quarterly basis. In addition, PGE established in June 2024, the Wildfire Steering Committee (WSC), a subcommittee of the ERC. The WSC, comprised of key executives, aids the ERC in performing risk analysis of PGE's wildfire risk management activities. The subcommittee also supports the ERC with its oversight and strategic direction on operational, policy (legal and regulatory) and financial activities related to wildfire risk management.

Topic	Data Request	PGE Response
Strategy Disclose the actual and potential impacts of climate-related risks and opportunities on the organization's businesses, strategy, and financial planning where such information is material.	Describe the climate-related risks and opportunities the organization has identified over the short-, medium-, and long-term.	PGE has identified and assessed various climate-related risks and opportunities across short-, medium-, and long-term horizons, leveraging a combination of regulatory frameworks, customer preferences, and environmental trends. These assessments inform the Company's strategic planning, capital investment, and operational decisions to support resilience and adaptability in a changing climate. **Risks:** PGE faces both physical and operational risks stemming from extreme weather and wildfire, and transitional risks associated with regulatory and market changes as the energy sector evolves toward a clean energy future. Key risks include: **Physical and Operational Risks** • **Wildfire Risk:** Wildfires of greater size and prevalence, as seen in recent years in Oregon, pose risks to public safety, grid resilience, the reliability of PGE's services and the financial health of the utility. Wildfires can damage generation facilities and transmission infrastructure, disrupt energy delivery, and increase the cost of power procurement. Drought conditions and declining tree health exacerbate wildfire risks, necessitating significant investments in vegetation management, grid hardening, and safety measures such as Public Safety Power Shutoff (PSPS) zones leading to higher capital and operating expenses. Capital investment and operating expenses related to this risk may not be recoverable through increases in customer prices or insurance proceeds. • **Severe Weather and Climate Change Impacts:** Climate change is driving more intense, frequent, and extreme weather events, including ice and snowstorms, high winds, flooding, heatwaves, and drought. These events can disrupt energy delivery, cause power outages, and damage PGE's transmission and distribution systems. Such disruptions often result in increased costs to restore service, repair facilities, and procure energy and fuel, which can adversely affect cash flow and liquidity. For instance: o Variations in seasonal temperatures increase energy demand, with warmer-than-normal summers or cooler-than-normal winters. o Rapid increases in load requirements during unexpected weather changes, particularly if coupled with transmission constraints, increase operational costs and risks. In recent years, PGE's territory has experienced unprecedented heat, historic ice and snowstorms, and wildfires. In August 2023 the region experienced a record-breaking heat wave with temperatures reaching all-time recorded highs for the month. This resulted in a peak load demand of 4,498 MW, exceeding the Company's previous all-time peak load demand. Beginning in January 2024, the Company's service territory encountered the first of a series of severe winter weather events, including snow, ice, and high winds that caused catastrophic damage to physical assets and resulted in widespread customer power outages. **Transitional Risks** • **Regulatory Compliance:** PGE is subject to various environmental laws and evolving GHG emissions reduction mandates, including Oregon's House Bill 2021. Compliance may require substantial investments in emissions reduction technologies, carbon offsets, and transitioning high-emitting facilities to non-emitting resources, with costs and timelines subject to regulatory and technological uncertainties. Environmental regulations protecting wildlife and endangered species can delay or restrict the development and operation of power generation, transmission, and distribution facilities, increasing costs and reducing renewable energy availability. Additionally, new or changes in regulations could further increase capital expenditures and operating costs. • **Economic and Market Risks:** Customer expectations for clean energy and decarbonization are driving rapid shifts in market dynamics. PGE must balance these evolving demands with the need to maintain reliability and affordability. Additionally, transitioning away from fossil fuels, including planned exits from coal-fired Colstrip Units 3 and 4, presents operational and economic challenges, particularly in ensuring sufficient resource adequacy during peak demand periods. • **Financial Risks:** Rising costs associated with climate-related events and the capital investments required to mitigate these risks may pose financial risks. Efforts such as grid hardening, wildfire mitigation, and the transition to renewable energy require substantial expenditures, which may not always be recoverable through customer pricing. These financial risks necessitate careful balancing of decarbonization goals with maintaining affordability and reliability for customers, while ensuring long-term financial stability for PGE. The potential for unlimited liability associated with catastrophic wildfires connected to utility infrastructure is increasing insurance costs and elevating the utility's risk profile, raising the cost of capital.

Topic	Data Request	PGE Response
Strategy Disclose the actual and potential impacts of climate-related risks and opportunities on the organization's businesses, strategy, and financial planning where such information is material. *(continued)*	Describe the climate-related risks and opportunities the organization has identified over the short-, medium-, and long-term. *(continued)*	**Processes for Assessing Financial Impacts** PGE employs a structured approach to determine which climate-related risks and opportunities could have a material financial impact. Climate-related risks are integrated into the Enterprise Risk Management (ERM) framework, which is overseen by the Audit and Risk Committee, where they are assessed alongside other operational and financial risks to determine whether they are material in nature. Refer to PGE's 2024 10-K Risk Factors for additional details related to the Climate Change risks that the Company has identified. **Climate-Related Opportunities** While climate change presents challenges, considerable opportunity exists as PGE works with customers, stakeholders and communities to lead the clean energy future. PGE is leveraging climate-related opportunities to advance decarbonization, enhance grid resilience, and deliver innovative energy solutions for customers. Key opportunities include: • **Renewable Energy Leadership:** PGE continues to be a national leader in renewable energy participation through its Green Future and Green Future Impact programs, empowering customers to meet their sustainability goals. The Green Future program is the largest renewable power program by participation in the nation, with over 235,000 residential and small commercial customers voluntarily enrolled. These programs highlight strong customer demand for clean energy solutions while driving progress toward PGE's clean energy targets and strengthening customer relationships. • **Electrification and Grid Modernization:** PGE is investing in the electrification of transportation and other sectors, supporting technologies such as electric vehicles (EVs) and heat pumps. Recent grid enhancements include the integration of geographically diverse energy markets, deployment of energy storage systems, and use of automation and control technologies to manage flexible loads and distributed energy resources. PGE's Virtual Power Plant (VPP) exemplifies this innovation, utilizing distributed resources such as rooftop solar, battery storage, and demand response programs to enhance grid reliability and reduce emissions. In 2024, the VPP helped manage record energy demand, reducing load by nearly 109 MW during peak conditions. • **Customer-Centric Innovation:** PGE uses advanced data analytics, automation, and communications networks to support energy-saving programs and demand response initiatives. These efforts reduce reliance on fossil fuel-based peaking resources, enhance grid flexibility, and provide customers with cost-effective, sustainable energy solutions. By modernizing the grid and expanding customer offerings, PGE works to keep customers engaged as active participants in the clean energy transition. • **Community Resilience:** PGE is committed to fostering equitable access to clean energy while enhancing community resilience. Efforts include developing connected neighborhood microgrids, deploying smart community initiatives, and upgrading design standards to withstand extreme weather conditions. Investments in wildfire mitigation, such as updated vegetation management practices and Public Safety Power Shutoff (PSPS) zones, further support grid resilience and public safety. In addition to large-scale wind and solar generation, PGE utilizes Community-based Renewable Energy (CBRE) resources. These resources are typically smaller-scale (< 20 MW) resources that are distribution-connected and provide a wider range of community benefits, including resiliency and bill savings for customers. These resources could include stand-alone community-scale solar photovoltaic resources, solar paired with storage microgrids for resilience and small low-impact hydro opportunities.

Topic	Data Request	PGE Response
Strategy Disclose the actual and potential impacts of climate-related risks and opportunities on the organization's businesses, strategy, and financial planning where such information is material. *(continued)*	Describe the impact of climate-related risks and opportunities on the organization's businesses, strategy and financial planning.	**Business** PGE operates in a region experiencing increasingly intense climate-related events, including unprecedented heat, historic ice and snowstorms, and wildfires. These events are not just abstract global statistics; they have tangible impacts on local communities and the electrical grid. For example, in January 2024, a severe winter storm brought snow, ice, and high winds to the Company's service area, causing extensive damage to physical assets and widespread power outages. With the support of over a dozen mutual assistance crews, PGE restored power to more than 400,000 customers in the days following the storm. Similarly, in August 2023, a record-breaking heatwave set all-time high temperatures for the month, driving peak load demand to 4,498 MW—exceeding the Company's previous all-time peak and surpassing the prior summer peak by nearly 6%. Such conditions underscore the critical need to combat the effects of climate change by decarbonizing the power supply and investing in a more reliable and resilient grid. The increasing frequency and intensity of extreme weather events, driven by climate change, amplifies the likelihood and consequences of certain risks, such as prolonged outages caused by ice storms that make roads impassable. Similarly, escalating risks from extreme heat, drought conditions, and declining tree health exacerbate wildfire threats. Addressing these challenges requires strategic investments in mitigation planning, including vegetation management, grid hardening, and safety measures such as Public Safety Power Shutoff (PSPS) zones. These investments drive higher capital and operating expenses but are critical to ensuring public safety and maintaining reliable service. PGE recognizes that global climate change has far-reaching consequences that shape its approach to risk management and infrastructure planning. For additional information on risk management, mitigation, and adaptation impacts, refer to PGE's Risk Management disclosures below. Further discussion of the impact of climate-related risks and opportunities on PGE's business is provided in the response to the question above, "Describe the climate-related risks and opportunities the organization has identified over the short-, medium-, and long-term," as well as in the Overview section of the Management's Discussion and Analysis in the 2024 10K. **Strategy** Climate-related risks and opportunities are central to PGE's strategic imperatives to electrify, decarbonize, and perform. The transition plan to a clean energy future is embedded in PGE's Clean Energy Plan, which is required for compliance with Oregon's House Bill 2021 emissions targets. This strategy prioritizes investments in renewable energy resources, transportation electrification, and advanced grid technologies. Strategic planning processes, including Integrated Resource Planning (IRP) and Distribution System Planning (DSP), integrate climate-related risk assessments to prioritize grid enhancements and decarbonization strategies.

Topic	Data Request	PGE Response
Strategy Disclose the actual and potential impacts of climate-related risks and opportunities on the organization's businesses, strategy, and financial planning where such information is material. *(continued)*	Describe the impact of climate-related risks and opportunities on the organization's businesses, strategy and financial planning. *(continued)*	**Financial Planning** PGE's financial planning processes integrate climate-related considerations, driving substantial capital investments to support decarbonization and resilience initiatives. Since 2021, PGE has issued $1 billion in green bonds to finance projects under its Green Financing Framework, supporting renewable energy integration, grid modernization, and community-based renewable energy development. These investments are complemented by cost-effective solutions such as energy efficiency programs and demand response initiatives, which reduce reliance on fossil fuel-based peaking resources and lower operational costs. Additionally, PGE actively incorporates climate-related scenarios into financial planning to evaluate risks and opportunities over the short, medium, and long term. For instance, scenario modeling informs resource adequacy decisions, including the development of storage solutions and community resilience microgrids. PGE also evaluates financial risks associated with regulatory compliance, market shifts, and physical impacts, while balancing decarbonization and affordability. By aligning its financial strategy with clean energy targets, PGE is positioned to deliver long-term value for shareholders and stakeholders alike. All material capital expenditures are discussed within PGE's annual 10-K filings. For more information on PGE's green bonds visit PGE's Green Financing Website.

Topic	Data Request	PGE Response
Strategy Disclose the actual and potential impacts of climate-related risks and opportunities on the organization's businesses, strategy, and financial planning where such information is material.	Describe the resilience of the organization's strategy, taking into consideration different climate-related scenarios, including a 2°C or lower scenario.	PGE defines resilience as the ability to anticipate, adapt to, withstand, and recover from disruptive events, including those driven by climate risks. PGE's strategy focuses on addressing critical risks to generation, transmission, and distribution systems while aligning efforts across business functions to enhance system and community resilience. PGE integrates climate resilience into the planning processes by considering and differentiating actions related to other plans, such as the Distribution System Plan (DSP) and Wildfire Mitigation Plan (WMP) analysis. These plans seek to advance resilience across three focus areas: • **PGE Infrastructure Resilience:** Investments in grid hardening and energy supply infrastructure aim to mitigate outages during disruptive events such as heatwaves, wildfires, wind, or ice storms. • **Operational Resilience:** Enhancements to emergency preparedness, outage response, cybersecurity, and customer support improve PGE's ability to meet customer needs during disruptive events and accelerate service restoration. • **Customer Infrastructure Resilience:** Exploration of customer-sited solutions, such as microgrids, batteries, and other distributed energy resources (DERs), empowers customers to maintain electric service during disruptive events and contribute to grid stability under normal conditions. This approach emphasizes the importance of addressing climate-related risks, such as wildfires and extreme weather events, as part of the company's broader resilience strategy. PGE's strategic planning incorporates extensive scenario analysis to assess resilience under varying climate-related scenarios, including those aligned with limiting global temperature rise to 2°C or lower. PGE's analysis emphasizes identifying, mitigating, and adapting to risks associated with transitioning to a low-carbon economy while considering increased physical climate risks such as extreme weather events. For example, PGE strives to account for, understand, and forecast wildfire risk factors across our service territory and generation areas. The Pacific Northwest faces significant and multifaceted challenges under the Representative Concentration Pathway (RCP) 8.5 climate scenario, which projects the most severe outcomes of greenhouse gas emissions. RCP 8.5 takes into account a 2°C or lower scenario. **Key considerations of PGE's resilience strategy include:** • **Impact Assessment Across Business Functions:** PGE evaluates resilience risks across generation, transmission, distribution, and customer-facing systems. Climate-related risks, including the frequency and intensity of extreme weather events, are modeled using data from studies conducted with organizations like the Oregon Climate Change Research Institute and Oregon State University. These studies evaluate potential outcomes under Representative Concentration Pathways (RCP 4.5 and RCP 8.5), providing insights into future weather extremes, including heatwaves, windstorms, and ice events. • **Integration into Operational and Capital Planning:** PGE's resilience strategy integrates predictive climate modeling into capital investments and operational practices. For example, grid-hardening initiatives and emergency response improvements aim to enhance infrastructure and operational resilience. Projects such as microgrids and distributed energy resources (DERs) are developed to support both system-wide and community-specific needs during disruptive events. • **Community Resilience and Equity Focus:** PGE incorporates equity considerations through tools like the Heat Vulnerability Index and the Equity Index, which help identify areas and populations most affected by climate risks. These tools guide resource allocation to help vulnerable communities benefit from investments in resilience, including cooling relief programs and distributed energy solutions.

Topic	Data Request	PGE Response
Strategy Disclose the actual and potential impacts of climate-related risks and opportunities on the organization's businesses, strategy, and financial planning where such information is material. *(continued)*	Describe the resilience of the organization's strategy, taking into consideration different climate-related scenarios, including a 2°C or lower scenario. *(continued)*	• **Deep Decarbonization Study Insights:** In 2018, PGE commissioned a study of pathways for deep decarbonization in its service territory to inform its Integrated Resource Planning process and the carbon policy discussion in Oregon. In 2022, the study was updated to account for new climate and clean energy laws and regulations in Oregon. The Deep Decarb Study explores potential pathways for economy-wide decarbonization across PGE's service territory given the enactment of House Bill 2021 and DEQ's Climate Protection Program emissions targets. It demonstrates that PGE's strategies are feasible for achieving compliance with HB 2021 and CPP targets, emphasizing the need for unprecedented renewable and storage procurement. Insights from the study have directly informed PGE's Clean Energy Plan and Integrated Resource Plan, ensuring alignment with long-term climate goals and policy requirements. • **Financial and Strategic Impacts:** PGE assesses the financial implications of climate scenarios by evaluating potential changes to revenue streams, operational costs, and asset performance. These assessments consider technology pathways, policy developments, and energy market shifts to keep resource procurement and strategic investments aligned with Oregon's clean energy targets. • **Scenario-Specific Adaptations:** PGE participates in initiatives like the EPRI Climate READi program to develop common frameworks for understanding climate risks and prioritizing mitigation investments. These efforts support adaptability and help align resilience measures align with evolving climate data and regional needs. • **Time Horizons and Scenario Models:** PGE's various scenario analyses spans short-, medium-, and long-term horizons, informed by climate projections through 2070. Resilience strategies are regularly updated to reflect emerging data, community feedback, and advancements in renewable energy and storage technologies. For additional details on PGE's scenario modeling and outcomes, refer to Section 13.2 (Evaluating Resilience Risks) and Section 13.5 (Programs and Opportunities) of the Clean Energy Plan and Integrated Resource Plan.

Topic	Data Request	PGE Response
Risk management Disclose how the organization identifies, assesses and manages climate-related risks.	Describe the organization's processes for identifying and assessing climate-related risks.	PGE employs a structured, risk-informed decision-making process to identify and assess climate-related risks, providing a comprehensive evaluation of risks and opportunities across the organization. By integrating industry-leading practices, such as the ISO 31000 standards and the Committee of Sponsoring Organizations of the Treadway Commission (COSO) framework, PGE applies a consistent methodology for risk identification, analysis, evaluation, and mitigation planning. **Risk Identification and Assessment Framework** PGE evaluates risks across multiple dimensions, including safety, environmental, reliability, financial, regulatory, and customer impacts. The process involves a combination of tools and methodologies, including: • **Scenario Analysis and Probabilistic Forecasting:** Projections of climate-related risks such as wildfires, extreme heat, freezing rain, and drought guide infrastructure planning and operational strategies. • **Iterative Risk Identification:** Surveys, workshops, expert judgment, and case studies inform a detailed understanding of emerging and existing risks. • **Stakeholder Engagement:** Collaboration with regulators, customers, and community partners aligns risk management strategies with shared priorities and compliance requirements, such as Oregon's HB 2021 and the Renewable Portfolio Standard (RPS). • **External Research and Partnerships:** PGE incorporates insights from studies like the Oregon Climate Change Research Institute and Oregon State University's projections for extreme weather events, which highlight how events such as once-in-a-century storms may become far more frequent, dramatically altering risk profiles. **Climate Change Variables and Risk Classification** Recognizing that historical data is no longer a reliable predictor of future climate impacts, PGE incorporates climate change variables into its risk models. Projections of increased wildfire severity, declining vegetation health, and heightened aridity are used to refine asset management practices, infrastructure investments, and emergency response protocols. For example: • **Fire Regime and Wildfire Risks:** PGE applies fire regime models that consider fuel loads, climate patterns, and ecosystem types to assess and prioritize mitigation measures in high-risk areas. • **High-Resolution Weather Models:** PGE utilizes a 2 km-resolution weather and vegetation moisture forecasting model to better understand and contextualize climate risks, allowing for improved operational planning and decision-making. **Governance and Oversight** PGE's integrated governance structure supports consistent evaluation and monitoring of climate-related risks. The Executive Risk Committee, chaired by the CEO and including senior leaders such as the CFO and Chief Legal Officer, oversees risk management processes. Specialized committees, including the Integrated Security Executive Committee and Compliance Committee, apply the same consistent framework to assess risks and prioritize actions. Refer to the Governance TCFD Disclosures above for further details on PGE's governance oversight of climate related risks. **Prioritizing and Addressing Risks** Climate-related risks are evaluated based on their likelihood, potential size, and scope. PGE employs methodologies such as Risk Spend Efficiency (RSE) and Value Spend Efficiency (VSE) to quantify the effectiveness of mitigation measures, helping to direct investments toward achieving the highest potential risk reduction per dollar spent. For example: • **Wildfire Mitigation:** Investments in covered conductors, vegetation management, and grid hardening are guided by models that incorporate climate change variables and collaboration with partners such as the Oregon Department of Forestry. • **Customer Resilience:** Distributed Energy Resources (DERs), such as microgrids and battery storage, are evaluated for their potential to enhance customer resilience during disruptive events and contribute to grid stability under normal conditions. **Integration into Strategic and Financial Planning** Identified risks and opportunities are incorporated into PGE's strategic and financial planning processes, including the Clean Energy Plan (CEP) and Integrated Resource Plan (IRP). Scenario analyses and climate projections help guide resource allocation, prioritize investments in grid resilience, and support compliance with regulatory mandates. For example, insights from wildfire risk models and climate studies inform PGE's Wildfire Mitigation Plan (WMP) and Distribution System Plan (DSP), aligning with broader resilience strategies. **Transparency and Reporting** PGE regularly evaluates and reports material climate-related risks in its annual Form 10-K filing and aligns its risk assessment processes with best practices and regulatory requirements. This includes identifying risks with potential financial implications and providing transparency around mitigation strategies. By combining robust internal frameworks with external benchmarking, PGE adapts its risk management approach to address the evolving challenges of climate change.

Topic	Data Request	PGE Response
Risk management Disclose how the organization identifies, assesses and manages climate-related risks. *(continued)*	Describe the organization's processes for managing climate-related risks.	**Processes for Managing Climate-Related Risks** Building on the identification and assessment processes described above, PGE employs a proactive and integrated approach to managing climate-related risks. These risks are addressed through robust governance, targeted mitigation strategies, and an emphasis on long-term adaptability to evolving climate challenges. PGE's management processes focus on prioritizing and mitigating risks across multiple dimensions, such as safety, environmental, regulatory, financial, and customer impacts. Climate-related risks—including severe weather events, wildfires, and regulatory changes—are evaluated for their materiality and managed through a combination of mitigation, transfer, and control strategies. **Risk Mitigation and Adaptation Measures** Key strategies include: • **Wildfire Mitigation and Resilience:** PGE's Wildfire Mitigation Plan (WMP) guides annual investments in system hardening, vegetation management, and operational measures such as Public Safety Power Shutoffs (PSPS). During 2024, PGE invested $40 million in capital projects related to wildfire mitigation and resiliency and utility asset management. These initiatives aim to reduce ignition risks, enhance grid resilience, and minimize customer impacts during wildfire events. • **Emergency Preparedness:** PGE employs meteorologists to assist in forecasting and event management, while also coordinating with local, county, and state agencies to reduce the impact of climate-related events on customers and communities. • **Grid Modernization:** Investments in Distributed Energy Resources (DERs) and Virtual Power Plants (VPPs) enhance grid flexibility, reliability, and the ability to integrate renewable energy sources. These initiatives support PGE's long-term decarbonization goals while addressing the risks posed by fluctuating demand and extreme weather. • **Distribution System Plan (DSP):** The DSP plays a critical role in managing climate-related risks by guiding infrastructure upgrades and resource integration. It aligns with PGE's Clean Energy Plan (CEP) to support grid resilience and accelerated decarbonization. **Prioritization of Climate-Related Risks** Materiality determinations for climate-related risks are conducted using established criteria, including likelihood, scope, and potential financial impact. High-priority risks—such as wildfire threats and regulatory compliance—are integrated into enterprise-level planning processes. PGE employs methodologies like Risk Spend Efficiency (RSE) and Value Spend Efficiency (VSE) to evaluate and prioritize mitigation projects based on estimated risk reduction value. **Integration with Strategic Planning** As outlined in the section above, climate-related risks are embedded into PGE's strategic and financial planning processes. Scenario analyses and predictive modeling guide resource allocation and help identify opportunities to enhance resilience while balancing affordability and reliability. PGE's plans, including the Wildfire Mitigation Plan (WMP) and Integrated Resource Plan (IRP), reflect a commitment to addressing climate risks holistically. **Ongoing Review and Adaptation** PGE continuously monitors and reviews the effectiveness of risk controls and mitigation activities through tools such as the Risk Dashboard and integrated risk assessments. These processes help refine strategies, track progress, and incorporate new data into planning efforts. Collaboration with regulators, customers, and community partners further supports alignment with shared priorities and helps maintain the effectiveness of mitigation efforts. By integrating climate-related risk management into its broader operational and strategic framework, PGE maintains its focus on delivering safe, reliable, and sustainable energy while adapting to the challenges posed by a changing climate.

Topic	Data Request	PGE Response
Risk management Disclose how the organization identifies, assesses and manages climate-related risks. *(continued)*	Describe how processes for identifying, assessing and managing climate-related risks are integrated into the organization's overall risk management.	Climate-related risks and processes for identifying, assessing, and managing those risks are a part of PGE's overall approach to enterprise risk management (ERM). PGE's ERM program facilitates the identification, analysis, evaluation, and treatment of risks across the company, including climate risks such as wildfires, major storms, and other natural disasters to determine their potential impact on operations and financials. These risks are evaluated alongside other enterprise risks, such as operational, financial, and regulatory risks, using a consistent framework designed to address interdependencies. The ERM process leverages tools such as probabilistic analysis, expert judgement, and scenario analysis to evaluate both current and future climate-related risks. For instance, wildfire and storm risks are assessed through predictive modeling that considers regional climate trends and are integrated into capital investment and operational planning. This work is conducted at multiple levels within the organization, involving line managers, senior management, and officers. PGE's ERM program reports directly to the Executive Risk Committee (ERC), which is composed of the CEO, CFO, and other senior leaders, which reviews key enterprise risks and current and planned mitigation actions. The ERC, in turn, reports to the Audit and Risk Committee, who is responsible for assisting the board of directors in overseeing PGE's Enterprise Risk Management program. Additionally, climate-related risks are embedded into PGE's overall business strategy, which centers on three long-term imperatives — electrify, decarbonize, perform. For example, climate-related risks influence resource allocation for infrastructure resilience, the prioritization of renewable energy projects, and investment in grid modernization. These strategic imperatives are overseen by the board of directors, ensuring alignment with PGE's long-term goals.

Topic	Data Request	PGE Response
Metrics and targets Disclose the metrics and targets used to assess and manage relevant climate-related risks and opportunities where such information is material.	Disclose the metrics used by the organization to assess climate-related risks and opportunities in line with its strategy and risk management process.	PGE has numerous metrics to guide the Company's actions in managing climate-related risks and opportunities. These metrics span decarbonization, greenhouse gas (GHG) emissions reduction, electrification, and performance. Key metrics, along with references to sources where historical data and methodologies projections can be found, are detailed below: **Decarbonization Metrics** • **Renewable energy capacity sourced and developed (MW):** Refer to the EEI report, page 79-81 • **Renewable energy procured and produced from the capacity above (MWh):** Refer to the EEI report, page 79-81 • **Annual renewable energy portfolio as a % of retail load served by qualifying renewable resources:** Refer to the EEI report, page 79-81 • **Percentage of retail load served by non-emitting resources:** Refer to the EEI report, page 79-81 **GHG Emissions Metrics** • **GHG emissions associated with the power delivered to Oregon retail customers:** Refer to the SASB report, page 58 • **Scope 1, 2, and 3 GHG Emissions:** Refer to the Metrics and Targets disclosure B below, page 76 **Electrification & Performance Metrics** • **Percentage of PGE's vehicle fleet electrified:** Refer to ESG report Key Metrics table, page 54 • **System reliability metrics, such as System Average Interruption Duration Index (SAIDI) and System Average Interruption Frequency Index (SAIFI), among many others:** Refer to the SASB report, page 62 • **Amounts issued under PGE's Green Financing Framework, created to support investments in projects and assets that advance PGE's sustainability goals** • **Voluntary renewable program participation:** Refer to ESG report Key Metrics table, page 54 **Water and Waste Management Metrics** PGE reports metrics on climate-related risks associated with water and waste management through the EEI ESG Quantitative Report and SASB Report. For additional details on PGE's methodologies and strategies for mitigating water and waste management risks, refer to the SASB and EEI ESG Quantitative reports. **Additional Information** For metrics used to measure and manage financial impacts of climate-related risks and opportunities, refer to the 2024 10-K, 2024 Annual Report, and 2025 Proxy Statement. **Incentive compensation tied to clean energy** PGE's long-term incentive (LTI) awards granted to our executives and other key employees includes a performance metric related to achievement of PGE's strategic goals surrounding clean energy. This metric is used to create incentive to reduce carbon potential in the Company's energy supply portfolio in support of Oregon's GHG emission reduction goals. The metric is to be measured based on average megawatts of forecast energy from carbon-free resources, Oregon's Renewable Portfolio Standard-qualifying resources, and low-carbon emitting (i.e., greater than or equal to 95% carbon-free) systems of resources added to the Company's energy supply portfolio during the performance period. For more information on metrics incorporated into PGE's renumeration policies, refer to the Company's 2025 Proxy statement.

Topic	Data Request	PGE Response
Metrics and targets Disclose the metrics and targets used to assess and manage relevant climate-related risks and opportunities where such information is material.	Disclose Scope 1, Scope 2 and, if appropriate, Scope 3 greenhouse gas (GHG) emissions, and the related risks.	**Scope 1*** Refer to the Greenhouse Gas Emissions section of the SASB Report for Scope 1 disclosures. **Scope 2*** Market Based — 39,314 MTCO2e Location Based — 39,507 MTCO2e This represents emissions from electricity purchased and consumed as well as T&D line loss associated with wheeled power in 2024. **Scope 3*** 2,062,153 MTCO2e from the generation of purchased electricity that is sold to end users. Reporting and data collection capabilities are still being developed for other Scope 3 sources of emissions. *These metrics are preliminary and have been calculated using the GHG Accounting Protocol's Corporate Standard. **GHG Intensity** 0.27 MTCO2e per MWh for PGE's total system load 0.28 MTCO2e per MWh for power served to Oregon retail customers** ** These figures are preliminary and based on generated and purchased energy associated with serving retail customers within the state of Oregon, as required by the Oregon Department of Environmental Quality (ODEQ). Some or all the renewable energy attributes associated with PGE's Basic Service Mix may be sold, claimed or not acquired. Refer to the Emissions section of the EEI ESG Quantitative report for more GHG efficiency ratios.

Topic	Data Request	PGE Response
Metrics and targets Disclose the metrics and targets used to assess and manage relevant climate-related risks and opportunities where such information is material.	Describe the targets used by the organization to manage climate-related risks and opportunities and performance against targets.	PGE has established ambitious climate-related targets to manage risks and opportunities in alignment with Oregon's regulatory requirements and voluntary commitments. These targets address greenhouse gas (GHG) emissions reduction, renewable energy integration, and transportation electrification. They are foundational to PGE's Clean Energy Plan and Integrated Resource Plan (CEP/IRP), guiding the Company's efforts toward a cleaner, more sustainable energy future. **1. HB 2021: State-Mandated GHG Emission Reduction Goals** Oregon's House Bill 2021 (HB 2021) established some of the most ambitious clean electricity targets in the nation, requiring utilities to reduce GHG emissions associated with the power served to retail customers. These reductions are measured against a 2010–2012 baseline of 8.1 million metric tons of CO2e and include the following interim targets: • 80% by 2030, • 90% by 2035, • 100% by 2040. These targets were informed by the Oregon Climate Change Research Institute's Sixth Climate Assessment and reflect a science-based approach to decarbonization. PGE uses the 2010–2012 baseline of 8.1 million metric tons of CO2e for HB 2021 emissions tracking, consistent with state mandates, and interim progress is reported in the Company's CEP and ESG filings. In 2024, emissions associated with retail power served were reduced by approximately 34% compared to the 8.1 million metric ton baseline. PGE continues to prioritize investments in renewable resources, storage solutions, and demand-side programs to meet these targets. **2. PGE's Climate Pledge: Voluntary Net-Zero Goal** In 2021, PGE joined The Climate Pledge, a voluntary commitment to achieve net-zero carbon emissions by 2040—ten years ahead of the Paris Agreement's target of 2050. This pledge includes: • Regular measurement and reporting of GHG emissions, • Implementation of decarbonization strategies through business innovations, efficiency improvements, renewable energy, and material reductions, • Offsetting residual emissions with socially beneficial, permanent, and quantifiable carbon offsets. This voluntary goal complements HB 2021, demonstrating leadership in transitioning to a low-carbon economy while maintaining reliability and affordability. **3. Oregon Renewable Portfolio Standard (RPS)** Oregon's Renewable Portfolio Standard (RPS) mandates that utilities deliver an increasing share of renewable energy to their customers, requiring: • 27% of retail load by 2025, • 35% by 2030, • 45% by 2035, • 50% by 2040. These targets use annual retail load as the baseline for measuring compliance. In addition to these thresholds, the RPS requires that coal-fired generation be eliminated from serving Oregon customers. PGE has consistently met RPS requirements through investments in wind, solar, and hydro resources. Progress is reported annually through compliance filings with the Oregon Public Utility Commission and detailed in the CEP/IRP.

Topic	Data Request	PGE Response
	Describe the targets used by the organization to manage climate-related risks and opportunities and performance against targets. *(continued)*	**Integrated Planning and Progress Measurement** To achieve these goals, PGE aligns its Integrated Resource Plan (IRP) and Clean Energy Plan (CEP) with state mandates and voluntary commitments. The 2023 IRP/CEP, filed with the Oregon Public Utility Commission, outlines a 20-year roadmap for decarbonization. PGE also engages in innovative projects like Electric Island, a heavy-duty electric truck charging site, to promote the adoption of clean energy technologies across sectors. **Key Performance Indicators and Methodologies** PGE tracks progress against these targets using both absolute and intensity-based metrics, including: • Annual GHG emissions reductions (in metric tons of CO2e) using the 2010–2012 baseline, • Renewable energy penetration (as a percentage of retail load), These metrics are regularly reported through regulatory filings and sustainability reports, providing transparency and accountability to stakeholders. For detailed methodologies, annual performance data, and future plans, refer to PGE's CEP/IRP and annual ESG report.

NOTES

(1) Generation MWhs, purchased MWhs, and greenhouse gas emissions data are reported based on the Oregon Department of Environmental Quality (ODEQ) Investor Owned Utility GHG report (oregon.gov/deq/FilterDocs/IOUProtocols.pdf). This report shows greenhouse gas emissions and MWhs in terms of power provided to PGE retail customers; it does not account for generation, purchases, or emissions associated with power delivered outside of PGE service territory.

(2) Greenhouse gas emissions are reported in terms of CO_2e only and are based on the ODEQ Investor Owned Utility GHG report. The ODEQ report shows greenhouse gas emissions associated with power provided to PGE customers and does not account for emissions associated with power delivered outside of PGE service territory.

(3) This calculation has been performed for inclusion in PGE's Environmental, Social and Governance report only and is not intended for other use. It represents preliminary MTCO2e/MWh associated with PGE's retail load. Some or all of the renewable energy attributes associated with PGE's retail load may be sold, claimed or not acquired.

(4) As reported to EPA under the mandatory GHG Reporting Protocols (40 CFR Part 98, Subpart DD).

(5) Calculated based off of total PGE system generation (which includes power served to retail customers and power served outside of PGE's service territory).

(A) These amounts have been restated from the prior year ESG report as a result of finalizing review and third-party verification procedures with the Oregon Department of Environmental Quality.

(B) These amounts are preliminary and could vary from those filed with ODEQ.

Blank cells indicate that the Company has not measured, is unable to track, or has not provided this data point. Cell values of zero indicate that the Company has measured the requested metric and has resulted in a measurement of zero.

Forward-Looking Statements

Statements in this report that relate to future plans, objectives, expectations, performance, events and the like may constitute "forward-looking statements" within the meaning of the Private Securities Litigation Reform Act of 1995, Section 27A of the Securities Act of 1933, as amended, and Section 21E of the Securities Exchange Act of 1934, as amended. These forward-looking statements represent our estimates and assumptions as of the date of this report. The Company assumes no obligation to update or revise any forward-looking statement as a result of new information, future events or other factors.

Forward-looking statements include statements regarding the Company's full-year earnings guidance (including assumptions and expectations regarding annual retail deliveries, average hydro conditions, wind generation, normal thermal plant operations, operating and maintenance expense and depreciation and amortization expense) as well as other statements containing words such as "anticipates," "assumptions," "based on," "believes," "conditioned upon," "considers," "could," "estimates," "expects," "forecast," "goals," "intends," "needs," "plans," "predicts," "projects," "promises," "seeks," "should," "subject to," "targets," "will continue," "will likely result," or similar expressions.

Investors are cautioned that any such forward-looking statements are subject to risks and uncertainties, including, without limitation: the timing or outcome of various legal and regulatory actions; changing customer expectations and choices that may reduce demand for electricity; the sale of excess energy during periods of low demand or low wholesale market prices; operational risks relating to the Company's generation and battery storage facilities, including hydro conditions, wind conditions, disruption of transmission and distribution, disruption of fuel supply, and unscheduled plant outages, which may result in unanticipated operating, maintenance and repair costs, as well as replacement power costs; delays in the supply chain and increased supply costs (including application of tariffs impacting solar module imports), failure to complete capital projects on schedule or within budget, failure of counterparties to perform under agreement, or the abandonment of capital projects, which could result in the Company's inability to recover project costs, or impact our competitive position, market share, revenues and project margins in material ways; default or nonperformance of counterparties from whom PGE purchases capacity or energy, which require the purchase of replacement power and renewable attributes at increased costs; complications arising from PGE's jointly-owned plant, including ownership changes, regulatory outcomes or operational failures; the costs of compliance with environmental laws and regulations, including those that govern emissions from thermal power plants; changes in weather, hydroelectric and energy market conditions, which could affect the availability, cost and required collateral for purchased power and fuel; changes in capital and credit market conditions, including volatility of equity markets, reductions in demand for investment-grade commercial paper or interest rates, which could affect the access to and availability or cost of capital and result in delay or cancellation of capital projects or execution of the Company's strategic plan as currently envisioned; general economic and financial market conditions, including inflation; the effects of climate change, whether global or local in nature; unseasonable or severe weather conditions, wildfires, and other natural phenomena and natural disasters that could result in operational disruptions, unanticipated restoration costs, third party liability or that may affect energy costs or consumption; the effectiveness of PGE's risk management policies and procedures; PGE's ability to effectively implement Public Safety Power Shutoffs (PSPS) and de-energize its system in the event of heightened wildfire risk; cyber security attacks, data security breaches, physical attacks and security breaches, or other malicious acts, which could disrupt operations, require significant expenditures, or result in claims against the Company; employee workforce factors, including potential strikes, work stoppages, transitions in senior management, and the ability to recruit and retain key employees and other talent and turnover due to macroeconomic trends; widespread health emergencies or outbreaks of infectious diseases such as COVID-19, which may affect our financial position, results of operations and cash flows; failure to achieve the Company's greenhouse gas emission goals or being perceived to have either failed to act responsibly with respect to the environment or effectively responded to legislative requirements concerning greenhouse gas emission reductions; social attitudes regarding the electric utility and power industries; political and economic conditions; acts of war or terrorism; changes in financial or regulatory accounting principles or policies imposed by governing bodies; changes in effective tax rate; and risks and uncertainties related to All-Source RFP projects, including, but not limited to, regulatory processes, transmission capabilities, system interconnections, permitting and construction delays, legislative uncertainty, inflationary impacts, supply costs and supply chain constraints. As a result, actual results may differ materially from those projected in the forward-looking statements.

Risks and uncertainties to which the Company is subject are further discussed in the reports that the Company has filed with the United States Securities and Exchange Commission (SEC). These reports are available through the EDGAR system free-of-charge on the SEC's website, www.sec.gov and on the Company's website, investors.portlandgeneral.com. Investors should not rely unduly on any forward-looking statements.

Metrics calculated using the Greenhouse Gas Reporting Protocol's Corporate Standard within this report are subject to change if changes in methodology occur, either as a result of a change in interpretation and application of the protocol or formal changes made to the protocol's guidance.

Mr. Clark,

Please find attached PGE's comments in response to the Proposed Order on the Request for Amendment 4 of the Biglow Canyon Wind Farm Site Certificate. Two attachments associated with our Goal 3 Comment Letter will be uploaded to a SharePoint site for you to download. That link will be shared shortly. The attachments will be PGE's 2023 Clean Energy Plan/Integrated Resource Plan Update and PGE's 2024 ESG Report.

Thank you.

BIGLOW CANYON WINDFARM HEARING BEFORE
OREGON DEPARTMENT OF ENERGY
ENERGY FACILITY SITING COUNCIL
HELD VIA WEBEX
THURSDAY, JANUARY 15, 2026
3:30 P.M.

CHAIR CONDON: Good evening and welcome.
I'm Cindy Condon. The time is now 3:32.
I would like to call the January 15, 2026, meeting of the Energy Facility Siting Council to order.
Mr. Secretary, please call the roll.
SECRETARY CORNETT: Cindy Condon?
CHAIR CONDON: Here.
SECRETARY CORNETT: Marcy Grail?
COUNCILOR GRAIL: Here.
SECRETARY CORNETT: Kent Howe?
COUNCILOR HOWE: Here.
SECRETARY CORNETT: Richard Devlin? Richard Devlin?
Do you know if Council Member Devlin is on?
COUNCILOR DEVLIN: Hello?
SECRETARY CORNETT: Okay.

COUNCILOR DEVLIN: Can anyone hear me?
SECRETARY CORNETT: Yep.
COUNCILOR DEVLIN: Yeah.
SECRETARY CORNETT: Yes. We can hear you. Thank you, Council Member Devlin.
COUNCILOR DEVLIN: Okay.
SECRETARY CORNETT: And Patty Perry?
COUNCILOR PERRY: Here if you can hear me.
SECRETARY CORNETT: We can. Thank you.
Chair Condon, you have a quorum.
CHAIR CONDON: Thank you.
Mr. Secretary, are there any agenda modifications?
SECRETARY CORNETT: Chair Condon, there are no agenda modifications at this time.
CHAIR CONDON: So we'll just get --
SECRETARY CORNETT: A little bit closer.
CHAIR CONDON: A little bit closer? How's this?
SECRETARY CORNETT: Yep, good.
CHAIR CONDON: I have the following announcements.
For council members and anyone addressing the Council, please remember to state your name clearly, and please do not use the speakerphone

feature as it will create feedback.

Please mute your phones, and if you are joining us by phone and receive a phone call, please hang up from this call and dial back if after finishing -- in after finishing your other call.

For those signed in onto the webinar, please do not broadcast your webcam.

For agenda Item C, public comment period and agenda Item F, the Biglow Canyon Amendment 4 Public Hearing, there are three ways to let us know you are interested in providing comments to the Council.

One, for those in person, please fill out a registration card and submit it to Nancy Hatch, who is our administrator.

Two, for those using the Webex, you will need to use the "raise your hand" feature.

Three, for those on the phone only, you will need to press “star 3”, which will alert us that you want to speak, and Nancy Hatch will unmute you as necessary.

We will go over these options again during that agenda item.

If you want to receive future email notifications of Council meetings, project

milestones, or rulemakings through our ClickDimensions program, you can do so by clicking on the link in the agenda or on the Council webpage. Look for the green box on the right-hand side of the page that says sign up for emails, updates.

You are also welcome to access the online project mapping tool and any documents by visiting our website. Please note that the audio and video of this meeting is being recorded and may be posted to the Council's website following the meeting.

Energy Facility Siting Council meetings shall be conducted in a respectful and courteous manner where everyone is allowed to state their positions at the appropriate times consistent with Council rules and procedures.

Willful, accusatory, offensive, insulting, threatening, insolent, or slanderous comments which disrupt the Council meetings are not acceptable.

Pursuant to Oregon Administrative Rule 345-011-0080, any person who engages in unacceptable conduct, which disrupts the meeting, may be expelled.

So first on our agenda is the consent calendar. And this is an action item, approval of the November 21, 2025, meeting minutes.

COUNCILOR HOWE: Chair Condon?
CHAIR CONDON: Yes, Councilor Howe?
COUNCILOR HOWE: I move that the Council approve the minutes of the November 21, 2025, meeting as presented and recommended by staff.
CHAIR CONDON: Do we have a second online?
COUNCILOR GRAIL: Chair Condon, this is Marcy. I second that motion.
CHAIR CONDON: Thank you, Councilor Grail.
COUNCILOR DEVLIN: Madam Chair?
CHAIR CONDON: Yes?
COUNCILOR DEVLIN: I was not present for this meeting so I'll be abstaining.
CHAIR CONDON: Thank you, Councilor Devlin.
Mr. Secretary, will you please call the roll -- or for the vote?
SECRETARY CORNETT: Kent Howe?
COUNCILOR HOWE: Yes.
SECRETARY CORNETT: Patty Perry?
COUNCILOR PERRY: Yes.
SECRETARY CORNETT: Cindy Condon?
CHAIR CONDON: Yes.
SECRETARY CORNETT: Marcy Grail?
COUNCILOR GRAIL: Yes.

SECRETARY CORNETT: The motion carries, Chair Condon.

CHAIR CONDON: Thank you, Councilors.

And now for the Council Secretary Report.

SECRETARY CORNETT: Thank you, Chair Condon. Give me one second.

I'm going to first start with project updates.

So the first project update is the Well Springs project.

So we received the Notice of Intent for that project on January 2nd. The project would be a 750-megawatt solar PV project with 500 megawatt of battery storage on approximately 7,365 acres or 11 square miles.

The project location is in Morrow County, approximately five miles northwest of the town of Ione. The parent company is MN8. And that's M-N-8 Energy Development Company LLC.

The Department's project webpage will be live tomorrow. This is a fairly new project, so the project page will be up tomorrow. And we anticipate sending the public notice of the receipt of the Notice of Intent and a comment period by next week as well.

That is also a reminder for at least state employees that Monday is the Martin Luther King Jr. holiday, so we won't be working on Monday, but we will try to get to it after that.

COUNCILOR HOWE: This is Kent.

Did you say that was Morrow County?

SECRETARY CORNETT: Yeah. That's in Morrow County.

So, I mean, generally, I mean, if you can kind of picture where the Boardman Bombing Range is --

COUNCILOR HOWE: Yeah.

SECRETARY CORNETT: And so if you go kind of south of the Boardman Bombing Range, kind of south and to the west of it, so it's --

COUNCILOR HOWE: Okay.

SECRETARY CORNETT: -- you know, I described it as sort of five miles northwest of Ione. And that's correct. But it's also kind of southwest of the Boardman Bombing Range.

COUNCILOR HOWE: Thank you.

SECRETARY CORNETT: The next update is the Sunstone Solar project.

So at the November Council meeting, there was a discussion regarding the parent company of the

Sunstone Solar project going into bankruptcy. So they were planning on submitting an amendment to split the site certificate. They withdrew that and there was some conversation that we had kind of explaining kind of all of that.

So as a reminder what that project is, it was approved by Council in November of 2024. It includes 1,200 megawatt of solar, 1,200 megawatt of battery storage, and it would be on approximately 9,442 acres or 14.75 square miles. That's also in Morrow County.

On Tuesday, I sent council members an article that Amazon won the bid to purchase the facility, although I just found out that I think you need a login to be able to access that. So my apology. We'll follow up with that with the information from the article, and we'll just copy and paste that and put it into an email so you can see that.

But I mean, again, Amazon won the bid for that, and they are now -- well, I don't know if now they're the owner, but they are essentially going to become the owner. But as we discussed in November -- the November meeting, just as a reminder, the -- Sunstone can sell it to them and Amazon can buy it,

but until Amazon comes in and requests and receives approval for a site certificate transfer amendment, they can't do anything with the project.

So again, a site certificate is functionally a business contract between the state of Oregon, EFSC on behalf of the state of Oregon and the developer. We currently do not have any business relationship with Amazon for this project. That will have to be established first before they can move forward on doing anything related to the site certificate.

The next project is the Saddle Butte Energy Facility. So at the December Council meeting, I let you know that we have received the Notice of Intent for that project. This would be a 488-megawatt wind energy project consisting of up to 70 wind turbines, each up to 698 feet tall. I'll say that again, 698 feet tall.

There would also be 488 megawatts of battery storage. The project location is in Gilliam County, approximately six miles southwest of the city of Arlington. The parent company is Brookfield Renewables. They own the Shepherds Flat facilities. So it's kind of in range -- geographic range of those facilities.

Since the December meeting, we have set up a project page. It's available. We provided public notice, and then we held a public information meeting in Condon on Tuesday. And the public comment period on the Notice of Intent concludes on January 30th.

Next is the Speedway Energy Facility. So like the Saddle Butte Energy Facility, at the December Council meeting I let you know that we received the Notice of Intent for that project. That would be a 1,400-megawatt solar PV and wind project including 500 megawatts of battery storage.

The project is located generally southeast and northeast of exactly where we're at right now. So if you look, you know, kind of in these directions of this building, it would be all around this building. Maybe not on that side, but all around where we're exactly at right now.

The parent company also is Brookfield Renewable, same as the Saddle Butte Energy Facility. And we had a public -- so yeah, we had a public information meeting in this room last night. And the Notice of Intent concludes on January 23rd. So it's been a bit of a busy week in terms of meetings and hearings and getting on the road.

Next is the Yellow Rosebush Facility. So the Yellow Rosebush Energy Facility. So this would be 800 megawatts of solar PV, 800 megawatts of battery storage on approximately 8,000 acres, about 12 square miles. The project location is in Wasco and Sherman Counties, east of the city of Maupin. The developer is Savion LLC, which is a division of the Royal Dutch Shell Company.

At the November meeting, the Council reviewed the draft Proposed Order and all comments that were made or that were received, and provided direction to staff to make changes in the Proposed Order, which we did. And we issued the Proposed Order and included also a notice of opportunity to request to participate in the contested case.

That's a mouthful, but I think it bears clarifying. Frequently, people say they've asked for a contested case. There is a contested case with every application. It is an automatic step in the process. The distinction is if anybody requests to participate in it. And we did have two requests to participate in the contested case.

So at this point that has gone to the -- we contract with the Office of Administrative Hearings. They provide a contested case -- or a

hearing officer for us for that, and that hearing officer will be the one that's evaluating those requests for a contested case to make sure that they justify participation.

And so we -- if there wasn't any request for participation in a contested case, we would have had the Council's review of the final decision tonight. But that will take some time. So we'll keep you up to date on that and that will certainly be updated in my Secretary Report, as well as in the Monthly Siting Report.

Next is the Leaning Juniper 2A Amendment Determination. So on December 21st, the Department issued its determination. We received a request for an amendment determination and that was that -- yeah, their request was that they wouldn't have to go through the amended process.

So the changes they were proposing wouldn't trigger an amendment. And the changes proposed included a tax equity sale leaseback transaction with certificate holder and a national financial institution under which that institution would acquire the legal title to certain facility equipment as personal property and simultaneously lease that equipment back to the certificate holder

under a long-term lease.

So the Department's determination was based on an evaluation of Oregon Administrative Rule 345, Division 27-0350, and those are the factors where an amendment is required. And none of those factors triggered.

We had this kind of request previously I believe one time and made the same determination. However, because this is a determination, you know, that an amendment is not required, Council has the opportunity to request that that be brought forth to Council as an agenda item where you would review it and you could then come to your own conclusion whether you agree or disagree with that determination.

CHAIR CONDON: I just raised my hand myself.

Thank you, Secretary Cornett. Question about that. And I am not sure about the review necessary, but this is the second time we've had something similar come up. And I'd like to make sure we understand what it -- as these get more complicated in terms of the structure, that we understand kind of the full responsibility associated with it and how it plays out over time.

I mean, I understand the words that you're using, but I'm not sure what it means to us versus what it means to the company itself. So I'm wondering if there's an opportunity to do it. Not necessarily to review the decision of the Department but to really understand why the decision was made or how the decision was made based on your understanding of the risks associated or long-term -- long-term process for it.

I hope that makes sense.

SECRETARY CORNETT: Yeah. I mean, this is something either, again, this particular one is totally within Council's authority to say we want to take a look at this ourselves. We want to take a, you know, review it and we would then put it on a future Council meeting. And then we would provide, you know, our analysis -- well, their requests, their analysis, our requests -- or our determination, our analysis to you and you could come up to your own conclusions and certainly ask us more questions. And then ask the certificate holder more questions about it as well.

That's an opportunity, you know, we've looked at it. We don't believe that it triggers an amendment as those rules kind of require right now.

This is also the second time, I believe. I'm going to look at Sarah -- yeah, second time that we've seen this. We don't know if there's going to be a pattern or not. So this could also be, you know, outside of this specific action, this could be determination. I won't say action. I'll say determination.

We could do this in the future as an information item where we explore this sort of outside the context of a request.

CHAIR CONDON: It's hard to do head nods in the room, you know, about whether we want to do it or not. I know I would like at least an informational session on it, especially as we're looking at Organizational Expertise standard and financial assurance standard. To me, that all fits together.

Councilor Howe, any --

COUNCILOR HOWE: Secretary Cornet, you said you bring it to us once you've made your determination.

SECRETARY CORNETT: That's what I'm doing now.

So the way the amendment determination process works is -- you know, and a site certificate

holder is not obligated to use this process.

COUNCILOR HOWE: Yeah.

SECRETARY CORNETT: It's to their benefit. They could make some choice, put it in their annual report, and include that as sort of a facility modification. We would then review that, and then the risk is that if we determine, no, that should have been an amendment, well, they've already made these changes. They then are forced to come back in. So it's to their benefit that they, you know, frequently choose this method, which is to get some, you know, validation.

COUNCILOR HOWE: Right.

SECRETARY CORNETT: You know, kind of officially that an amendment is not required. And so what they do is they make their case. They say here's the requirements when an amendment is required. This is what we're proposing. You know, presumably they're going to say we don't believe this triggers these things.

We then review that ourselves and then the requirement is at the next Council meeting after we make our determination, I provide this update to you and then, again, your ability is to either say, yeah, that sounds great, or if you're like, we

really want to take a look at this ourselves and we want to do the evaluation of all of that information, that's absolutely within your authority.

COUNCILOR HOWE: I, myself, am fine with the staff evaluation.

COUNCILOR GRAIL: This is Marcy, and I agree with Council Member Howe. I'm fine with the staff evaluation as well.

CHAIR CONDON: And just to clarify, I'm fine with the decision. It's the information that I'm -- an informational item that I'm asking about, not necessarily related to this project. But how these structures -- they're different. And how they -- how they work in a project for both the developer and the state.

SECRETARY CORNETT: And we could absolutely put it on the list for a future Council meeting if you want to do it as an information item.

COUNCILOR HOWE: Yeah, as an information item that doesn't hold this out then that sounds fine to me.

SECRETARY CORNETT: Sure.

Sorry, Nancy, can we turn the heat down a little bit? It's starting to get warm right here.

CHAIR CONDON: Councilor Devlin or Perry, any -- any thoughts?

COUNCILOR PERRY: Yes. Thank you, Chair Condon.

I would be interested, as you are, with the information, making it an informational item on one of our agendas to just understand a little bit more about that process. I totally agree with, you know, allowing the staff to be able to make those -- or the reviewing body review those requests as appropriate. And I -- I would just like to know how they do that.

CHAIR CONDON: Councilor Devlin?

COUNCILOR DEVLIN: I would actually concur with those statements. I would be fine with having a presentation about the process. But I mean, ultimately, the process, I think, should stay at the staff level to make that determination.

SECRETARY CORNETT: Sorry. For the record, Todd Cornett.

Just for clarification, my understanding was not the amendment determination process and how that works, but it was more specifically this specific type of request.

CHAIR CONDON: Yes.

SECRETARY CORNETT: The sale lease back on the equipment?

CHAIR CONDON: Yes.

COUNCILOR DEVLIN: Yeah.

SECRETARY CORNETT: Okay.

CHAIR CONDON: Which was the previous one as well.

SECRETARY CORNETT: Correct.

CHAIR CONDON: With the sale on the lease back. So yeah.

I think we're all in agreement.

SECRETARY CORNETT: Okay. We'll make a note of that.

Nancy, can you make a note of that for a future agenda item? Thank you.

Okay. Moving on to compliance updates.

So, you know, as I've indicated before, the way that the annual reports work is the -- so for, in this case, the 2024 annual reports, every certificate holder has to submit a report annually. The ones that they did for the calendar year 2024 have to be submitted, most of them, by the end of April 2025.

So then that gives us the, you know, the time to start working and reviewing those. We're

getting to the end of those reviews. Didn't quite finish. We've done all of the initial reviews. We've requested some additional information from some of the certificate holders to provide additional information to clarify that they meet conditions. We're still waiting to hear some -- from some back, but we're getting close to concluding those, which is great. Having more staff resources is hugely beneficial.

But I do have two quick updates on two of the Shepherds Flat facilities. So the Shepherds Flat Central, again, we kind of talked about that. Brookfield in Gilliam County just to the south of Arlington, that's a 265-megawatt facility. It's been in operation since 2012. And with regard to their meeting their conditions, I provided an update on Shepherds Flat Central last Council meeting. And really, these are the same things.

There have been sort of persistent issues with weed control and revegetation management since construction or reconstruction of the -- well, initial construction of the process of the project, and then also following the 2019 repower. So they know that. We know that. They're working on it. We're, you know, being clear with them. So we're

looking for more information.

Yes, thank you. I meant to say turn it on there.

And yeah. That won't be concluded until 2026. It's just, you know, we're -- I know we're in 2026 now, but it'll take a while because there's some pretty significant, you know, sort of detailed information that has to be evaluated and provided. So, but as I said, they're diligently working on it. We're diligently working on it. And we do believe that we can kind of come up to speed on those in 2026.

Shepherds Flat South, kind of similar. That's a 290-megawatt facility located in Gilliam and Morrow Counties. Also operational since 2012. The majority of the site is under cultivation for wheat production, but the site also has had persistent weed control and revegetation kind of management issues. So really the same thing as the other one. They are diligently working on it, and we do expect to have that all concluded in 2026.

Okay, next on my list is Executive Order 2529. So I brought this up at the -- I don't know, was it the last Council meeting or the one previous to that?

So Governor Kotek issued this Executive Order in November. This order requires the Department of Energy to take several -- undertake several directives in coordination with other state agencies. And it includes two required studies to be submitted to the governor by September 1, 2026. And these studies are being led by our P&I Division, Policy and Innovation, and also us to some degree. And I'll indicate what that means in a second.

So for one of the studies, ODOE is directed to inventory, assess, and analyze barriers to permitting, construction, and interconnection of clean energy projects and associated infrastructure.

For the other study, ODOE is directed to evaluate and recommend actions to update siting and permitting processes to facilitate deployment of renewable energy, energy storage, and grid infrastructure. Those are the mandates in the executive order.

So we will be looking -- we'll be working on this, you know, in the coming months, and we'll be giving you updates as to what we're doing. We will likely be doing some outreach on that as well, but again, we will ultimately have to provide a report to the governor by September.

And then, great, next slide. You got it.

So we are soon to be entering into the short legislative session. So I've included on this slide the schedule. Again, it's the short session, so it really isn't very long, but that doesn't mean it won't be significant. It just means it's short. And we do already anticipate there being some legislation related to energy facility siting and maybe Energy Facility Siting Council, your statutes specifically.

But you can see, you know, the session starts on February 2nd, and then there are always deadlines or bills basically start to die. So bills have to be posted for a work session. Then they actually have to have a work session. And if they don't meet those thresholds, then they basically just move out. So there always ends up being like some huge volume of bills and it starts narrowing down pretty significantly.

So you can see the deadlines for the first chamber and then the deadline for second chamber. And then March 8th is the constitutional end of session. So it has to be done by then.

So like the long session, I'll be providing updates in the Monthly Siting Report and

the Secretary Report. The difference is in the long session, there's a lot more time to sort of understand what's going on and see this and with a short session, it's February, and by the time we have March, it's done anyway. So there won't be much time.

So I might be submitting information to Council outside of the Monthly Siting Report and outside of the Council Secretary Report at a Council meeting just so you're updated as to what kind of legislation relates to you.

Another update, and you're probably not tracking this, but there are now new federal visual accessibility requirements. And these are applicable to all government agencies, state agencies, I believe local governments as well. The purpose of those is to ensure that all people, including any with any kind of visual limitations can access all websites and digital information.

So, you know, you go onto a, you know, a website, and if you have sort of visual impairments you may not be able to see that information. So now you have pretty sophisticated screen readers and other types of devices that actually can provide, you know, the content to somebody who has, you know,

sort of visual limitations. And so by the end of April, we have to be compliant with those federal requirements.

The agency is moving forward. We're moving forward. Bebe and Nancy have already been working on templates. Really, this is just a way to kind of make sure that -- you're going to start to see some variations and some differences in the PowerPoint presentations. You know, if we have a map or a chart or a graph or a screenshot, there has to be alternative text associated with that because somebody can't necessarily see that. The screen reader would have to be able to read what that image or what that graph is.

So we're just coming up to speed, you know, but we have until April to figure that out. So again, we're already working on it, but you know, just as a -- you'll start to see those changes. And we also will need to provide a handout to anybody who submits slides for the Council meeting or anybody, you know, all of our applicants, they will have to submit information, digital information that meets those requirements as well.

COUNCILOR GRAIL: Just a question on that. I presume that the agency gets support from a

resource. You're not doing all of the work to get it done, or you are doing the work?

SECRETARY CORNETT: I mean it's an enterprise-wide thing. Everybody within the state of Oregon. I'm not sure how much sort of direction and detail is coming out of the Department of Administrative Services. My understanding is a lot of state agencies are really sort of having to chart this course by themselves for now.

I'm sure as anything changes, you know, that sort of change is difficult, likely we'll see probably more consistency in the future. But my understanding is right now it is largely at the individual agency level.

COUNCILOR GRAIL: Interesting. Thank you.

SECRETARY CORNETT: My list is the next Council meeting, that will be February 13th, Friday the 13th. We'll be in Salem, and we only need that Friday meeting. And we anticipate right now that that would end around 1:00 p.m. So it won't be a very long meeting.

COUNCIL MEMBER: And I will not be at that meeting.

SECRETARY CORNETT: Correct.

COUNCIL MEMBER: I'm just going to say I'm

not going to -- I was going to try and make it, but I will be absent.

SECRETARY CORNETT: I think being out of the country is a realistic absence.

And that concludes my Secretary Report unless any council members have any questions.

COUNCILOR DEVLIN: Madam Chair?

CHAIR CONDON: Yes. Councilor Devlin?

COUNCILOR DEVLIN: Madam Chair, just a quick question to the secretary.

I was looking in previous evenings on the website, and sometimes you can find things on the websites and sometimes you can't. Sometimes they exist. Sometimes they don't.

But I was trying to look to see if there were any cumulative reports from -- on the compliance side or any cumulative reports on I think what we refer to as incident side. What I mean is some way to query. Like if you had a particular applicant before you who perhaps had an amendment, not necessarily speaking just about the one -- of the ones we have today, but where you could actually do a query where you could find out what previous compliance reports have shown, and cumulatively what incidents there have been at that site.

And if it's not available, that's fine because I, at this point, cannot estimate what it would take to actually make it available, other than a member just simply making a specific inquiry.

SECRETARY CORNETT: Yeah. Thank you, Council Member Devlin.

The timing is interesting that you ask for this because we just had a compliance meeting today. The compliance team is working on their presentation for next Council meeting, and this is exactly one of the things that we discussed. What are the types of things that the Council is interested in either being, you know, presented at a Council meeting, during like the Monthly Siting Report, or in other avenues?

I mean, so that information is sort of theoretically available. We'd have to conduct the research and then pull it all together. So we don't have it sort of nice and packaged up right now, but it is a good question. And this is one of the things I want Council to think about as the compliance team comes next month. What are you interested in on the compliance side? What do you think the public is interested in from the compliance side? We have the resources now to be

able to spend a lot more time and pull that kind of data together.

So your question is, yeah, can we do that? Absolutely can we do that. You know, could we do that today? No. You know, but this is the kind of stuff that will be very helpful to hear about at the next Council meeting so we can start changing that program to have more information available to the Council and members of the public.

You know, and then also thinking about, you know, as we've initiated the rulemaking for compliance, you know, what kind of rule changes, you know, may or may not relate to some of these questions? You know, we don't have to create rules to do those types of things, but there can be overlap. So I think it will be helpful to be thinking about that.

And so I appreciate the timing of your question. It was literally like three hours ago we had a similar type of conversation. So it was very good timing.

COUNCILOR DEVLIN: Thank you.

CHAIR CONDON: Thank you, Councilor Devlin.

And just a comment about that. I think

that is the next stage in a process that we started I think two years ago to have a compliance report every meeting. And so I think all of us are probably getting more comfortable with, okay, here are the issues, here are the projects involved. And so the logical next step is, I think exactly what Councilor Devlin is asking about.

SECRETARY CORNETT: Yeah. And as I said, now that we have the actual resources, the staffing resources to do that, now that we have three people, it makes it much easier to do those kinds of projects. With one person, you know, scrambling just to try to keep up with everything, a huge volume of work that had to be done on an annual basis, it was overwhelming. It's still overwhelming even with three people, but we can start to do these things.

And as I always say, you know, we do three things, you know, within the Siting division. You know, we do the review of applications and amendments, we do rulemaking, and we do compliance. And you see the first two, you know, almost every meeting. You don't see compliance as much, but it is just as important as the other two. And so we want to kind of amplify that program and provide the

information that you want in the way you want it. So please be thinking about that.

CHAIR CONDON: And the other thing I'll say is I also think that as we get these compliance reports, at least it makes me think about, well, what could we do at the beginning of the process as we see the projects start to make sure we have that in place? So.

SECRETARY CORNETT: And that's tying the compliance team with, you know, reviews of the applications and amendments to ensure that those conditions that are being created are as clear and implementable as possible. Yeah, there's a lot of overlap between, you know, these sort of subprograms within the division.

CHAIR CONDON: That's great.

Thank you, Councilor Devlin.

Any other questions? Again, I can't see on the screen so feel free to just speak up. Okay.

Thank you. Thank you. Thank you, Mr. Secretary.

And now we'll move on in the agenda and we'll have Summit Ridge Renewable Energy Facility Notice of Intent Extension Request, Sarah Esterson, senior policy advisor. And we will review the

request beginning with the presentation from Ms. Esterson.

SARAH ESTERSON: Good afternoon, Chair Condon, Vice Chair Beier, and members of the Council.

If we could go to the next slide, please, Nancy.

So let's start with a little background. Summit Ridge Wind LLC, the certificate holder, has requested to extend the notice -- the expiration date of their Notice of Intent for the Summit Ridge Renewable Energy Facility from January 25, 2026, to January 25, 2027.

The Summit Ridge Renewable Energy Facility is a 261-megawatt wind and solar facility proposed in Wasco County for your reference.

So you have rules that apply to a Notice of Intent extension request, and those rules establish your scope of review. That scope includes review of two criteria. One is a timely criteria and the other is good cause.

The timely criteria establishes that a request for extension of a Notice of Intent expiration date must be submitted at least 45 days prior to the expiration date. And as I mentioned,

they also have to provide or describe a good cause for the extension request.

Okay, so let's review the criteria. The first criteria of timely. So the NOI expiration date was January 25, 2026. The request to extend the expiration date was received on November 24, 2025, which was 62 days prior to that deadline, so we are recommending that the timely submission criteria is met.

And then for good cause -- and I said certificate holder earlier. I meant applicant. The applicant provided two reasons to justify the extension request which are somewhat interrelated. But they've requested more time to allow landowner negotiations primarily due to uncertainty and changes in Bonneville Power administration's planning for a substation that the applicant had been planning to interconnect to. So they said they need more time to negotiate siting given changes.

And then the additional reason was that BPA has sort of changed their mind on the funding of the substation. But they still want an agreement in place so that they can tie in. Applicant has indicated that they would come to an agreement, execute an agreement in late January or February.

And we did ask for some sort of additional description and details so that we could evaluate the merits of this representation of landowner negotiation, and we feel like they provided that upon request.

So now I think -- next slide, please, Nancy.

We are recommending that Council find that the criteria have been met and that the NOI expiration date may be extended by one year.

And we'll now turn it over to you for deliberation and possible decision.

CHAIR CONDON: Council members, any comments? Questions?

COUNCILOR GRAIL: This is Marcy. I have none.

CHAIR CONDON: Councilor Howe?

COUNCILOR HOWE: I have none.

CHAIR CONDON: I have one.

Can you go back to the previous slide?

It's just -- do you have a feel for the order of -- the sufficient time -- does the planning with BPA and the negotiation with landowners occur at the same time or do landowners want to understand that there is a BPA and an agreement with BPA first

or vice versa? BPA wants to understand that, no, you have the -- you have the agreements with landowners and you're ready for the interconnect. Do you have --

SARAH ESTERSON: I don't think I know the answer to that. But in their discussion, they described that there's been like years of waiting for BPA to move forward on a decision on the substation. And then there was significant staff turnover earlier in the year. And then there were changes with the substation that necessitated new negotiation with landowner in terms of siting. So I can't speak to what the landowners knew to be true before the uncertainty came about.

CHAIR CONDON: An additional question. How many extensions are allowed for the Notice of Intent?

SARAH ESTERSON: One.

CHAIR CONDON: Is it just one? Okay. Thank you.

If there are no other questions or comments --

COUNCILOR HOWE: Chair Condon, I move that the Council find the petition by the applicant to extend the expiration date of the Notice of Intent

for the proposed Summit Ridge Renewable Energy Facility was timely submitted and demonstrates good cause for the extension for the reasons described in the staff report. I further move that the Council approve the extension of the expiration date of the Notice of Intent for the proposed Summit Ridge Renewable Energy Facility by one year for a new expiration date of January 25, 2027.

CHAIR CONDON: Do we have a second?

COUNCILOR PERRY: Patty Perry here. I will second that.

CHAIR CONDON: Thank you, Councilor Perry.

Any more discussion?

With that, Secretary Cornett, can you call for the vote?

SECRETARY CORNETT: Cindy Condon?

CHAIR CONDON: Yes.

SECRETARY CORNETT: Richard Devlin?

COUNCILOR DEVLIN: Yes.

SECRETARY CORNETT: Marcy Grail?

COUNCILOR GRAIL: Yes.

SECRETARY CORNETT: Kent Howe?

COUNCILOR HOWE: Yes.

SECRETARY CORNETT: Patty Perry?

COUNCILOR PERRY: Yes.

SECRETARY CORNETT: The motion carries, Chair Condon.

CHAIR CONDON: Thank you.

And now to the next item. We have a public comment period. Sorry. We're a little bit late in that according to the timeline. This time is reserved for the public to address the Council regarding any item within Council jurisdiction that is not otherwise closed for comment.

In the agenda, we have set the amount of time for individual commenters to seven minutes.

Nancy, how many comment cards and raised hands on the webinar and phone do we have?

NANCY HATCH: At this point, we have one commenter in the room, and there are no hands raised yet. So we can go ahead and call Jennifer Miller to go ahead and come on up and make your comments.

And if you could start with name -- name and address and spell your name, that would be great.

JENNIFER MILLER: My name is Jennifer Miller. Boring. J-E-N-N-I-F-E-R M-I-L-L-E-R. And I live in Hermiston, Oregon.

And my comments are just really general. I have a letter that I'm reading from, and I will

hand that over when I am finished so it can be submitted to the record or however you do that.

NANCY HATCH: Thank you.

JENNIFER MILLER: So my name is Jennifer Miller, and I'm here representing both myself and OCTA, Oregon and California Trails Association.

My comments at this moment, excuse me, are general ones. I would like to ask the Council to look at projects -- projects from, say, a helicopter view.

This area of Eastern Oregon is being covered rapidly by wind, solar, and transmission activities. Valuable farmland and native flora and fauna is being crowded out almost daily. Exclusive farming/wheat fields are being bought or signed over for projects with little guard to how our food will be produced in the future.

Wheat fields, grazing, and rural means of making a living are being drastically affected. It seems as if the locals have to operate under one set of rules while energy projects get others, and there's not much consistency.

In this particular area, and I mean this Grass Valley area, of course, there are historic trails that need to be considered. The Barlow Road

cutoff runs through this area, and I do know that this Council was addressed last night by Wendell Baskins, so I'm -- we're part of the same group and I'm just continuing some of those comments.

SECRETARY CORNETT: Very quickly --

JENNIFER MILLER: Sure.

SECRETARY CORNETT: I think only Chair Condon was online last night.

JENNIFER MILLER: Oh.

SECRETARY CORNETT: The other council members didn't hear Mr. Baskins. So, and if that makes you want to change your public comment today, you can. But just to make sure you know that the rest of them didn't hear that.

JENNIFER MILLER: That's fine. I was just saying, yeah. So I'm just saying that some of the projects that are happening in this area are not -- I think some of them are not knowledgeable that there is the Barlow road cutoff and that projects do need to know about that going into, you know, just from the very beginning, knowing that this historic trail cutoff does exist.

And it would be really helpful if that cutout route could be added to layers on the project maps. So like when we go in and look at things, we

can see where the main historic Oregon Trail is, but we also feel that the Barlow Road cutoff needs to be added as well because it is also a very historic trail within the site, within the boundary of Oregon. Plus, the other 15-16 major historic trails.

So we're just -- I'm asking if that map could be added. And I know OSU has something to do with the mapping, so some kind of coordination perhaps could be done to make sure that that cutoff map can be included.

I do have two maps that were also here last night, but I will submit mine as well so that people today can look at them. And hope that that this blue line that's on these maps could be added.

So in conclusion, my request is just that a bigger picture is viewed instead of the projects or piece, you know, looking at piecemeal. The overall impact to this whole area is huge. It's just not a series of parcels, but a unique and amazing landscape that has its own beauty and importance.

Any questions?

CHAIR CONDON: Thank you for your comments, Ms. Miller.

Any questions?

I don't hear anybody but I do have one.

JENNIFER MILLER: Okay.

CHAIR CONDON: So I'm curious, and I did apparently hear the comments last night. I am curious if the association that you're a part of, if you have -- if you have communication or scheduled meetings with landowners who are all part of this process.

JENNIFER MILLER: We often don't know which landowners are impacted until we can look at the project on the map. So sometimes we don't even know about it until it's almost too late that it's even happening. As people are learning more about OCTA, the Oregon and California Trails Association, some projects are reaching out to us so that we can start working on things ahead of time and trying to create that space where, you know, preservation can be worked into the project if at all possible.

And so, does that answer your question?

So yes and no. Like we don't always know who owns what and, of course, most projects have nondisclosure agreements signed. And so it's hard to know who knows what and who's willing to talk about what. And we understand that projects are

going to happen. We understand that we need energy. We're just trying to do what we can do to save as much as we can while it is possible.

CHAIR CONDON: Thank you. Yeah. I appreciate that. It's just, it kind of was opaque to me about what happens beforehand. You know, what communication could be done.

JENNIFER MILLER: It would be great if we could get in on projects way sooner so that we could look up and then say, oh, that's not any threat of the trail. That's, that's fine. Like that's not a problem. Or this is going to be a huge visual impact. Let's see what we can do about that. Or please don't put that transmission line directly along the length of this section of the trail. Perhaps cross it instead and parallel it, you know, a further distance away so that it's not such a big impact.

So I mean, there's lots of things that we try to do to keep the story alive.

CHAIR CONDON: Okay. Secretary Cornett?

SECRETARY CORNETT: Yeah. Thank you, Chair Condon.

For the record, Todd Cornett.

Are you signed up to receive our Monthly

Siting Report?

JENNIFER MILLER: Yes.

SECRETARY CORNETT: Okay, good. Because frankly, we usually don't even know the details of a project until they submit their Notice of Intent. So, you know, whatever has occurred before then, we're not even in the loop on. So when we get that Notice of Intent and then we start to put it in the Monthly Siting Report or we provide the notice, that's really the first time that we have any indication. But it is important to know that that's the preapplication stage.

So identifying anything, any resources, obviously your interest is in, you know, primarily with the trails, but that's the time to do it is during those Notice of Intent comment periods.

JENNIFER MILLER: Right. And I'm sure that, I mean, you know, it's not just the trails. I mean like there was a huge native presence in this area for hundreds of years, and so that is also an important thing.

CHAIR CONDON: Thank you.

JENNIFER MILLER: You're welcome.

CHAIR CONDON: Thanks for being here.

Nancy? Sorry.

NANCY HATCH: Alright, so at this point there is one person with their hand raised. But let me just go ahead and remind everyone how to raise their hand. You see it on the screen in front of you. If you are on the webinar, you are going to click on the participant window at the bottom of the screen. You're going to push the hand icon and that will raise your hand. When you're finished commenting, you're going to click it again to lower it.

If you are on the phone, push “star 3” on your keypad to raise your hand and “star 3” again to lower your hand.

So at this moment I will unmute -- I have Ms. Irene Gilbert. I am going to go ahead and unmute your mic. And you are ready to leave your comment?

IRENE GILBERT: Thank you. Thank you for allowing me to speak. Can you hear me?

CHAIR CONDON: Yes.

IRENE GILBERT: Okay, great.

I wanted to comment on a couple of things. One is, as I've followed the Council over several years, I've noted that the opportunity for the public to actually access the council members has

become less and less easy and available. And one thing, I sent a couple of notices, a couple of information items to -- specifically to the Council regarding the Wildlife Mitigation Plan because of the exceedances.

Basically, I said that I felt that with an error rate doing mitigation that was projected to only bring the bat deaths down to one one-hundredths of a percentage below the threshold of concern should be of concern to the Council. And also, that there's nothing that I can see in terms of a follow-up evaluation or surveys to determine whether or not they actually stayed below the 2.5 standard. So I am concerned about that kind of thing.

I also wanted to comment on the decision regarding an amendment to whether or not an amendment was needed due to the sale of the BQH interest in the transmission line to a private enterprise.

Issues include this is a non-energy organization which was -- has never done this before. They were created just to have this sale. They don't fall -- they are not going to fall under the authority of the PUC because they're not an energy company. And so there's going to be no

control over how much they're charging for energy or any of those kinds of things that are controlled that way.

The fact that there is no longer going to be the stated customers or owners that were in the original certificate for public convenience and necessity has resulted in at least three appeals of the PUC determination that they were not going to rescind that certificate of public convenience and necessity.

I'm also concerned because PacifiCorp is basically wanting to sell this because their financing rating has fallen so much. And I'm concerned about the ability to access -- even access any funds from this shell company if it is needed to restore the site.

So lots and lots of concerns that should be of concern to the Council. And the PUC has not approved this sale. They're going to have to have full contested cases because of the substantial impacts and the unusual nature of this sale.

So to think that the Energy Facility Siting Council does not believe that you should have a full amendment process really is a real surprise to me. And frankly, I'll be really surprised if

there isn't, you know, some kind of legal response to it just given the fact that it's no longer the same owner. It's no longer to the same customers.

There's a question about whether or not they should even be condemning property to build this. And part of that question is related to the fact that this new company has no experience and nobody is going to control what they do to the customers.

So I encourage you to have some more discussion about this and perhaps decide that a decision to not provide an amendment isn't the wisest choice given. I mean this is a big deal. A big deal legally. A big deal publicly. And it's not going to go away.

So that's my comment about BQH. Be careful what you do.

And I wanted to say I'm sorry to see Katie gone. She was asking questions that needed to be asked, especially since the public has such a hard time getting to the Council with information. I was really surprised to see the email that I sent to the council members returned saying we aren't taking comments on this. And I'm assuming you never saw my email. But to have that kind of a blockade between

the public and EFSC, it seems to defeat your entire reason for existing. So thank you.

Any questions?

CHAIR CONDON: Thank you, Ms. Gilbert.

Any questions from the Council or comments?

Thank you very much.

Nancy, any more hands raised?

NANCY HATCH: There are no more hands raised at this time. We'll do a last call. If you'd like to make a comment, please raise your hand.

CHAIR CONDON: I think that'll do it for us. So we will move on. Thank you, Ms. Miller. Thank you, Ms. Gilbert for your comments.

And we'll move on to our next item, which is the Stateline Wind Project Wildlife Monitoring and Mitigation Plan Amendment. And this is an action item for the Council.

Christopher Clark, senior siting analyst will be guiding us through the review. Thank you.

CHRISTOPHER CLARK: Thank you, Chair Condon, Council members.

For the record, my name is Christopher Clark. I'm a senior siting analyst with the

Department, and I've been assigned to monitor compliance for the statewide wind project.

So Nancy, if I could get the next slide, please.

So the Stateline Wind Project is an operational wind power facility located in Umatilla County, Oregon and Walla Walla County, Washington. The Council has jurisdiction over the components cited in Oregon.

As shown on this slide, the facility consists of three phases that are separated into two distinct geographic and operational units. Those are Stateline I and II, which are the black dots, and the Vansycle II portion of the facility, which are the red dots. I'm going to be talking mostly about Vansycle II today as that's what this mitigation proposal is for.

I also just wanted to point out that there's different certificate holders for each of the geographic units, but both certificate holder LLCs are subsidiaries of NextEra Energy Resources LLC.

So moving specifically into the discussion of Vansycle II, that portion of the facility includes 43 Siemens, 2.3 megawatt turbines. The

Council approved the final order on Request for Amendment 7 in 2022, and that authorized that the turbines, which had been commissioned in 2009, can be repowered with larger diameter rotors.

If I could get the next slide, please.

So that repowering was completed in 2023. Sorry.

And then a post-repowering fatality monitoring study that was required by the Wildlife Monitoring and Mitigation Plan that was included as part of that final order on Request for Amendment 7 required one year of post-repowering fatality monitoring, which was completed between 2023 and 2024.

After the monitoring was complete in April of last year, the certificate holder notified us that there was an exceedance of the threshold of concern for bat fatalities. And based on the estimation methods required by the WMMP, the report estimated that there were approximately 5.86 bat fatalities per megawatt attributable to the facility in the monitored year compared with the threshold of 2.5 fatalities per megawatt. No other thresholds of concern were exceeded.

And I did want to note that all recorded

bat fatalities were from two migratory bat species. That's the hoary bat and silver-haired bat.

After an opportunity for public comment on the monitoring results and consultation with the Oregon Department of Fish and Wildlife (ODFW), the Department notified the certificate holder that based on the magnitude of the exceedance and the species affected, that mitigation was necessary. We received the mitigation proposal that was included as Attachment 1 to your staff report in October.

I'll go into the details on the next slide, but I did want to remind the Council that the approved Wildlife Monitoring and Mitigation Plan authorizes the Department to agree to mitigation actions and changes to the WMMP, but it requires us to notify the Council of any agreements and the Council retains the authority to approve, reject, or modify the actions or agreements.

Okay, so any questions so far? Sorry, I'm going a little fast.

Okay. So in the mitigation proposal itself, the certificate holder proposes to curtail operations of all Vansycle II turbines for the life of the facility. Curtailment would occur when wind speeds are below the manufacturer's recommended cut-

in speed of 3.0 meters/second year-round. And then the cut-in speed would increase to 5.0 meters/second in July and October, and 6.0 meters/second in August and September.

Curtailment essentially means feathering or breaking turbine blades so that the rotation of the blades slows. I can go into exactly the definition of curtailment that we've worked out or received from the certificate holder in a couple of slides, but I just wanted to make sure that was clear.

And then I wanted to kind of illustrate what this graph is showing is that we have studies showing that curtailment is an effective strategy to reduce bat mortality associated with wind facility operations and that mortality rates are -- or reductions in mortality rates are positively associated with increased curtailment wind speeds. So the more you curtail, the less likely it is that there will be fatalities.

I don't want to present myself as an expert on all the science on this, but the general idea is that bats are more active at lower wind speeds since very windy conditions make it harder for them to fly and hunt. So stopping or slowing

blades to less than dangerous speeds at these low wind speeds is a really good strategy to reduce mortality without impacting the power production of the wind farm as much as other things might.

And then I wanted to point out that the yellow line on this graph is showing the proposed cut-in speed for wind. So if winds are below 3.0 meters/second, you round it. It shows the flat part of the line. That's when the wind turbines would not rotate as quickly. That wind speed increases during the months when the most fatalities were reported. Those months also coincide with the migration periods for the two bat species that are affected.

So this proposal was based on the threshold of concern and based on the statistical analysis provided in a meta-analysis of a number of different curtailment studies. There's a link to that meta-analysis in your staff report. The proposal would be expected to reduce fatalities to 2.49 fatalities per megawatt per year, which is just below the threshold.

We did consult with our colleagues at ODFW on the review of the proposal and whether it would be effective in addressing the concern, and they

provided support for curtailment as a strategy to minimize and mitigate bat mortality risks. And they noted that if this proposal was accepted, it would be the first time that curtailment was implemented at an Oregon facility.

I did want to note; one thing is that there are no follow-up requirements for monitoring of the effectiveness of this proposal. But ODFW outside of the regulatory process is working to connect an independent researcher with the facility to conduct a study of fatalities after curtailment is implemented.

So based on the comments we received from ODFW and review of the evidence provided, the Department notified the certificate holder that we agreed with the proposal in December.

And if I could get the next slide.

We are still in the process of working with the certificate holder to document the specifics and details of the agreement as an amendment to the WMMP. Specific items that we've discussed or have resolved so far is the standard for curtailment which is that they would reduce the speeds of turbines -- turbine blade rotation to less than one rotation per minute when the 10-minute

average of wind speed is below the applicable cut-in speed.

We are still working to solidify the reporting and validation requirements, although they've informed us that their SCADA system can give a report of whether or not the curtailment was implemented to the minute and that they're working on a way to include that into the annual compliance report that would be submitted to us each April.

They're also looking at a way to notify us if there was a significant failure of the system and curtailment didn't happen when it was supposed to for a prolonged amount of time.

The certificate holder also notified us that they intended for this mitigation proposal to only be implemented from dusk to dawn because it is a proposal related to that mitigation. We let them know that we thought that was a material change since it wasn't specified in the original thing. Although we don't necessarily object to it, we wanted to talk to our colleagues at ODFW again and make sure there weren't any additional concerns. They're also working on getting the specifics of what dusk to dawn means and how that will be determined.

So, all that to say on this slide is that while we don't have a red line for you at this time, we thought it would still be valuable to get additional feedback. If the Council's comfortable with moving forward with this information, I think it would still make sense to vote. I'll leave that up to you. But if you have any questions, I'm happy to answer them.

CHAIR CONDON: Council members, any questions or comments about the presentation?

Councilor Howe?

COUNCILOR HOWE: Yeah, this is Kent. Great staff report. Good explanation.

When I was going through it, it was kind of -- what's the word for when it's not straightforward in the way that you're thinking -- in the way I'm thinking anyway. And so like when I was reading in November to June, when the blade rotation would be limited when the wind speed is below 3.0 meters/second -- I looked that up. That's about 7 miles an hour -- then the manufacturer is going to cut the speed of the blade, I think, is what that means.

CHRISTOPHER CLARK: Thank you, Council Member Howe.

So the manufacturer's cut-in speed is the speed at which the wind has to be blowing for the turbine to begin producing electricity.

COUNCILOR HOWE: Okay.

CHRISTOPHER CLARK: So if the wind is not that fast, they will feather it out of the wind so that the blades don't spin as fast.

COUNCILOR HOWE: Okay. Okay. So on that graph, when the winds are higher in those months, it seemed like it was -- the way it was showing was --

CHRISTOPHER CLARK: Nancy, can you go back to that slide? Perfect. Thank you.

COUNCILOR HOWE: It looks like it allows them to go faster because the line goes up as opposed to dipping down. And that just confused me. And it's not you. It's not the -- it's just my brain was looking at it and thinking, okay. I think what I wanted to do is have it show a reduction in the speed of the blade, but that's showing how much it's going to reduce the speed of the blade.

CHRISTOPHER CLARK: Council Member Howe, I'd say what the line on the graph represents is how fast the wind has to be blowing before the turbine starts spinning. It's not related to the speed of the turbine itself.

COUNCILOR HOWE: Oh.

CHRISTOPHER CLARK: It's related to the speed of the wind. And once the wind starts blowing, if it starts -- for most of the year outside of the migration period, if the wind's at 2.9 meters/second based on their meteorological towers --

COUNCILOR HOWE: Yeah.

CHRISTOPHER CLARK: -- the turbines will be stopped from spinning as quickly.

COUNCILOR HOWE: Okay.

CHRISTOPHER CLARK: Once it hits 3.0 meters/second or more, they will feather the blades back into the wind and it'll start spinning normally.

COUNCILOR HOWE: Okay.

CHRISTOPHER CLARK: And I do not know how fast those turbine blades go, but it is fast when they are into the wind. So yeah.

Chair Condon?

CHAIR CONDON: Secretary Cornett?

SECRETARY CORNETT: So just for clarification. So to me this graph represents the fatalities.

Is that right?

CHRISTOPHER CLARK: It's a two-axis graph. So the axis on the left, the Y axis on the left is the number of fatalities and that would be the bar graph. And then the line graph is the cut-in speed.

SECRETARY CORNETT: Right.

CHRISTOPHER CLARK: Right.

SECRETARY CORNETT: Yeah, and so the, you know, obviously August, September, October, that's where the majority or much higher levels of bat fatalities are occurring.

CHRISTOPHER CLARK: Right.

SECRETARY CORNETT: And so trying to adjust the cut-in speed during those months to a different level to reduce those fatalities.

Is that the basic concept?

CHRISTOPHER CLARK: That's correct. Yeah.

And in the meta-analysis, it kind of indicates that for each additional meter per second of wind speed that you allow curtailment to continue basically, you get a greater number of -- you get fewer and fewer reductions.

So bats are still active above 3.0 meters/second. So if you increase it to five or six, more bats -- or less bats will be negatively impacted by the turbines.

COUNCILOR HOWE: So the yellow line is the proposed cut-in speed. And so theoretically, a year from now if you showed this graph, the yellow line would be the same because that's their established cut-in speed.

CHRISTOPHER CLARK: Yeah.

COUNCILOR HOWE: But if it works as it's supposed to work, those numbers probably in July, August, September October, those should be reduced below that because those cut-in speeds changed according to that yellow line.

CHRISTOPHER CLARK: Right. Yeah.

COUNCILOR HOWE: I knew that's what it all was saying, but intuitively it seemed like to reduce the wind speed, the graph shouldn't go up. It ought to be reducing the wind speed, you know the speed of the -- like, I get it, and I think you did a great job. Thank you.

CHRISTOPHER CLARK: Thanks. I'll take full credit for this graphic. It made sense in my brain, but I understand why it's not intuitive.

CHAIR CONDON: But just, can you go back to the graph? I just want to make sure.

So from November -- well, as it says, from November to June, the turbines are basically still.

Right?

CHRISTOPHER CLARK: Alright, Council Member Condon, between November and June, curtailment would only occur when wind speeds are below 3.0 meters/second. So that's actually the most they would be operating -- they would be operating most of the time between November and June.

CHAIR CONDON: So bats don't fly in higher wind -- at higher wind speeds?

CHRISTOPHER CLARK: Yeah. And I don't know exactly where that ceiling is for them, but they are more active at low wind speeds. That's correct.

CHAIR CONDON: Yes, okay.

COUNCILOR HOWE: That helps too. I didn't understand that.

CHAIR CONDON: Okay, I think I was kind of thinking about this backwards.

COUNCILOR HOWE: I was, too.

CHAIR CONDON: So I have a question related to curtailment. Has curtailment been used in a, I mean, I'm presuming that the Oregon Department of Fish and Wildlife has lots of information about this issue. Is curtailment used

in other states effectively, and therefore this should be meaningful curtailment here? Should be meaningful to decrease fatalities?

CHRISTOPHER CLARK: All right, Chair Condon, yes. I don't know how often it has been used as a regulatory instrument, but the meta-analysis provided is actually based on real studies that happened across the United States, including studies, I think in the Northwest, but definitely studies that included the two species that are present here were present in those studies. And they look at both a pre-curtailment study and a post-curtailment study to a certain extent and then see how the reductions played out.

So I think there are -- I couldn't tell you the exact number of studies, but it being a meta-analysis that does include several that were conducted over a decade. So empirically supported to be an effective strategy. Yes.

CHAIR CONDON: Okay. Thank you. And the final question for me on it is, given the higher than anticipated fatalities before, is there any mitigation, you know, post-mitigation? You know, we've seen contributions to wildlife centers or whatever to speak to the over fatalities.

CHRISTOPHER CLARK: When we had our initial consultation with ODFW, we kind of asked about that. There's two reasons why that sort of compensatory mitigation was not preferred and this sort of operational curtailment that's actually designed to reduce future fatalities was the option that we pushed for and what was proposed.

So there's not a lot of data available about migratory bats. There's not a lot of science on them, so not a lot of studies. And biologists don't even know a ton about their migration patterns. So we see them when they show up in a fatality study, but it's hard to kind of estimate what would really help them as far as that sort of compensatory mitigation.

And the other thing is where raptors might be able to go to a rehabilitation study, bats are both very small, and I think any interaction they have with a wind turbine that results in an injury or a fatality is almost always a fatality. So there's not a lot of like opportunities for rehabilitation of injured bats just because of the nature of how they are affected by the turbines.

CHAIR CONDON: Yes. And to be clear, I wasn't suggesting that -- I think the mitigation

approach as it is here going forward is much better than a compensatory approach. But it was the compensatory compensation for the higher than expected that I was questioning. But just a question.

CHRISTOPHER CLARK: Thank you, Chair Condon.

One comment on the thresholds of concern is they are a signpost. So it's, you know, we have requirements for post-construction fatality monitoring often. And then if the threshold is exceeded, it's not necessarily like they need to meet the threshold, like that triggers a conversation with us and then we see if this is an impact that wasn't considered in the permitting that needs to be addressed. And that's what we found was the case in this case. A lot of times there will just be another year monitoring and it'll be found to be an anomaly.

So, it is, you know, a little more nuanced than we just need them to get down to 2.5.

CHAIR CONDON: Okay. Thank you.

Any other comments or questions?

Seeing or hearing none.

COUNCILOR HOWE: Chair Condon, I move that

the Council approve the proposed amendments to the Stateline Wind Project Wildlife Monitoring and Mitigation Plan that curtails turbine operations at the Vansycle II unit below specified wind speeds to address an exceedance of the threshold of concern for bat fatalities as presented in the staff report.

CHAIR CONDON: Thank you, Counselor Howe.

COUNCILOR DEVLIN: Second.

CHAIR CONDON: We have a second from Councilor Devlin.

COUNCILOR PERRY: Yeah. Patty Perry seconds the motion.

CHAIR CONDON: Oh, we had a second from Councilor Devlin.

COUNCILOR PERRY: Okay.

CHAIR CONDON: Thank you, Councilor Perry.

And Secretary Cornett, can you please call the vote?

SECRETARY CORNETT: Patty Perry?

COUNCILOR PERRY: Yes.

SECRETARY CORNETT: Richard Devlin?

COUNCILOR DEVLIN: Yes.

SECRETARY CORNETT: Kent Howe?

COUNCILOR HOWE: Yes.

SECRETARY CORNETT: Cindy Condon?

CHAIR CONDON: Yes.

SECRETARY CORNETT: Marcy Grail?

COUNCILOR GRAIL: Yes.

SECRETARY CORNETT: The motion carries, Chair Condon.

CHAIR CONDON: Thank you, Secretary Cornett and councilors.

COUNCILOR PERRY: Chair Condon?

CHAIR CONDON: And thank you.

Yes?

COUNCILOR PERRY: This is Marcy.

And Christopher, I've just got to tell you, thank you for what you're doing. I tell you, everybody every year, this is the hardest thing for me to do on EFSC.

I can't -- the whole bat thing just wigs me out, so good on you for getting in there and pulling it together for us, Christopher. Because if I had to read very much, I don't -- I don't think I'd be pulling my weight. So thanks as always for a great presentation.

CHAIR CONDON: Yes. Thank you.

Is it the picture that wigs you out?

COUNCILOR GRAIL: When I see you again I will amuse you with all my nuanced fears and

paranoia and all the things bat related. Bats and rats, all the things just, I can't even tell you. I can't look at them on TV without getting the heebie-jeebies. Yes, technical term heebie-jeebies. I turn into a five-year-old child. I just -- I'm sitting here with my eyes kind of open, like squinting, trying to not be a child about it. But oh, that's a rough one.

CHAIR CONDON: Well, thanks for sticking with us.

Okay, next item on the agenda is the Oregon Trail Solar Facility Revegetation and Noxious Weed Plan Amendments. It's an action item. And Sarah Esterson is once again policy advisor for a presentation. Thank you.

SARAH ESTERSON: Thank you. Good evening, Chair Condon, Vice Chair Beier, and members of the Council.

So the site certificate for the Oregon Trail Solar Facility authorizes up to 41 -- you can go back just one second.

It authorizes up to 41 megawatts of a combination of wind and solar powered generation components within an approved site located in Gilliam County. The certificate holder is Oregon

Trail Solar LLC, which is a wholly-owned subsidiary of OVIN Grid Power LLC.

So for this facility, the preconstruction and construction is being phased, and it's currently in both phases with plans to move forward with construction of a 31-megawatt solar facility and 20-megawatt Battery Energy Storage System on Monday.

So as you know, as we talk about compliance, that preconstruction compliance is a phase where the certificate holder is required to comply with preconstruction conditions that are established in the site certificate that you've issued prior to moving forward with construction. And this is a process where the certificate holder is submitting information to the Department for review and approval or (inaudible). Mitigation plans are almost always preconstruction requirements that have to be finalized and approved prior to construction.

So in this instance, for this facility, we're here to discuss changes related to two mitigation plans, the revegetation and noxious weed plans. So as part of preconstruction compliance or this facility for these two plans, the certificate holder requested changes that are beyond the scope

of changes contemplated in the draft plan.

So while we've reviewed for approval for finalization, they've requested substantive changes that we want to bring back to the Council for transparency to make sure that you would agree with these types of changes. And as we've discussed in a couple of meetings over the last year, if not a lot, that mitigation plans do have an amendment clause that allows for changes to be reviewed outside of the amendment process that maintains an obligation that we bring it forward to Council for concurrence, modification, or rejection.

Okay. So let's move into the substantive changes that the certificate has proposed. So first, the revegetation plan. The revegetation plan applies to temporary impacts to habitat predominantly. And then it has general requirements for restoration of temporary impacts to cropland.

So the proposal is to remove all requirements that apply to temporarily impacted habitat because based on the solar facility there really isn't temporary impacts outside the fence line that are considered habitat. What they have is a little sliver of a collector line that is -- it has grassland dispersed throughout other ag land in

between the Pachwaywit Facility and active ag.

So if you look at it on its own, it's grassland. That's considered habitat. But when you look at it overall and you consider habitat function and value based on consultation with ODFW, we agree to categorize it as category six, which relieves the obligation to do a habitat restoration level plan that is within the revegetation plan.

So just to note, general revegetation requirements still apply. You have a mandatory condition that applies to all temporary impacts, and it says you have to restore temporarily impacted land commensurate with adjacent lands. And then they have an obligation under the 1200 C permit that DEQ issues, all EFSC facilities have to get this permit, that also has a vegetation, a stabilization requirement before they can close that permit out. So while the proposal is to basically remove this habitat restoration level requirement because there's no real habitat, know that revegetation is still a requirement.

Okay, so, and then we are going to lift the general restoration of cropland -- temporarily impacted cropland over into the noxious weed plan. So now we can go over into the noxious weed plan.

That noxious weed plan also has a seeding and weed treatment obligation. So you're going to get revegetation through the noxious weed plan as well.

But the substantive change here that was beyond finalization requires amendment is that they again want to use sheep grazing as a vegetation management strategy at this site. You have evaluated this request for several solar to date, including the Montague Solar also known as Pachwaywit, as well as Bakeoven and Daybreak.

And as you know with ODFW coming forward, you received a presentation a few months ago, their biggest concern with sheep grazing is the potential for disease transmission to big game or to Bighorn sheep. And so we did consult with the regional biologist, Lindsay Somers at ODFW to confirm whether that disease transmission risk concern existed for this site, and they confirmed that it did not.

But they do have a set of best management practices they've recommended be included in the plan, so that is included in red line and the Attachment 2 for your consideration. But it includes doing fence checks to make sure that the fence is intact and that sheep can't escape, and that they would be monitoring and reporting to

evaluate if there are Bighorn sheep identified or if any of sheep escape from the site should they choose to use it.

And then we've recommended that the noxious weed plan make clear that use of sheep grazing and the success thereof is reported annually to the Department as we do want to understand if this is working or what type of problems are occurring, and that they are following through with those ODFW notification elements.

Okay. And yeah, I summarized that on the slide too.

Okay, so those are the substantive changes proposed that would necessitate an amendment of both the revegetation plan and the noxious weed plan. And we are recommending that Council concur with staff and agree that these changes can be incorporated.

So I'll hand it over to you for deliberation and decision.

CHAIR CONDON: Council members, any comments or questions?

COUNCILOR GRAIL: No questions. This is Marcy.

CHAIR CONDON: Thank you. Thank you, Ms.

Esterson for the presentation.

And I think we might be ready for a motion.

COUNCILOR HOWE: Chair Condon, I move that the Council approve the proposed amendments to the Oregon Trail Solar Project Revegetation Plan and the Noxious Weed Plan as presented in the staff report.

CHAIR CONDON: Thank you, Councilor Howe.

Do we have a second?

COUNCILOR GRAIL: This is Council Member Grail. I second the motion.

CHAIR CONDON: Thank you, Councilor Grail.

Any discussion?

Secretary Cornett, I think we're ready for a vote.

SECRETARY CORNETT: Richard Devlin?

COUNCILOR DEVLIN: Aye.

SECRETARY CORNETT: Kent Howe?

COUNCILOR HOWE: Yes.

SECRETARY CORNETT: Marcy Grail?

COUNCILOR GRAIL: Yes.

SECRETARY CORNETT: Patty Perry?

COUNCILOR PERRY: Yes.

SECRETARY CORNETT: Cindy Condon?

CHAIR CONDON: Yes.

SECRETARY CORNETT: The motion carries, Chair Condon.

CHAIR CONDON: Again, thank you, Ms. Esterson, for the presentation.

And now we have on the schedule a break. So we'll take a break at this point. And our next agenda item is at 6 o'clock. And so this will be a longer break than normal break. Sorry about that. We don't have circus animals or anything. So bear with us.

We do have some refreshments and some people to talk to. So thank you very much. We'll break until 6:00.

(WHEREUPON, a recess was taken.)

CHAIR CONDON: Good evening. My name is Cindy Condon. It is now 6:00 -- 5:59, almost 6 o'clock, and I would like to call the meeting back from recess and continue on with our next agenda item, which is Biglow Canyon Amendment 4, a public hearing.

And with us tonight is Chris Clark, senior siting analyst, who will provide an overview of the siting process and the proposed amendment as the hearing progresses -- and the hearing will progress.

Thank you, Chris. You have --

CHRISTOPHER CLARK: Thank you, Chair Condon, Council members.

For the record, my name is Chris Clark. I'm a senior siting analyst with the Department, and we are here tonight for the public hearing on the Proposed Order for Request for Amendment 4 of the site certificate of the Biglow Canyon Wind Farm.

I am going to start the presentation tonight with an overview of the Proposed Amendment and the Proposed Order.

I'll then turn it over to our senior siting analyst, Sarah Esterson, who will be serving as the presiding officer for tonight's hearing.

Sarah will give an overview of the hearing process itself and then open the floor to public hearing and oral testimony. The order of testimony will be the certificate will be given an opportunity to speak followed by members of the public, and then the Council will have an opportunity to ask clarifying questions.

To get into the overview of the Proposed Order, this project, the Biglow Canyon Wind Farm, is an operating wind power generation facility in Sherman County. The facility includes 217 Vestas and Siemens turbines and related and supporting

facilities, including a collector substation and an O&M facility. The facility is located within an approximately 39 square mile site located about two miles from the city of Wasco at its closest point.

In Request for Amendment 4, the certificate holder proposes to construct and operate a 125-megawatt solar photovoltaic power generation facility, 500 megawatt- hour Battery Energy Storage System, or BESS, and new related or supporting facilities at the existing site.

The proposed facility components would be located within a proposed solar micrositing area, which is represented by the pink hashed outline on this map. The proposed solar micrositing area includes approximately 1,924 acres, which is -- that is located entirely within the approved site boundary. That proposed micrositing area is located approximately 4.8 miles northeast of the city of Wasco.

This Request for Amendment is being processed under the amendment rules that were adopted by the Council last October. The Department received the preliminary application or preliminary Request for Amendment, excuse me, on April 21, 2025.

We conducted a completeness review in

coordination with reviewing agencies, and after receiving responses to requests for additional information between July and September of last year, and then in a revised amendment request in November, we issued a determination that the request was complete on December 5, 2025.

On December 16th, we issued the Proposed Order, as well as a public notice establishing the comment period on the Proposed Order and tonight's hearing.

After the close of the public hearing period, the certificate holder will be required to respond in writing to comments, and the Department will have the option to respond as well. And then there will be an opportunity for commentors to reply to those responses and certificate holder to provide sur-replies to those replies. Sarah Esterson will go over this process in more detail during her presentation.

No later than 21 days after the deadline for sur-replies, the Department must issue a draft of the final order with written analysis of any comments on the Proposed Order, including analysis of responses and replies and sur- replies and whether we recommend any changes to the Proposed

Order. And then if we recommend any changes, we will include them in a draft final order which we will present to the Council. The Council can review, and then modify, reject, or approve as their final order.

If the Council grants issuance of an amended site certificate, the Council will then issue an amended site certificate effective upon execution by the Council Chair and by the site certificate holder.

So this request would add new energy facilities to the existing site and the existing site certificate. And for that reason there were a lot of existing conditions in the approved site certificate which were applicable to preconstruction and construction phases of the existing facility, which while no longer applicable to the existing facility could be updated and amended to apply to the proposed facility components. Some of those conditions, particularly mandatory conditions, would also apply to both the operation of existing and proposed components.

To make applicability of the existing and proposed conditions more clear, the Department has recommended that the site certificate be reorganized

and that all conditions be renumbered with an identifier that includes phase and standards, similar to more recent site certificates. But many of those changes aren't changing, and some of the conditions that are new or proposed to be amended are very similar to conditions that have been imposed or adopted by the Council in recent proceedings.

So I'm not going to go into the standards which only have those kinds of conditions in them in a lot of detail during this presentation. They are shown on this slide, the standards that I won't cover more here, but I did want to give the opportunity to the Council to ask questions now if you want, just so you know that there are findings and conditions associated with all these. I just don't have more in my presentation about them at this time.

Yeah. Is that better? Excellent.

Okay. I'll hear any questions. I'm going to go over some select issues and conditions in the Proposed Order. I do know we have a lot of interest tonight, so I will try to keep it brief.

For the general standard of review, the Department is recommending that the Council find

that this facility or the Request for Amendment would comply with the applicable standards and that the Council approve this as part of a general standard review.

As far as conditions, we do have two fairly standard conditions for construction deadlines that I did just want to highlight. These are similar to what the Council has done recently. But given some legislative changes recently I thought it would be worth just pointing out that our recommended general standards 1 and 2 would recommend that the Council impose construction deadlines.

That for the beginning of construction, construction would be required to start within six years after the date the amended site certificate is issued and then construction would be required to complete -- be completed within three years after the date that construction actually begins.

This is, again, consistent with the mandatory condition language that requires the Council to set deadlines and with the requirements of HB 3681, which requires the Council to give at least six years to the start of construction. But I did want to point out that in the Request for

Amendment, the certificate holders indicated that they intend to begin construction in the second quarter of this year and that construction would take 17 to 19 months.

Okay. Moving to Organizational Expertise. We wanted to highlight that this project is somewhat unique in that the certificate holder, which is Portland General Electric Company, would construct and operate the solar components in partnership with another entity, BIGL bn, LLC BIGL, which is a subsidiary of BrightNight LLC, under a Build Transfer Agreement.

So given this partnership, we are both looking at the expertise of Portland General Electric and BrightNight. BrightNight, as it says on the slide, is based in Florida and has designed and constructed over 6 gigawatts of solar and storage projects in the United States. And in the Request for Amendment, BrightNight and PGE have committed to having stringent contracting standards to ensure the selected contractors and vendors can adequately support the construction and operation of facility components proposed in the Request for Amendment.

To ensure that this happens, the

Department has recommended the Council adopt and amend several conditions. Recommended amended Condition 1 would require the certificate holder to provide notice of the identity and qualifications of all primary contractors and vendors involved in the construction of the solar facility, which is a fairly standard condition and similar to what is in current Condition 1. The change is that the condition would also require PGE to identify the individuals at BIGL that will manage and oversee the selected vendors and contractors. So there's an additional layer of oversight included.

Similarly, recommended amended Condition 2, which currently only applies to construction, would require the certificate holder and BIGL to contractually require all contractors and subcontractors for the construction -- and operation it should say on the slide -- of the solar facility to comply with all applicable laws and regulations and the terms and conditions of the site certificate.

Next, we just wanted to highlight -- and I think this is one of the things you will hear about during the hearing tonight -- is that the existing wind facility has experienced substantial equipment

and maintenance issues over the past few years and that we have been documenting incidents since 2022, including blade detachment, oil and grease releases, multiple transformer failures, multiple turbine door and hatch malfunctions. Those are things that have been reported to the Council in your regular compliance reports. There are also things that are being addressed through corrective action plans and other compliance actions at the site.

But we have given those issues and the lessons learned identified by the certificate holder in their request. I recommended a few additional conditions, new conditions be imposed to enhance the oversight of operations and maintenance activities at the site, recommended Organizational Expertise. Conditions 1 and 2 would require finalization and implementation of a draft framework operations maintenance plan prior to and during operations.

That plan outlines the operational responsibilities, long-term maintenance protocols, quality assurance processes, environmental compliance measures, and emergency response and monitoring systems that would be relied upon to safely operate and maintain the solar components. A version of that draft framework plan that includes

information the Department believes will be required to be included prior to operation is included as Attachment C to the Proposed Order. The additional information requirements included by the Department include things like budgeting, community outreach, and reporting protocols.

Recommended Organizational Expertise Condition 3 would incorporate construction progress reporting requirements which are established in OAR Chapter 345, Division 26. But where those reports are typically provided semiannually, the recommended condition would increase the frequency of reporting to every three months to allow the Department to track progress and compliance more closely.

And then recommended -- and the last bullet should read recommended amended Condition 4 would impose enhanced incident reporting requirements, similar to the requirements provided in OAR Chapter 345, Division 29.

Moving to land use. We just wanted to highlight that there are numerous land use conditions intended to ensure compliance with the Sherman County Zoning Ordinance and other local land use criteria. But we wanted to focus on the goal exception and Recommended Land Use Condition 6,

which would be implementing part of that exception request.

So in the goal exception request, the certificate holder provides several reasons why the policy underlying statewide planning goal three should not apply. And the Department recommends that the Council grant a goal exception based on two of those reasons which are locational dependence to both existing infrastructure, including transmission and transportation infrastructure, as well as a rural economic development reason.

And the Council -- or the Department has recommended the Council reject proposed minimal impacts to other resources in consistency with the state climate goals and policy reasons.

As part of the local rural economic development benefit reasons, the certificate holder has represented that it will finalize and implement a draft Community Investment Plan and contribute $1,600 per acre of cultivated land that would be occupied by the solar components to a Community Investment Plan that would be administered by the Mid-Columbia Economic Development District. Recommended Land Use Condition 6 would require the certificate holder to implement those

representations.

For fish and wildlife habitat, the -- and my apologies for not having the exact number, but the facility would occupy mostly cultivated farmland but there would be, I think, around 24 acres. My apologies again for that not being the exact number of category two sage brush -- sage brush, shrubland habitat and other habitat areas, to mitigate for those impacts. The Recommended Fish and Wildlife Habitat Conditions 1 and 2 would require the certificate holder to finalize and implement a draft habitat mitigation plan and provide in kind in proximity mitigation for habitat impacts.

This is a pretty standard approach for mitigation to habitat impacts. And one thing we wanted to flag here is that the habitation mitigation area that was identified in consultation with the Oregon Department of Fish and Wildlife is a habitat mitigation area adjacent to the Carty generation facility in Morrow County. We understand that that site is preferred because it provides high-quality grassland habitat of a similar kind to the habitat that would be impacted and is adjacent to other habitat mitigation areas which would enhance the conservation value of the habitat

mitigation area.

We also have a condition which is fairly similar to standard conditions requiring seasonal restrictions on construction work near active nest sites, and those were recommended in accordance with recommendations from ODFW.

We have several public services conditions that are amended from conditions that would be in the existing site certificate, as well as new conditions for Public Services. I want to highlight in particular Recommended Amended Conditions 74 and 76, and then recommended new public services Conditions 1 and 2.

Recommended Amended Conditions 74 and 76 would require the certificate holder to demonstrate that an adequate water supply for construction and operation has been secured and that all water for construction will be legally obtained. That's similar to the conditions the Council has adopted in other water-constrained areas in the state.

For Recommended Public Services Conditions 1 and 2, they would require the certificate holder to develop and implement a construction worker housing plan to provide strategies to minimize impacts to the local housing supply. That is in

part due to the limited nature of RV parking here in Sherman County and the potential for adverse impacts if there's not a coordinated effort to make sure construction workers get appropriate housing options.

In addition to Organizational Expertise, as I mentioned earlier, I think one of the things the Council will hear a lot about tonight and the thing that the Council has heard about in comments already submitted on the record is wildfire prevention and risk mitigation. We just wanted to summarize some of the findings in the Proposed Order.

So conditions in -- in Sherman County are conducive to large and fast-moving fires, grass fires, and the probability of a fire in the proposed solar micrositing area is high, particularly in the summer months according to data from the community wildlife -- the community wildfire protection planning tool, as well as the Oregan wildfire explorer map data. Areas of elevated fire risk in the proposal or micrositing area which are shown by the darker red areas on the map on the slide are concentrated around existing residential structures and infrastructure.

We also want to point out that damage to agricultural lands and other areas is possible. You can see in this map, too, that there are some areas within canyons that are mapped as having, you know, wide benefits from fire. Those are really ecosystem benefits and don't reflect the hazard of a fire spread.

Design features and maintenance standards to reduce wildfire risks that are discussed both in the Request for Amendment, as well as the draft construction wildfire management, Wildfire Mitigation Plan that's attached to the Proposed Order and the Proposed Order itself, in orienting arrays adjacent and parallel to existing roads for access and fire breaks, setting perimeter fences back at least 50 feet from property lines and facility components, 20 feet back from those fences, installing 20-foot service roads with 10-foot vegetation clearance zones on either side, maintaining 20-foot vegetation clearance areas around the outside of all perimeter fences, and maintaining 20-foot gravel or compacted soil buffers around the O&M building, collector substation, and a proposed battery energy store system.

And to show in a little bit more detail

inside those areas called vegetation clearance zones and areas within the solar array fence vegetation would be limited to a height of 10 to 12 inches during the rainy season when fires are less likely, and then one to three inches during the dry season.

A minimum vegetation clearance of 12 inches would also be maintained from electrical equipment at all times.

As far as the conditions, Wildfire Prevention and Risk Mitigation Conditions 1 and 2 would require the certificate holder to develop and implement a Construction Wildfire Mitigation Plan, whereas Wildfire Prevention and Risk Mitigations Conditions 3 and 4 would apply to the operation of the facility.

The certificate holder would be required to develop and implement an operational Wildfire Mitigation Plan. But the condition as recommended would allow the certificate holder to rely on the Public Utility Commission reviewed wildfire protection plan or other plans included in the final order or approved by the Department to satisfy the requirement.

And I'm highlighting this. I do want to point out that there is a draft Construction

Wildfire Mitigation Plan attached to the Proposed Order, but there's not an operational Wildfire Mitigation Plan at this time, although some of the requirements and vegetation standards have been incorporated into other plans.

In particular, vegetation management conditions would be incorporated into a draft Comprehensive Revegetation and Soil Management Plan which is required under Recommended Soil Protection Conditions 1 to 4. And then I wanted to just highlight that the setbacks from the property lines are being recommended under a Land Use condition, recommended land use Condition 1.

That concludes my review of the things that we thought would be most important for the Council to be aware of and things that the public might be interested in before this.

I do want to go quickly over a review of the comments that we've received to date, and then I'll turn things over to Sarah. But I'll just pause for a second in case there's any questions.

Okay. So my site is a little out of date. I put this together at about noon today, but since that time we've received one additional comment. So as of today, the Department has received nine

written comments. Six of those comments are from Kathryn McCullough. One of the comments was from the Mid-Columbia Economic Development District. The certificate holder provided comments, and then we also received comments from the Confederated Tribes of the Warm Springs Reservation of Oregon.

I believe most of the folks who provided comments are here tonight, so I'm going to go over what's in there very, very briefly. I do not have a slide for the Mid-Columbia Economic Development District's comments, and I'll just summarize that they explained their relationship with the Community Investment Plan and their partnership in implementing it. So good comments to review.

Issues raised in comments by Ms. McCullough include concerns about the certificate holder's ability to safely operate and maintain the proposed facility components. And those comments provide documentation of ongoing maintenance issue at the existing wind facility.

The comments provide concerns about the certificate holder's ability to maintain vegetation equipment on site in a manner that provides protection from wildfire. Concerns about potential liability for damages to the solar facility from a

wildfire arising from farm practices. Concern over the lack of the operational Wildfire Mitigation Plan.

A comment that Exhibit P, which is the wildlife habitat exhibit and the biological assessment in the request do not adequately address impact to mammals and other species that could be present at the sites such as pronghorn and mule deer. And concern about the adequacy of a single hearing.

Again, I'm summarizing this very quickly. There's obviously more detail in those comments and the commenter herself, I believe, will be touching on a lot of these topics tonight. But I just wanted to give an overview of what was in there.

The certificate holder also provided very extensive comments requesting corrections to the facility description, minor corrections to certain findings and conditions in the site certificate. I'm sure you will hear in more detail from them about those tonight.

They've requested additional flexibility in transmission corridor siting under the proposed Recommended Condition GEN-TL-05. Request for changes on timing of compliance with Water Rights

Conditions PRE-WR-01, and Operations WR-01, relating to the timing of providing a well log for new wells and flowmeter readings for existing wells based on when it's possible to get that information.

And request for a release of the prohibition on vegetation removal during critical periods for ground nesting birds if clearance surveys are conducted prior to removal.

And then I will -- I don't have a slide for the comments from the Confederated Tribes of Warm Springs, but I do think it's important just to raise those, that they requested a specific review of a condition related to the scope of when cultural resource monitoring would be required. They've asked that it'd be required during all ground disturbing activities, not just in ground disturbing activities within an avoidance buffer.

And so that concludes my presentation, and unless there's questions for me, I will turn it over to the presiding officer to give an overview of the hearing process.

SARAH ESTERSON: Okay, good evening and welcome. This is the public hearing on the Proposed Order on Request for Site Certificate Amendment 4 for Biglow Canyon Wind Farm.

I'm Sarah Esthersen, senior policy advisor for the Oregon Department of Energy Siting Division. I'm serving as the presiding officer for this hearing.

Today is 15 January 2026. The time is 06:27.

This public hearing is being held at an Energy Facility Siting Council Meeting in person here at the Grass Valley Pavilion in Grass Valley, Oregon. This hearing is also being held via Webex webinar with a call-in option for those who cannot participate in person or via webinar.

Please note that this hearing is being recorded and the presentations, written comments, and all verbal testimony are part of the decision record for this amendment request.

Okay, so hopefully you're aware the comment period on the Department's Proposed Order on Request for Amendment 4 extends through January 30th at 5:00 p.m. It is important that you know the following information.

A person who contends that the Council should reject the request to amend this site certificate or that Council in its final order should reject or revise certain aspects of the

Department's Proposed Order must meet the following.

You must comment in person or in writing prior to the close of the comment period. Again, that January 30, 2026, 5:00 p.m. deadline.

You must raise your issue with sufficient specificity to afford the Council, the Department, and the certificate holder an adequate opportunity to respond. To raise an issue with sufficient specificity, you must in your comments identify the recommended findings of fact, conclusions of law, or conditions of approval that are included in the Proposed Order to which you object. You need to specify the Council standard or other applicable state or local requirement on which your objection is based. And present facts or statements that support your objection. If your comment is not made with sufficient specificity, the Council will not be able to make changes in its final order based on your comments.

Okay, so if you comment during this comment period, which started December 5th, again, extends through January 30th, you will automatically be part of a subsequent process, which is designed to further evaluate the issues that you raise. This is a new process for us, so it's going be

interesting.

So the certificate holder, which is Portland General Electric, is required to respond to all comments. The Department may respond, but the certificate holder is required to respond to all comments. So the certificate holder and the Department have a deadline of February 13 to respond to your comments. These responses are going to be provided to you in the same method that you commented.

So if you email your comments and we have your email address, that's how you're going receive responses. If you submit your comments in hard copy with a physical address and we don't have an email, we will respond -- the certificate holder will respond in writing to your physical address. If you don't provide an address, no email, no physical address, you will not be able to participate in the subsequent process. We will have no way to communicate with you and respond.

So what to expect. So first and foremost, certificate holder and the Department are going to be trying to determine if your comments have been raised with sufficient specificity. So I just read through that.

Did you identify recommended findings of fact that you have an issue with? Have you identified a Council standard or applicable requirement that you believe is not being met, and have you provided facts or supporting information to support your objection?

If you haven't met any of those, the response is going to identify that, one or all of those things.

If you have provided comments that meet the sufficient specificity criteria, certificate holder and the Department are going are going to say that, and we are going to either identify where your issue is believed to be addressed and potentially already resolved within the Proposed Order, or it's going provide a resolution to your issue if it's not yet addressed.

So it's kind of a big step. Again, February 13th, you will be getting this response that has all of these words you may or may not be familiar with, but that's coming.

In the Department's response, we plan to provide, you know, helpful information to help you understand how to navigate through this process. And this, you know, this is intended to help further

evaluate your comments and make sure that we understand and that we get it right.

Okay, so then, that's not the end of it. So February 13th, certificate holder and the Department are responding. Then you, as a commenter, will have an opportunity to reply to those responses. And you have a deadline that's already been established in the Department's notice. That deadline is February 27th.

So you don't have to, but you can choose. If the Department and/or the certificate holder has said your comments were not raised with sufficient specificity -- we don't know what standard your comments are related to, you didn't provide any facts -- you can then take that and identify the Council standard and provide facts.

You can disagree. It's a process designed to sort of continue evaluating those comments.

And then after you respond, if you choose to respond, both certificate holder and the Department have a final opportunity to provide surreply. Again, ideally it's a resolution. We will see how that works out. I believe our deadline for surreply is March 6th. So that's kind of the whole extent of the comment process.

And feel free to ask any of us questions after the meeting. Chris Clark's information will be on a slide later. You're free to reach out to him at any time and ask how this is going to work or how it's working once it gets -- once that February 13th date comes forward.

Okay, so there are several acceptable means for submitting comments on the record. You can submit comments electronically through our comment portal. This is a link to our comment portal.

If you submit through our comment portal, you will get an email confirmation that you have submitted comments, so please make sure you get that. It is important that you include your contact information in comments you submit on the comment portal so that you have an opportunity to get a response and further the evaluation.

You can also submit comments in hard copy by mailing to the Department's Salem office, 550 Capital Street NE, Salem, Oregon, Attention Chris Clark.

And of course, you can provide comments verbally tonight.

As I said, this meeting -- this hearing is

being recorded. We will have the recording transcribed, and that information will be available on our website.

Okay. So we're almost getting started with your turn. The order tonight will start with an opportunity for the certificate holder. Then, we'll open it up to members of the Council. After that -- I'm sorry, then we'll open it up to members of the public. And after that we'll open it up to members of the Council. And then we'll return to the certificate holder. We may establish a time limit on members of the public depending on how many individuals are interested in commenting tonight.

So let's go ahead and start with the certificate holder.

Is the certificate holder interested in providing comments?

KRISTEN SHEERAN: Testing. That sounded good. Okay, great.

Good evening, everyone, Chair Condon, members of the Council. For the record, my name is Kristen Sheeran. I'm vice president for public policy and resource planning for Portland General Electric.

PGE is a fully integrated electric utility

that has a service population of nearly 2,000,000 Oregonians. And two-thirds of the state's economic activity occurs within our service area.

Can you hear me all now? That's better?

Okay, great.

As owner and operator of the Biglow Canyon Wind Farm, PGE has a long-standing history in connection to Sherman County. In 2024, PGE -- yeah?

UNIDENTIFIED SPEAKER: Can you (indiscernible)?

KRISTEN SHEERAN: I can. Here we go.

All right, let's try that again.

In 2024, PGE contributed $7.3 million in property taxes, about a third of the county's property tax base, helping to support schools, parks, infrastructure. Sherman County is a very special place, and the opportunity to represent PGE in the community here tonight is not lost on me.

But I'm here today to discuss the importance of the Biglow Canyon Wind Farm RFA4 site certificate amendment to PGE's resource portfolio, to our customers, and to Oregon's clean energy and economic development goals. We appreciate the Oregon Department of Energy's staff recommendation to EFSC to approve this amendment.

The Biglow Canyon Wind Farm has supplied clean, affordable energy to Oregonians since 2007. Being one of the first major wind operations in the state, there were learning lessons along the way, including around maintenance and performance. And since that time that we began Biglow Canyon, we have added thousands of megawatts of clean energy to our system. PGE and our partners, including a wind farm in southeast Washington; a wind farm in Montana; a combined wind, solar, and battery here in Oregon, the largest of its scale to open in the United States.

But we are committed to continuously improving and upgrading equipment to increase efficiency and reduce costs for our customers. An ongoing maintenance and overall project at Biglow Canyon Wind Farm to continue safe and reliable plant operations for years to come is well underway as we pursue now adding solar and battery storage to the site.

Through this amendment that we're proposing, the addition of solar and battery storage at the site will help to optimize clean energy generation and delivery in support of our customers' growing electricity, clean energy, and emissions

reduction requirements.

As we plan our system, affordability for customers remains top of mind, and PGE has aggressively pursued federal production and investment tax credits that have reduced the cost of clean energy projects on our system by at least 20 to 40 percent. To date, PGE and its partners have secured over a billion dollars in federal tax credits for our clean energy portfolio to the benefit of our customers.

However, recent changes in federal policy will rapidly sunset clean energy tax credits, escalating the long-term cost of renewable energy and storage, and threatening customer affordability and the pace of achieving the state's clean energy and economic development objectives.

An amended site certificate allows this project to move forward on a timeline that can capture the value of those existing federal tax credits while they're still available for our customers before they're phased out, aligning with PGE and the state's focus on delivering affordable, reliable, and increasingly clean power while acknowledging -- while achieving the directives outlined in Governor Kotek's recent executive order

to accelerate renewable energy siting.

Colocating solar and wind power generation equipment allows us to take advantage of the existing infrastructure on the site, like transmission lines and substations, and to reduce the overall impact to the land and to the environment.

Adding solar capacity complements the existing wind capacity since wind and solar typically produce peak power production at different times of the day. This allows both renewable energy resources to work together to meet a broader range of our customers' energy needs, increasing PGE's overall system reliability and the value of the site overall to our customers.

The addition of battery storage will also provide flexibility to the grid, allowing energy storage when demand is low and its use when demand is high. The right mix of energy resources in the right locations can help reduce reliance on fossil fuels and drive a cleaner, more affordable, and reliable energy resource mix.

PGE has already made strong progress towards achieving the state's emissions targets with an overall resource portfolio that is 45 percent

non-emitting as of the close of 2024. And this includes projects like the Biglow Canyon Wind Farm. The site certificate we're seeking today to add solar and storage will further PGE's progress toward meeting our 2030 state emission targets.

To identify the least cost, least risk portfolio of resources that are needed to meet our customers' current and future energy needs, as well as state clean energy requirements as overseen by the Oregon Public Utility Commission, PGE engages in long-term, integrated resource planning.

In our most recent integrated resource plan updated in July of 2025, PGE identified a need to procure an additional 4500 megawatts of clean energy resources. This represents about a 16 percent increase since PGE's prior IRP that had been filed only in 2023.

Projects like the proposed addition of 125 megawatts of solar and 25 megawatts of storage at Biglow are critical contributors to this growing clean energy need.

PGE's all source request for proposals is a transparent, regulated, competitive process by which interested developers submit detailed project proposals for consideration as we plan to meet our

customers' energy needs.

The 1,600 megawatts of resources that PGE identified on the final short list of projects that resulted from our 2023 all source request for proposals competitive bidding process included the Biglow Solar Project, was acknowledged by the Oregon Public Utility Commission, and the projects were selected for their potential to deliver affordable, reliable, and cleaner energy.

By selecting projects through this competitive process verified by an independent evaluator, PGE can add high-value, responsible projects that capture significant federal incentives and reduce costs while meeting the state's growing energy needs.

Given the shortened timeline that now exists to capture tax credits, the importance of maintaining a project schedule is paramount. We have partnered with BrightNight to ensure responsible and timely delivery of this project that recognizes that this is a critical opportunity in time for Portland General customers, the state and Sherman County. The certificate amendment will allow critical energy need and capacity to meet Oregon's economic development needs and the state's

emission targets.

So we urge the Energy Facility Siting Council to approve the site certificate amendment recommended by staff, thereby maintaining the development schedule with a final decision in March 2026.

And with that, I want to thank you for your time, and I want to hand this over to our project partners at BrightNight to provide more details on the project itself as proposed.

JESS MALIN: Thank you Kristen. And thank you Chair Condon and members of the Council.

My name is Jess Malin. I'm executive vice president of development at BrightNight. I've spent nearly 20 years developing renewable power projects across the United States.

Earlier in my career, I served as a U.S. Air Force pilot, an experience that continues to shape how I approach complex infrastructure development, balancing creativity and innovation with discipline, precision, and an unwavering focus on safety and reliability.

Those same principles guide BrightNight as a company. BrightNight is developing over 30 gigawatts of clean energy projects nationwide with

11 gigawatts located in the Pacific Northwest.

Across our portfolio, we are committed to safety, responsible cost management, and building durable partnerships with the communities where we operate.

Our team consists of some of the most accomplished energy project development and operation professionals within the entire industry. The team at BrightNight is like-minded. We want to be part of a company that is a reliable partner and committed to the communities we invest and operate in, and one that has a strong financial backing with leading edge system design.

Our ability to deliver projects responsibly and on schedule is validated by our backing by investment partners at Goldman Sachs, global infrastructure partners now owned by BlackRock, and Cordelio Power, providing the financial strength and stability our utility partners and their customers expect.

Optimizing projects to deliver maximum value to customers and communities while minimizing impacts is central to how BrightNight operates. We have taken those lessons learned and built on that track record here with the Biglow Solar and Energy

Storage Project.

You will hear this evening in detail the innovative planning and design that has gone into this project, the increased efficiencies and output that Biglow will add to the grid and the best-in-class features to improve operational safety and resilience.

BrightNight is pleased to be here this evening in partnership with PGE to speak with Council about the Biglow Solar and Storage Project and the steps that our teams have taken to develop a thoughtful, responsibly-sited project. Thank you.

And now we'll bring up the actual experts.

KATHLEEN CAMPANELLA: Thank you, Chair Condon and members of the Council. We also want to thank the Oregon Department of Energy staff for their thorough review and the work reflected in the Proposed Order.

For the record, my name is Kathleen Campanella, and I'm senior director of development for BrightNight. And I'm responsible for the development of the Biglow Solar and Storage Project.

I'd like to begin this evening with a simple question. What does it mean to site a project responsibly?

For this project, responsible siting wasn't a single decision or a single mitigation measure. It's a principle -- excuse me for that -- it's a principle that affected nearly every aspect of the project's development and engineering. It shaped where the project is located, how the site boundary was drawn, how impacts were avoided and minimized, and how remaining impacts are addressed.

I want to briefly summarize that approach and how it is reflected in the Department's analysis.

I'll start by discussing colocation. This is a renewable energy project, and by definition, it delivers an environmental benefit. But like any infrastructure project, it also has impacts. Responsible siting means acknowledging that reality and finding the option with the least impacts.

Colocation is just that. For this project, it integrates solar and battery storage with the existing Biglow Canyon Wind Farm, therefore, reducing the need for new transmission lines, new access roads, and disturbing additional land.

Another core element of our approach to responsible siting is community engagement and

listening. This allows us to better understand and address local concerns, resulting in a design that is responsive to the community's voice. We participated in dozens of one-on-one conversations with local leaders, neighboring landowners, agricultural producers, and community members.

Finally, I want to highlight our outreach and coordination with local organizations and public service providers, including county departments, agricultural and conservation groups, economic development entities, and emergency service providers. These discussions are reflected in project plans and in the conditions of the Proposed Order that ensure ongoing coordination with public service providers. Taken together, these efforts reflect the same responsible siting approach I referenced at the outset -- anticipating impacts, engaging early, and responding in a way that aligns with local priorities.

With that, I'll pass it on Todd to discuss vegetation and wildfire management and project safety considerations.

TODD ELWOOD: Thank you, Kathleen.

Chair Condon, Councilors, my name is Todd Elwood. I'm the senior permitting director for

BrightNight.

BrightNight and PGE have heard from the very beginning how important vegetation management and wildfire risk are for this project. We appreciate the input received from ODOE staff, the reviewing agencies and the community that have all informed the design of the project and the draft plans before you today.

Rather than relying on any single measure, the project uses an integrated approach. Project design, construction planning, long-term operations, and community coordination and investment all work together to support long-term landscape resilience. The goal is to reduce ignition risk, limit fuel build up, support early detection and response, and strengthen regional wildfire preparedness.

The project is designed to reduce risk from the outset. The layout, materials, access roads are all planned to minimize ignition sources, break up fuel continuity, and create defensible space around solar panels, the BESS, the substation and related infrastructure. The project has been designed to exceed fire code requirements by maintaining no less than a 20-foot noncombustible buffer around the perimeter of the site.

This conservative approach reflects our commitment to fire safety and directly responds to input received through outreach with local fire agencies and local -- and neighboring landowners.

Wildfire mitigation is addressed during every phase of the project. There will be dedicated Wildfire Mitigation Plans for both construction and operations, including equipment standards, weather-based work restrictions, active monitoring, and coordination with fire agencies and local responders. There will also be emergency responses plans for each phase of the project and training for all contractors as well as local responders.

The project will use low fuel vegetation. Restoration seed mixes are comprised of native grasses and (inaudible) that produce less biomass, cure more slowly, and do not create continuous fine fuels. Our proposed seed mix will reduce the need for repeated mowing or treatment, which in turn lowers ignition risk from maintenance activities.

We also take a proactive approach to noxious weed prevention. Rapid revegetation, clean equipment practices, and ongoing monitoring help prevent invasive weeds that increase fire risk and reduce land productivity. Over the long term,

vegetation management continues through the operation and maintenance plan. This includes regular inspections, adaptive management, and ongoing fuel load control for the life of the project.

Soil stability and erosion control are also key parts of this strategy. Proper soil handling and restoration will reduce weed invasion and help prevent conditions that can worsen wildfire behavior. Revegetation and weed control contractors will be held to stringent qualification standards. All of these measures help protect adjacent agricultural and grain land uses by reducing the potential for wildfire spread beyond the project site.

Did it advance?

Taken as a whole, our commitment to a comprehensive management program demonstrates the project will coexist with and not undermine ongoing agricultural use in the area. As previously mentioned, the use of setbacks and micrositing also help ensure the project will be compatible with neighboring farming operations. BrightNight has implemented setbacks, buffers, and will have three 2,000-gallon fire water tanks outside the perimeter

fence that can be used by our neighbors.

The Proposed Order contains numerous conditions to require accountability and long-term enforcement, and we support staff's recommendations.

Thank you for your time, and I'll hand it off to Lenna to discuss goal three.

LENNA COPE: Chair Condon, Council Members, my name is Lenna Cope. I am an environmental specialist with Portland General Electric, and we wanted to cover a couple of things regarding the goal three exception and a little bit more information about the Community Investment Plan.

As you heard from Chris's presentation, the staff is recommending that the goal three exception be approved based on the locational dependency and the creation of rural economic benefits.

As Kathleen spoke to earlier, colocating the solar facilities with this particular location is very important to be able to take advantage of the existing transmission lines, surplus capacity on those transmission lines, and existing BPA substations.

The real economic benefits will be

realized through the implementation of a Community Investment Plan, which was developed from extensive community engagement and listening. The plan includes prescreening projects identified through outreach, such as dryland wheat, agrivoltaics, agricultural wildfire risk minimization and capacity building, fund matching for Solar and Water Conservation District programs for wheat farmers, next generation farming innovation and technology training program, and capacity building for wheat growers. So those are the prescreened projects included in the Community Investment Plan.

The plan also includes provisions for additional projects to request funding and a local governance structure through the Mid-Columbia Economic Development District.

The analysis of indirect economic impacts performed during our amendment preparation indicate that 1,600 acres (sic) per acre of farmland taken out of production prior to starting construction will be applied to the fund.

This is in addition to the projected $40,000,000 in property tax revenue. And we also estimate that on average will be 165 union workers on site each day during the approximately 18-month

construction period generating additional spending in the local community.

In addition to staff's acceptance of RFA's locational dependency and rural economic benefit reasons, PGE will be advocating for the Council to recognize the project's consistency with state climate goals and policies.

As Kristen discussed in her comments, the site certificate amendment to add solar and storage will further PGE's progress towards the meeting our 2030 mission targets mandated by the state. And for that reason, we will be requesting the Council recognize an additional reason to support the goal three exception, and we will provide additional evidence in the written record to support that request.

Okay. I also wanted to touch on operations and maintenance. We know that there are community concerns with the past maintenance and performance of the Biglow Phase 1 wind assets. PGE's ongoing maintenance and overall project has been addressing those concerns and root issues, and Dan will be speaking to those in just a moment.

But regarding the solar and battery, as has been mentioned by previous speakers and the

staff's presentation, the Proposed Order requires a standalone O&M plan to be approved by the Department with review and updates if needed on an annual basis. The O&M plan covers ongoing inspection, monitoring, reporting, and enforcement by the Department at a level not previously specified in the existing Biglow site certificate or any site certificate issued by the Council previously.

The plan will also integrate commitments from the other major operational plans, such as the Comprehensive Revegetation and Solar Management plan and the Operational Wildfire Mitigation Plan. The content in all the plans is informed by the Department's involvement in other recent solar and battery projects and addresses the challenges faced at those sites with the goal to reduce those challenges at future sites.

The development and approval of the plans are mandated by the site certificate and will be reported on for the life of the project at varying frequencies.

In addition to all those improved details and specific requirements, the Department itself has put significant efforts into their compliance program, has additional compliance staff, and

retains the authority to inspect the facility and require corrective action if anything is found to not meet the requirements.

And now I will hand it over to Dan.

DAN WILSON: Thank you, Lenna.

For the record, my name is Dan Wilson, and I'm the director of renewable operations for Portland General Electric.

In addressing the age and the material condition of the Biglow Wind Farm, at its 18-year age and after a long period of stable operation, the Biglow Wind Farm has shown an increase in equipment failures over the past four years. And this has signaled a condition of age-related degradation, a trend that we confirmed by benchmarking against other industry leaders.

In direct response, we have implemented a comprehensive and proactive enhancement plan to secure the asset's future reliability. The key strategic actions include, first, to operate and maintain, we have hired a new service provider that is an industry leader for all wind generation. The performance of the service is reviewed by PGE's leadership to ensure top-notch compliance to the maintenance standards.

Second, we've increased inspection frequencies for key components.

Third, we are executing a critical redesign and replacement program for the obsolete and failure-prone V82 pitch systems, which have been a primary source of downtime.

Fourth, after completing the pitch system replacements, we are cleaning the towers, hubs, and blades.

In summary, the winds farm's current condition reflects its age, but we are actively mitigating those risks through a targeted capital enhancement and maintenance strategy. The centerpiece of this effort, the pitch system overhaul, directly addresses most of the significant historical failure mode positioning an asset of improved reliability and extended operational life.

Thank you very much, and we look forward to hearing from public comments and will return after our closing. Thank you.

SARAH ESTERSON: Is there a separate presentation that goes on now?

UNIDENTIFIED SPEAKER: Why, is it the last slide?

SARAH ESTERSON: Okay, thank you

certificate holder representatives.

We'll now move to members of the public.

Nancy, could you confirm how many comment cards we have?

While she's doing that, is there anyone in the room that would like to provide verbal testimony tonight that has not filled out a comment card?

If you could raise your hand.

Seeing none, okay.

Five? And if you are on the webinar or on the phone, could you raise your hand if you're interested in providing a verbal testimony.

She can call them.

Do you want to do a time limit on five? Do you want to do a time limit? Let's do seven minutes.

Okay, so we have eight individuals that are interested in providing testimony. And the Council has an opportunity to provide comments and questions and the certificate holder can come back. So we're going put a seven-minute time limit on your comments. Note, this is -- you can provide comments all the way through January 30th.

Can you put a timer on the screen?

Okay, so will you stand up and waive your

hands when your timer goes off?

Okay, so I'm going to let you call the commenters since you have the cards.

Okay, so again, just as a reminder for any individuals that wish to provide testimony tonight, please state your name. Identify if you're representing anyone other than yourself, and confirm your physical mail or email address or make sure that it's written on the comment card.

Okay, now we'll turn it over to you.

NANCY HATCH: Okay, our first commenter is Kathy McCullough.

Come on up, Kathy.

KATHY MCCULLOUGH: All right.

NANCY HATCH: Okay, and just so you know -- go ahead and come on up -- I'll start the timer when you start to present. And then I'll just raise my hand when you're at one minute left to go.

SECRETARY CORNETT: And then just a note, if you're going use the pictures as part of your comments, we'll just take photos of them. So, but we need to do that before you take them away because once you enter them into the record, they're part of the record.

KATHY MCCULLOUGH: Should I sit down or

stand up?

SECRETARY CORNETT: I mean, probably sit down because I don't think standing up it's going pick up on it.

KATHY MCCULLOUGH: Okay, I can talk loud. There you go.

Okay, thanks. So pick up the whole thing?

NANCY HATCH: If you're going to stand up you need to have it close to you.

KATHY MCCULLOUGH: Okay. I think I can sit.

Kathy McCullough, and I live right under the project about a half mile from the PGE building. And I'm retired 747 captain for Delta, and I'm also a microbiology environmental health graduate from Colorado State.

When this project was first started, you wouldn't have found anybody more excited about it than I was because to me these looked like giant propellers. I loved it. I wanted clean energy and wind, and we could farm around them. That was the best. In fact, it helped us. We got new roads. We got in and out of fields we could never get into before. It was amazing. We were probably the biggest proponents of this project. Until.

Construction was great. The first five years, great manager, new equipment, everything was perfect. The next 10 years, horrible. I mean horrible. We were picking up pieces in our field. There were nose cones dropping. They all started leaking, all of them in Phase 1.

And the culmination was when a blade dropped in February 2022, waking up my husband and my dog. I wasn't home at the time. This is the blade down here on the ground there. This is our house across the road. It was really close. It was really loud. We had been complaining for a while because there had been so many pieces.

PGE wouldn't listen to us. They really would not listen. And we didn't know what else to do. I mean, even after the blade fell and PGE got Alltite to come in and start inspecting all the bolts in all 76 of the first Vestas towers, nothing changed.

Alltite came. Alltite went. One company before them said it was the greasiest mess that they had ever seen and it was unsafe and they quit. They had to throw their coveralls away after one day. It was one of those things that we knew would happen. We'd been watching.

This is what they still all look like. They haven't -- they haven't gotten better. They aren't cleaner. None of them have -- there's one that has the new prototype on it, but four years after the blade drop, nothing has been fixed. They have all the parts ordered, but nothing is different to us.

And, in fact, the old -- Brad Jenkins, who was in charge of the project before, lied to the newspaper and said just because they're dirty outside doesn't mean they're dirty inside. Well, I have a picture of the inside. It's horrible. The wiring's cracked. It's really bad. And, and they flat out lied to us.

So, my problem is, how do I trust this company for solar in a county that is so fire prone you would not believe it. Our fires -- this is under Biglow. This is one of the fires we've had. We have six to 10 fires a year during harvest and around the dry season. And they're scary. I mean they are. They move fast. My neighbor barely got in the car and out of her house as a wall of flames was coming towards her.

We all run to fight them. We all have water on the back of our pickups. We have shovels.

We have hoses. We have everything like that, but they still move fast. And I mean fast. There were probably 50 pickups and farmers fighting this fire. And this was a couple of years ago. And it's just one of the many.

And if I trusted PGE with their -- with their wind, I can't trust them with their solar. I can't trust that I'm safe in my house if they're not going to be honest. And if they're going to tell people that we lie.

There's a whole new regime at PGE now. I admit that because I like Dan. I like the people who are there now. And I think we're on a different path. I think we're going in a different direction, but unless it's in the site certificate, they're not going to do anything. And most of this -- most of this amendment is construction. Very little of it concerns actual operation once the construction phase is over.

We really need a strong site certificate. Even with PGE knowing all that, they never reported anything until I went to the paper and got The Oregonian to write four months after -- no, wait. February is when the blade dropped, and I think the paper, maybe September, came out and there was no

change. Nothing. They knew pieces were dropping.

And I just -- I'm glad they have new maintenance. I really am. Or new, you know, new people. But we've got to have a strong site certificate. We could not get them to give us a hold harmless clause for farming. So if we accidentally start a fire and it burns into their facility, that's a $2,000,000,000 facility we don't have money for.

The only other thing I was going say is BrightNight has got great ideas, I mean, for fire. And as a 747 captain, lithium-ion batteries are scary. They are just plain scary. My vinyl siding on my house melted in 2021 to the west side. That's how hot it gets there. So if you don't have good, you know, good protection, you're in trouble.

So this is how they look. They say, oh no, they look great. They're white. They're clean. Yes, they are. This is how the transformer boxes look that PGE has under the towers. How am I supposed to think that the batteries are going to look okay?

I just -- so I hope -- I understand we have to have this green energy mandated, et cetera. Can we get some real teeth in the site certificate?

Can we get some real help out where we are? And if there's a fire, please don't let them sue us so that we can't farm anymore because we only have 5,000,000 liability. We can't pay for that facility.

We've never started a fire during harvest, but we fight four to six a year. Well, no, six to 10. One of these days it's going be our turn.

SARAH ESTERSON: Okay, thank you so much for your comments. Appreciate it.

You will get a designated time, but you can ask whenever you want.

NANCY HATCH: All right, so our next commenter is Kevin McCullough.

KEVIN MCCULLOUGH: Obviously I'm Kathy's wife -- or husband, excuse me. Kathy's husband.

I farm underneath the project. PGE has not done what they said they were going to do, and now that we have new management, this is a good thing. But they need to -- they need to prove that they can operate this. I don't know why you would give them their certificate to put in a solar farm when they have not proven that then they can operate what they have. They keep saying they need more green power.

Do you know how many towers we have

sitting every day out of those 217? Forty to 50 every day. Makes no sense to me why you would be willing to give them a certificate to build a solar thing until they fix this problem over here. It's bizarre to me.

And the other thing is the fires. Like she just said, it's not if we start a fire, it's when we start a fire. And your setbacks aren't even close to deep enough to keep us from having to pay. They're going to sue us and we will no longer be in business.

So, thank you for your time and hopefully you take some of this into account.

NANCY HATCH: Okay, my next commenter is Colton McCullough.

COLTON MCCULLOUGH: Good evening, everyone. I should be the last McCullough commenting, I think, unless there's someone I don't know about.

My name is Colton McCullough, and I am the current farmer on the land that the proposed project would be built on. As some of you know from experience and have learned recently, Sherman County is extremely wildfire prone from late May through October. My main concern with the proposed project

is both fire starting within the project and fire starting outside the project and burning into the project.

I farm on nearly every side of the project and potentially in the middle if approved. Sherman County is an agricultural community with the primary crop grown being wheat. Wheat is typically harvested -- wheat harvest typically happens in July and August. This is when the crop dries out and can be harvested, but it is also when it is most likely to burn. We do a lot to prevent and stop fire from always having a fire-fighting pickup and tractor with a disk in the field, to preventive maintenance on our combines and other equipment, to putting fire breaks around houses and other infrastructure, to shutting down on days of extreme heat and high wind.

Even taking these precautions, there is no way to eliminate the chance that we will start a fire. As they've said, it's not if, it's when. I do my best to prevent fire and will continue to do so, but I am very worried about starting a fire and having it burn into the solar facility. I carry a large liability policy, but not even close to large enough if I burn up a solar facility. There is no economical way to carry a large enough policy.

I don't want to lose the farm or have my son lose the farm because we burned a solar facility sited in the middle of wheat fields where seasonal fire risk is extremely high. I have been told that the panels will not burn, and that may or may not be true. But that doesn't mean that they won't be damaged or melted by the heat of the vegetation burning below them.

The best way to reduce the fire risk in the solar project is to reduce the amount of vegetation available to burn. Under the Request for Amendment 4 currently submitted, it is suggested that the maximum height of the vegetation be 12 inches year-round. This is far too tall and would be a significant wildfire risk during fire season.

Under the Proposed Order submitted by ODOE, it has suggested the vegetation be kept to a maximum height of 12 inches during the rainy season, November to May, and one to three inches during the dry season, June to October, for all areas within the solar fence line. Along with several other stipulations on page 233 of the Proposed Order, I strongly support ODOE's suggestions and feel that it would make the project safer and far less likely to have a wildfire. The small change in management

practice would drastically reduce the wildfire potential within the solar facility.

From what I can tell, ODOE's changes would go under the Comprehensive Solar Revegetation and Soil Management Plan, although redlined in by ODOE. If this is the case, I would like to see some other language addressed in that section. As it currently states, this is only the plan in the interim until an operational Wildfire Management Plan is put in place. It concerns me that there is no operational wildfire plan to be reviewed yet, and PGE's systemwide Wildfire Mitigation Plan may be used.

PGE systemwide Wildfire Mitigation Plan (WMP) primarily focuses on power transmission and some limited information on the generating facilities. It is not a site-specific plan that considers specific wildfire risks for a project like this in a location like here.

I would like to see language saying ODOE's vegetation height and clearances suggestion would be implemented into the operational Wildfire Mitigation Plan and remain a basic requirement for the life of the operation of the facility, if not included into the operational Wildfire Mitigation Plan. Basically, I want to see the vegetation height

suggested by ODOE be a permanent, not easily amended part of the facility requirement throughout the operation of the project, and not be ignored because the operation Wildfire Mitigation Plan says something different or doesn't specify vegetation height.

My intent of public commenting is not to show support for or against the project, but to ensure that critical wildfire preventative strategies are used during building and operation of the project. I would like to see the project be an asset to fire prevention in the county, not a risk. I would like to see it be a fire break where people know when the fire gets to the actual project that it is going be stopped. But there has to be stuff in the site certificate that puts teeth that make them maintain it to the standard.

But if vegetation isn't managed properly, it's not fair to ask the farmers and community members around the project to take the risk associated with the solar facility. I want the Council to realize that this proposed project is being sited in the middle of wheat country that is associated with very high seasonal fire risks. Setting a standard of vegetation management and

making sure that standard is upheld throughout the operations of the facility would address a large part of the fire concern with this solar project. Thank you.

NANCY HATCH: Okay, our next commenter is Mr. Hilderbrand.

ORMAND HILDERBRAND: Greetings. Ormand Hilderbrand is my name, and I am not a McCullough.

I manage my family's farm, which is near the proposed Biglow Renewable Power Project and have been involved with Oregon's environmental and land use issues for years. I am submitting this statement for the record regarding the Biglow Renewable Power Project.

I approach projects like this with a clear understanding that development has impacts. The question is not whether impacts exist, because they do, but whether they are acknowledged, responsibly mitigated, and managed through a rigorous public process.

Even farming has impacts on our land. You know, some may argue that our land shouldn't have been put to the plow back in the 1880s, but it was done. Impacts happen. But based on my experience, I am confident that the impacts associated with this

project can be addressed appropriately. And I'm confident that after 50 to 70 years of the project being a major solar producer, if we get to that point and we need to have the land back for agricultural production, it can come back to agricultural production with improved soil health. That is critical.

I'm a strong believer in clean energy. I've been a director of the Community Renewable Energy Association (CREA) for many years. CREA is a strong advocate for shaping policy to benefit rural Oregon.

And I personally have been involved in the development of my own renewable energy project, PaTu Wind Farm, which is a 9 megawatt, six GE 1.5 SLE turbines that are adjacent to Portland General Electric's Biglow Canyon. I supply power to over 3,000 homes in the Portland area.

That experience has given me a practical understanding of what responsible project planning looks like, including the importance of environmental review, mitigation commitments, and ongoing accountability. You know, we must hold companies accountable for what they say they're going to do.

The Biglow project reflects this level of responsibility. The developer has engaged seriously with the permitting process and has demonstrated willingness to address environmental considerations. I have attended several of the discussions myself, including the presentation of the North Sherman County Fire District that discussed these fire mitigation procedures.

It used to be that we on the east side felt that we had the fire risk all to ourselves. Now that you on the west with the climate change, you are the fire risk, too. So I think everybody can appreciate, especially in a rural county, where the land and agriculture, natural resources are deeply interconnected, the importance of this fire mitigation.

I also believe it's important to consider projects like this in a broader, long-term context. Sherman County's economy has changed significantly over time and the pressures facing agriculture and rural communities continue to evolve. We had -- in the 1920s, we had over 4,000 people living in the county. That's more than twice what we have right now. We had the hotels in the towns and restaurants and theaters, and I've read even Rufus had a golf

course.

That's all -- most of that is gone now. And primarily due to consolidation of farms enabling our producers to reduce their production costs, and they've done a damn good job of it, they've really driven down their costs to compete in a tight environment. And I appreciate people, young farmers like Colton coming on, because we need them to continue this into the future.

But it's going to become tougher. Our farmers have to consolidate, and they have to become larger. And those that don't are not going to be with us anymore.

And can anybody doubt that the drive for more -- that we will see more capital-intensive equipment powered by artificial intelligence? That will continue and further fuel consolidation amongst the farms in Sherman County.

Thoughtfully planned energy projects represent one step in a more diversified and resilient future, one that balances environmental stewardship with economic stability. In this case, it is true that solar saves farms.

Last month, Governor Kotek issued an executive order to state agencies to move faster on

clean energy projects. And recently, even Representative Bentz acknowledged that Oregon will have a critical shortfall in energy unless drastic steps are taken, including expansion of our transmission facilities.

The Biglow Renewable Energy Project is low-hanging fruit with the existing underutilized PGE transmission. While recognizing the project is not without impact, I view the Biglow Renewable Project as a positive contribution when evaluated through the established EFSC process and supported by enforceable mitigation measures.

Thank you for the opportunity to provide this statement and for your careful consideration, positive consideration of this -- these issues as part of the record. Thank you.

NANCY HATCH: Okay, our next commenter in the room is Chad Higgins.

CHAD HIGGINS: Audio check. Okay.

Honorable committee, my name -- thank you for the opportunity for me to present testimony and comments.

My name is Chad Higgins. I'm an associate professor at Oregon State University and a farmer in Linn County. My area of expertise is in integrated

farming and energy systems, agricultural sustainability, and ag tech.

I spent more than the past decade working on ways to integrate solar energy production into agricultural practice and mitigate the conflict between the renewable energy and agricultural production, so called agrivoltaics systems. I'll keep my testimony to the agricultural aspects that pertain to goal three.

Broadly speaking, I care deeply about agricultural land protection and agree with the principle that protection of agricultural land is of critical importance. Indeed, my entire research portfolio and a good part of my life's work has been devoted to serving farmers in local rural communities.

There would be no farms without the land to support them, but farming is incredibly challenging and requires brilliant folks to do it under the current conditions. It isn't sufficient to simply protect land as it's only one piece of the puzzle that makes farming possible.

An economically vigorous agricultural system depends on the land and soil, of course, but it also depends on the skilled farmers, access to

the needed agricultural inputs, access to sufficiently developed agricultural markets, and enough regulatory freedom to allow land managers to adapt to new economic and resource availability conditions. I'm an advocate for balancing agricultural land use tradeoffs with energy tradeoffs wherever possible, and I applaud your efforts in doing that in a respectful and sensitive manner.

My research on agrivoltaics systems has shown that the benefits of shade to cropping systems most critically depend on the dry soil's fertility. That is, crops generally benefit more in water-limiting conditions and with the benefit of good soil. This means that agrivoltaics are appropriate in some locations and not appropriate in others. Note that the proposed project is not an agrivoltaics project.

I will say that the three most common criticisms in my research are one, that I haven't tested any particular crop in a particular region. Afforded to this particular region, it would be you haven't tried, say, wheat in Central Oregon, which is true. It's a fair criticism.

The second major criticism of my work is

that my experimental trials are small compared to proposed commercial projects. That's also fair. I don't have the money to build a multibillion-dollar large project for my research. They tend to be of the multiple-acre size as opposed to multiple thousands of acres.

And third is I just don't believe you, Chad, that this is possible. And if you are a critical thinker, you first have to be critical, and I take that challenge on.

These are fair critiques, even though I endeavor to perform transferable research for maximum social benefits. My research team and I have done most of our work in the Willamette Valley, a location with drastically different hydrology and soil to here.

I will note that we have done a trial in Madras on irrigated carrot seed production that showed consistent results with all of our other studies, and the carrot seed benefited from the energy system. But that trial was limited in scope, and it was not a dryland crop as this situation is.

On the point of scaling, I'll take issue and say if I can make it work profitably at a small scale, the economies of scale dictate that it should

work at the larger scale because you just turn the tractor around less.

The main point is that more research that's targeted to the local region, specific crops and unique conditions, like the fire risk condition that's unique to this area and so critical here, more research would help inform future development in a sustainable way. And I really support the inclusion of the competitive research funding to be managed by the economic development district.

In full disclosure, I will absolutely enter that competition, and my approach would be to work with the community to address their most prescient concerns and questions. But should I not win, I'll applaud any (indiscernible) because I believe that that work would strongly help the community because it's no secret that there's many projects proposed for this area.

Solar siting tends to be local in scope, as you know. But when you find a good spot, there tends to be a concentration in that spot, as you know. And Gilliam County here -- sorry, Sherman County here, I misspoke -- is one of those Goldilocks zones. May the best researcher win. I welcome the competition.

Secondly, I do want to say that these projects are long-lived but ultimately temporary installations. A natural question that a farmer may ask is, what's the agricultural potential of the soil at the end of the project's life? To answer that, my research team, in collaboration with soil scientists at OSU are in a third year of a multi-decadal study where we rest the soil on under solar panels to see the change in soil condition.

As part of that project, we're monitoring the soil's health annually, and thus far at this early stage, we've observed increased soil carbon and fertility relative to the non-solarized control under the same management practice. Of course, there are many years of observation ahead of us here, but the preliminary observations are promising.

Finally, I understand if anyone is skeptical of my science. They don't believe that this is possible or that the benefits are there, but I ask you to believe the evidence of your own eyes, and I invite you to come to my research facilities and tour it for yourself. Anyone here on the committee, anyone in the community, I welcome. Please come out. I know it's a bit of a drive from

here, but I would hope to make it worth our while.

I'm open to the public the second Tuesday of every month at 1:00 p.m. The location is the North Willamette Research and Extension Center in Aurora, Oregon. Please come out. You're most welcome. And I will answer -- I'll make myself available to answer any questions that the committee has or the community that's based on my research in the systems. And yeah, thank you very much.

NANCY HATCH: Okay. Anybody in the room that would like to make a comment that has not turned a form in?

Okay, go ahead and step up to the mic. Just be sure to give us your name and your address, please.

JOHN LANGDON: Thank you. My name is -- Chair Condon, Secretary of Cornett. We -- my name is John Langdon, and I filled out a form and mishandled the application process. I apologize, Sarah.

So I do believe Chad, and I do believe Ormond, that solar saves farms. And so I am a fourth-generation farmer. My address is 30574 Diamond Hill Drive in Harrisburg. I have some property that has a particular interest for solar,

so I've been approached many, many times over the years, and that's led me to have solar companies come to us with proposals. And there's always been a level of understanding and education there.

But I got to go to a meeting like the one last night, a letter of intent meeting, where I got to see Todd in action. And it was pretty impressive. And in that meeting I decided that I needed to educate myself on the ag and solar.

And so for the last 30 months, there's rarely been a day where I -- me and my partners haven't taken that path. We were at Chad's facility on Tuesday, and I think that was our 30th tour in the 30th month. And every time we learn something new. We bring a lot of solar developers, a lot of VIPs. We actually had some shepherdesses out there last time.

And our mission is to learn all we can about ag and solar working together -- communities, agricultural systems, agricultural neighbors, all of those things together, and try to educate myself to be qualified to speak to it and help other people, whether it's this Council or farmers or developers.

So we also -- one of my partners likes to travel, so we went to Europe. We heard that they do

it better over there. They're ahead of us. So we went to Europe. We've been to a multitude of countries and saw a lot of different projects. A lot of those were farm projects. And quite frankly, after dozens and dozens of conversations with developers in a multitude of countries, BrightNight is great. They've done a great job.

I've been in multiple conversations with them about vegetation management. One of the things that we've done in our learning is we've had the opportunity to become vegetation managers. So we are vegetation managers in Oregon. The best way to learn something is to go do it. So we've done that.

And we've looked at every system we can find where agriculture and solar works together in ag communities and with farmers and with those systems. And I can tell you that the conversations with BrightNight have been as outstanding and as advanced as anyone I've had in the world. I would trust them with my land.

So what I'm telling you is these guys seem to be listening to the farmer. Todd and Kathleen have been -- I think they're genuinely interested in the community, the farmer, making it work, making it great, and making it a win-win-win for everybody.

And so I would encourage the Council to look upon them favorably. So, thank you.

NANCY HATCH: Okay, anybody else in the room that would like to make a comment?

Okay, seeing none, we're going to go ahead and move on to the people on the webinar.

Just as a reminder, if you are in the webinar and you would like to raise your hand, at the bottom of the icon -- the main window, excuse me, is a set of icons. Click on that participant, and you'll see a hand icon. You're going to click on that to raise your hand, and you will click it again to lower your hand after you have commented.

If you're on the phone, press “star 3” on your keypad to raise your hand, and then again press “star 3” to lower your hand.

Okay, so our first commenter is Dan Hilderbrand.

Oh, no, he lowered his hand. Okay. If you need to, you can raise your hand again, Dan, if you -- if that was a mistake.

So we're going move on to Ms. Irene Gilbert.

Okay. All right, let's see.

Okay, Irene, don't touch your button. I'm

unmuting you. We're playing a game back and forth right now.

Okay, she's working.

Alright, I can't get Irene on, so Dan, I see your mic is open. You can go ahead with your comment.

DAN HILDERBRAND: Okay, thank you. Can you hear me okay? Hello, can you hear me okay?

NANCY HATCH: Yes, we can hear you just fine.

DAN HILDERBRAND: I'm sorry. Okay.

I'm representing my brother and I, Randy. He's the -- since we've inherited the ranch from my father, he's now the general manager of our operation. We represent the fourth generation of Hilderbrands farming our ranch.

And it's been a struggle as it always has been. Ormand and I grew up on the ranch. As kids, our family every year worrying that we were going have enough yield with the price of wheat combined together, and it's always been a struggle to be an efficient farmer. Now with the exponential increase in not only equipment but the inputs of the farming practices, it's been that much more of a struggle.

The nice thing about this project is it's

going to give us some more flexibility and continuity as far as the dependability of our economical strength to keep the farm going and make a sustainable career rather than a constant financial gamble.

Approving the Biglow Renewable Project is a decision to keep the farmland in production and diversify the economic face of Eastern Oregon. And we want to be responsible stewards of the ranch and farming in general, and this will provide a more predictable revenue stream that we can depend on.

This is not going to replace farming. It's just going to help support and diversify. In the past, farmers had very few opportunities to approve the wind turbines. We're one of the first ones. A lot of people were skeptical of the wind turbines, and we still do to this day.

And one of my first concerns when I heard about this is I was very positive on it, and I thought it was a very good thing for us.

And I went to one of the public comment meetings that the Wasco Activity Center there in Wasco and was pretty confident in what I heard coming from BrightNight and where they were going with it. And they want to be good (indiscernible)

in this project.

And I really feel with the input as far as the wildfires go, yes, we do have them from time to time. It's only in the summer, and it's something that farmers -- we grew up as kids, it's something that you always had to concern yourself with. And it's just something we've grown up with along with the wind and everything else.

The project itself, the 1,400 acres represents about, according to Randy, about one half of one percent of the total acreage. So it's not going to replace farming in any stretch of the imagination.

Originally, when Randy and I were talking about it, he was actually quite skeptical about it. And I said, Randy, look at it like this. We're not farming -- we aren't farming photons or electrons coming from the sun. We're just farming something else.

Our dad was behind the wind turbines. My dad and our Uncle John, Ormand's dad, were very strong advocates of it. And I see what it's done for the county and the income that has helped the entire county. The businesses in Wasco and Morrow and the surrounding areas, it's been a very

beneficial opportunity.

And I had to remind Randy once. I said, Randy, the solar panels are going to look really good out the side of the windshield -- as you're looking at them through the windshield of your new combine.

So I think we could look at this as a very valuable partnership for everybody. And I think with the wildfires, yes, that is a huge concern. It is a very huge concern. I understand that, but that's something the farmers have always had to fight for about six weeks every summer. It's just something that we've always had to learn to live with.

If there's any questions, any correspondence can be directed in care of my brother Randy at Post Office Box 326, Wasco, Oregon.

SARAH ESTERSON: I'm sorry, Dan, could you repeat your address for the record?

DAN HILDERBRAND: You can -- I almost said email. You can send any correspondence in care of Randy Hilderbrand, Post Office Box 326, Wasco, Oregon 97065.

SARAH ESTERSON: Thank you.

DAN HILDERBRAND: Well, I also -- one last

comment.

I do share Council Member Grail's ick factor towards the bats and the rats. They're nothing but large flying rats, so I stand in solidarity with her.

COUNCILOR GRAIL: Thank you, sir.

NANCY HATCH: All right. Thank you very much, Mr. Hilderbrand.

It looks like our next commenter is going to be Amanda Whitman.

Amanda, I'm going to go ahead and unmute your mic. You are ready to comment.

AMANDA WHITMAN: Can you hear me?

NANCY HATCH: Yes, we can hear you.

AMANDA WHITMAN: Okay. Hi, I'm Amanda Whitman, and I am the district manager for Sherman County's Soil and Water Conservation District. I have lived in Sherman County for about 16 years now.

And one of my concerns is that no one from this project has contacted the District as far as conservation issues that would arise with the construction of this project or the outcome of the construction of this project.

In the past, we have been very involved with the original wind farm projects in Sherman

County, and I have noticed with the solar that is not the case. They like to meet with me once and listen to what I have to say, but they're not listening to what I have to say. So that is a concern.

We had significant erosion issues with the one solar project that has been implemented in this county, and there was damage to neighboring land from that project. A lot of this land is prime farmland, and it is also highly erodible land. So no matter how much rainfall we get in the county, we still have major erosion issues that go along with rain.

I have asked multiple solar companies about the long-term effects of solar on our soil and water tributaries, long-term effects, and no one has given me any answers on that.

So there's a lot of concerns that the District has with these projects, especially these larger scale projects that could really affect our watersheds in the county.

The other thing as far as fire goes, we have been working for over a year now with Natural Resource Conservation Services (NRCS) to incorporate a fire break project in the county to help with

these fires that come through our county every year. And you mentioned that you were going to put in 20-foot buffers. The minimum for NRCS is 30 foot. And that is the absolute minimum they're suggesting.

So it's imperative that I think they talk to the partners in this about what they're suggesting. USDA has been active in this county for many years and we know the land. We know the vegetation. We know how fire moves, and I think that's very important.

Another issue is the weeds and annual grasses. We've seen that with other solar projects and wind farms. There's no immediate control over weeds. The Russian thistles in this county, for instance, grow rapidly. They don't need water. They catch on fire very quickly. So if we don't have weed and annual grass control around these projects, it's going to be detrimental.

I'm trying to think what else. I think those are my main concerns. I did not plan on talking tonight, but I felt like those were a few things that I needed to bring up.

The Conservation District has been in this county for 75 years now. We've had over $2,000,000 worth of conservation work implemented in this

county, and a lot of these projects take out those conservation practices. And then what do we do to fix that? We're going back in time on all of the work that we've put in to fix our riparian areas, and I know you think it's upland, but upland affects riparian and the streams and the rivers.

So those are my main concerns tonight, and I will submit a letter before the comment period is over. Thank you.

NANCY HATCH: Alright, thank you, Ms. Whitman.

All right. Well, I'm going to circle back to Ms. Gilbert. I do not see your hand raised, Ms. Gilbert, but if you are interested in commenting, please just raise your hand. And that will bring me -- oh, she's got her hand up. And she's unmuted.

Go ahead, Ms. Gilbert.

IRENE GILBERT: Hello. Are we talking now?

NANCY HATCH: We are talking.

IRENE GILBERT: Okay. Irene Gilbert, 2310 Adams Avenue, La Grande, Oregon. I'm co-chair of the Stop B2H group and I've spent quite a bit of time representing the public interests before EFSC.

So I do have a few -- I haven't done a

thorough review of this, but I will say that the people who did the presentation did a very professional job and I appreciate that.

My concerns lie along the lines of the fact that this group has a really poor track record in terms of compliance or holding their people accountable for following the site certificate conditions. And specifically, the ones that really jump out to me are the fire plan and the noxious weed plan.

Now, the statutes require monitoring and mitigation plans. And what has been happening with the site certificates is that they're approved with a lack of details regarding what is to be included in the monitoring and mitigation plan. And site certificates are issued, but those plans are not finalized until after the public process has ended.

So based on that, I believe there's a really important issue in that the draft plans need to be very detailed, very specific, and include the requests that are being made for specific mitigation methods. And I don't -- I have not found that to be the case so far.

It becomes even more important since the Oregon Department of Energy has been making changes

to monitoring and mitigation plans without amendments to site certificates, so it's making it difficult for landowners and the public to trust that the site certificates are actually going to be complied with.

One thing that I'm very concerned about is the fact that this site certificate references the use of the Public Utilities Commission wildfire plan once the operation of the development begins. So you're working on this for the construction period and getting a lot of feedback. But if you're using the PUC Fire Mitigation Plan without adding specific local criteria, what ends up happening is, for example, developers rate fire hazard differently oftentimes than local areas.

So for example, with the B2H transmission line, Idaho Power found no high-risk areas for fire across any of the five counties that that transmission line crosses. So I think it's important that it be more or less cast in stone that this area will be treated as a high-risk area in terms of fire.

The other thing, the issue of landowner liability for damages to their facilities as a result of fires. And I was glad to hear the last

person comment on this. Twenty feet is not providing the protection or the mitigation for that risk to the property owners that are facing the risk of being sued for damages to the area. I personally think 30 feet is not enough. I would say that in order to issue a site certificate that mitigates for that risk, there needs to be some research into how far do these fires jump when they are in a wheat area and assure that the no fire zone is wide enough to actually provide that.

The EFSC makes a determination about significance of impacts and it's not going to be a significant impact. But I just wanted to remind you that that does not exclude the fact that the developer is supposed to mitigate for all of the impacts. They are to leave these agricultural landowners basically at the same point as they are going into this by addressing the increased risks that are created by this development. Certainly, one of those increased risks is that they could be sued for a fire that happens in their area jumping into this new development.

At any rate, I'm going to spend some more time looking through these, and will make some specific comments and reference the mitigation and

plan statutes, which I understand is required for this. But I do think that while it's a good start, the draft of the fire, and also the noxious weed plans, are not developed to the extent that the public can have any kind of assurance that you're actually going to be, number one, implementing mitigation that leaves the public free of risk of, or addresses the increased risk, or that the monitoring is going to be adequate to assure long-term protection.

The plans don't address, for instance, state requirements for weed management. And there's been a lot of concern from the tribes, from individuals, about the level of weeds that are being spread by these renewable energy projects.

And I would really encourage you to require the developer to comply with the state requirements and to leave the landowners financially free of the consequences of having to go to the county and file against a developer because they're failing to manage the weeds according to the state's statutes.

I guess that's enough. For once I didn't use my seven minutes, I don't believe.

Anyway, thank you for your time.

Any questions?

NANCY HATCH: No. There are no questions. Thank you for your comments.

Alright. So at this point I see no other hands raised.

Is there anyone else in the room that would like to provide a comment? Last call.

SARAH ESTERSON: Okay, so now we're going to provide an opportunity to members of the Council to ask questions or make any recommendations to staff.

COUNCILOR GRAIL: Chair Condon, this is Marcy.

CHAIR CONDON: Thank you, Marcy.

COUNCILOR GRAIL: First of all, I would like to say I wish I had been there in person, but nonetheless, thank you to everyone who took the time to so clearly state your concerns.

One of the things that I've most appreciated about serving on this Council is it has been absolutely educational for me, not just as an Oregonian but professionally.

Sarah, to directly respond to your request about, you know, comments to staff, I'm well aware of the separation between the Department of Energy

and the Oregon Public Utility Commission, but I strongly encourage and ask whether it's just to -- and I'm happy to do some of my own research, but I'm really concerned about our limits that I'm aware of that may or may not align with what can be done elsewhere.

So for example, like I know we can't say, oh, you must have blank number of people, or we can't say you must double whatever the average, you know, standards are or exceed minimum standards. But I'd just -- I really would like to know that there's a way to provide some more assurance to the public.

It's no secret. I've said it probably every meeting since we've started talking about wildfire. Someone mentioned that PGE's plan tends to lean towards -- I don't know if they said transmission or distribution, but anyway, I really just am curious if there's things that we can glean from other areas that can align and help the public get some of the reassurance they need.

And I would just encourage the developer to really think about how they can invest to the public to meet some of these things. Because while you as a, you know, as a developer have a lot of

risk, this is their livelihood. This is their legacy, their communities as well.

So I believe, you know, I have to believe people are operating in good intent, but I really hope that the comments around the noxious weeds and the wildfires are really, really taken to heart.

And lastly, I'll just say that anyone who's participated over the last couple years has heard this Council talk a lot about operational or excuse me, Organizational Expertise. And I think we heard a lot of comments directed at that today. So I hope the developer plans to address those things to provide reassurance to the public and to our Council. Thank you.

NANCY HATCH: Thank you, to Councilor Grail.

Any other comments or questions from the council members?

CHAIR CONDON: I have a question.

COUNCILOR DEVLIN: Madam Chair?

CHAIR CONDON: Yes?

COUNCILOR DEVLIN: I'll be second.

CHAIR CONDON: No, go ahead, Councilor Devlin.

COUNCILOR DEVLIN: Okay. Madam Chair, I

don't know if I have a statement or a question.

It seems to me that, you know, some of the things that people are talking about in terms of past performance there is actually some agreement on. I mean, within the statements from staff, there were some statements about the fact that the actual performance, particularly on the first phase, over time has not been what was expected.

Obviously, some of the people that are critical of the proposal are saying that very clearly, and even the applicant is now admitting that some of that performance has been less than desirable.

Now, the problem I have is I don't have an answer for this. I'm not an attorney. I am not our -- obviously our representative from the Attorney General's office, but we have specific criteria that we view every project in. And I'm not sure that we can actually apply or create a new criteria that in a sense tries to enforce perhaps some shortcoming from a past approval or the performance in a past area.

I'm just not sure of that, how you would do that or if it -- if it even could be done in a matter that would be, let's say, where litigation

would be limited.

The second thing is I clearly doubt that this body has any authority, and I'm not even sure the legislature would have authority to limit the liability of various parties that might be involved in something that would cause damages to another. I mean, that's clearly outside the purview of this Council.

And I'm not even sure about all the ramifications of that if that would even be within the legislature's purview on a statutory basis.

I just want to put those comments on the record. I do think the concerns are real. I do think that turbines wear out. I do believe there have been quite a number of issues with them, particularly that sort of first phase. And I don't know which generation of turbines that was. I know turbines are actually under an enormous amount of stress over time.

It's interesting that one of the speakers is a former 747 pilot, and she's obviously probably aware of the metal fatigue in aircraft over time. And the fatigue and the blades of those turbines, there are significant issues there also.

And I just wanted to put all that on the

record. I'll be probably thinking about what our actual authorities are, but I clearly believe people have made some clear, and to a large degree, some compelling arguments.

NANCY HATCH: Thank you, Councilor Devlin.

Councilor Perry, do you -- do you have your hand raised? I can't see it.

COUNCILOR PERRY: Yes, I did. Thank you.

NANCY HATCH: Yeah. Feel free, yes.

COUNCILOR PERRY: Thank you.

I did have a couple of points. And along the same lines as Councilor Devlin was mentioning.

First of all, about the fire concerns. It seems like when there's a concern with property owners and developers, as a planner, you know, there's been situations where, you know, a covenant not to sue would be in order. But that's not something that this Council has any purview over. That's more like Councilor Devlin was saying, a legal matter between the owners and the developer to work that out on who's responsible for what on the property.

But the other -- the other point I wanted to make was about, you know, as a planner, you know, we've had situations before where we have a property

that, you know, may have a violation on it of some sort and then they want to come in and apply for a land use application to do something else.

And if there's a violation on the property, then you wouldn't necessarily want to approve or be able to approve based on the regulations of that local jurisdiction to approve a new thing on a property if there is some kind of a compliance issue.

And I'm new to this. I'm not as familiar with the administrative rules and the siting standards as experts are and the staff and secretary and our legal office.

But I was just, I guess a question now to the staff, Chris. Would there be some kind of regulation that I may not be aware of that would prohibit the approval of an amendment to an existing site certificate when the existing site certificate's requirements may or may not be satisfactory? But in looking through the staff report, it looks like you have addressed those and with the addition of some additional amendments to the conditions that were placed on there that would remedy some of that.

And I was just wondering if there was

anything that the Siting Council needs to consider on that situation where we have -- if we look at -- if the existing facility is in compliance with everything, then there isn't an issue with moving forward with looking at specifically this in relationship to that with the addition of the solar to this siting certificate.

I just wanted to make sure that that we're covering all those bases. Thank you.

NANCY HATCH: Thank you, Councilor Perry.

And we have Christopher now at the mic.

CHRISTOPHER CLARK: Thank you, Council Member Perry.

For the record, this is Christopher Clark, senior siting analyst.

Just since you called out me specifically, I will respond with two things.

One, I think the relevant standard is the Organizational Expertise standard. And so I'll just read that, at least in part.

So the standard provides that to issue a site certificate, the Council must find that the applicant, or in this case certificate holder, has the Organizational Expertise to construct, operate, and retire the proposed facility in compliance with

Council standards and conditions of the site certificate.

I am not aware of a separate rule that would prohibit the Council from approving a facility if there were a violation in place or something like that or a requirement to cure.

I do want to point out though, and I think this is important for the record, at this point in time, the certificate holder has not been issued any notice of violation, or I maybe can be corrected, but even a notice of noncompliance for these issues. They have been responsive to the Department's requests for corrective action plans and things like that.

So there have been a number of compliance issues at the facility, and that is well documented, but not violations themselves.

COUNCILOR PERRY: Thank you, Christopher.

CHAIR CONDON: Counselor Perry, sorry, was that a thank you, or did you have something further?

COUNCILOR PERRY: No. I think we just kind of talked over each other. I was just thanking Christopher for that response.

CHAIR CONDON: Okay. Thank you very much.

And I do have a question, but I'm

wondering if the McCulloughs can come up to the microphones.

Yeah, you can go first.

COUNCILOR HOWE: This is Kent.

Tonight we heard a lot about Organizational Expertise.

CHAIR CONDON: Hold on just one second.

Oh, sorry. I thought you had a question.

COUNCILOR HOWE: No, no, no.

CHAIR CONDON: Sorry. Go ahead.

COUNCILOR HOWE: Organizational Expertise while -- or the noxious weeds and vegetation management. But we did hear regarding wildfire, a recommendation from the SWCD to I think it was 35 feet. And that probably has some science behind it that could withstand a challenge or whatever, so I think we ought to kind of look into that. That's all.

CHAIR CONDON: Thank you, Councilor Howe.

And now a question for you. I think one of the things this meeting has really brought into focus is our work on compliance. The wildfire rules are pretty new to us. I think we're now in our third year of wildfire rules and working through projects and what's appropriate, what is -- what are

compliance issues. And every step we go we learn more.

But one of the things that is -- has been very opaque to me and it sounds like you are big supporters of renewable energy and certainly went into this project with great enthusiasm. Yes. Passion and enthusiasm. And you -- it worked well and then it didn't.

And so I am wondering, one, some of the issues you have as underlying property owners of the project -- I guess I have operated on the thought that all the underlying property owners have an agreement with the -- with the developer. And in those agreements there are some provisions that we just asked about here that are simply not -- not necessarily open to us. We don't have the authority to do much with it.

So could you enlighten just -- I know some of it is proprietary information, but speak a little bit about the leases, and do your lease agreements speak anything -- speak to anything that you spoke to us about today?

KATHY MCCULLOUGH: What do you think?

You're looking at me blank. You probably know more.

KEVIN MCCULLOUGH: You're talking about -- are you talking about leases or the solar?

KATHY MCCULLOUGH: Solar or wind?

CHAIR CONDON: Well, right now it sounds to me -- I guess the premise for my question is it sounds like it's just a matter of understanding and coming to some agreement. It sounds like the developer is really now concerned with compliance. You've certainly suggested that they have been more proactive. But in their your agreements with them, does it call for action of compliance? Or are you depending on us?

KATHY MCCULLOUGH: We're depending on you because after 10 years of reporting pieces and our concerns and having them ignore us and lie to us, we don't trust them anymore.

And since the blade fell four years ago, more towers are down than ever. And we're just stymied. We don't know -- we're not signed up for solar because we would not sign up for them, period, after what we've seen with the wind.

CHAIR CONDON: Okay.

KATHY MCCULLOUGH: And it's not really addressed in the lease, but it's in the site certificate. And no, there are no violations on PGE

because they never told you guys. Hello?

CHAIR CONDON: Well, and as I see at this meeting, we've talked a lot about it in the last, I don't know, five meetings, some of these issues have come up and are now being addressed. And there seems to be a plan going forward. And I'm wondering if you are aware of that, you know, part of your -- are you included in those conversations with the developer?

KATHY MCCULLOUGH: Yes.

CHAIR CONDON: Okay. All right.

KATHY MCCULLOUGH: You can answer that.

KEVIN MCCULLOUGH: Well, yeah. Yes, we are. And the PGE crew that is there now have been very open in coming and talking to us and wanting our opinions on how things are.

But it's just we have lack of faith in PGE right now. They haven't proven anything to me. They are a disappointment, unfortunately. They need to keep moving forward and figure out how to fix this and then prove to me that this is going to work because they haven't done anything yet other than shut the towers off because they're dangerous.

CHAIR CONDON: Well, you presented your message well, or at least in my opinion, and I thank

you for being here and sharing, one, your experience.

But I also, just given the wildfire mitigation risk, if you have some ideas that you don't see in the mitigation plan -- the draft mitigation plans for construction or that should be there on the solar project that is now proposed, you know, the more detail you can give to us and staff, the better it informs us for our decision-making.

KATHY MCCULLOUGH: Okay. And since Colton is actually farming now, he's --

COLTON MCCULLOUGH: My biggest issue is -- my biggest issue is --

Can you hear me now?

CHAIR CONDON: Yeah.

COLTON MCCULLOUGH: My biggest issue is there's no operational Wildfire Mitigation Plan to even look at right now. So how am I even supposed to comment on something that doesn't even --

CHAIR CONDON: Yeah.

COLTON MCCULLOUGH: I don't have privy to it, so all I'm going off is what ODOE is saying that they're going to put in in the interim. But then I'm not going to have any say when it actually comes out.

CHAIR CONDON: Okay. Okay, thank you.

And it's, you know, I know it's coming. We've heard that. And just keep your ear attuned.

KATHY MCCULLOUGH: Yes. And just as an aside, even BrightNight hasn't been forthcoming with us. This is like the fourth or fifth representatives that have come through that, you know, that are now the experts.

And we were told that the panels weren't going to be within view of our house, and then they were right across the road. So we just panicked. And then our landlord is the one that got them to move them back. Everything we've been promised, somebody reneges on.

And it's getting really frustrating because we feel like we're just in a wave that we can't stop. We keep hearing the right things. We just haven't seen them.

KEVIN MCCULLOUGH: It's not in writing. Until I see it in writing from now on, I will not believe it. It needs to be put in writing and signed by whoever the proper authority is. And that's what needs to happen.

I used to do business on a handshake. Not going to happen ever again. I had really good

intentions with PGE and their wind project, and they kept telling us they're going to do it, but they kept cutting their maintenance budget on the project. How do you -- I don't know how you run anybody's farm or you do anything.

We spend money on our equipment to keep it up and make it work. So we're not going to be out there intentionally starting fires. Their solution was not to do anything. With this new management team, I have great hopes.

CHAIR CONDON: Well, thank you. Thank you for being here and coming up twice.

KATHY MCCULLOUGH: Thanks.

CHAIR CONDON: And having such strong representation.

And I'm wondering if PGE wants to come and respond or -- you don't have to. It's just --

UNIDENTIFIED SPEAKER: (Indiscernible) final comments.

CHAIR CONDON: Okay, yeah. Okay. Thank you.

KATHY MCCULLOUGH: Thanks for listening.

CHAIR CONDON: Okay, yeah. And I will say, and you've heard from all of the, yeah, every -- all the council members spoke today, and these

are of real concern to us. The issues that came up today are of concerns with this project, but overall they have been a real area of focus for us. So thank you for being here for the hearing.

And if there are no more comments from the Council, I'll turn this over.

SARAH ESTERSON: Thank you very much.

Okay, so to close this out, would the certificate holder like to respond to any comments you've received today or this evening?

KRISTEN SHEERAN: Chair Condon, members of the Council, and folks in the room this evening, thank you very much for your time and energy and for the -- for the input.

I'll just say two things and then I'll hand and it over to Lenna to wrap us up here in response to what we've heard tonight.

So one, you know, I think to reiterate, we recognize that some of the concerns raised about the operation of the Biglow Canyon Wind Farm do not meet the standards for excellence that PGE expects of all of its sites, and we are taking appropriate actions.

We also operate thousands of megawatts of clean energy across this region with an excellent track record of safety and reliability.

With regard to wildfire, let me reiterate. The safety and well-being of the communities we serve is paramount, and we recognize the existential risk of operating a utility today in the west amidst growing wildfire risk from climate change.

We maintain and implement robust Wildfire Mitigation Plans as required by the state and submit them to the Oregon Public Utility Commission on a regular basis. Those plans are evaluated by an independent evaluator, by the safety staff at the Oregon Public Utility Commission, and it is through a very public process with robust stakeholder input. We just submitted our most recent Wildfire Mitigation Plan in December, and it is currently under review.

Right now we're forecasting about $120,000,000 annually in wildfire mitigation investments to protect the safety and well-being of the communities we serve. And that includes things that have been discussed tonight, such as grid hardening and vegetation management, situational awareness, so think risk modeling, as well as the use of like AI panoramic cameras. It includes operational procedures across our system -- distribution, transmission, and generation. And it

includes the work that we do with our communities around education and outreach.

So wildfire safety is important, and we continue to evolve our Wildfire Mitigation Plans in response to changing technology, improving technology, as well as evolving industry best practice. And unfortunately, the growing risk of wildfire in this region. Thank you.

LENNA COPE: Thank you.

We just want to again say that we appreciate all the comments and people taking the time to review these documents and come here in person to provide your testimony. We will review all the comments and provide written responses.

But we do want to reiterate that the level of detail in the plans and the monitoring, the inspection, the reporting, and the enforcement by the Department in these plans is at a much greater level than any previous plan. The Department's staff and the staff that we have supporting the development of these plans have identified these improvements to the site certificate and associated plans. And they have teeth. We heard, you know, we want teeth, and we believe these plans do have that.

Additionally, in the written comments, we

will be submitting our communications log with stakeholders into the record to show our outreach to the stakeholders.

Okay, and with that, thank you again for your time, and get home safe tonight.

SARAH ESTERSON: Okay, any final comments or questions from Council to the certificate holder?

Okay. Thank you again, certificate holder.

I need to amend one statement that I previously made about the comment deadline. So all comments must be received by January 30th at 5:00 p.m. Not submitted by but received.

So if you're paper mailing your comments to the Department, make sure you've mailed them in a manner that they can be received by our office on January 30th at 5:00 p.m.

Okay. So it is now 8:20 p.m. on January 15, 2026, and the public hearing portion of the comment period on the Proposed Order for Request for Amendment 4 of Biglow Canyon Wind Farm site certificate has concluded.

I'm going to hand it over to Chair Condon to close the meeting.

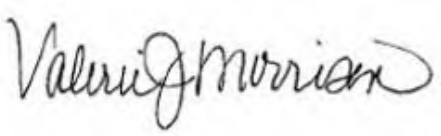
SECRETARY CORNETT: Chair Condon, if I

may.

CHAIR CONDON: Secretary Cornett?

SECRETARY CORNETT: Yeah. I just want to take the opportunity to thank everybody for coming out tonight. We really appreciate it. Our process is designed to include public participation. Local participation. That's why we're here. It works better if there is good, robust participation, so I encourage you, if you have comments, please do submit those comments. As you've heard from the Council, we take them very seriously, so please do comment. Thank you.

CHAIR CONDON: I want to add my thanks again for everyone who came to the hearing tonight, and especially those who sat through the whole meeting tonight. So thank you.



The time is now 8:21, and the January 15, 2026, meeting of the Energy Facility Siting Council is now adjourned. Thank you.

(WHEREUPON, the BIGLOW CANYON WINDFARM HEARING BEFORE OREGON DEPARTMENT OF ENERGY adjourned at 8:21 p.m.)

CERTIFICATE

I, Valerie J. Morrison, do hereby certify that the proceeding named herein was professionally transcribed on the date set forth in the certificate herein; that I transcribed all testimony adduced and other oral proceedings had in the foregoing matter; and that the foregoing transcript pages constitute a full, true, and correct record of such testimony adduced and oral proceeding had and of the whole thereof.

IN WITNESS HEREOF, I have hereunto set my hand this 6th day of February, 2026.

Valerie J. Morrison

To Commenters
Sent via email or physical address

Dear Commenter,

The Oregon Department of Energy (Department or ODOE) provides this "Response to Comments" document per OAR 345-027-0367(8)(b), which summarizes and responds to all comments submitted during the comment period on Portland General Electric's (PGE or certificate holder) Request for Site Certificate Amendment 4 for the Biglow Canyon Wind Farm (RFA4) and the Department's Proposed Order on RFA4. This evaluation, and the evaluation of any subsequent replies, will inform the draft of a Final Order that the Department will present to the Energy Facility Siting Council (EFSC or Council.)

The procedural timeline for the public participation process for RFA4 is presented below:

- Proposed Order on RFA4 was issued for public review and comment on December 16, 2025, establishing a 45-day comment period, which concluded on January 30, 2026;
- A public hearing was held on January 15, 2026 at the Grass Valley Pavillion in Grass Valley Oregon.
- At the conclusion of the comment period (January 30, 2026, at 5 p.m.), 17 commenters had submitted comments on the record, including the certificate holder.

This Response to Comments document addresses the comments received during the public comment period. A list of issues raised in comments, with the names of the commenters who raised them, is included in Table 1 below. Each issue has been assigned a unique ID number based on the standard the comment was determined to be associated with. For example, "Issue OE-01" is the first issue raised in comments and is related to the Organizational Expertise (OE) standard (OAR 345-022-0060).

For the purpose of orderly presentation, the comments have been organized by standard, in the order they appear in the Department's Proposed Order on RFA4. Comments that are similar in nature are grouped, rather than repeated in this document.

As described in a separate "Amendment Comment Review Process Doc Navigation Help Letter", attached with the Department's Response, we have provided instructions on how to access comments and other documents associated with this process; and, provided an

explanation on the Department's file management system and how to navigate PDF documents.

Replies must be received by **5:00 pm on February 27, 2026**, to be included in the record. Please note, I will be out of the office from February 13 to February 23, 2026. If you have questions about the process or how to submit replies to the Department or certificate holder's responses to your comments during this timeframe, please contact Sarah Esterson at sarah.esterson@energy.oregon.gov or call (503) 559-9218.

Respectfully,

Christopher M. Clark, Senior Siting Analyst
Oregon Department of Energy

Table 1: List of Issues and Commenters

Issue ID	Issue Summary	Commenter
General Standard of Review (OAR 345-022-0000)		
Issue GS-01	Concern about single hearing for a complex amendment	Kathryn McCullough
Issue GS-02	Request for correction to Existing Facility Site Location	Certificate Holder
Issue GS-03	Request for correction to Turbine Dimensions in Existing Energy Facility Description	Certificate Holder
Issue GS-04	Request for correction to Existing Related or Supporting Facilities Description	Certificate Holder
Issue GS-05	Request for correction to Existing O&M Building Description	Certificate Holder
Issue GS-06	Request for revision of proposed road dimension width, from 20 to 16 feet	Certificate Holder
Issue GS-07	Request to allow Temporary Construction Areas outside fenceline, within Solar Micrositing Area	Certificate Holder
Issue GS-08	Request for flexibility in perimeter fencing design	Certificate Holder
Issue GS-09	Request for correction of description of Solar Micrositing Area	Certificate Holder
Issue GS-10	Property owner does not consent to project being developed on his private property, as currently proposed.	Jered Reid/Donald Hilderbrand
Organizational Expertise (OAR 345-022-0060)		
Issue OE-01	Maintenance issues at existing wind facility	Kathryn and Kevn McCullough
Issue OE-02	Request to amend recommended Amended Condition 3 (CON-OE-01), removing reference to fax number as contact method for construction managers.	Certificate Holder
Issue OE-03	Request to revise requirement to provide executed Build Transfer Agreement in draft Operations and Maintenance Plan Framework, allowing for submission of redacted copy	Certificate Holder
Issue OE-04	Request to amend frequency of performance monitoring reports	Certificate Holder
Issue OE-05	Request to clarify frequency of inspections using thermal imaging	Certificate Holder
Structural Standard (OAR 345-022-0020)		
Issue SS-01	Request for flexibility to conduct ground disturbing activities on areas with steep slopes with engineer review	Certificate Holder
Soil Protection (OAR 345-022-0022)		
Issue SP-01	Questions the type and height of weeds required to be controlled	Kathryn McCullough

Table 1: List of Issues and Commenters

Issue ID	Issue Summary	Commenter
Issue SP-02	Requests to clarify statement referring to the use of Sherman County for weed control.	Certificate Holder
Issue SP-03	Requests Revisions to Mapped Soil Units in Analysis Area	Certificate Holder
Issue SP-04	Concerns related to 1-3" veg height under WMP and ability of that height to provide erosion control	Sherman County Weed District
Issue SP-05	Long-term soil health	Kathryn McCullough
Issue SP-06	Requests to develop a strong working relationship with certificate holder/BrightNight to ensure soil protection measures are in place.	Sherman County Soil and Water Conservation District, A. Whitman
Issue SP-07	Potential soil contamination from fire-damaged photovoltaic modules or battery components.	Sherman County Soil and Water Conservation District, A. Whitman
Issue SP-08	Enforcement of requirements for natural resource protection.	Sherman County Soil and Water Conservation District, A. Whitman
Issue SP-09	Requests to Clarify Terms, Clear Brush Free and Vegetation Clearance Area/Zone	Certificate Holder
Issue SP-10	Recommended edits to Draft Comprehensive Revegetation and Solar Management Plan	Certificate Holder
Issue SP-11	Erosion Issues	Sherman County Soil and Water Conservation District, A. Whitman
Issue SP-12	Weed Control	Sherman County Soil and Water Conservation District, A. Whitman
Land Use (OAR 345-022-0030)		
Issue LU-01	Request for reduction in requirements for Site Plan Review	Certificate Holder

I. Introduction 1

II. Public Comment Process Overview 1

III. Evaluation of Issues by Standard 2

III.A. General Standard of Review (OAR 345-022-0000) 2

Issue GS-01 (McCullough, Kathryn): Concern about single hearing for a complex amendment 2

Issue GS-02 (Certificate Holder): Request for correction to Existing Facility Site Location 2

Issue GS-03 (Certificate Holder): Request for correction to Turbine Dimensions in Existing Energy Facility Description 3

Issue GS-04 (Certificate Holder): Request for correction to Existing Related or Supporting Facilities Description 3

Issue GS-05 (Certificate Holder): Request for correction to Existing O&M Building Description 4

Issue GS-06 (Certificate Holder): Request for revision of proposed road dimension width, from 20 to 16 feet 4

Issue GS-07 (Certificate Holder): Request to allow Temporary Construction Areas outside fenceline, within Solar Micrositing Area 5

Issue GS-08 (Certificate Holder): Request for flexibility in perimeter fencing design 6

Issue GS-09 (Certificate Holder): Request for correction of description of Solar Micrositing Area 6

Issue GS-10 (Jered Reid/Donald Hilderbrand): Property owner does not consent to project being developed on his private property, as currently proposed. 7

III.B. Organizational Expertise (OAR 345-022-0060) 8

Issue OE-01 (McCullough, Kathryn; McCullough, Kevin); Maintenance issues at existing wind facility 8

Issue OE-02 (Certificate Holder): Request to amend recommended Amended Condition 3 (CON-OE-01), removing reference to fax number as contact method for construction managers 8

Issue OE-03 (Certificate Holder): Request to revise requirement to provide executed Build Transfer Agreement in draft Operations and Maintenance Plan Framework, allowing for submission of redacted copy 9

Issue OE-04 (Certificate Holder): Request to amend frequency of performance monitoring reports 9

Issue OE-05 (Certificate Holder): Request to clarify frequency of inspections using thermal imaging 10
III.C. Structural Standard (OAR 345-022-0022) 11
Issue SS-01 (Certificate Holder): Request for flexibility to conduct ground disturbing activities on areas with steep slopes with engineer review 11
III.C. Soil Protection (OAR 345-022-0022) 12
Issue SP-01 (McCullough, Kathryn); Questions the type and height of weeds required to be controlled 12
Issue SP-02 (Certificate Holder); Requests to clarify statement referring to the use of Sherman County for weed control. 12
Issue SP-03 (Certificate Holder); Requests Revisions to Mapped Soil Units in Analysis Area 13
Issue SP-04 (Sherman County Weed District) Concerns related to 1-3" veg height under WMP and ability of that height to provide erosion control 14
Issue SP-05 (McCullough, Kathryn); Long-term soil health 14
Issue SP-06 (Sherman County Soil and Water Conservation District, A. Whitman); Requests to develop a strong working relationship with certificate holder/BrightNight to ensure soil protection measures are in place. 15
Issue SP-07 (Sherman County Soil and Water Conservation District, A. Whitman); Potential soil contamination from fire-damaged photovoltaic modules or battery components. 15
Issue SP-08 (Sherman County Soil and Water Conservation District, A. Whitman); Enforcement of requirements for natural resource protection. 16
Issue SP-09 (Certificate Holder); Requests to Clarify Terms, Clear Brush Free and Vegetation Clearance Area/Zone 16
Issue SP-10 (Certificate Holder); Requests revisions to Draft Comprehensive Revegetation and Solar Management Plan 17
Issue SP-11 (Sherman County Soil and Water Conservation District, A. Whitman); Erosion Control 18
Issue SP-12 (Sherman County Soil and Water Conservation District, A. Whitman); Weed Control 18
III.D. Land Use (OAR 345-022-0030) 19
Issue LU-01 (Certificate Holder); Request for reduction in requirements for Site Plan Review 19
Issue LU-02 (Certificate Holder); Objection to Evaluation of Compliance with SCZO 5.2(5) 20
Issue LU-03 (Certificate Holder); Objection to Evaluation of Compliance with SCZO 5.2(6) 21

Issue LU-04 (Certificate Holder); Objection to Evaluation of Compliance with SCZO Section 5.8(20)(1) 21

Issue LU-05 (Certificate Holder) Objection to Evaluation of Compliance with SCZO 5.8(20)(3) 21

Issue LU-06 (von Borstel, Alan); Concern with cumulative impacts of solar development in Sherman County 22

Issue LU-07 (Multiple Commenters); Recommendation that "Right to Farm" protections are needed to protect farmers from wildfire liability 22

Issue LU-08 (Certificate Holder); Objection to Evaluation of OAR 660-033-0130(38)(G) 23

Issue LU-09 (Oregon Wheat Growers League); Recommendation to include impact of lost assessments in economic impact analysis 23

Issue LU-10 (Oregon Wheat Growers League); Objection to claim that Community Investment Plan will offset impacts to agricultural economy 24

Issue LU-11 (Oregon Wheat Growers League): Recommendation to include Oregon Wheat Growers League in Community Investment Selection Committee 25

Issue LU-12 (Oregon Wheat Growers League): Need for engagement with Market Development Organizations in developing Community Investment Plan 25

Issue LU-13 (Oregon Wheat Growers League): Concern with inclusion of agrivoltaics research as pre-screened project in Community Investment Plan 26

Issue LU-14 (Oregon Wheat Growers League): Concern with including weed management projects as pre-screened project in Community Investment Plan 27

Issue LU-15 (Oregon Wheat Growers League): Concern with including fire mitigation projects as pre-screened project in Community Investment Plan 28

Issue LU-16 (Oregon Wheat Growers League): Objection to statement that lease payments will compensate for lost agricultural revenue 29

Issue LU-17 (Certificate Holder); Land Use/Goal Exception – Project Furthers Oregon's Clean Energy Directives and Goals 30

Issue LU-18 (Certificate Holder); Land Use/Goal Exception – Minimal impacts to Other Resources 31

III.E. Fish and Wildlife Habitat (OAR 345-022-0060) 33

Issue WR-01 (Certificate Holder); Requests Revisions to recommended Amended Water Rights Condition 1 (PRE-WR-01) to Clarify Well Log Submission Timing 47

Issue WR-02 (Certificate Holder); Requests Revisions to recommended Amended Condition 75 (OPR-WR-01) on Applicability of Groundwater Usage Monitoring 47

Issue WR-03 (Certificate Holder); Requests Revisions to recommended Amended Condition 75 (OPR-WR-01) on Applicability of 5,000 gallon/day limit 48

I. Introduction

Portland General Electric Company (certificate holder) filed Request for Amendment 4 of the Site Certificate for the Biglow Canyon Wind Farm (RFA4) to the Energy Facility Siting Council (EFSC or Council) seeking authorization to expand the existing 450-megawatt (MW) wind power generation facility to allow construction and operation of a 125-MW solar power generation facility and related or supporting facilities within a 1,924-acre solar micrositing area.

On December 16, 2025, the Oregon Department of Energy (Department or ODOE) issued its Proposed Order on RFA4. On the same date, in accordance with OAR 345-027-0367(4), the Department issued a Public Notice, initiating a 45-day comment period, to conclude on January 30, 2026. The Notice also established deadlines for the subsequent comment evaluation process, including:

- February 13, 2026, for the Department and certificate holder responses to comments;
- February 27, 2026, for commenters to reply to Department/certificate holder responses; and,
- March 6, 2026, for the Department/certificate to file sur-replies.

Participants to the public comment process may request more time to submit their response, reply, and sur-reply to the Council or Council Chair, who shall grant the extension on a showing of good cause.

II. Public Comment Process Overview

The Council adopted changes to the Site Certificate Amendment comment process (OAR 345-027-0367) in September 2025, effective October 2025. This is the first amendment request under the new rules.

The purpose of the rule changes was to make the site certificate amendment review process more efficient and effective, improve the public comment process and increase the public's understanding of how to participate in the process. As presented above, the new process includes a step for the certificate holder and the Department to respond to comments; allows for those commenters to then reply; and then concludes with an opportunity for the Department and certificate holder to offer sur-reply.

The rules require that the certificate holder respond to all comments received during the comment period; the Department does not have the same obligation but may choose to respond. As presented in the document below, the Department has provided responses to commenters in a manner that provides organization for the public, the Department and the Council.

The intent of this new comment process is for each commenter to receive feedback from the Department and the certificate holder on the nature of their comments – specifically, whether they were raised with sufficient specificity so that the commenters can then reply with additional information or clarification. Where comments were raised with sufficient specificity, the process is intended to provide each commenter with feedback on whether those issues warrant remedy or change to a recommended finding of fact or recommended new or amended condition, and provide an opportunity for commenters to further explain and provide factual reasoning to support the Department and Council's evaluation of whether the certificate holder has met their burden of proof that they either can or have satisfied the requirements of applicable Council standards and other laws.

III. Evaluation of Issues by Standard

III.A. General Standard of Review (OAR 345-022-0000)

Issue GS-01 (McCullough, Kathryn): Concern about single hearing for a complex amendment
Comment ID: BCWAMD4Doc24-06 Proposed Order Public Comment McCulloughK-6 2026-01-09

Comment Summary
Commenter raises concern about single hearing for complex amendment.

Department Evaluation
On December 16, 2025, the Department issued public notice of the complete RFA4 and the Proposed Order on RFA4 which included notice of a 45-day comment period closing on January 30, 2026. The public notice included information for the in-person and remote public hearing held in Grass Valley on January 15, 2026.

The Department followed procedural rules and no requests were made to Council with a good cause justification for time extensions or additional hearings, therefore, the Department does not recommend any further action is needed on this issue.

Issue GS-02 (Certificate Holder): Request for correction to Existing Facility Site Location
Comment ID: BCWAMD4Doc24-08 Proposed Order Public Comment Certificate Holder 2026-01-14

Comment Summary
Certificate holder requests correction to description of facility site location. The Proposed Order Cover Letter identifies the Facility Site Location being 4.8 miles northeast of the City of Wasco. The proposed Solar Micrositing Area is 4.8 miles northeast of the City of Wasco, but the Facility Site Location is 2.5 miles northeast of the City of Wasco.

Department Evaluation
The Department's draft Final Order will not include the Cover Letter with the referenced discrepancy. However, the Department agrees that the corrections should be incorporated into

the Proposed Order Section I.C., Approved Site Description and in Section I.D.4., Proposed Solar Micrositing Area; and, in Section 3.3. of the draft Amended Site Certificate, as presented below.

> Proposed Order Section I.C. The site is located approximately 2.5 miles northeast of the City of Wasco in Townships 1 and 2 North, Ranges 17 and 18 East, Willamette Meridian.
>
> Proposed Order Section I.D.4. The facility components proposed in RFA4 would be located within a proposed 1,924-acre Solar Micrositing Area. The Solar Micrositing Area is located approximately 4.8 miles northeast of the City of Wasco.
>
> Draft Amended Site Certificate Section 3.3. The facility is located about 2.5 miles northeast of the City of Wasco in Townships 1 and 2 North, Ranges 17 and 18 East, Willamette Meridian, Sherman County, Oregon. The Solar Micrositing Area is located approximately 4.8 miles northeast of the City of Wasco.

Issue GS-03 (Certificate Holder): Request for correction to Turbine Dimensions in Existing Energy Facility Description
Comment ID: BCWAMD4Doc24-08 Proposed Order Public Comment Certificate Holder 2026-01-14

Comment Summary
The Certificate Holder requests the following corrections be made to the description of turbine dimensions in the Proposed Order, Section I.B.1, to reflect the facility as built:

> ~~The wind turbines are located on private land that the certificate holder has leased from the affected landowners.~~ The Siemens 2.3 MW turbines are mounted on tubular steel towers with a ~~hub~~ height of ~~280~~ 262 feet at the hub and ~~maximum blade tip~~ an overall height of ~~445~~ 413 feet including the turbine blades. The wind turbines are located on private land that the certificate holder has leased from the participating landowners.

Department Evaluation
The certificate holder seeks to clarify the description in the Proposed Order and draft Amended Site Certificate of the dimensions of existing, operational wind turbines based on actual dimensions. Because the certificate holder has the best information about actual turbine dimensions at the facility, the Department agrees to amend Section I.B.1. of the Proposed Order and Section 3.1 of the draft Amended Site Certificate accordingly.

Issue GS-04 (Certificate Holder): Request for correction to Existing Related or Supporting Facilities Description
Comment ID: BCWAMD4Doc24-08 Proposed Order Public Comment Certificate Holder 2026-01-14

Comment Summary

The certificate holder requests the following revisions to Table 1 of the Proposed Order be made to reflect existing facility components as built:

- Collector line length, underground: ~~106~~75 miles
- Collector line length, overhead: ~~3.9~~5 miles
- O&M Building Quantity: ~~2~~3 each

Department Evaluation
The certificate holder seeks to clarify the description in the Proposed Order Table 1 and draft Amended Site Certificate Section 3.1, Subsection 2.a of existing facility components, consistent with final design. Because the certificate holder has the best information about existing facility components/final design, the Department agrees to amend the Proposed Order Table 1 and draft Amended Site Certificate Section 3.1, Subsection 2.a, based on the changes presented above.

Issue GS-05 (Certificate Holder): Request for correction to Existing O&M Building Description
Comment ID: BCWAMD4Doc24-08 Proposed Order Public Comment Certificate Holder 2026-01-14

Comment Summary
The certificate holder requests that the total square footage of the as built O&M buildings total identified in Section 3.1, Subsection 2.d of the site certificate be changed from 17,500 square feet to 19,500 square feet due to the building evaluated through ODOE's Change Request process.

Department Evaluation
Based on review of the record, the Department confirms that on January 12, 2017, it issued a determination under previous rules referring to a Change Request process, confirming that construction of an additional warehouse at the O&M site could occur without being reviewed through the site certificate process. The square footage of the additional warehouse was 3,600 feet (the amount reflected in the certificate holder's revision).

It is the Department's intent to incorporate changes reviewed through Change Requests, Facility Modifications and Amendment Determination Requests into a Site Certificate when the Site Certificate is open through the amendment process. Therefore, the Department agrees to incorporate changes in the O&M square footage reference, consistent with the dimensions reviewed through the Change Request process, into the draft Amended Site Certificate Section 3.1, Subsection 2.d.

Issue GS-06 (Certificate Holder): Request for revision of proposed road dimension width, from 20 to 16 feet
Comment ID: BCWAMD4Doc24-08 Proposed Order Public Comment Certificate Holder 2026-01-14

Comment Summary

The certificate holder requests that the Proposed Order Section I.D.3 be amended to clarify that all new facility access roads will be 16, rather than 20, feet in width.

Department Evaluation
In RFA4, Section 4.1.3.6, the certificate holder represented that "all newly constructed roads within the Solar Micrositing Area will be graveled to meet load requirements for all equipment. These internal access roads are expected to be approximately 20 feet in width." In RFA4, Exhibit V, Attachment V-1, the Draft Construction Wildfire Mitigation Plan states that "new roads proposed within the Solar Micrositing Area shall be sufficiently sized for emergency vehicle access in accordance with 2022 Oregon Fire Code requirements, including Section 503 and Appendix D - Fire Apparatus Access Roads. Specifically, the new roads proposed within the solar area fence lines will be 20 feet in width." In a subsequent comment, the certificate holder clarified that this representation was only intended to apply to certain external access roads and other roads needed for emergency access (See Issue WF-04.)

While design changes are permissible at this stage in the process, additional information is requested to support the Department's evaluation. Please provide a site plan showing the location and width of designated emergency access roads and other internal access roads.

Issue GS-07 (Certificate Holder): Request to allow Temporary Construction Areas outside fenceline, within Solar Micrositing Area
Comment ID: BCWAMD4Doc24-22 Proposed Order Public Comment Certificate Holder-2 2026-01-30

Comment Summary
Certificate holder requests clarification in the Proposed Order Section I.D.3 that temporary construction areas may be placed anywhere within the proposed Solar Micrositing Area, not only within perimeter fenceline. The certificate holder indicates that this clarification is consistent with the RFA and ensures construction logistics are not inadvertently limited.

Department Evaluation
In RFA4, Section 4.1.3.7., the certificate holder represented that temporary construction yards would be located within the fenceline (permanent disturbance footprint) of the proposed facility:

> "During construction, one 8.7-acre temporary construction area (laydown area) within the perimeter fencing will be used to support construction, store supplies and equipment, and facilitate the delivery and assembly of materials and equipment…Additional temporary construction areas may be used as determined by the construction contractor, but these would be within the solar areas considered permanent disturbance; therefore, maximum impact is evaluated in RFA4"

Certificate holder indicates that the proposed clarification is consistent with the RFA. Please clarify the locations in the RFA where a request for temporary construction areas outside the

fenceline have been presented and evaluated. If the information is not in the RFA, please identify the potential sizes and locations of temporary construction areas outside the perimeter fenceline and provide an evaluation of potential impacts and whether the conditions included in the draft Amended Site Certificate are adequate to address the associated impacts.

Issue GS-08 (Certificate Holder): Request for flexibility in perimeter fencing design
Comment ID: BCWAMD4Doc24-22 Proposed Order Public Comment Certificate Holder-2 2026-01-30

Comment Summary
Certificate holder requests additional flexibility in perimeter fencing materials, including use of wire mesh or similar perimeter fencing up to 8 feet in height.

Department Evaluation
The description of perimeter fencing in the draft Site Certificate is consistent with information provided in RFA4, Section 4.1.3.6; however, the Department agrees that flexibility in the final design and type of fencing is allowable as long as the fencing is constructed and grounded in accordance with NESC Rule 110, would maintain public health and safety by preventing unauthorized entrance to the site, and would not create an unnecessary hazard for wildlife. The Department will incorporate changes in the draft Final Order Section I.D.3, draft Amended Site Certificate Section 3.2, and Section 4.1.5 of the Construction Wildfire Mitigation Plan, to allow the additional flexibility requested.

Issue GS-09 (Certificate Holder): Request for correction of description of Solar Micrositing Area
Comment ID: BCWAMD4Doc24-22 Proposed Order Public Comment Certificate Holder-2 2026-01-30

Comment Summary
Certificate holder requests changes to a footnote in Facility Component Table to clarify Solar Micrositing Area is larger than permanent disturbance footprint, as presented below:

> ~~The Solar Micrositing Area would occupy approximately 1,445 acres within fenced areas and transmission line corridor. The entire solar facility footprint is considered a permanent disturbance area for the purposes of evaluating and mitigating impacts to resources such as Fish and Wildlife Habitat; however, soil reclamation and weed management is applicable to the solar facility footprint as discussed in applicable section in this order.~~
>
> The approved BCWF site boundary encompasses approximately 25,000 acres and includes all existing and approved BCWF components. The Certificate Holder proposes to modify the use of approximately 1,924 acres within the approved BCWF site boundary (Figure 3) to accommodate the Solar Components. These 1,924 acres

comprise the Solar Micrositing Area (also referred to as the RFA 4 Site Boundary), within which construction of the Solar Components may occur.

Department Evaluation
The Department agrees with the certificate holder that the description of the Solar Micrositing Area and maximum permanent disturbance of the Solar Facility, as provided in the Proposed Order Section I.D, Table 2 footnote 1, should be clear and consistent with the table itself, (e.g. 1,924 acre Solar Micrositing Area and 1,445 acre maximum permanent disturbance.)

The footnote is intended to clarify the term "permanent footprint" from an impact assessment perspective. For example, impacts within the perimeter fence of a solar facility are a permanent impact under the Fish and Wildlife Habitat standard. But that does not mean impacts to soils and vegetation within the fenceline are permanent. In fact, impacts to soils and vegetation within the fenceline are not permanent and these impacts need to be minimized and mitigated under other standards, such as Soil Protection and Land Use.

The certificate holder's proposed revisions are providing a different intent – of clarifying that the existing site boundary is being used to accommodate solar, which has nothing to do with the impact assessment under Fish and Wildlife, Soil Protection or Land Use for this amendment. The Department disagrees with the incorporating the certificate holder's proposed language, but agrees to make the following change:

> Solar facility components would permanently occupy up to 1,445 acres within the 1,924 acre ~~The~~ Solar Micrositing Area~~would occupy approximately 1,445 acres within fenced areas and transmission line corridor~~. Areas within the perimeter fenceline of the solar facility ~~The entire solar facility footprint is~~ are considered a permanent ~~disturbance area for the purposes of evaluating and mitigating impacts to resources such as~~ impact under the Fish and Wildlife Habitat standard; however, impacts within the perimeter fenceline to soils, vegetation and noxious weeds are not considered permanent under the Soil Protection and Land Use standards and must be minimized and mitigated, ~~soil reclamation and weed management is applicable to the solar facility footprint~~ as discussed in applicable sections in this order.

Issue GS-10 (Jered Reid/Donald Hilderbrand): Property owner does not consent to project being developed on his private property, as currently proposed.
Comment ID: BCWAMD4Doc24-16 Proposed Order Public Comments HilderbrandD via Law Office of Jered Reid 2026-01-29

Comment Summary
Mr. Hilderbrand, a person with an ownership interest in real property included in the proposed site, commented that he does not consent to his property being included in the project.

Department Evaluation

Matters related to property rights, including land access, purchasing, and leasing are generally outside of EFSC jurisdiction, meaning that EFSC cannot resolve disputes associated with these issues between landowners and the certificate holder, or between individual owners of a property. Because the commenter has not raised an issue related to a matter within the Council's jurisdiction, the Department does not intend to make any changes to the draft of the Final Order based on this comment.

III.B. Organizational Expertise (OAR 345-022-0060)

Issue OE-01 (McCullough, Kathryn; McCullough, Kevin); Maintenance issues at existing wind facility
Comment ID: BCWAMD4Doc24-01 Proposed Order Public Comment McCulloughK-1 2025-12-23

Comment Summary
Commenters object to approval of RFA4 until maintenance issues at the existing wind facility are addressed, stating that the certificate holder "should not be allowed to build solar until the Vestas towers are fixed." Commenter provides documentation of ongoing maintenance issues at existing wind facility, including blade throw, leaks of hydraulic oil from nacelles and turbine towers, transformer failures, multiple fallen bolts, hatch doors, nose cones, and other objects from turbines.

Department Evaluation
As discussed on page 40 of the Proposed Order, the Department acknowledges that the existing wind facility has experienced substantial equipment and maintenance issues over the past several years. While the Department does not agree that the maintenance issues demonstrate that the certificate holder, in partnership with BIGL, LLC, cannot operate or maintain a solar facility in compliance with site certificate conditions, the issues do demonstrate a deficiency in the adequacy of the existing site certificate conditions in ensuring systematic oversight of vendor performance, preventive maintenance, and safe, reliable construction and operation.

The Department has recommended the Council adopt additional conditions of approval to improve oversight and ensure the safe operation of the proposed solar components, including recommended Organizational Expertise Conditions 1 and 2 which require the finalization of the Draft O&M Framework Plan included as Attachment C to the Proposed Order. The Department may consider additional changes to these conditions or plan should the commenter suggest any in their reply. However, based on the comment and information provided to date, the Department does not intend to make any revisions in the draft Final Order.

Issue OE-02 (Certificate Holder): Request to amend recommended Amended Condition 3 (CON-OE-01), removing reference to fax number as contact method for construction managers.
Comment ID: BCWAMD4Doc24-08 Proposed Order Public Comment Certificate Holder 2026-01-14

Comment Summary
Certificate holder requests changes to recommended Amended Condition 3 (CON-OE-01) to remove requirement to provide fax numbers for construction managers.

Department Evaluation
The Department agrees that requiring a fax number is unnecessary given the other communication methods included in the recommended amended condition, including phone number and email address. The Department agrees to remove reference to "fax number" in recommended Amended Condition 3 (CON-OE-01) in the draft Final Order.

Issue OE-03 (Certificate Holder): Request to revise requirement to provide executed Build Transfer Agreement in draft Operations and Maintenance Plan Framework, allowing for submission of redacted copy
Comment ID: BCWAMD4Doc24-08 Proposed Order Public Comment Certificate Holder 2026-01-14

Comment Summary
Certificate holder requests changes to recommended Organizational Expertise Condition 1 and Proposed Order Table 5, which requires submittal of an executed Built Transfer Agreement (BTA) as part of finalization of the O&M Framework Plan. Specifically, certificate holder requests that they be authorized to submit a redacted copy, redacting confidential terms and conditions.

Department Evaluation
The Department agrees that there are likely confidential terms and conditions of the BTA which do not have a nexus with the Organizational Expertise standard and therefore do not need to be included in the version submitted to the Department. Receipt by the Department of an executed BTA is a recommended requirement because it is the mechanism that will establish the certificate holder's role and responsibility for oversight and control over a third-party; and, the third-party's role and responsibility in selecting and managing construction contractors, construction and operation of the proposed solar components. The Department proposes to incorporate the following language in Proposed Order Table 5 and Table 1 of the draft O&M Framework Plan.

> <u>Confidential terms and conditions, unrelated to the roles, responsibilities, oversight and control of the certificate holder, third-parties, site certificate and facility, may be redacted from the executed BTA provided to the Department.</u>

Issue OE-04 (Certificate Holder): Request to amend frequency of performance monitoring reports
Comment ID: BCWAMD4Doc24-22 Proposed Order Public Comment Certificate Holder-2 2026-01-30

Comment Summary

Certificate holder requests changes to recommended Organizational Expertise Condition 1 (PRO-OE-01) through Table 1 of the O&M Framework Plan (Proposed Order Attachment C) and Proposed Order Table 5, to reduce the frequency of reporting results of vendor performance from monthly to quarterly. Certificate holder states that monthly reporting may over-emphasize short-term variability that does not reflect underlying performance trends, while quarterly reporting allows for more meaningful evaluation of system performance and provides sufficient time for the certificate holder and O&M contractors to address identified issues.

Department Evaluation
As presented in Table 1 of the O&M Framework Plan (Proposed Order Attachment C) and Proposed Order Table 5, under the heading "Reporting," the proposed monthly reporting requirement applies to identification of any significant performance issues and corrective actions taken by or for the participating entity, contractor(s) and vendor(s). Further, monthly reporting shall identify corrective actions, including stop work or removal from site, required of the vendor(s) for any performance scores less than 95% percent on-time inspection and repair completion rate.

The Department understands the certificate holder's concerns but disagrees that a lessor frequency be established prior to establishing a cadence or implementation and evaluation of the plan. The Department's experience with the existing operating facility demonstrates that more frequency is necessary to track and understand operational and maintenance issues and status and/or plan for repairs.

The draft O&M Framework Plan allows for annual review and update of the plan (see Proposed Order Attachment C, Section 5, Conclusions. The Department maintains that changes in monitoring and reporting frequency be evaluated once the plan is implemented, based on revisions necessary to support effective review and understanding of vendor performance.

The Department recommends an additional change to Section 5.0 of the draft O&M Framework Plan, stating that:

> <u>All changes are subject to review and approval by the Department.</u>

Issue OE-05 (Certificate Holder): Request to clarify frequency of inspections using thermal imaging
Comment ID: BCWAMD4Doc24-22 Proposed Order Public Comment Certificate Holder-2 2026-01-30

Comment Summary
Certificate holder requests to modify Proposed Order Attachment C, draft O&M Framework Plan, Section 3.4.2 as presented below:

Routine module inspections and annual infrared/aerial thermal imaging with anomalies detected via SCADA generating corrective work orders ~~within 48 hours~~ according to the final Operations and Maintenance Plan.

Certificate holder requests this change stating that it is unlikely that SCADA will detect module-level anomalies for work order creation.

Department Evaluation
The Department accepts the certificate holder's clarification on the frequency of thermal imaging because it is the certificate holder's proposal, but requests further clarification related to SCADA's identification of anomalies and generation of work orders. Certificate holder states that the SCADA is unlikely to detect anomalies that would generate work orders, but that language is not proposed to be removed, only the reference to the 48-hour generation of work order. The Department proposes the following language based on the certificate holder's explanation:

Routine module inspections and annual infrared/aerial thermal imaging with anomalies detected and addressed ~~via SCADA generating corrective work orders within 48 hours~~ according to the final Operations and Maintenance Plan.

The Department seeks certificate holder confirmation of accuracy on the above proposed language.

III.C. Structural Standard (OAR 345-022-0022)

Issue SS-01 (Certificate Holder): Request for flexibility to conduct ground disturbing activities on areas with steep slopes with engineer review
Comment ID: BCWAMD4Doc24-22 Proposed Order Public Comment Certificate Holder-2 2026-01-30

Comment Summary
Certificate holder requests that recommended Amended Condition 68 be changed to allow ground disturbing activities in areas with slopes exceeding 20 percent when reviewed and approved by the Geotechnical Engineer of Record and designed to adequately address non-seismic hazard risks, as presented below.

Proposed Clarified Condition 68 (CON-SS-03):
The Certificate Holder shall design, engineer, and construct the solar facility to avoid dangers to human safety presented by non-seismic hazards, including but not limited to settlement, landslides, flooding, erosion, and collapsible soils. Ground-disturbing activities shall be avoided in areas with slopes exceeding 20 percent unless such activities are reviewed and approved by the Geotechnical Engineer of Record and designed to adequately address non-seismic hazard risks.

Department Evaluation
Recommended Amended Condition 66 requires that the certificate holder complete and submit a final Geotechnical Investigation prepared, which must be prepared for Geotechnical Engineer of Record and would evaluate seismic and non-seismic hazards at the site, based on final design. The language proposed by the certificate holder therefore is duplicative. Any changes to recommended Amended Condition 68 must be reviewed in tandem with recommended Amended Condition 66.

To assist in the evaluation of relaxing the prohibition of ground disturbing works on slopes exceeding 20%, the Department requests additional information regarding the types of ground disturbing activities on slopes exceeding 20 percent that are under consideration, the locations at the site where they are being considered, and any supporting evidence demonstrating how non-seismic geologic hazards in these areas will be mitigated. Please note that the recommended Condition 68 was intended to ensure compliance with the requirements of Sherman County's Natural Hazards (NH) Combining Zone and SCZO Section 3.7. If work on steep slopes within the NH Combining Zone is proposed, all information required under SCZO 3.7(5) must be included in RFA4.

III.C. Soil Protection (OAR 345-022-0022)

Issue SP-01 (McCullough, Kathryn); Questions the type and height of weeds required to be controlled
Comment ID: BCWAMD4Doc24-06 Proposed Order Public Comment McCulloughK-6 2026-01-09

Comment Summary
Commenter questions whether weeds are allowed to be a foot in height and whether noxious weeds, or all weeds, are required to be controlled/mitigated.

Department Evaluation
Noxious weeds will not be allowed to be 1-foot in height. The vegetation height limit of 1-foot established in the draft Construction Wildfire Mitigation Plan (WMP) Section 4.6.1. applies to beneficial vegetation, not noxious weeds.

Noxious weeds and invasive annual grass are required to be treated, controlled and monitored during construction and operation (see recommended Soil Protection Conditions 1 to 3).

The Department considers this issue resolved.

Issue SP-02 (Certificate Holder); Requests to clarify statement referring to the use of Sherman County for weed control.
Comment ID: BCWAMD4Doc24-08 Proposed Order Public Comment Certificate Holder 2026-01-14

Comment Summary

Certificate Holder requests to clarify that while there is intent to contract the Sherman County Weed Control District to implement measures of the Weed Control Plan, the District may not have sufficient capacity to manage implementation, in which case other qualified vendors may be contracted to implement the measures of the Weed Control Plan.

Department Evaluation
RFA4 Exhibit K Land Use, Section 8.1.3.1 states, "The Certificate Holder currently contracts with the Sherman County Weed Control District to inspect and treat weeds at BCFW and will continue to use their staff's services to treat the Solar Micrositing Area." This representation was incorporated into the Proposed Order Section D.1. Soil Protection; however, it was not expressly incorporated into a condition or weed-related mitigation requirement.

Recommended Soil Protection Conditions 1 to 3 require finalization and implementation of the draft Comprehensive Solar Vegetation and Soil Management Plan (Proposed Order Attachment D). Weed control requirements applicable prior to and during construction and operation are included in this plan. The plan does not require that the certificate holder contract with Sherman County Weed Control District to implement and monitor the requirements of the plan but rather requires that it be implemented by a qualified Weed Control Contractor.

The Department agrees that the recommended findings of fact can be updated based on the certificate holder's revised representation. Rather than revising the facts to refer to the potential of contracting with Sherman County Weed District or qualified vendors for weed control, the Department recommends that the findings of fact be revised to refer to the requirements of the draft Comprehensive Solar Revegetation and Soil Management Plan, as presented below:

> ~~The certificate holder has indicated that the District will be contracted to implement the measures of the Weed Control Plan.~~[1] Prior to and during construction and operation of the facility components proposed in RFA4, the certificate holder will be required to hire a Weed Control Contractor responsible for performing weed control in accordance with the Comprehensive Solar Revegetation and Soil Management Plan under recommended Soil Protection Conditions 1 through 3.[2]

The Department considers this issue resolved.

Issue SP-03 (Certificate Holder); Requests Revisions to Mapped Soil Units in Analysis Area
Comment ID: BCWAMD4Doc24-08 Proposed Order Public Comment Certificate Holder 2026-01-14

[2] BCWAMD4DocXX. Proposed Order on AMD4 Attachment D, Table A-2, pg. A-3. The draft Comprehensive Solar Revegetation and Soil Management Plan includes additional experience requirements for the Weed Control Contractor.

Comment Summary
Certificate holder requests revision of percentage of Solar Micrositing Area in Soil Unit 16D in Proposed Order Table 7. Commenter recommends amount should be 0.1%, not 0.2%.

Department Evaluation
Based on review of AMD4 Exhibit I, the Department agrees to correct Table 7 in the draft Final Order, as requested.

The Department considers this issue resolved.

Issue SP-04 (Sherman County Weed District) Concerns related to 1-3" veg height under WMP and ability of that height to provide erosion control
Comment ID: BCWAMD4Doc24-15 Proposed Order Public Comment Sherman County Weed District 2026-01-28

Comment Summary
Sherman County Weed District (SCWD) recommends vegetation be maintained at 4-8 inch height during dry season to support erosion control. SCWD suggests that a vegetative height of 1-3 inches will not support erosion control. SCWD also expresses concerns with the viability of bunchgrass species if maintained at the 1-3 inch height.

Department Evaluation
The Department is evaluating several comments related to the recommendation that vegetation within the solar facility and other vegetation clearance areas be maintained at 1 to 3 inches during fire season to mitigate fire risk. Mr. McCullough recommends the recommendation be implemented throughout the life of the facility (Issue WF-09). SCWD recommends that the vegetation height standard be increased to 4 to 8 inches to support erosion control and enhance viability of bunchgrass species. The certificate holder requests that the height standard be increased to 10 to 12 inches year-round.

The Department will continue to evaluate these recommendations, along with any additional evidence submitted in replies, to identify vegetation management standards that provide adequate fuel management to minimize wildfire risk while maintaining appropriate conditions for erosion control and beneficial vegetation.

Issue SP-05 (McCullough, Kathryn); Long-term soil health
Comment ID: BCWAMD4Doc24-17 Proposed Order Public Comment McCulloughK-10 2026-01-29

Comment Summary
Ms. McCullough raises concerns about lack of evidence supporting claims related to long-term soil improvement following use of the site for solar after 50 years.

Department Evaluation
Ms. McCullough does not identify a specific recommended finding, condition, or conclusion for which she objects Vegetation management and erosion control is required under the Draft Comprehensive Revegetation and Soil Management Plan established under recommended Soil Protection Conditions 1 to 3, however commenter has not explained how plan is deficient or could be improved.

At this time, the Department does not intend to make any revisions in the draft of the Final Order based on this comment because the comment has not been made with sufficient specificity – *i.e.*, the commenter does not "[i]dentify the recommended findings of fact, conclusions of law or conditions of approval identified in the proposed order to which they object." OAR 345-027-0367(7),(8).

Issue SP-06 (Sherman County Soil and Water Conservation District, A. Whitman); Requests to develop a strong working relationship with certificate holder/BrightNight to ensure soil protection measures are in place.
Comment ID: BCWAMD4Doc24-21 Proposed Order Public Comment Sherman SWCD 2026-01-30

Comment Summary
Ms. Whitman of Sherman County Soil and Water Conservation District (SCSWCD) requests to develop a strong working relationship with certificate holder/BrightNight to ensure soil protection measures are in place.

Department Evaluation
Ms. Whitman does not identify a specific recommended finding, condition, or conclusion for which she objects. If Ms. Whitman believes there is a regulatory nexus for requiring consultation, and adherence to recommendations provided during consultation, please provide. As such, the Department does not believe the commenters issue was raised with sufficient specificity to afford the Council, Department, or certificate holder an opportunity to respond. If the commenter objects to one or more findings of fact, conclusions of law, or conditions of approval in the Proposed Order, the Department requests that commenter identifies these findings, conclusions, or conditions in their reply.

Issue SP-07 (Sherman County Soil and Water Conservation District, A. Whitman); Potential soil contamination from fire-damaged photovoltaic modules or battery components.
Comment ID: BCWAMD4Doc24-21 Proposed Order Public Comment Sherman SWCD 2026-01-30

Comment Summary
Ms. Whitman of SCSWCD raises concerns about potential for panels or batteries damaged by fire or other cause to release toxins into soils and waterways.

Department Evaluation

Ms. Whitman does not identify a specific recommended finding, condition, or conclusion for which she objects. Control of noxious weeds and annual grasses is required under the Draft Comprehensive Revegetation and Soil Management Plan established under recommended Soil Protection Conditions 1 to 3, however Ms. Whitman has not explained how the plan is deficient or could be improved. Wildfire minimization and mitigation are required under Wildfire Prevention and Risk Mitigation Conditions 1 to 3, however commenter has not explained how plan is deficient or could be improved.

At this time, the Department does not believe the commenters issue was raised with sufficient specificity to afford the Council, Department, or certificate holder an opportunity to respond. If the commenter objects to one or more findings of fact, conclusions of law, or conditions of approval in the Proposed Order, the Department requests that commenter identifies these findings, conclusions, or conditions in their reply.

Issue SP-08 (Sherman County Soil and Water Conservation District, A. Whitman); Enforcement of requirements for natural resource protection.
Comment ID: BCWAMD4Doc24-21 Proposed Order Public Comment Sherman SWCD 2026-01-30

Comment Summary
Ms. Whitman of SCSWCD raises concerns about enforcement of measures to protect environment and natural resources. She suggests that the State hold the certificate holder accountable for controlling weeds, preventing soil erosion, promoting fire prevention, and any other practices that ensure the health of the surrounding community and watersheds.

Department Evaluation
Ms. Whitman does not identify a specific recommended finding, condition, or conclusion for which she objects. Control of noxious weeds and annual grasses is required under the draft Comprehensive Revegetation and Soil Management Plan established under recommended Soil Protection Conditions 1 to 3, however Ms. Whitman has not explained how plan is deficient or could be improved. Wildfire minimization and mitigation are required under Wildfire Prevention and Risk Mitigation Conditions 1 to 3, however Ms. Whitman has not explained how plan is deficient or could be improved.

At this time, the Department does not believe the commenters issue was raised with sufficient specificity to afford the Council, Department, or certificate holder an opportunity to respond. If the commenter objects to one or more findings of fact, conclusions of law, or conditions of approval in the Proposed Order, the Department requests that commenter identifies these findings, conclusions, or conditions in their reply.

Issue SP-09 (Certificate Holder); Requests to Clarify Terms, Clear Brush Free and Vegetation Clearance Area/Zone
Comment ID: BCWAMD4Doc24-22 Proposed Order Public Comment Certificate Holder-2 2026-01-30

Comment Summary
Certificate holder provides the following clarification to ensure consistent interpretation of buffer area requirements along roads and perimeter fencelines within the Solar Micrositing Area. The terms "clear, brush-free area" and "vegetation-clearance area/zone" are used in multiple locations in the Proposed Order and Attachments D and G without consistent definition. To improve the clarity and avoid misinterpretation, the certificate holder requests that these terms be replaced with "low-growing, fire-resistant vegetation," or that the documents otherwise clarify that these buffer areas are intended to be maintained with low-growing, fire-resistant vegetation rather than fully devoid of vegetation.

In addition, the certificate holder notes an inconsistency regarding whether the required buffer along the perimeter fenceline is intended to be 10 feet on each side or 20 feet measured along the exterior or interior and requests clarification from ODOE to ensure consistent understanding and implementation of the buffer requirement.

Department Evaluation
In the Proposed Order Attachment G Section 4.1.6 (draft Construction WMP), the Department recommended the following:

> During construction clearing, grubbing, and grading, the contractor will establish a noncombustible buffer zone extending a minimum of 10 feet inside the fenceline and another minimum 10-foot limits of disturbance buffer outside the fenceline for a total of a minimum of 20 feet of noncombustible buffer around the perimeter of the site.

Also as presented in the draft Amended Site Certificate Table 1, the vegetation management buffer for the perimeter fenceline is established at 20 feet. These requirements were based on the draft Construction Wildfire Mitigation Plan and draft Comprehensive Revegetation and Soil Management Plan provided by the certificate holder. While design changes are permissible at this stage in the process, additional information is requested to support the Department's evaluation. Please provide specific revisions to the draft Comprehensive Solar Revegetation and Soil Management Plan and draft Construction Wildfire Mitigation Plan. Please explain how public comments discussed under Issue SP-04, WF-08, and WF-09 were considered in developing the revisions.

The Department agrees that the varying terms used in Section III.D.1 and draft Amended Site Certificate should be replaced with a consistent term, "noncombustible buffer" and be further clarified that for the perimeter fenceline, the buffer extends 10-feet on either side.

Issue SP-10 (Certificate Holder); Requests revisions to Draft Comprehensive Revegetation and Solar Management Plan
Comment ID: BCWAMD4Doc24-22 Proposed Order Public Comment Certificate Holder-2 2026-01-30

Comment Summary
Certificate holder provides additional recommended edits to the draft Comprehensive Revegetation and Solar Management Plan presented as Attachment D to the Proposed Order.

Department Evaluation
The Department reviewed the certificate holder's proposed changes to the draft Comprehensive Revegetation and Solar Management Plan and generally agrees to administrative changes and clarifications. As presented for Issue FW-03, the Department's requests reasons and explanation to support the certificate holder's request for flexibility in ground disturbing activities during the sensitive ground nesting bird season. In addition, the certificate holder requests changes to the seed mix presented in Appendix F Table 2. The Department is reviewing with ODFW and will provide any agreed upon changes in the draft Final Order.

Issue SP-11 (Sherman County Soil and Water Conservation District, A. Whitman); Erosion Control
Comment ID: BCWAMD4Doc25-03 Proposed Order Public Hearing Transcript 2026-01-15

Comment Summary
Ms. Whitman of SCSWCD raises general concerns about the spread of noxious weeds and annual grass at the site and their potential to increase wildfire risk.

Department Evaluation
Ms. Whitman does not identify a specific recommended finding, condition, or conclusion that is objected to. Control of noxious weeds and annual grasses is required under the draft Comprehensive Revegetation and Soil Management Plan established under Recommended Soil Protection Conditions 1 to 3, however commenter has not explained how the plan is deficient or could be improved.

At this time, the Department does not believe the commenters issue was raised with sufficient specificity to afford the Council, Department, or certificate holder an opportunity to respond. If the commenter objects to one or more findings of fact, conclusions of law, or conditions of approval in the Proposed Order, the Department requests that commenter identifies these findings, conclusions, or conditions in their reply.

Issue SP-12 (Sherman County Soil and Water Conservation District, A. Whitman); Weed Control
Comment ID: BCWAMD4Doc25-03 Proposed Order Public Hearing Transcript 2026-01-15

Comment Summary
Ms. Whitman of SCSWCD raises general concerns about the spread of noxious weeds and annual grass at the site and their potential to increase wildfire risk.

Department Evaluation

Ms. Whitman does not identify a specific recommended finding, condition, or conclusion that is objected to. Control of noxious weeds and annual grasses is required under the draft Comprehensive Revegetation and Soil Management Plan established under Recommended Soil Protection Conditions 1 to 3, however commenter has not explained how the plan is deficient or could be improved.

At this time, the Department does not believe the commenters issue was raised with sufficient specificity to afford the Council, Department, or certificate holder an opportunity to respond. If the commenter objects to one or more findings of fact, conclusions of law, or conditions of approval in the Proposed Order, the Department requests that commenter identifies these findings, conclusions, or conditions in their reply.

III.D. Land Use (OAR 345-022-0030)

Issue LU-01 (Certificate Holder); Request for reduction in requirements for Site Plan Review
Comment ID: BCWAMD4Doc24-22 Proposed Order Public Comment Certificate Holder-2 2026-01-30

Comment Summary
Certificate holder requests the following changes be made to recommended Land Use Condition 3:

a. Prior to construction of any component or phase of the solar facility, the certificate holder shall submit, to the Department and the Sheman County Planning Commission, an application for Conditional Use Permit ~~pursuant to ORS 469.401(3) meeting the requirements of SCZO Section 5.4(1) and (3).~~
b. ~~The Site Plan required under SCZO 5.4(1) must demonstrate compliance with all applicable local ordinances and site certificate conditions.~~
[Final Order on AMD4]

The certificate holder asserts that because it has elected to seek a Council determination of compliance with statewide land use planning goals under ORS 469.504(1)(b), Sherman County would not have discretionary approval of a CUP or Site Plan, and compliance with applicable sections of the Sherman County Zoning Code (SCZO) would be determined by Council and memorialized in the Final Order and Site Certificate.

Department Evaluation
The certificate holder is correct that under ORS 469.401(3), an affected County does not have general discretion to reject a permit addressed in an amended site certificate, the statute explicitly authorizes the County to consider whether the permit is consistent with the terms and conditions of the amended site certificate. The statute also requires the certificate holder to submit “proper applications and payment of the proper fees” for any permit addressed in the site certificate, including the Conditional Use Permit.

The Department believes the condition is appropriate as written. The language proposed to be stricken explains what information the Department believes is necessary for the CUP application to be complete. In addition, the Department and the County will need a final site plan in order to verify that the facility will comply with setback, dimensional requirements, and other restrictions imposed through site certificate conditions and applicable local ordinances. If the certificate holder believes this is incorrect, or that additional clarification is needed, the Department requests that additional explanation be provided in the certificate holder's reply.

Issue LU-02 (Certificate Holder); Objection to Evaluation of Compliance with SCZO 5.2(5)
Comment ID: BCWAMD4Doc24-22 Proposed Order Public Comment Certificate Holder-2 2026-01-30

Comment Summary
Certificate holder objects to the Department's recommended finding that the proposed facility would not comply with SCZO 5.2(5) and requests that the Department reconsider its recommended finding that the acreage thresholds under OAR 660-033-0130(38)(k) are a "land standard" within the meaning of the SCZO, arguing instead that they are thresholds that, if triggered, require the application of more stringent review criteria under the exceptions test.

Department Evaluation
In the Proposed Order, the Department recommends the Council find:

> "…the facility components proposed in RFA4 would generally comply with applicable air, water, and solid waste standards; however, as described in the evaluation of directly applicable state rules and laws under ORS 197.646, below, the facility components proposed in RFA4 would exceed the maximum amounts of arable and high-value farmland allowed under OAR 660-033-0130(38), and for this reason cannot be approved without an exception to Statewide Planning Goal 3."

OAR 660-033-0130 establishes the minimum standards applicable to the schedule of permitted and conditional uses under OAR 660-033-0120. OAR 660-033-0130(38)(g) provides as follows: "For high-value farmland described at ORS 195.300(10), a photovoltaic solar power generation facility shall not use, occupy, or cover more than 12 acres" unless certain standards are met. A similar standard is established under OAR 660-033-0130(38)(i) which provides; "For arable lands, a photovoltaic solar power generation facility shall not use, occupy, or cover more than 20 acres..."

Similar to all other standards set in the rule and the SCZO, if a facility would use, occupy, or cover, more land than allowed by the rule, then the facility cannot be approved as a conditional use. Instead, the project proponent must seek an exception to the standards and the Statewide Planning Goal the standards implement. Because the acreage thresholds in OAR 660-033-0130(38) are used to determine whether a facility can be approved as a Conditional Use, and because they are directly applicable to any Sherman County Land Use decision under ORS

197.646, the Department maintains that they are effectively land use standards within the meaning of SCZO 5.2.

Issue LU-03 (Certificate Holder); Objection to Evaluation of Compliance with SCZO 5.2(6)
Comment ID: BCWAMD4Doc24-22 Proposed Order Public Comment Certificate Holder-2 2026-01-30

Comment Summary
Certificate holder objects to the Department's recommended finding that the proposed facility would not comply with SCZO 5.2(6) and requests that the Department reconsider its finding that failure to comply with acreage threshold under OAR 660-033-0130(38)(k) is a "use violation" within the meaning of the SCZO.

Department Evaluation
The Department agrees with the certificate holder that the obligation to receive approval of a Goal 3 exception does not constitute a "use violation" of the SCZO, and agrees to revise the analysis.

Issue LU-04 (Certificate Holder); Objection to Evaluation of Compliance with SCZO Section 5.8(20)(1)
Comment ID: BCWAMD4Doc24-22 Proposed Order Public Comment Certificate Holder-2 2026-01-30

Comment Summary
Certificate holder objects to the Department's recommended finding that the proposed facility would not comply with SCZO 5.8(20)(1) and request that the Department reconsider its finding that failure to comply with acreage threshold under OAR 660-033-0130(38) would result in the proposed facility being incompatible with farm use.

Department Evaluation
The Department interprets the "compatibility with farm use" standard under SCZO 5.8(20)(1) to mean that the non-farm use is compatible with farm uses on the subject tract, which is a distinct issue from the compatibility with adjacent uses criteria found in SCZO 5.8(20)(2) and in the Council's exception criteria under ORS 469.504(2)(c)(C). The Department maintains that the minimum standards applicable to conditional uses under OAR 660-033-0130 are an appropriate measure of whether a proposed facility is compatible with farm use when the County has not adopted its own standards or criteria.

Issue LU-05 (Certificate Holder) Objection to Evaluation of Compliance with SCZO 5.8(20)(3)
Comment ID: BCWAMD4Doc24-22 Proposed Order Public Comment Certificate Holder-2 2026-01-30

Comment Summary
Certificate holder objects to the Department's recommended finding that that proposed facility would not comply with SCZO 5.8(20)(3) and requests that the Department reconsider its finding that conversion of approximately 1,445 acres of cultivated land, including 1,006 acres of high-value farmland, to a non-farm use has the potential to materially alter the overall land use pattern of the analysis area by reducing the number of tracts available for farmland and potentially affecting the local agricultural economy.

Department Evaluation
The Department disagrees with the scope of the analysis provided by the certificate holder, including 130 square miles. The Land Use analysis area includes the area within and extending ½-mile from the site boundary. The Department requests that the certificate holder provide an analysis of SCZO 5.8(20)(3) based on the established Land Use analysis area, to support review of this comment.

Issue LU-06 (von Borstel, Alan); Concern with cumulative impacts of solar development in Sherman County
Comment ID: BCWAMD4Doc24-11 Proposed Order Public Comment Von BorstelA 2026-01-20

Comment Summary
Mr. Von Borstel raises concern that cumulative impacts of solar development in Sherman County may adversely affect wildlife, wildfire protection, cultural, historic and scenic the agricultural community, and supporting industries.

Department Evaluation
Mr. Von Borstel raises concerns about the cumulative impact of solar development in Sherman County. He did not identify a specific standard or legal requirement or a specific impact that would result from the construction and operation of the proposed facility under consideration.

As such, the Department does not believe the commenters issue was raised with sufficient specificity to afford the Council, Department, or certificate holder an opportunity to respond. If the commenter objects to one or more findings of fact, conclusions of law, or conditions of approval in the Proposed Order, the Department requests that commenter identifies these findings, conclusions, or conditions in their reply.

Issue LU-07 (Multiple Commenters); Recommendation that "Right to Farm" protections are needed to protect farmers from wildfire liability
Comment ID: BCWAMD4Doc24-02 Proposed Order Public Comment McCulloughK-2 2025-12-24; BCWAMD4Doc24-04 Proposed Order Public Comment McCulloughK-4 2026-01-05; BCWAMD4Doc24-22 Proposed Order Public Comment Certificate Holder-2 2026-01-30; BCWAMD4Doc25-03 Proposed Order Public Hearing Transcript 2026-01-15

Comment Summary
Commenters raise concerns about the increased risk of liability to farmers that could arise if a fire started by farming practices damaged the solar facility. Commenters object to recommended approval of solar facility in "high fire risk area" without hold harmless clause. Commenters assert that potential liability for a wildfire started by normal farming practices could result in bankruptcy, and without protections from liability the project infringes on the commenters "right to farm" under ORS 30.930 to 30.947.

Department Evaluation
Matters of liability are generally not within the Council's jurisdiction. Providing farmers the suggested liability protections would be a matter to take up with the state legislature. The Department does not intend to make any revisions in the draft of the Final Order based on this comment because the comment raises an issue that is not within the scope of Council's authority.

Issue LU-08 (Certificate Holder); Objection to Evaluation of OAR 660-033-0130(38)(G)
Comment ID: BCWAMD4Doc24-22 Proposed Order Public Comment Certificate Holder-2

Comment Summary
Certificate holder objects to Departments recommended findings under evaluation of OAR 660-033-0130(38)(h)(G).

Department Evaluation
In its evaluation of this criteria, the Department states, "No solar facilities have been constructed or have been approved within the study area identified by rule, so no further analysis is necessary; however, the rule was intended to apply to a facility less than 12 acres in size and does not accurately capture the proposed facilities' potential impacts on the stability of the overall land use pattern..."

As stated, the Department's recommended finding is that no further analysis of the criteria is needed. The additional explanation is intended to provide context for recommended findings under the evaluation of SCZO 5.8.20(3). The Department will include clarifying changes in both sections to clarify that the Department's evaluation of the proposed facilities potential impacts on the stability of the overall land use pattern of the area is informed by, but independent of, the test required under OAR 660-033-0130(38)(h)(G).

Issue LU-09 (Oregon Wheat Growers League); Recommendation to include impact of lost assessments in economic impact analysis
Comment ID: BCWAMD4Doc24-20 Proposed Order Public Comment OWGL 2026-01-30

Comment Summary
Commenter raises a concern that the certificate holder's analysis of economic impacts of the RFA4 facility changes does not account for lost agricultural assessments that fund research,

market development, and grower services. Recommends updating the impact analysis to account for lost assessment revenues.

Department Evaluation
The commenter has not objected to a Department recommended finding of fact, conclusion of law or condition of approval in the Proposed Order, but rather to the scope of the certificate holder's analysis of the indirect economic impacts of the proposed RFA4 changes.

Based on the comment and information provided to date, the Department will not make any revisions in the draft of the Final Order based on this comment because the comment has not been made with sufficient specificity – *i.e.*, the commenter does not "[i]dentify the recommended findings of fact, conclusions of law or conditions of approval identified in the proposed order to which they object." OAR 345-027-0367(7),(8).

Issue LU-10 (Oregon Wheat Growers League); Objection to claim that Community Investment Plan will offset impacts to agricultural economy
Comment ID: BCWAMD4Doc24-20 Proposed Order Public Comment OWGL 2026-01-30

Comment Summary
Commenter contends the draft Community Investment Plan (CIP) "does not deliver" on a statement by the certificate holder that the CIP will "ensure any negative economic impacts that could result from the decrease in total acres of wheat production in the county will be offset by investments in the local agricultural community."[3] Contends that mitigation cannot fully offset the loss of agricultural land into an industrial use.

Department Evaluation
The commenter has not objected to a Department recommended finding of fact, conclusion of law or condition of approval in the Proposed Order regarding the CIP, but rather to a statement the certificate holder made about the CIP. Council must consider whether the proposed CIP supports a "rural economic benefits" reason for granting an exception to statewide planning Goal 3, which seeks to preserve agricultural land. The Department has not contended the CIP will fully offset any/all negative economic impacts to the local agricultural community. Rather, the Department has recommended the Council find the proposed CIP "*reasonably addresses* the indirect impacts of converting agricultural lands in the proposed Solar Micrositing Area to nonfarm use"[4] and recommended Council find that implementation of the CIP supports a rural economic benefits reason for granting an exception to Goal 3.

Based on the comment and information provided to date, the Department will not make any revisions in the draft of the Final Order based on this comment because the comment has not been made with sufficient specificity – *i.e.*, the commenter does not "[i]dentify the

[3] RFA4, Exhibit K, Land Use, p. 71.
[4] Proposed Order, pp. 139-140.

recommended findings of fact, conclusions of law or conditions of approval identified in the proposed order to which they object." OAR 345-027-0367(7),(8).

Issue LU-11 (Oregon Wheat Growers League): Recommendation to include Oregon Wheat Growers League in Community Investment Selection Committee
Comment ID: BCWAMD4Doc24-20 Proposed Order Public Comment OWGL 2026-01-30

Comment Summary
Commenter recommends that farmer representatives should be included in decision making process. Recommends Oregon Wheat Growers League be included in structure.

Department Evaluation
The commenter expresses concern there is no guarantee a farmer representative will be "built into the decision-making process" and proposes to "update the structure to include a representative from the Oregon Wheat Growers League."

To help inform the development of the CIP and to identify potential projects that would support the local agricultural economy the certificate holder met with, among other persons and groups, local wheat farmers and the Oregon Wheat Commission. That coordination led to the certificate holder including in the CIP five "pre-screened" projects that would qualify for funding.

For other proposals, a five-person advisory committee (Selection Committee) would review applications and make recommendations to the Sherman County Board of Commissioners on funding. The Selection Committee would include one representative from Sherman County government; one representative from an academic institution engaged in agriculture research in Sherman County or an agricultural-related nonprofit entity located in Sherman County; *one dryland farm producer in the County*; one community member; and one representative with expertise in wildfire as it relates to agricultural lands.[5]

At this time, the Department does not intend to make any changes in the draft Final Order based on this comment because wheat farmers were consulted in developing the five pre-screened projects, and the Selection Committee that may recommend other possible projects will include a dryland farm producer. The Department may consider additional changes to findings or conditions based on additional information provided on the record.

Issue LU-12 (Oregon Wheat Growers League): Need for engagement with Market Development Organizations in developing Community Investment Plan
Comment ID: BCWAMD4Doc24-20 Proposed Order Public Comment OWGL 2026-01-30

[5] Proposed Order, p. 139 and Attachment E (the draft CIP), Section 4.2.1.

Comment Summary
Commenter recommends that further consultation with market development organizations (e.g. , Oregon Wheat Commission, U.S. Wheat Associates, National Association of Wheat Growers and Northwest Grain Growers) seeking to understand the long-term markets in domestic and international capacities "is needed to clarify statements listed in the market statements."

Department Evaluation
It is not clear to the Department to what "market statements" the commenter is referring, nor what further consultation with the recommended organizations would achieve.

Based on the comment and information provided to date, the Department will not make any revisions in the draft of the Final Order based on this comment because the comment has not been made with sufficient specificity – *i.e.*, the commenter does not "[i]dentify the recommended findings of fact, conclusions of law or conditions of approval identified in the proposed order to which they object." OAR 345-027-0367(7),(8).

Issue LU-13 (Oregon Wheat Growers League): Concern with inclusion of agrivoltaics research as pre-screened project in Community Investment Plan
Comment ID: BCWAMD4Doc24-20 Proposed Order Public Comment OWGL 2026-01-30

Comment Summary
Commenter raises concern with inclusion of agrivoltaics research in pre-screened mitigation project list, alleging "[t]his areas is overstated" and the project "would not produce meaningful results." Recommends producer-led analysis of research proposals would allow research investments to match the growing area most effectively.

Department Evaluation
Dryland wheat agrivoltaics research is one of five pre-screened projects identified in the draft Community Investment Plan (CIP) as having a direct benefit to the rural agricultural economy of Sherman County. These five projects were developed based on outreach and coordination with key stakeholders from the Sherman County agricultural community, as well as state-wide agricultural-related organizations including local wheat farmers, the Oregon Watershed Enhancement Board (OWEB), Oregon State University (OSU) including its extension service in Sherman County and the College of Agricultural Sciences, the Oregon Wheat Commission, the Sherman County Fire District, Sherman County Emergency Services, the Rural Sherman County Fire Board, the Weed Master, the Road Master, the County Planning Office, and County Judge. Further, as noted above, the Selection Committee for CIP mitigation projects will include one representative one dryland farm producer in the County.

The Department does not intend to make any revisions in the draft of the Final Order based on this comment because the agrivoltaics project was identified after consultation with a range of stakeholders, not just agricultural producers, and because producers will be represented on the Selection Committee that will make the final choices for mitigation projects.

Issue LU-14 (Oregon Wheat Growers League): Concern with including weed management projects as pre-screened project in Community Investment Plan
Comment ID: BCWAMD4Doc24-20 Proposed Order Public Comment OWGL 2026-01-30

Comment Summary
Commenter raises concern with inclusion of weed management projects in the pre-screened mitigation project funding list. Asserts the project adds burden to neighboring properties and recommends weed management be incorporated into the project requirements rather than diminishing agricultural mitigation funds.

Department Evaluation
The commenter contends "the project should ensure that a weed management plan that can be reasonably enforced is completed outside of ag mitigation efforts."

Weed control is a requirement under Proposed Order. The certificate holder has prepared the Comprehensive Solar Revegetation and Soil Management Plan (Comprehensive Plan) to serve as a primary source of commitments related to revegetation, soil management, dust control, stormwater management, and noxious weed control through the pre-construction, construction, and operations phases for the photovoltaic solar energy generation and battery storage (Solar Components) associated with RFA4.

Under the Proposed Order recommended Soil Protection Conditions 1 through 3, the certificate holder would be required to finalize the draft Comprehensive Plan (included as Attachment D), and construct and operate the solar facility in compliance with the Plan. As with all site certificate conditions, the Department and Council maintain authority to enforce these condition requirements. The commenter has not raised any issues related to the adequacy of the draft Comprehensive Plan or Recommended Soil Protection Conditions 1 through 3.

The weed control measures funded under the draft CIP would not address weeds related to the Biglow facility but rather would provide a grant program for county wheat farmers to invest in precision agricultural technology such as weed management equipment, remote sensing technology to assist with weed mapping or soil mapping.

The draft CIP Project 4 is a "[g]rant program for county wheat farmers to invest in precision agricultural technology such as weed management equipment, remote sensing technology to assist with weed mapping or soil mapping, variable rate technology to collect data on soil variability to inform application of fertilizers, and other technologies." The description further states "[t]he cost-share grant program for precision agricultural technology is assumed to increase the number of farmers who otherwise would not have access to precision management technology due to the significant upfront cost barrier."[6]

[6] Proposed Order Attachment E, Draft Community Investment Plan, pp. 10-11.

The Department does not intend to make any revisions in the draft of the Final Order based on this comment because recommended conditions in the Proposed Order would already require the certificate holder to take weed control measures, and the weed control funding measures described under the draft CIP would not be used to control weeds related to the certificate holder's project but rather would be utilized by county wheat farmers.

Issue LU-15 (Oregon Wheat Growers League): Concern with including fire mitigation projects as pre-screened project in Community Investment Plan
Comment ID: BCWAMD4Doc24-20 Proposed Order Public Comment OWGL 2026-01-30

Comment Summary
Commenter raises concern with inclusion of investments in minimizing fire risk in the pre-screened mitigation project funding list. Recommends fire mitigation should be considered separately from agricultural mitigation.

Department Evaluation
Under Council's Wildfire Prevention and Risk Mitigation standard, OAR 345-022-0115, Council must find the certificate holder has adequately characterized wildfire risk within the analysis area and that the proposed facility will be designed, constructed, and operated in compliance with a Wildfire Mitigation Plan approved by the Council.

In the Proposed Order, the Department recommends the Council impose new conditions requiring the certificate holder to submit plans addressing wildfire risks associated with the construction and operation of the solar facility. Recommended Wildfire Prevention and Risk Mitigation Conditions 1 and 2 require the certificate holder to submit to the Department, for review and approval, a Construction Wildfire Mitigation Plan (WMP), (consistent with Attachment G to the Order) and to adhere to the WMP during construction of the solar facility. And Recommended Wildfire Prevention and Risk Mitigation Conditions 3 and 4 require the certificate holder to submit to the Department for review and approval an Operational Wildfire Mitigation Plan and adhere to it during operations.

In 2024, separate from the Council process related to the proposed Biglow solar facility, Sherman County developed and adopted a Community Wildfire Protection Plan (CWPP) to identify and mitigate wildfire risk in the county and to develop a strategy to reduce those risks. The CWPP identifies several projects that would assist the County in mitigating wildfire risk (e.g., upgrading, maintaining, or adding firefighting equipment for Sherman County's Rural Fire Protection Districts and training for volunteers).

In the certificate holder's draft CIP, "Agricultural Wildfire Risk Minimization and Capacity Building" is one of the five pre-screened projects identified as having a direct benefit to the rural agricultural economy of Sherman County. Under the draft CIP Project 2, the County could allocate mitigation funding to support either partial or full implementation of the projects

identified in its CWPP, as well as other initiatives aimed at supporting the County's agricultural community in wildfire mitigation and response.

The Department does not intend to make any revisions in the draft of the Final Order based on this comment because recommended conditions in the Proposed Order already require the certificate holder to take measures to comply with the Council's Wildfire Prevention and Risk Mitigation standard. Separately, the wildfire risk minimization measures described under the draft CIP would not be used to address wildfire risks related to the certificate holder's project but rather would benefit the County overall.

Issue LU-16 (Oregon Wheat Growers League): Objection to statement that lease payments will compensate for lost agricultural revenue
Comment ID: BCWAMD4Doc24-20 Proposed Order Public Comment OWGL 2026-01-30

Comment Summary
Commenter objects to a statement by the certificate holder that lease payments will compensate for any lost agricultural revenue incurred by a landowner/farmer due to conversion of farmland to energy use[7]; the commenter contends that the farm operator may not own the subject parcel and may not benefit from lease payments and suggests clarification is needed to determine if the persons who provided statements are only landowners or if they are also farm operators.

Department Evaluation
The commenter has not objected to a Department recommended finding of fact, conclusion of law or condition of approval in the Proposed Order, but rather to a statement the certificate holder made that lease payments will offset the direct loss of agricultural production resulting from its proposed solar facility.

As discussed in the Proposed Order, because the proposed solar facility would use, occupy, or cover more farmland than allowed under state laws and regulations, for Council to approve the facility, it would have to provide an exception to Statewide Planning Goal 3, which seeks to preserve and maintain agricultural lands for farm use.

The certificate holder argues that one reason Council should provide an exception to Goal 3 is because its proposed solar facility will promote rural economic development in several ways including through lease payments to affected landowners. The Department analyzed this argument in the Proposed Order and, while it agreed that some aspects of the proposal support Council granting an exception to Goal 3 because of the rural economic development that will result (e.g., through the proposed Community Investment Plan), the Department recommended Council find that the certificate holder has not provided sufficient evidence to demonstrate that lease payments will benefit agricultural operations because the participating

[7] RFA4, Exhibit K, Land Use, p. 18.

landowner or individuals farming the land have not demonstrated, or even indicated, they intend to use the lease payments from the proposed solar facility to make or allow for new farm investment.[8]

Therefore, it is not necessary to seek clarification regarding the landowner statements and the Department does not intend to make any revisions in the draft of the Final Order based on this comment because the Department has recommended Council reject the certificate holder's position that the lease payments support Council granting an exception to Goal 3.

Issue LU-17 (Certificate Holder); Land Use/Goal Exception – Project Furthers Oregon's Clean Energy Directives and Goals
Comment ID: BCWAMD4Doc25-03 Proposed Order Public Hearing Transcript 2026-01-15; BCWAMD4Doc24-23 Proposed Order Public Comment Certificate Holder-3 2026-01-30

Comment Summary
Certificate holder objects to the Department recommending Council reject their argument that an exception to Goal 3 is justified because authorizing the facility components proposed in RFA4 is consistent with State policies and goals addressing climate change and encouraging the acceleration of Oregon's clean energy transition.

In their comments on the Proposed Order, the certificate holder provides additional evidence and argument in support of its position. The certificate holder discusses state legislation (SB 1547, ORS 469A.005-469A.210) mandating that large investor-owned utilities, including PGE, meet Renewable Portfolio Standard targets. The certificate holder also addresses two recent Executive Orders issued by Governor Kotek, Executive Order 25-25, *Accelerating Wind and Solar Energy Development in Advance of Elimination of Federal Clean Energy Tax Credits* (EO 25-25), and Executive Order 25-29 *Reducing Greenhouse Gas Emissions and Advancing Oregon's Clean Energy Future* (EO 25-29). The certificate holder contends "a Goal 3 exception is justified because the facility, as amended, directly furthers Oregon's clean energy directives and goals."

Department Evaluation
The Department does not intend to make any revisions in the draft of the Final Order based on this comment and recommends Council not make changes in its Final Order based on this comment.

The State of Oregon has taken several measures to combat climate change and encourage the development of renewable energy, including those discussed by the certificate holder. At the same time, Oregon has a rigorous land use system that seeks, among other goals, to preserve the state's agricultural lands, via Goal 3. None of the statutes or Executive Orders the certificate holder cites require EFSC to grant an exception to Goal 3 for a renewable energy facility. Indeed, per statute, EFSC "*may* find goal compliance for a facility that does not otherwise

[8] Proposed Order on RFA4, pp. 141-142.

comply with one or more statewide planning goals by taking an exception to the applicable goal" (ORS 459.504(2), emphasis added). Therefore, as the certificate holder has noted, EFSC has the discretion to decide when to grant an exception to a statewide planning goal.

In recent years, most projects reviewed by EFSC have sought an exception to Goal 3. That is because large renewable energy facilities, in particular solar photovoltaic power generation facilities, require significant amounts of land and that land is often zoned for Exclusive Farm Use. Therefore, it is up to EFSC to balance Oregon's goals and directives to combat climate change/encourage renewable energy against the state's Goal 3, seeking to preserve agricultural land. This is a responsibility the Department and EFSC take seriously. The Department believes that granting an exception to Goal 3 based solely on the fact that a proposal would result in the construction or expansion of a renewable energy facility is tantamount to ignoring Goal 3 altogether. Indeed, EFSC has consistently rejected arguments that because a proposed facility would assist in meeting Oregon's climate change and renewable energy policies, that alone is a reason justifying taking an exception to Goal 3. Rather, the Department and Council have sought to take a closer look at the impacts a proposed facility would have on agricultural lands and the agricultural economy. This is a location-specific and project-specific analysis. Council has regularly approved exceptions to Goal 3 where the project proponent can demonstrate the facility is located near existing energy or transportation infrastructure (and thus would displace less agricultural land than a facility farther from such infrastructure), will have minimal impacts to agriculture and/or provide a benefit to the rural/agricultural economy.

In the Proposed Order the Department recommends Council find that the certificate holder has provided sufficient evidence to justify an exception to Goal 3 based on the RFA4 facility components being locationally dependent on nearby major transmission infrastructure and transportation corridors and because the proposed Community Investment Plan funds are likely to be used in a manner that benefits the local agricultural economy and provide rural economic development benefits. Therefore, should Council agree with the Department's recommendation, it would grant an exception to Goal 3 for the proposed additions to the facility, not based solely on the fact that those additions will further Oregon's clean energy directives and goals, but because it makes sense to site an energy facility at that location, given the presence of nearby energy and transportation infrastructure and because the certificate holder will implement measures that will benefit the rural/agricultural economy.

The Department maintains its recommendation that Council not base a goal exception on the proposed facility components furthering Oregon's clean energy directives and goals. Were Council to do so, proponents of future renewable energy projects may cite such a decision as a basis for Council to grant an exception to Goal 3 even if their projects, unlike this one, are not locationally dependent, would not provide a benefit to the rural/agricultural economy and/or would have greater impact on agricultural lands and productivity.

Issue LU-18 (Certificate Holder); Land Use/Goal Exception – Minimal impacts to Other Resources

BCWAMD4Doc24-23 Proposed Order Public Comment Certificate Holder-3 2026-01-30

Comment Summary
Certificate holder objects to recommended rejection of Minimal Impacts to Other Resources Reason to support an exception to Statewide Planning Goal 3. Provides comparison of potential impacts compared to other recent orders.

Department Evaluation
The Department does not intend to make any revisions in the draft of the Final Order based on this comment and recommends Council not make changes in its Final Order based on this comment.

The certificate holder maintains that an exception to Goal 3 is justified because their proposed Solar Micrositing Area would have minimal impacts on other resources protected by Council standards since it would avoid sensitive environmental features, including Washington ground squirrel occupied habitat, FEMA 100-year floodplains, U.S. Fish and Wildlife Service-designated critical habitat, and ODFW-designated big game winter ranges, and wetlands and waters. They contend their proposal would impact less Category 2 through 4 habitats than three other facilities to which Council granted a Goal 3 exception and that the permanent habitat loss that would occur will be mitigated according to ODFW Habitat Mitigation Policy goal.

Per ORS 469.504(2)(c) the Council may take an exception to a statewide planning goal if it finds the following standards are met:

> *(A) Reasons justify why the state policy embodied in the applicable goal should not apply;*
> *(B) The significant environmental, economic, social and energy consequences anticipated as a result of the proposed facility have been identified and adverse impacts will be mitigated in accordance with rules of the council applicable to the siting of the proposed facility; and*
> *(C) The proposed facility is compatible with other adjacent uses or will be made compatible through measures designed to reduce adverse impacts.*

Thus, for Council to grant an exception to Goal 3, in addition to finding there are sufficient reasons to justify taking an exception, ORS 469.504(2)(c)(B) requires Council to also find that the significant environmental, economic, social and energy consequences anticipated as a result of the facility components proposed in RFA4 have been identified and adverse impacts will be mitigated in accordance with rules of the Council. Here, because the Department believes the certificate holder had already demonstrated sufficient reasons to grant an exception to Goal 3, it recommended Council reject minimal impacts as a reason for granting an exception under ORS 469.504(2)(c)(A) and instead consider those minimal impacts and mitigation per the ODFW Habitat Mitigation Policy as meeting the mitigation requirement in

ORS 469.502(2)(c)(B).[9] This approach avoids "double counting" - *i.e.*, finding the same underlying facts and evidence as meeting two separate criteria necessary for granting an exception. Accordingly, the Department recommends Council not make any changes to the Proposed Order in response to the certificate holder's comments.

III.E. Fish and Wildlife Habitat (OAR 345-022-0060)

Issue FW-01 (McCullough, Kathryn); Adequacy of Exhibit P and Evaluation of Impacts to Wildlife
Comment ID: BCWAMD4Doc24-03 Proposed Order Public Comment McCulloughK-3 2026-01-01

Comment Summary
Ms. McCullough raises concerns regarding the adequacy of RFA4 Exhibit P and the evaluation of impacts to wildlife. She states that the Exhibit P (to the preliminary RFA4) is incomplete and appears to apply only to birds and bats, arguing that other mammals should be addressed. She provides photographic documentation of other animals in the vicinity of the site.

Department Evaluation
The Department believes RFA4 Exhibit P, and associated findings in the Proposed Order, adequately address potential impacts to fish and wildlife species, including the species identified by Ms. McCullough. Because impacts to all wildlife and wildlife habitat, not just bird and bat species, were considered in the evaluation of the RFA4, the Department does not recommend any additional changes to the Proposed Order are warranted at this time.

Under OAR 345-022-0060(3)(d) [formerly OAR 345-021-0010(1)(p)(D)], Exhibit P must identify all *state sensitive species* that might be present in the analysis area, based on consultation with ODFW and appropriate field study and literature review. Information about state sensitive species is required to be included in the Fish and Wildlife Exhibit, in part, to inform habitat categorization based and determine appropriate measures to avoid and minimize impacts in accordance with ODFW's Habitat Mitigation Policy, but the importance and use of habitat to wildlife more generally is also considered when making these determinations.

In Exhibit P, Section 6.1, of the final RFA4, the certificate holder identifies that 16 *state sensitive species* that have the potential to occur in the analysis area. This list is not intended to be a list of all species that are potentially present at the site, only those species identified by ODFW as State Sensitive, or Sensitive-Critical, which for the proposed Solar Micrositing Corridor, includes primarily bird and bat species and two reptile species.

[9] See Proposed Order, p. 146: ". . . the construction and operation of the facility components proposed in RFA4 could have significant adverse impacts on soils, fish and wildlife habitat, cultural resources, and waters of the State, but the Department recommends the Council find that existing and recommended conditions of approval are adequate to avoid, minimize, or mitigate these impacts."

As referenced by the commenter, the biologists conducting field surveys of the site also recorded non-listed species encountered during surveys in the Biological Survey Reports included in Attachment P-1, including some of the species identified in the comments and associated photographs. Impacts to non-listed species were further addressed in Exhibit P, and the Proposed Order, through the consideration of mapped Big Game Winter Range (for Elk and Mule Deer) and Priority Wildlife Connectivity Areas (based on connectivity needs for 54 surrogate species) in the categorization of habitat, which resulted in additional areas shrubland-steppe and grassland habitat being considered Category 2 "essential and limited" habitat. ODFW also recommended additional measures to protect wildlife and habitat which were incorporated into the draft Comprehensive Solar Revegetation and Soil Management Plan included as Attachment D to the Proposed Order.

At this time, the Department does not intend to make any revisions in the draft of the Final Order based on this comment, for the reasons described above.

Issue FW-02 (Certificate Holder); Srivener's Error
Comment ID: BCWAMD4Doc24-08 Proposed Order Public Comment Certificate Holder 2026-01-14

Comment Summary
Certificate holder requests correction of a Scrivener's error in Condition GEN-FW-02. Notes that GEN-FW-02 references Condition 63 (should now be GEN-FW-03)

Department Evaluation
The Department agrees to make the recommended change, applicable language where the change would be presented is shown below, in red underline, strikethrough font:

Condition GEN-FW-02:…

a. …
b. ….
c. … If the construction would result in additional permanent impacts, the certificate holder shall increase the area of mitigation for permanent loss of Category 3 and Category 4 habitat as described in the Habitat Mitigation Plan incorporated herein by ~~Condition 63~~ GEN-FW-03.

Issue FW-03 (Certificate Holder) Flexibility on ground clearing activities in Category 2 Habitat
Comment ID: BCWAMD4Doc24-08 Proposed Order Public Comment Certificate Holder 2026-01-14

Comment Summary
The certificate holder comments that the proposed restrictions on vegetation removal in Category 2 habitat during the critical period for ground nesting birds (Apr 15 to Sept 1) would preclude almost all work in those areas and would incentivize grading instead of mowing or drive and crush. The certificate holder requests that the Department make the following

changes to Section 5.0, Table 4 of the draft Comprehensive Solar Revegetation and Soil Management Plan included as Attachment D to the Proposed Order:

> ~~On or before April 15 of any year in which construction occurs within Category 2 habitat, all mowing, vegetation removal and/or ground disturbance associated with site preparation must be completed. No mowing, vegetation removal and/or ground disturbance associated with site preparation may occur within Category 2 habitat between April 15 through September 1.~~
>
> To the extent practical, mowing or other vegetation removal activities in Category 2 habitat will be scheduled to occur outside the critical period for ground nesting birds (April 15 – September 1), to avoid disturbing active nests. If mowing or other vegetation removal activities in Category 2 habitat are necessary between April 15 to September 1, the Certificate Holder shall hire a qualified biologist to conduct a clearance survey for nesting birds prior to vegetation removal. The Certificate Holder shall ensure that active nest sites identified during the clearance survey are flagged and marked as sensitive areas for avoidance on construction maps.

Department Evaluation
As explained on page 181 of the Proposed Order, the language in the draft Comprehensive Solar Revegetation and Soil Management Plan was intended to require the certificate holder to complete all initial mowing, vegetation removal and ground disturbance *associated with site preparation* in Category 2 habitat before April 15 or after September 1, and not to prohibit any subsequent vegetation management activities such as mowing. The location and extent of Category 2 habitat is isolated, within a distinct location expanding 20 acres.

The Department agrees that the flexibility requested by the certificate holder can be evaluated, but requests that the certificate holder provide reasons why, for the isolated area of Category 2 habitat, site preparation activities would not be able to planned and completed at time that would avoid the critical period for ground nesting birds.

Issue FW-04 (Certificate Holder); Recommended edits to Draft Habitat Mitigation Plan
Comment ID: BCWAMD4Doc24-22 Proposed Order Public Comment Certificate Holder-2 2026-01-30

Comment Summary
Certificate holder provides additional recommended edits to the Draft Habitat Mitigation Plan presented as Attachment F to the Proposed Order.

Department Evaluation
The Department reviewed the certificate holder's proposed changes to the draft Habitat Mitigation Plan and considers the changes not to modify the substantive intent of the plan, but rather clarify to ensure appropriate approach for evaluating success for noxious weed control

and shrub planting. The Department is reviewing the proposed changes with ODFW and will provide any agreed upon changes in the draft Final Order.

III.F. Historic, Cultural and Archaeological Resources (OAR 345-022-0090)

Issue HCA-01 (Certificate Holder): Supplement Record with Tribal Consultation Details
Comment ID: BCWAMD4Doc24-08 Proposed Order Public Comment Certificate Holder 2026-01-14

Comment Summary
Certificate holder requests additional details about its outreach to Tribes be incorporated into the Proposed Order.

Department Evaluation
The Department appreciates the certificate holder's efforts to engage with Tribes regarding this project; however, we do not agree with the proposed additions for the draft Final Order. The Tribes themselves have had the opportunity to provide input on the record, and as described under Issue HCA-02, the Confederated Tribes of the Warm Springs Reservation of Oregon have expressed concerns with recommended conditions of approval. In the draft of the Final Order the Department will make clarifying changes to Section III.K.1 explaining that additional information regarding the certificate holder's outreach efforts is provided in Exhibit K and comments on the Proposed Order.

Issue HCA-02 (Confederated Tribes of Warm Springs) Adequacy of archaeological monitoring and protective measures
Comment ID: BCWAMD4Doc24-09 Proposed Order Public Comment CTWS 2026-01-15

Comment Summary
CTWS express concerns that the certificate holder characterized archaeological monitoring as limited in scope and duration, focused on a single location, rather than implementing monitoring for all ground-disturbing activities within proximity to recorded cultural resources, as recommended. CTWS requests that the full suite of cultural resource protection measures identified through survey and consultation be implemented."

Department Evaluation
There are two proposed conditions that require avoidance and monitoring.

- Recommended Historic, Cultural, and Archaeological Condition 1 (GEN-HC-02) requires the certificate holder to avoid ground disturbing activities within 20-meters of all sites and isolates identified as eligible for, or likely eligible for, listing on the National Register of Historic Places during construction and operation of the proposed solar facility.
- Recommended Historic, Cultural, and Archaeological Condition 2 (GEN-HC-03) requires the certificate holder to submit a Cultural Resources Monitoring Plan demonstrating that an Oregon Qualified Archaeologist or Tribal Cultural Resource Monitor will be onsite during ground disturbing activities that would occur within the 20-meter buffer.

The Cultural Resources Survey Report provided as Attachment S-1 to RFA4 Exhibit S, includes several recommendations for monitoring, including the following:

> "GeoVisions recommends a monitoring plan and Inadvertent Discovery Plan be in place prior to Project construction, that an archaeological monitor who meets the standards of "qualified archaeologist" as defined by the existing site certificate be present during and observe all ground disturbing activities, as well as construction activities in and around recorded archaeological sites and isolates, as well as the probable location of the Oregon Trail, and that a tribal monitor is present for all construction activities within 20 meters of sites and isolates with precontact or culturally important material to ensure that no identified or unidentified archaeological sites are "excavat[ed], injur[ed], destroy[ed] or alter[ed]," (ORS 358.920(1)(a) to identify and to ensure that any subsurface archaeological objects, sites, and/or historic properties be properly identified and preserved over the course of Project construction activities and uphold the intent of the State of Oregon (ORS 358.910(2))." RFA4, Att S-1, pg. 102.

The Department acknowledges that the monitoring requirements of these conditions are more limited than what was recommended by Geovisions, which recommends that a Qualified Archaeologist be on site during all ground disturbing activities and that a Tribal Cultural Resource Monitor be present when ground disturbing activities occur within a 20-meter avoidance buffer. The Department believes the request to have a qualified archaeologist on site during ground disturbing activities is reasonable given the history of the area and potential for additional unidentified pre-contact sites or isolates to be present at the site documented in the cultural resources survey report. Accordingly, the Department requests that the certificate holder provide a draft Cultural Resources Monitoring Plan that is consistent with the recommendations included in the Geovisions Report. The Department may recommend additional changes to conditions based on the draft Plan and any replies on the record.

III.G. Public Services (OAR 345-022-0110)

Issue PS-01 (McCullough, Kathryn); Concerns about capacity of local fire responders to fight fire at energy facility
Comment ID: BCWAMD4Doc24-05 Proposed Order Public Comment McCulloughK-5 2026-01-06

Comment Summary
Commenter raises concerns about the adequacy of fire protection services at the site and potential risks to volunteer firefighters, particularly risks associated with fighting fire involving BESS components. Provides examples of risks, including toxic fumes, thermal runaway, and the ineffectiveness of water-based firefighting, in combination with challenging fire environment and rural setting.

Department Evaluation

In Section 4.4.7 of RFA4 Exhibit V, PGE explains that it would provide the North Sherman County Rural Fire Protection District with construction plans, schedules, and locations prior to the start of construction and that the Construction and Operations Wildfire Management Plans required under Wildfire Prevention and Risk Mitigation Condition 1 to 4 would address structural, BESS, and wildfire scenarios, and would include provider training on facility-specific hazards, established communication channels, site access, and firefighting resources. The Department will consider whether to include any changes to findings or conditions of approval associated with these plans in the draft Final Order based on all responses and replies on the record.

Issue PS-02 (McCullough, Kathryn); Concern that local fire responders do not have adequate training to respond to fire at energy facility or BESS
Comment ID: BCWAMD4Doc24-05 Proposed Order Public Comment McCulloughK-5 2026-01-06

Comment Summary
Ms. McCullough provides specific recommendations for improving training and recruitment of volunteer firefighters:

- Provide specialized (NFPA-855 compliant) training to local firefighters for BESS response.
- Fund and/or create a dedicated BESS response unit within existing RFPDs.
- Conduct annual drills at BESS site, simulating windy conditions.
- Conduct outreach to improve volunteer recruitment/retention.
- Conduct community outreach to increase awareness/transparency around BESS Safety Issues.
- Require facility staff to have BESS-fire response capability until firefighters arrive.
- Provide insurance coverage and financial incentives to volunteer firefighters that respond to BESS fires.
- Supply RFPDs with SCBA, foam kits, and hazmat suits
- Create a community fund to cover:
    - Emergency payouts for injured/killed volunteers' families.
    - Training and equipment upgrades.
    - Community wildfire prevention (e.g., vegetation control).

Department Evaluation
As described in the Proposed Order Section III.M, the certificate holder provided a record of correspondence documenting coordination with the North Sherman Rural Fire Protection District (NSRFPD) Fire Board and Chief Jacob Burbank indicating that NSRFPD raised several concerns about access considerations, training, and equipment needed to address fire risk associated with the facility components proposed in RFA4. In response the certificate holder indicated that they intend to provide annual training that would cover response procedures, the risks associated with PV and BESS systems, and protocols for both fire and non-fire emergencies. Training would be provided by Coffman Engineers.

Some of the mitigation proposed by Ms. McCullough, such as providing insurance coverage, financial incentives, and emergency payouts to volunteer firefighters that respond to BESS fires, may be outside of the scope of the Council's authority, but others, including providing training and equipment needed to respond to fires at the site would be established under the Wildfire Mitigation Plans required under recommended Wildfire Prevention and Risk Mitigation Conditions 1 to 4. The Department will consider whether to include any changes to findings or conditions of approval associated with these plans in the draft Final Order based on all responses and replies on the record.

III.H. Wildfire Prevention and Risk Mitigation (OAR 345-022-0115)

Issue WF-01 (McCullough, Kathryn); Concerns about burn probability data in fire risk analysis
Comment ID: BCWAMD4Doc24-04 Proposed Order Public Comment McCulloughK-4 2026-01-05

Comment Summary
Ms. McCullough raises concerns about the adequacy of the wildfire risk analysis provided in RFA4, Exhibit V. Specifically, she takes issue with the estimate of burn probability in Section 2.1.5. of Exhibit V.

Department Evaluation
Commenter takes issue with the description of burn probability in RFA4 Exhibit V, stating "high burn probability is much higher than 66%, but 66% is very high, especially in an area that already has 6-10 fires in a normal year…"

Ms. McCullough did not identify a recommended finding of fact, conclusion of law or condition of approval identified in the Proposed Order to which she objects but instead takes issue with evidence in the record provided to support the evaluation of wildfire risk at the site. In preliminary RFA4 Exhibit V, the certificate holder noted that 66 percent of the Solar Micrositing Area was rated with "a High to Very High (1-in-100 to 1-in-50) burn probability." In the complete RFA4, this estimate was revised to 98 percent of the wildfire analysis area based on the refined Solar Micrositing Area. The Department notes that the revised estimate is derived from the 2023 Pacific Northwest Quantitative Wildfire Risk Assessment (McEvoy, Andy; Dunn, Christopher; Rickert, Ian), and not the certificate holder's own data or methods.

The Department generally considers the Pacific Northwest Quantitative Wildfire Risk Assessment to be a reputable source of data for wildfire risk, and as noted above, the revised estimate that resulted from its use includes a larger portion of analysis area than the initial estimate. As a result, the Department does not intend to make changes in the draft Final Order based on this comment.

Issue WF-02 (McCullough, Kathryn); Concerns about use of climate normal for fire risk analysis
Comment ID: BCWAMD4Doc24-04 Proposed Order Public Comment McCulloughK-4 2026-01-05

Comment Summary
Ms. McCullough objects to use of "climate normal" to reflect temperature data of site in RFA4 Exhibit V Section 2.1.4 and Table V-4. Ms. McCullough asserts that use of the climate normals "effectively lower the high temperatures" experienced in the area. As an example, the she provides data showing high temperatures of 101 – 103° F measured at the Arlington Weather Station in July 2018, compared to the 1991-2020 Average (normal) maximum temperature for July of 88.9° F at the Arlington Station.

Department Evaluation
The Department believes that climate normals, published by the National Oceanic and Atmospheric Administration in accordance with global climate data reporting standards, are a reputable source of climate data. As an average, the data does not reflect extreme temperatures that may occur in a given year, but they still provide valuable data on seasonal conditions at the site that can be used to inform the overall risk analysis. The Department also notes that the draft Construction Wildfire Mitigation Plan also accounts for extreme weather events by imposing work restrictions and additional requirements during fire weather watches and red flag warning events. As such, no substantive changes are recommended but the Department will consider including clarifying changes in the draft Final Order explaining the limitations on the climate normal data.

Issue WF-03 (McCullough, Kathryn); Concerns about fuel models used for fire risk analysis
Comment ID: BCWAMD4Doc24-04 Proposed Order Public Comment McCulloughK-4 2026-01-05

Comment Summary
Ms. McCullough objects to fuel models used in RFA4 Exhibit V Section 2.1.2. She notes that Fuel Models 102 and 93 used for agricultural lands in the site do not reflect fallow conditions at the site.

Department Evaluation
In the complete RFA4, the certificate holder notes that 93 percent of the proposed solar Micrositing Area is described by Fuel Model 102 or 242, which reflect low load, dry climate grasses and burnable wheat fields, respectively. These fuel models are derived from data from the Community Wildfire Protection Plan (CWPP) Planning Tool (Oregon Explorer 2025), which in turn, is based on the 2023 Pacific Northwest Quantitative Wildfire Risk Assessment (McEvoy, Andy; Dunn, Christopher; Rickert, Ian).

The Department generally considers the Pacific Northwest Quantitative Wildfire Risk Assessment to be a reputable source of data for wildfire risk. Accordingly, the Department does not intend to make changes in the draft Final Order based on this issue.

Issue WF-04 (Certificate Holder); Request for flexibility in road design standards for roads not needed for fire access
Comment ID: BCWAMD4Doc24-22 Proposed Order Public Comment Certificate Holder-2 2026-01-30

Comment Summary
Certificate holder requests clarification of design standards for internal access roads. States that exterior roads and other roads designated for emergency access will be designed in accordance with 2022 Oregon Fire Code Section 503. Certificate holder requests that other interior roads not intended for fire access not be required to comply with Oregon Fire Code Standards.

Department Evaluation
The Department appreciates the clarification of conflicting statements in RFA4. To assist in the evaluation of this issue, the Department requests the certificate holder provide the site plan showing the designated emergency access roads and documentation of any additional correspondence with the North Sherman Rural Fire Protection District other than what was included in RFA4 Attachment U-1.

Issue WF-05 (McCullough, Kathryn); Recommendations for BESS design criteria to minimize fire risk
Comment ID: BCWAMD4Doc24-05 Proposed Order Public Comment McCulloughK-5 2026-01-06

Comment Summary
Ms. McCullough recommends specific design criteria that could be incorporated into the design of the BESS to minimize fire risk. Specifically, the commenter recommends:

- That BESS enclosures be made of metal or fiberglass with steel reinforcements to resist turbine debris impacts
- That windbreaks (e.g., berms, fences) be installed around BESS components to reduce debris and ember spread
- That multiple generators/solar-powered cooling units be installed to prevent overheating.

Department Evaluation
The Department will evaluate these recommendations after considering the information provided by the certificate holder in its response to this comment.

Issue WF-06 (Certificate Holder); Request for clarification of setback requirement
Comment ID: BCWAMD4Doc24-22 Proposed Order Public Comment Certificate Holder-2 2026-01-30

Comment Summary
Certificate holder requests clarification that perimeter fencing must be set back 50 feet from property line of *non-participating* landowner.

Department Evaluation
The Department agrees to make the requested change in Section III.N.1 of the draft Final Order and Section 4.1.3 of the draft Construction Wildfire Mitigation Plan.

Issue WF-07 (Multiple Commenters); Concerns about adequacy of 50-foot fire setbacks
(Commenters include: Kathryn McCullough; Kevin McCullough; Colton McCullough; Sherman County Soil and Water Conservation District, Whitman, A.; Irene Gilbert)
Comment ID: BCWAMD4Doc25-03 Proposed Order Public Hearing Transcript 2026-01-15

Comment Summary
Commenters raise concerns with the adequacy of 50-foot setbacks imposed in recommended Land Use Condition 1. Suggests that larger setbacks may be needed.

Department Evaluation
The commenters have identified an issue related to a condition of approval but have not provided sufficient evidence to 1) support the claim that the 50-foot setback does not provide adequate protection from wildfire or access to emergency responders; or 2) support the imposition of a greater setback. The Department will consider any additional evidence provided in the applicant's response and subsequent replies regarding this issue.

Issue WF-08 (Multiple Commenters); Concern about adequacy of 20-foot fuel breaks
(Sherman County Soil and Water Conservation District, Irene Gilbert)
Comment ID: BCWAMD4Doc25-03 Proposed Order Public Hearing Transcript 2026-01-15

Comment Summary
Commenters raise concern about adequacy of 20-foot fire break around the perimeter of the facility to stop fire from spreading from the facility. Recommends additional research is needed. Sherman County Soil and Water Conservation District suggests that 30-foot is minimum recommended by NRCS. Ms. Gilbert recommends that 30-feet may not be adequate, and that additional research is needed.

Department Evaluation
The commenters have identified an issue related to a condition of approval but have not provided sufficient evidence to 1) support the claim that the 20-foot fuel break does not provide adequate protection from wildfire; or 2) support the imposition of a greater setback. The Department is also not clear on what NRCS standard was referenced or how it is applied to utility facilities. The Department will consider any additional evidence provided in the applicant's response and subsequent replies regarding this issue.

Issue WF-09 (McCullough, Colton); Support for recommended vegetation maintenance standards for wildfire season
Comment ID: BCWAMD4Doc25-03 Proposed Order Public Hearing Transcript 2026-01-15

Comment Summary
Mr. McCullough supports recommendation that vegetation be maintained at 1 to 3 inches during fire season to mitigate fire risk. The recommended finding in the Proposed Order, pg. 233, for a 1 to 3 inch vegetation height is not reflected in the draft Comprehensive Solar

Revegetation and Soil Management Plan. He requests that the requirement be binding through construction and operation.

Department Evaluation
The Department is evaluating several comments related to the recommendation that vegetation within the solar facility and other vegetation clearance areas be maintained at 1 to 3 inches during fire season to mitigate fire risk. Mr. McCullough recommends the recommendation be implemented throughout the life of the facility. The Sherman County Weed Control District recommends that the vegetation height standard be increased to 4 to 8 inches to support erosion control and enhance viability of bunchgrass species. The certificate holder requests that the height standard be increased to 10 to 12 inches year-round.

The Department will continue to evaluate these recommendations, along with any additional evidence submitted in replies, to identify vegetation management standards that provide adequate fuel management to minimize wildfire risk while maintaining appropriate conditions for beneficial vegetation.

Issue WF-10 (Certificate Holder); Objection to Vegetation Maintenance Standards for Wildfire Season
Comment ID: BCWAMD4Doc24-22 Proposed Order Public Comment Certificate Holder-2 2026-01-30

Comment Summary
Certificate holder objects to the Department's recommendation that vegetation be maintained at 1 to 3 inches during fire season to mitigate fire risk. Requests that the vegetation height requirements be set to limit a height of 10 to 12 inches year-round.

Department Evaluation
The Department is evaluating several comments related to the recommendation that vegetation within the solar facility and other vegetation clearance areas be maintained at 1 to 3 inches during fire season to mitigate fire risk. Mr. McCullough recommends the recommendation be implemented throughout the life of the facility. The Sherman County Weed Control District recommends that the vegetation height standard be increased to 4 to 8 inches to support erosion control and enhance viability of bunchgrass species. The Certificate Holder requests that the height standard be increased to 10 to 12 inches year-round.

The Department will continue to evaluate these recommendations, along with any additional evidence submitted in replies, to identify vegetation management standards that provide adequate fuel management to minimize wildfire risk while maintaining appropriate conditions for beneficial vegetation.

Issue WF-11 (Certificate Holder); Request to remove requirement for drip can with fire suppression equipment.
Comment ID: BCWAMD4Doc24-22 Proposed Order Public Comment Certificate Holder-2 2026-01-30

Comment Summary
Certificate holder requests that the Department remove a requirement in the Construction WMP that a 5-gallon Drip Can be carried in maintenance vehicles and stored on-site at the O&M building. Certificate holder clarifies that the project would not conduct activities requiring use of drip cans, and that workers would not have adequate experience to use drip cans.

Department Evaluation
Inclusion of drip cans in the draft Construction WMP was a representation made by the certificate holder, versus a recommended requirement. Given that the certificate holder seeks to clarify equipment that would not be needed or appropriate for the site, the Department agrees to remove the requirement as requested.

Issue WF-12 (McCullough, Kathryn; Gilbert, Irene); Concern about lack of availability of Operational Wildfire Mitigation Plan.
Comment ID: BCWAMD4Doc25-03 Proposed Order Public Hearing Transcript 2026-01-15; BCWAMD4Doc24-06 Proposed Order Public Comment McCulloughK-6 2026-01-09

Comment Summary
Commenters raise concern about lack of availability of Operational Wildfire Mitigation Plan for review as part of Proposed Order.

Department Evaluation
Under OAR 345-022-0115(1)(b), the Council must find that a proposed facility will be designed, constructed, and operated in compliance with a Wildfire Mitigation Plan approved by the Council. The rule sets forth the requirements that must be met in the plan. While it is preferred that draft plans for both the construction and operations phases of a facility be included in an application or request for amendment, it is not required by the standard. The Department has described the requirements that must be satisfied in Section III.N of the Proposed Order.

The Department will not make any revisions in the draft of the Final Order based on this comment because the comment has not been made with sufficient specificity – *i.e.*, the commenter does not "[i]dentify the recommended findings of fact, conclusions of law or conditions of approval identified in the proposed order to which they object." OAR 345-027-0367(7), (8).

III.I. Siting Standards for Transmission Lines (OAR 340-035-0090)

Issue TL-01 (Certificate Holder); Request for additional flexibility in transmission line siting
Comment ID: BCWAMD4Doc24-08 Proposed Order Public Comment Certificate Holder 2026-01-14

Comment Summary
Certificate holder requests changes to recommended Amended Condition 119 to provide additional flexibility in transmission line siting, as presented in red underline, strikeout font below:

> ~~(119) OAR 345-027-0023(5): If the proposed energy facility is a pipeline or a transmission line or has, as a related or supporting facility, a pipeline or transmission line, the Council shall specify an approved corridor in the site certificate and shall allow t~~ The certificate holder ~~to~~ shall construct the ~~pipeline or~~ 230-kV transmission line connecting the Biglow Canyon Substation to the Solar Substation ~~anywhere~~ within a 150-foot corridor, as identified in the final site design ~~presented in Figure 2 of the Amended Site Certificate identified in the final site design the corridor, subject to the conditions of the site certificate. If the applicant has analyzed more than one corridor in its application for a site certificate, the Council may, subject to the Council's standards, approve more than one corridor.~~

Department Evaluation
Under OAR 345-025-0010(5), the Council must specify an approved corridor for any transmission line approved in a site certificate. The Department disagrees with the certificate holder's proposed changes. The certificate holder only included one proposed corridor for the 600-foot segment of 230 kV transmission line, which was presented in RFA4 Figure 2.2. If the certificate holder wishes to change the alignment of the transmission line it must present the alternate corridors so that they can be evaluated for compliance with applicable laws, rules and standards.

III.J. Noise Control Regulation (OAR 340-035-0035)

Issue NC-01 (Certificate Holder) Requests Proposed Order Table 26 be revised to add NSR13 and reference to RFA Exhibit Y Table Y-7.
Comment ID: BCWAMD4Doc24-08 Proposed Order Public Comment Certificate Holder 2026-01-14

Comment Summary
Certificate holder requests for Table 26, *Modeled Operational Noise of the Facility, As Amended*, to be revised to include NSR 13, and requests for Table 26 to include Table Y-7 as a source included in the noise modeling.

Department Evaluation
RFA4 Exhibit Y includes Tables Y-6 and Y-7. Both tables include 6 NSRs, including NSR 13. The data from Tables Y-6 and Y-7 are represented in the Proposed Order Table 26, but NSR is

omitted and reference to RFA4 Exhibit Y Table Y-7 is also omitted, as indicated by the certificate holder.

Changes to Proposed Order Table 26 will be incorporated into the draft Final Order to be consistent with RFA4 Exhibit Y, as requested by certificate holder.

Issue NC-02 (Certificate Holder) Requests revisions to recommended Noise Control Condition 2 (PRE-NC-02) allowing for general waiver versus solar specific
Comment ID: BCWAMD4Doc24-22 Proposed Order Public Comment Certificate Holder-2 2026-01-30

Comment Summary
Certificate holder requests that Noise Control Condition 2 (PRE-NC-02) be amended to allow any waivers needed to demonstrate compliance be general, rather than specifically reference the solar facility, consistent with the fact that the noise analysis is based on the facility as a whole.

Department Evaluation
As presented in Section IV.A Noise Control Regulation, the existing, operational wind facility relies on noise waivers to comply with the antiambient degradation standard. The addition of the facility components proposed in RFA4 would not change or increase the predicted exceedances of the existing, operational wind facility; however, the facility, as amended, must demonstrate compliance with the regulation (i.e., obligation to have an executed waiver where exceedances occur).

To ensure that the facility maintains compliance but is not obligated to update waivers solely to refer to a wind and solar facility, the Department agrees to modify recommended Noise Control Condition 2, as provided below in red, underline/strikeout, to be able to accept noise waivers that are applicable to the "facility." The intent of the condition is to receive waivers that align with the NSR ID's and property owners with exceedances identified in RFA4 for compliance verification.

> **Recommended Noise Control Condition 2 (PRE-NC-02)**: Prior to construction of the solar facility, the certificate holder must submit to the Department copies of executed legally effective easement(s) or real covenant(s) for all Noise Sensitive Properties impacted by the ~~solar~~ facility with noise exceedance. ~~The easement or covenant must authorize the solar energy facility to increase the ambient statistical noise levels, L10 or L50, on the sensitive property by more than 10 dBA at the appropriate measurement point.~~
> [PRE-NC-01; OAR 340-035-0035(1)(b)(B)(iii)~~(III)~~; Final Order on AMD4]

III.K. Water Rights (OAR Ch. 690)

Issue WR-01 (Certificate Holder); Requests Revisions to recommended Amended Water Rights Condition 1 (PRE-WR-01) to Clarify Well Log Submission Timing
Comment ID: BCWAMD4Doc24-08 Proposed Order Public Comment Certificate Holder 2026-01-14

Comment Summary
Certificate holder requests to modify the language of recommended Water Rights Condition 1 (PRE-WR-01) to clarify that the obligation to submit a well leg to Oregon Water Resources Department (OWRD) applies within 30-days of well construction rather than prior to well construction. Certificate holder describes that the requested changes are consistent with ORS 537.765.

Department Evaluation
The Department agrees with the certificate holder as ORS 537.765(2) states:

> *(2) The business or activity of constructing new wells or altering, abandoning or converting existing wells is declared to be a business or activity affecting the public welfare, health and safety. In order to enable the state to protect the welfare, health and safety of its residents, any licensed or permitted person shall keep a log of each well constructed, altered, abandoned or converted and shall electronically file a certified copy of the log with the Water Resources Department within 30 days after the completion of the construction, alteration, abandonment or conversion.*

Based on the above statutory language, in the draft Final Order the Department will include the condition language changes, as presented in red, underline/strikeout font below, as requested.

> **Recommended Water Rights Condition 1 (~~PRE~~CON-WR-01)**
> No later than 30 days after completing construction ~~prior to construction~~ of any new well, the certificate holder shall provide the Department a copy of the map, well log and all other information it provided to OWRD pursuant to ORS 537.545 and ORS 537.765 to qualify for an exempt ground water use for any onsite exempt wells.
> [Final Order on AMD4]

Issue WR-02 (Certificate Holder); Requests Revisions to recommended Amended Condition 75 (OPR-WR-01) on Applicability of Groundwater Usage Monitoring
Comment ID: BCWAMD4Doc24-08 Proposed Order Public Comment Certificate Holder 2026-01-14

Comment Summary
Certificate holder requests for recommended Amended Condition 75 (OPR-WR-01) to be amended to clarify that onsite well usage monitoring will not be required until a new well is installed, at which point meters would be installed.

Department Evaluation

Recommended Amended Condition 75 (OPR-WR-01) is intended to limit onsite well groundwater usage to 5,000 gallons per day and establishes a requirement for daily monitoring and usage recordkeeping. The recommended amended condition requiring use of flow meters to monitor combined water usage is intended to apply if new well(s) are constructed to support construction and operation of the facility components proposed in RFA4. Therefore, the Department agrees with the certificate holder and recommends that the applicability of the monitoring requirements be clarified. In the draft Final Order, the Department will include the condition language changes, as presented in red, underlined font below.

Recommended Amended Condition 75 (OPR-WR-01)

a. For any onsite exempt wells, ~~Before beginning operation of the facility, the certificate holder shall have in operation a well suitable for delivering water,~~ combined water usage shall not exceed~~ing~~ 5,000 gallons per day~~,~~ for domestic use at the facility's O&M buildings and~~, provided the rate of extraction would not exceed 5,000 gallons per day,~~ solar panel and blade-washing activities.
b. If new exempt well(s) are constructed for the solar facility, certificate holder shall install flow meters on the existing and new well(s); monitor the volume of groundwater used from all onsite wells on a daily basis; maintain a record of such use; and, make the monitoring records available to the Department upon request. ~~The certificate holder shall not change the source of water for the facility's domestic use without prior Council approval.~~

[Final Order on AMD4]

Issue WR-03 (Certificate Holder); Requests Revisions to recommended Amended Condition 75 (OPR-WR-01) on Applicability of 5,000 gallon/day limit

Comment ID: BCWAMD4Doc24-22 Proposed Order Public Comment Certificate Holder-2 2026-01-30

Comment Summary

Certificate holder seeks clarification that the 5,000 gallon per day limitation on groundwater usage only applies to onsite exempt wells.

Department Evaluation

The Department confirms that recommended Amended Condition 74 (OPR-WR-01) is only applicable to exempt wells. In the draft Final Order, the Department will add reference to "exempt wells" to the condition, as presented in the Department Evaluation of Issue WR-02.

Subject:	ODOE Responses to Public Comments on Proposed Order on Request for Amendment 4 of the Site Certificate for the Biglow Canyon Wind Farm.
Attachments:	BCWAMD4Doc26-01 ODOE Public Comment Evaluation Cover Letter and Response 2026-02-12.pdf; BCWAMD4 Amendment Comment Review Process Doc Navigation Help Cover Letter 2026-02-06.pdf

Hello,

You are receiving this message because you provided comments on the Proposed Order on Request for Amendment 4 of the Site Certificate for the Biglow Canyon Wind Farm. The Department's responses to all comments provided on the record are attached (Department Response). In the Department's Response, we have included an explanation of how the document is organized, and how to locate the issues identified by the Department as having been raised in your comments. The certificate holder, Portland General Electric Company, will be providing its responses directly to commenters by February 13, 2026, as required by OAR 345-027-0367.

The Department has also created an OneDrive folder that includes all copies of all comments provided on the Proposed Order. The attached "Amendment Comment Review Process Doc Navigation Help Letter" provides more information on how to access the OneDrive, the Department's file management system, and how to navigate PDF documents. The OneDrive can be accessed via the links in this email or by accessing the Biglow Canyon Wind Farm Webpage.

Please "reply all" to this email message when providing any replies to either the Department's or certificate holder's responses to your comments. Reply and sur-reply documents from the certificate holder and participants can also be uploaded directly to the OneDrive.
Replies must be received by **5:00 pm on February 27, 2026**, to be included in the record. Participants to the public comment process may request more time to submit their replies. The Council Chair may grant a requested extension on a showing of good cause. Please note the Department will only consider replies to issues raised in your own comments in preparing the draft Final Order.

Please note, I will be out of the office from February 13 to February 23, 2026. If you have questions about the process or how to submit replies to the Department or certificate holder's responses to your comments during this timeframe, please contact Sarah Esterson at sarah.esterson@energy.oregon.gov or call (503) 559-9218.

Thank you,

OREGON DEPARTMENT OF ENERGY

Subject: Biglow Canyon RFA4 Response to Certificate Holder Response to Public Comment - von Borstel
Attachments: BIGL RFA4_Comment Letter to Alan von Borstel_02132026.pdf

Dear Mr. von Borstel,

Thank you for your comments regarding the Proposed Order on Request for Amendment 4 of the Biglow Canyon Wind Farm Site Certificate. As required by Oregon Administrative Rule 345-027-0367(8)(a), please find attached Portland General Electric's and the project developer, BrightNight's, written responses to your comments. Yesterday you should have received an email from Christopher Clark, the Oregon Department of Energy (the Department) Senior Siting Analyst for this amendment. The email contains the Department's Responses to comments and, should you choose to, directions for how to reply to our comment responses. Please refer to that email for guidance.

Thank you.

Re: Biglow Canyon Wind Farm Request for Amendment 4 – Response to Comments on Proposed Order (BCWAMD4Doc24-11)

Dear Mr. Von Borstel,

The Oregon Department of Energy (ODOE) shared with us your comment letter on the NOI for the Speedway Energy Facility and indicated that you also wanted to include the comments in the record of the Proposed Order on the Request for Amendment 4 (RFA 4) of the Biglow Canyon Wind Farm (BCWF or Facility) Site Certificate. PGE and the project developer BrightNight (BN) recognize the importance of dryland wheat production to Sherman County and values your perspective on agricultural viability, impacts to wildlife, and wildfire risk as a community member and past president of the Oregon Wheat Growers League.

OAR 345-027-0367(8) requires PGE to respond to all comments that are made with "sufficient specificity," as that term is defined in OAR 345-027-0367(7)(a). We note that your comments do not necessarily meet that standard but are valuable to inform the process, and we offer this response to the issues you raised in your letter, even if none specifically referenced Biglow Solar. The responses below are organized by the interpretations of your comments received and are further identified with the same issue identification number provided in Table 1: List of Issues and Commenters, in the Oregon Department of Energy's Response to Comments document dated February 12, 2026.

1. Impacts on Dryland Wheat Lands (LU-06)

We recognize your concerns regarding the conversion of agricultural lands to renewable energy development and hope the robust Community Investment Plan (CIP) contained in the Proposed Order helps with those concerns as they may relate to Biglow Solar. The CIP was developed based on outreach with agricultural organizations including the Oregon Wheat Commission, Mid-Columbia producers, and regional grain cooperatives to better understand grower perspectives on agricultural mitigation, soil health, and wildfire risk. The CIP proposes mitigation projects that will offset the impacts of removing land from dryland wheat production, as described in the Agricultural and Fiscal Impact Analysis included as BCWF RFA4 Attachment K-2. The mitigation dollars proposed in the CIP are intended to confirm that there is no negative impact on the Sherman County agricultural economy. Further, landowner participation in renewable energy development in Sherman County provides an opportunity to diversify finances and invest additional capital in their farming businesses, as described in the Biglow record. Finally, the Facility will be decommissioned at the end of its useful life, and the land will be restored and

returned to agricultural use. The Proposed Order imposes a financial assurance obligation to guarantee that the Facility is successfully decommissioned, and the site is restored.

2. Public Safety and Wildfire Risk (LU-06)

You noted Sherman County's elevated wildfire risk and expressed concern regarding wildfire risk mitigation, the development and use of wildfire mitigation plans, and the adequacy of buffers to prevent wildfire spread. Wildfire mitigation plays a critical role in how the proposed Biglow solar facility is designed, constructed, and operated.

The wildfire mitigation measures outlined in the Construction Wildfire Mitigation Plan (WMP) included as Proposed Order Attachment G, the forthcoming Operations WMP, and the vegetation management measures outlined in the Comprehensive Solar Revegetation and Soil Management Plan (Proposed Order Attachment D) are intended to protect agricultural operations, nearby homes, and natural areas in Sherman County. Dry vegetation, high summer temperatures, and windy conditions increase fire risk, so these plans include soil and vegetation management to reduce the introduction and spread of weeds, maintenance buffers around the site perimeter and along roads to serve as firebreaks.

In closing, PGE and BN appreciate your comments and hope these responses help alleviate concerns as they may relate to the Biglow Solar project. PGE and BN welcome any additional questions you may have regarding the project.

Sincerely,

Lenna Cope

Re: Biglow Canyon Wind Farm Request for Amendment 4 – Response to Comments on Proposed Order (BCWAMD4Doc25-03-P5)

Dear Mr. Higgins,

Portland General Electric (PGE) and the project developer BrightNight (BN) appreciate your oral comments regarding the Oregon Department of Energy's Proposed Order on the Request for Amendment 4 of the Biglow Canyon Wind Farm Site Certificate.

PGE and BN appreciate your perspective and expertise on the topic of agrivoltaics systems. We value your insight on ways to integrate solar energy production into agricultural communities while mitigating potential conflict between renewable energy and agricultural production. In your comments, you assert that a strong agricultural system depends on quality land and soil, skilled farmers, access to supplies and markets, and flexible rules that let farmers adapt to change. We agree with your assessment about the many factors that contribute to the strength of an agricultural system and appreciate your acknowledgment of our efforts to respectfully balance farming needs with renewable energy development.

We appreciate your comments and look forward to continued coordination as the project moves forward.

Sincerely,

Lenna Cope

Re: Biglow Canyon Wind Farm Request for Amendment 4 – Proposed Order Response to Comment (BCWAMD4Doc25-03-P3)

Dear Mr. McCullough,

Portland General Electric (PGE) and the project developer BrightNight (BN) appreciate your comments regarding the Proposed Order on Request for Amendment 4 (RFA 4) of the Biglow Canyon Wind Farm (BCWF) Site Certificate. Oregon Administrative Rule (OAR) 345-027-0367(8) requires PGE to respond to all comments that are made with "sufficient specificity," as that term is defined in OAR 345-027-0367(7)(a). We note that your comments may not necessarily meet that standard but are valuable to inform the process and offer the following response.

The responses below are organized by the interpretations of your comments received and are further identified with the same issue identification number provided in Table 1: List of Issues and Commenters in the Oregon Department of Energy's Response to Comments document dated February 12, 2026. As we have previously committed, PGE and BN are dedicated to the responsible management of vegetation and soil health at the site, as well as minimizing fire risk. We recognize that these issues are closely interconnected and have been consistently identified by both you and the broader community as primary concerns.

1. Vegetation Management and Fire Prevention (WF-09, WF-12, SP-04)

The Proposed Order provides a comprehensive vegetation and fire risk management structure from construction through operational phases of Biglow Solar. The Oregon Department of Energy (ODOE), recognizing neighbor concerns, recommended conditions of approval that go above and beyond other existing site certificates. PGE and BN provided comments to ODOE on the plans and conditions contained in the Proposed Order to ensure that there was common understanding of the requirements and that the plans and conditions contained best practices, informed by local stakeholders.

You requested in your testimony that the vegetation height and clearance recommendations be implemented into the Operational Wildfire Mitigation Plan (WMP). These clearances are documented in the Operations and Maintenance Framework Plan (Proposed Order, Attachment C) and the Comprehensive Solar Revegetation and Soil Management Plan (Proposed Order, Attachment D) that are required to be finalized per Site Certificate conditions PRO-OE-01 and PRE-SP-01, respectively. The Draft Construction WMP (Proposed Order, Attachment G) also includes these vegetation management requirements; Condition PRE-WF-01 requires finalization of the Construction WMP prior to construction. The site-specific Operations WMP currently under development for the Biglow Solar facility will also incorporate these requirements and will be

submitted to ODOE for review and approval prior to beginning operation of the solar facility, per PRO-WF-01.

You may have seen the comment in the record from the Sherman County Weed District (BCWAMD424-15) stating that maintaining vegetation at 1 to 3 inches does not appear feasible if erosion control is a priority. The Weed Supervisor recommended, instead, a grass height of 4 to 8 inches during the dry season. PGE and BN recognize the Weed District's local expertise regarding appropriate vegetation height standards; we believe this input contributes meaningfully to the broader discussion regarding wildfire risk reduction, erosion control, and long-term vegetation health.

To address your concerns about accountability, the Proposed Order contains conditions that have greater severity. Conditions of approval require compliance and accountability with the requirements of these plans. For example, CON-SP-02 requires all work during and following construction to be conducted in compliance with the Comprehensive Solar Revegetation and Soil Management Plan, and OPR-SP-06 requires adherence to the plan during operation of the facility and includes reporting requirements as outlined under OPR-OE-01. CON-WF-01 requires onsite contractors and employees to adhere to the Construction WMP during construction, and OPR-WF-01 requires adherence to the Operational WMP during operation of the facility.

We also want Biglow Solar to be an asset to the community by helping with fire prevention and response by providing 20-foot fire breaks around the perimeter of the Solar Micrositing Area and 10 feet on each side of all roads; emergency vehicle access roads that are 20-feet wide; graveled areas around O&M buildings, substations, and battery energy storage system (BESS) with no vegetation; a 50-foot setback from all non-participating landowner properties; and placing water tanks at three locations around the site to support firefighting efforts.

The proposed BESS uses advanced fire safety and containment systems designed to detect, isolate, and neutralize potential thermal events before they can spread. These systems are built with multiple layers of protection, including thermal sensors, automatic shutdown systems, and dedicated containment compartments to prevent propagation. The units are UL 9540A tested, which means they've been stress-tested under extreme conditions to meet national safety standards. The BESS system design uses a central BESS yard where all batteries will be housed and uses containerized batteries, each with monitoring and alarming capabilities to support preventative measures during operation. The BESS yard will also be graveled and designed to maintain non-combustible clear zones, eliminating available fuel and limiting fire spread potential.

Our communities' concerns are very important to us, and we are committed to operating this facility in a way that reflects our shared interest in protecting people, property, and the landscape we all value.

Please reach out if you have questions or would like to discuss further. As previously discussed, there will be continued engagement of the community and neighbors as this project moves forward.

Sincerely,

Lenna Cope

Re: Biglow Canyon Wind Farm Request for Amendment 4 – Response to Comments on Proposed Order (BCWAMD4Doc25-03-P7)

Dear Mr. Hilderbrand,

Portland General Electric (PGE) and project developer BrightNight (BN) appreciate your oral comments regarding the Oregon Department of Energy's Proposed Order on the Request for Amendment 4 of the Biglow Canyon Wind Farm Site Certificate.

PGE and BN appreciate your perspective as a fourth-generation farmer in Sherman County and recognize the challenges facing many family farms today. We value your insight into how projects like the Biglow Solar facility can provide a stable, predictable source of income that makes farming a more sustainable career. PGE and BN agree that renewable energy development can support a strong agricultural system and contribute to the economic diversification and long-term resilience of Sherman County, and we value your support for this project.

We appreciate your comments and look forward to continued coordination as the project moves forward.

Sincerely,

Lenna Cope

Re: Biglow Canyon Wind Farm Request for Amendment 4 – Response to Comments on Proposed Order (BCWAMD4Doc24-16)

Dear Mr. Reid,

The Oregon Department of Energy (ODOE) provided Portland General Electric (PGE) and project developer BrightNight with your January 29, 2025, letter submitted on behalf of Donald Hilderbrand regarding the Proposed Order on the Request for Amendment 4 (RFA 4) of the Biglow Canyon Wind Farm (Facility) Site Certificate. We appreciate the opportunity to respond. While your letter does not raise comments specific to the proposed addition of solar photovoltaic generation and battery energy storage to the existing Facility, we offer the following clarification for the record.

As described in RFA 4, submitted on December 16, 2025, and reflected in the Proposed Order (Section III.E.1), the proposed solar and battery facilities are located entirely on lands owned by PGE and Scharf, R & A LLC. No portion of the proposed facilities described in RFA 4, or associated infrastructure, is planned on property owned by Mr. Hilderbrand, nor does the request contemplate the inclusion of non-participating landowners' property.

Thank you for your time and participation in this process.

Sincerely,

Lenna Cope

Re: Biglow Canyon Wind Farm Request for Amendment 4 – Response to Comments on Proposed Order (BCWAMD4Doc25-03-P9)

Dear Ms. Gilbert,

Portland General Electric (PGE) and project developer BrightNight (BN) appreciate your oral comments regarding the Oregon Department of Energy's (ODOE's) Proposed Order on the Request for Amendment 4 (RFA 4) of the Biglow Canyon Wind Farm (BCWF or Facility) Site Certificate. OAR 345-027-0367(8) requires PGE to respond to all comments that are made with "sufficient specificity," as that term is defined in OAR 345-027-0367(7)(a). We note that your comments do not necessarily meet that standard but are valuable to inform the process.

The responses below are organized by the interpretations of your comments received and are further identified with the same issue identification number provided in Table 1: List of Issues and Commenters, in the Oregon Department of Energy's Response to Comments document dated February 12, 2026. PGE and BN understand your testimony to focus on two primary topics: noxious weed control and wildfire risk, which are captured on ODOE's Issues List under LU-07, WF-07, WF-08, and WF-12.

1. Vegetation Management and Weed Control

You expressed concern regarding vegetation management, noxious weed control, and not placing an undue burden on neighboring landowners. PGE and BN recognize the importance of proper soil and vegetation management to maintain native vegetation for watershed health, prevent the spread of noxious weeds, and reduce fuels to mitigate wildfire risk. The Biglow Comprehensive Solar Revegetation and Soil Management Plan is included in the Proposed Order as Attachment D, and contains considerable detail regarding the required measures to manage vegetation and prevent the introduction or spread of weeds:

- Use Best Management Practices to minimize erosion and prevent the introduction or spread of noxious weeds and invasive plants. Appendix C addresses best practices for preventing erosion and managing sediment at the site during construction and is enforceable by Oregon Department of Environmental Quality through the site's 1200-C construction stormwater permit. Appendix D Table D-1 describes the Reasonable Available Control Measures to control dust at the site, such as daily monitoring and sweeping, graveling and stabilizing all access roads with water or palliative, restricting construction access and limiting vehicle speeds on access roads, and minimizing

disturbance areas and soil exposure. A dust inspection log will be completed following dust inspections and made available to ODOE upon request.

- Pre-construction compliance, including coordination with the County and ODOE; soil compaction testing; installation of stormwater, erosion, and sediment controls as required by the 1200-C construction stormwater permit; and conducting noxious weed surveys and maintaining weed control activities until just prior to construction. (Section 4.0 Table 3)
- Construction compliance activities to limit soil disturbance, control dust, and prevent the introduction or spread of noxious weeds. Soil stabilization and reclamation activities will take place during and following construction, and disturbed areas will be revegetated using approved seed mixes appropriate for the local soils and climate. (Section 5.0 Table 4)
- Vegetation health at the Biglow Solar site will be maintained through proper care to prevent erosion, while ongoing weed monitoring throughout the life of the facility will identify and treat problem areas using appropriate methods before they have a chance to spread. Section 6.0 Table 5 includes regular inspection and monitoring actions during the first year of operations and annual monitoring of revegetated areas in years 2 through 6 compared against success criteria outlined in the plan; regular reporting to ODOE, the Oregon Department of Agriculture, and the Sherman County Weed District are outlined to ensure compliance requirements are met.

Appendix F outlines specific required actions for soil stabilization and reclamation, site preparation, revegetation methods (including an approved seed mix for revegetating disturbed areas, seeding methods, and shrub planting requirements), and criteria for determining revegetation success. Appendix G outlines the state and county regulatory framework for weed control, lists the individual weed species found at the site, and describes the biological, mechanical, and chemical control methods and species-specific treatment plan that will be used to treat weeds and prevent their spread. Weed control will be paired with ongoing consultation with the Sherman County Weed Board.

The draft Comprehensive Solar Revegetation and Soil Management Plan in Attachment D combines erosion control, soil management, site revegetation, and noxious weed control in one plan to ensure consistency in soil and vegetation management from pre-construction preparation, through construction, and during operation of the Facility. The actions in this draft plan are detailed and specific, and only minor changes are expected prior to finalization. Site condition PRE-SP-01 mandates finalization of this plan prior to construction; conditions CON-SP-02 and OPR-SP-06 require adherence to the final plan during construction and operations of the facility, respectively.

2. Public Safety and Wildfire Risk (WF-07, WF-08, WF-12)

You noted Sherman County's elevated wildfire risk and expressed concern regarding wildfire risk mitigation, the development and use of wildfire mitigation plans, and the adequacy of buffers and fuel breaks to prevent wildfire spread. The Council's public safety standard requires that facilities be designed and operated to protect public health and safety. Consistent with this standard, the Proposed Order requires development and approval of wildfire mitigation and emergency response measures prior to construction, including coordination with local fire agencies. These

requirements are sufficiently specific to guide on-site implementation and coordinated response and are enforceable through ongoing compliance obligations. These concerns are addressed through PRE-WF-01 / PRO-WMP-01 (Wildfire Mitigation Planning) and OPR-WF-01 (Operational Wildfire Mitigation), as well as incident reporting and corrective action requirements under GEN-OE-05 through GEN-OE-07.

PGE and BN recognize that vegetation management is integral to wildfire mitigation and serves as a primary risk-reduction measure during both construction and operations. The recommended setbacks and vegetation management buffers reflected in the ODOE's Proposed Order were carefully developed to integrate industry best practices, applicable regulations, and relevant operational experience. These setbacks and buffers are incorporated into the associated draft plans and site design and will be carried out through implementation.

- Vegetation will be managed in accordance with the applicable provisions of the Oregon Fire Code:
    - Non-combustible buffer (10 feet) shall be required around either side of the perimeter fence
    - A maintained vegetative surface or non-combustible base shall be installed and maintained under the photovoltaic arrays and associated electrical equipment
- Vegetation standards apply (in addition to the above):
    - Within the solar arrays – vegetation maintained at a height of less than 12 inches, with a minimum vertical clearance of 12 inches from all electrical and mechanical equipment
    - Along access roads – 10-foot low-growing, fire-resistant vegetation buffer on either side
    - The BESS yard is designed with non-combustible materials (e.g., metal, etc.). No vegetation is allowed inside the BESS yard, and all surfaces are gravel or pavement.
    - The areas surrounding the O&M, BESS, and substations and within defensible space areas will implement a 20-foot non-vegetated perimeter buffer maintained as graveled or earthen surface

In closing, PGE and BN share your goal of ensuring that renewable energy development proceeds responsibly and with strong natural resource protections in place. Thank you for taking the time to offer comments.

Sincerely,

Lenna Cope

Re: Biglow Canyon Wind Farm Request for Amendment 4 – Response to Comments on Proposed Order (BCWAMD4Doc24-07)

Dear Ms. Metta,

Portland General Electric (PGE) and the project developer BrightNight (BN) appreciate your written comments regarding the Oregon Department of Energy's Proposed Order on the Request for Amendment 4 of the Biglow Canyon Wind Farm Site Certificate.

PGE and BN appreciate Mid-Columbia Economic Development District's (MCEDD) efforts to work collaboratively, in coordination with the Sherman County Court, to develop a Community Investment Plan. PGE and BN agree that the memorandum of understanding reflects collaboration among the parties and demonstrates our shared commitment to supporting economic development and community investment. We appreciate MCEDD's willingness to serve as administrator of the Community Investment Fund and believe that MCEDD's experience and established working relationship with the Sherman County Court provide a strong foundation for effective administration of the fund. PGE and BN value our partnership with MCEDD and look forward to continued coordination on the Community Investment Plan.

Sincerely,

Lenna Cope

Subject: Biglow Canyon RFA4 Response to Certificate Holder Response to Public Comment - Langdon
Attachments: BIGL RFA4_Comment Letter to John Langdon_02132026.pdf

Dear Mr. Langdon,

Thank you for your comments regarding the Proposed Order on Request for Amendment 4 of the Biglow Canyon Wind Farm Site Certificate. As required by Oregon Administrative Rule 345-027-0367(8)(a), please find attached Portland General Electric's and the project developer, BrightNight's, written responses to your comments. Yesterday you should have received an email from Christopher Clark, the Oregon Department of Energy (the Department) Senior Siting Analyst for this amendment. The email contains the Department's Responses to comments and, should you choose to, directions for how to reply to our comment responses. Please refer to that email for guidance.

Thank you.

Re: Biglow Canyon Wind Farm Request for Amendment 4 – Response to Comments on Proposed Order (BCWAMD4Doc25-03-P6)

Dear Mr. Langdon,

Portland General Electric (PGE) and the project developer BrightNight (BN) appreciate your oral comments regarding the Oregon Department of Energy's Proposed Order on the Request for Amendment 4 of the Biglow Canyon Wind Farm Site Certificate.

In your comments, you discussed your efforts to learn about how solar development and agricultural systems can work together and to implement vegetation management practices. PGE and BN value your expertise and the work you have done to educate others about the benefits of renewable energy development to agricultural systems. We share your goal of ensuring that renewable energy development proceeds responsibly and with strong natural resource protections in place.

We appreciate your comments and look forward to continued coordination as the project moves forward.

Sincerely,

Lenna Cope

Re: Biglow Canyon Wind Farm Request for Amendment 4 – Response to Comments on Proposed Order (BCWAMD4Doc24-19)

Dear Mr. Scharf,

Portland General Electric (PGE) and the project developer BrightNight (BN) appreciate your written comments regarding the Oregon Department of Energy's Proposed Order on the Request for Amendment 4 of the Biglow Canyon Wind Farm (BCWF) Site Certificate.

PGE and BN appreciate your perspective as a fourth-generation farmer in Sherman County and recognize the challenges facing many family farms today. We value your insight into how projects like Biglow Solar can help provide farmers with diversified and reliable income, which supports long-term farm viability, succession planning, and the ability to keep family farms intact and in agricultural production. In your letter, you note PGE and BN's efforts to address concerns about past management of BCWF and potential wildfire risk posed by the solar facility. We take these concerns seriously. PGE and BN appreciate your confidence in our plan to manage the solar facility and your support of our work to mitigate wildfire risk.

We appreciate your comments and look forward to continued coordination as the project moves forward.

Sincerely,

Lenna Cope

Re: Biglow Canyon Wind Farm Request for Amendment 4 – Response to Comments on Proposed Order

Dear Mr. and Mrs. McCullough,

Portland General Electric (PGE) and project developer BrightNight (BN) appreciate your comments regarding the Oregon Department of Energy's Proposed Order on Request for Amendment 4 (RFA 4) of the Biglow Canyon Wind Farm (BCWF) Site Certificate. Oregon Administrative Rule (OAR) 345-027-0367(8) requires PGE to respond to all comments that are made with "sufficient specificity," as that term is defined in OAR 345-027-0367(7)(a).

We note that your comments contained in the 13 written comment letters and oral testimony provided at the public hearing may not necessarily meet that standard but are valuable to inform the process. PGE and BN reviewed your comments carefully and offer the following responses, organized into five categories of issues that we hope accurately respond to your concerns. The responses below are organized by the interpretation of your comments received and are further identified with the same issue identification number provided in Table 1: List of Issues and Commenters in the Oregon Department of Energy's (ODOE) Response to Comments document dated February 12, 2026.

1. Organizational Expertise (OE-01)

PGE recognizes that one of your primary concerns regarding RFA 4 relates to maintenance issues at the existing BCWF. PGE acknowledges the operational incidents documented at the BCWF and has implemented targeted improvements specific to the BCWF, including changes to internal management structure and personnel; a change in the turbine operations and maintenance provider with a newly negotiated contract to mitigate future technical challenges and better align with site-specific performance goals; and improved monitoring of contractor performance. Improved preventative maintenance, robust monitoring, and corrective action planning will be the result of these changes, which are still ongoing.

As we talked about with you previously, and addressed during our public testimony at the hearing, lessons learned from past challenges have resulted in more robust preventative maintenance and corrective action protocols, stronger vendor performance accountability, clearer performance standards tied to equipment health, and improved quality assurance and quality control oversight. These lessons have informed the design, operational planning, and compliance framework for the proposed solar and battery energy storage systems under RFA 4 (Solar Components or Biglow Solar).

Most notably, the Proposed Order introduces a new requirement for a Comprehensive Operations and Maintenance Plan (O&M Plan) for the Solar Components (*see* Proposed Order

Attachment C; and draft amended Site Certificate conditions OPR-OM-01 through OPR-OM-03). This O&M Plan is intended to serve as the governing operational document for the Solar Components and must be finalized and approved by ODOE prior to commencement of operations.

Under draft amended condition OPR-OM-01, PGE must submit a final O&M Plan consistent with the framework outlined in Attachment C and Table 5 of the Proposed Order. The O&M Plan consolidates and carries forward commitments from multiple operational plans introduced under RFA 4, including:

- The Operational Wildfire Mitigation Plan;
- The Comprehensive Solar Revegetation and Soil Management Plan; and
- Hazardous materials management and emergency response plan requirements.

The O&M Plan establishes preventive maintenance procedures, monitoring protocols, documentation standards, emergency preparedness measures, and regulatory compliance procedures that will govern the facility throughout its operational life. It also requires submission to ODOE of contact information, qualifications, and defined roles for primary vendors, contractors, and management personnel responsible for operations.

In addition, draft amended condition OPR-OM-02 requires annual reporting to ODOE that includes detailed information regarding facility status, power production reliability and efficiency, monitoring results, compliance activities, and any facility modifications. While annual reporting has existed previously, the scope and specificity of the required documentation under RFA 4 are expanded and more detailed.

Draft amended condition OPR-OM-03 strengthens incident reporting requirements by requiring timely notification to ODOE, written documentation within defined timelines, and tracking of corrective actions. Significant events require root cause analysis and documentation of corrective measures. ODOE retains inspection and enforcement authority and may require additional corrective actions, if warranted. Retirement and restoration surety requirements (RET-01 through RET-03) remain in place to ensure financial resources are available for remediation or decommissioning, if necessary.

The O&M Plan Framework (Attachment C and Table 5 of the Proposed Order) establishes enforceable requirements in the following areas:

a. Preventive Maintenance and Asset Monitoring (Section 3.4)
    - Routine, scheduled inspections and condition-based maintenance consistent with manufacturer specifications and industry standards;
    - Supervisory control and data acquisition (or SCADA)–based monitoring of solar arrays, substations, and battery energy storage system (BESS) components; and
    - Documentation and tracking of maintenance activities in auditable logs.

b. Regulatory Compliance and Site Certificate Conditions (Section 3.5; OPR-OE-01)
    - Integration of all applicable Site Certificate conditions into day-to-day operational procedures;
    - Clear assignment of roles and responsibilities, including required submission of

contact information and qualifications for key personnel and contractors; and

- Requirement that material plan changes be submitted to ODOE for review and approval.

c. Emergency Preparedness and Incident Response (Section 3.6; PRO-OE-01; OPR-OE-01)

- A site-specific Emergency Response Plan prior to operations;
- Fire detection, alarms, and shutdown capabilities integrated with monitoring systems;
- Mandatory incident reporting to ODOE "as soon as reasonably possible," followed by written documentation within defined timelines; and
- Required root cause analysis and documented corrective action tracking for significant events.

d. Monitoring, Reporting, and Public Accountability (OPR-OM-02 and OPR-OM-03)

- Mandatory annual reporting to ODOE detailing facility status, reliability and efficiency metrics, compliance activities, and any facility modifications;
- Expanded scope and specificity of reporting compared to the legacy wind facility;
- Defined reporting timelines and written documentation requirements; and
- ODOE inspection authority and enforcement authority, including the ability to require corrective actions, additional inspections, or modifications if warranted.

e. Long-Term Operational Continuity and Transition Planning (Section 4.0)

- Defined roles during the initial Build-Transfer Agreement period;
- Clear transition of full O&M responsibility to PGE after Year 5; and
- Ongoing regulatory responsibility always remains with PGE as Certificate Holder.

These requirements are enforceable through the amended Site Certificate. Noncompliance may result in inspection findings, corrective action requirements, or enforcement action by ODOE. In addition, retirement and restoration surety requirements (RET-01 through RET-03) remain in place to ensure financial resources are available if remediation or decommissioning becomes necessary.

Your comments under the Energy Facility Siting Council (EFSC or Council) Organizational Expertise Standard express concerns regarding whether the facility will be adequately maintained and whether there will be accountability for operational issues. The Proposed Order and the implementing plans and conditions directly address those concerns through mandatory reporting, defined timelines, corrective action tracking, inspection authority, and enforceable Site Certificate conditions. We hope this response helps address your concerns regarding organizational expertise and PGE's ongoing accountability and compliance.

2. Wildfire Prevention and Risk Mitigation (issue numbers identified in subsections)

PGE and BN recognize that another one of your primary concerns regarding RFA 4 is wildfire prevention and risk mitigation. Living and farming next to new energy infrastructure raises

important questions, especially about safety and wildfire risk. Wildfire mitigation plays a critical role in how Biglow Solar is designed, constructed, and operated. The Proposed Order contains integrated requirements, both in conditions and in plans, to ensure that wildfire risks are managed to acceptable levels.

a. Construction Phase Wildfire Mitigation (PS-01, PS-02, SP-01, SP-04)

The Draft Construction Wildfire Mitigation Plan (WMP; Attachment G of the Proposed Order) includes the following actions and information to mitigate wildfire risk during construction:

- Onsite training that covers best practices to prevent fire ignition; type, location, and proper use of fire protection equipment; location of water sources and proper usage; and specific procedures and actions applicable during fire season and red-flag warnings (Attachment G, Section 3.1).
- Facility design features intended to reduce fire risk, with a section dedicated to BESS fire protection that describes BESS components, all applicable standards and codes that must be followed, and other facility components installed to ensure proper testing, handling, and back-up protection (Attachment G, Section 4.1.4).
- Specifications for fire protection equipment to ensure firefighter safety (Attachment G, Section 4.2).
- Vehicle use Best Management Practices to minimize fire risk from vehicle travel, equipment use, and fueling activities (Attachment G, Section 4.4).
- Fire weather monitoring and restrictions during fire season (Attachment G, Section 4.5).
- Vegetation management (Attachment G, Section 4.6), aligned with the draft Comprehensive Solar Revegetation and Soil Management Plan (Attachment D of the Proposed Order), to ensure consistent vegetation management that prevents erosion, supports native vegetation for watershed health, reduces wildfire fuels, and prevents the introduction or spread of noxious weeds. This includes vegetation height restrictions, especially around electrical equipment; non-combustible buffers around buildings, roads and the site perimeter; and weed monitoring and removal in coordination with the Sherman County Weed Board and Oregon Department of Agriculture.

PGE and BN acknowledge ODOE's recommendation in the Proposed Order to maintain vegetation at a reduced height of 1 to 3 inches during the dry season (June–October). PGE and BN also note the comment submitted by the Sherman County Weed District (BCWAMD424-15), which advises that maintaining vegetation at 1 to 3 inches may not be feasible if erosion control is a priority and instead recommends a grass height of 4 to 8 inches during the dry season for the proposed bunchgrass species. We recognize the Weed District's local expertise regarding soil stability and vegetation performance and appreciate the perspective provided.

The vegetation height standards identified in the draft Comprehensive Vegetation and Soil Management Plan and draft Construction Wildfire Mitigation Plan (WMP) provide for vegetation to be maintained below 10 to 12 inches year-round. These standards were developed based on practical vegetation management considerations intended to support long-term wildfire risk reduction while maintaining vegetation health and site stability. Maintaining vegetation at 1 to 3

inches during the dry season presents several practical and ecological considerations:

GE and BN acknowledge ODOE's recommendation in the Proposed Order to maintain vegetation at a reduced height of 1 to 3 inches during the dry season (June–October) and request that the vegetation height requirements be limited to a height of 10 to 12 inches year-round. Based on practical vegetation management considerations, this approach best supports wildfire risk reduction for the following reasons:

- Repeated low mowing to such reduced heights would be detrimental to perennial grasses included in the approved seed mix, as repeated damage to bunchgrass crowns would likely result in plant mortality within a few growing seasons.
- Extremely low mowing would favor the establishment of annual grasses, thereby increasing fine fuels rather than reducing fire risk.
- Low mowing would significantly reduce or eliminate wildlife habitat, particularly for ground-nesting birds and beneficial insects.
- Mowing at such low heights at the beginning of the dry season increases the risk of fire ignition due to sparks generated when mowing equipment contacts rocks or hard surfaces.
- Maintaining vegetation at a 1- to 3-inch height would substantially increase vegetation management costs without providing commensurate fire-risk reduction benefits.

The draft Construction WMP will be finalized prior to construction as required by draft amended condition PRE-WF-01, and contractors and employees must adhere to the plan pursuant to CON-WF-01.

a. Operational Phase Wildfire Mitigation (WF-12)

Wildfire mitigation does not end at construction. PGE is developing a site-specific Operational WMP, which will provide any site-specific information outlined in ODOE's Operational WMP template that is not already addressed in PGE's 2026-2028 Corporate WMP which was filed with the Oregon Public Utility Commission on December 31, 2025. The Operational WMP will include the same components as described for the Construction WMP above; however, the construction-specific actions will be replaced with site-specific operations and maintenance actions.

The site-specific Operational WMP under development for the Biglow Solar facility will be submitted to ODOE for review and approval prior to beginning operation of the solar facility, as required by PRO-WF-01; onsite contractors and employees will adhere to this plan as required by OPR-WF-01, as well as incident reporting and corrective action requirements under GEN-OE-05 through GEN-OE-07. Importantly, wildfire prevention and response measures are also integrated into the enforceable O&M Plan required under draft amended conditions OPR-OM-01 through OPR-OM-03. The O&M Plan:

- Incorporates operational wildfire mitigation requirements into day-to-day procedures;
- Requires ongoing vegetation management to reduce fuel loads and maintain defensible space;
- Integrates fire detection, alarm systems, and shutdown capabilities with 24/7 monitoring systems;

- Establishes incident reporting, documentation, and corrective action requirements if a fire-related event occurs; and
- Subjects wildfire-related operations to mandatory annual reporting, inspection, and enforcement oversight by ODOE.

Through this integrated framework, wildfire mitigation is not a stand-alone document, but an ongoing operational obligation embedded within the broader compliance and accountability structure governing the facility.

b. Setbacks and Vegetation Management Buffers (WF-07, WF-08)

PGE and BN recognize that vegetation management is integral to wildfire mitigation and serves as a primary risk-reduction measure during both construction and operations. The recommended setbacks and vegetation management buffers reflected in ODOE's Proposed Order were carefully developed to integrate industry best practices, applicable regulations, and relevant operational experience. These setbacks and buffers are incorporated into the associated draft plans and site design and will be carried out through implementation.

- Vegetation will be managed in accordance with the applicable provisions of the Oregon Fire Code:
    - Non-combustible buffer (10 feet) shall be required around either side of the perimeter fence.
    - A maintained vegetative surface or non-combustible base shall be installed and maintained under the photovoltaic arrays and associated electrical equipment.
- Vegetation standards apply (in addition to the above):
    - Within the solar arrays – vegetation maintained at a height of less than 12 inches, with a minimum vertical clearance of 12 inches from all electrical and mechanical equipment.
    - Along access roads – 10-foot low-growing, fire-resistant vegetation buffer on either side.
    - The BESS yard is designed with non-combustible materials (e.g., metal, etc.). No vegetation is allowed inside the BESS yard, and all surfaces are gravel or pavement.
    - The areas surrounding the O&M, BESS, and substations and within defensible space areas will implement a 20-foot non-vegetated perimeter buffer maintained as graveled or earthen surface.

c. Coordination with Local Fire Authorities (PS-01, PS-02)

PGE and BN have conducted extensive outreach in the community and with local emergency responders. On August 12, 2025, BN presented at a North Sherman County Rural Fire Protection District Board meeting, where proposed project details were shared alongside an overview of planned fire prevention and wildfire mitigation measures (presentation as given at the meeting is provided as Attachment A to this comment letter). In addition to this presentation, the project team has been coordinating closely with Sherman County Emergency Services and the North Sherman County Rural Fire Protection District, and has met multiple times, both in person and

over the phone, with Fire Chief Burbank to review site-specific fire mitigation measures, including:

- Adequate perimeter access for firefighting equipment;
- Placement of three on-site water tanks, including one located at the BESS yard; and
- Support for firefighter training and equipment through the Proposed Community Investment Fund (Proposed Order, Attachment E).

Feedback provided by Chief Burbank on the Construction Wildfire Mitigation Plan indicates that the plan is sufficient to address and mitigate wildfire risk during construction.

d. Fire Risk Analysis (WF-01, WF-02, WF-03)

Your comments raised several questions concerning the wildfire risk analysis included in the record. The first was related to burn probability data, the second was use of climate normals, and the third was in regard to fuel models.

With respect to climate normals, the data used to describe climate normals in BCWF RFA 4 Exhibit V are published by the National Oceanic and Atmospheric Administration, a widely accepted and respected source of climate data. These data indicate seasonal average temperatures which, when combined with precipitation and wind speed data, can be used to paint a full picture of wildfire risk at a given site. Wildfire mitigation actions described in the Construction WMP and the Certificate Holder's system-wide Operational WMP take into account high summer temperatures, low precipitation, and other factors (including extreme weather events) that affect the risk of wildfire ignition and spread.

With respect to burn probability and fuel models, BCWF RFA 4 Exhibit V Section 2.1.2 describes the fuel models used to analyze risk of wildfire within the Biglow Solar Micrositing Area. Including Fuel Models 102 (low load, dry climate grass) and 242 (burnable wheat fields), which describe 93 percent of the Solar Micrositing Area, in the risk analysis establishes a more conservative model than the existing conditions and overestimates the fuel load due to current fallow practices on fields at the Biglow Solar site, including chemical fallow, as you noted in your comment. Thus, the analysis results indicating a high burn probability may be greater than the actual risk at the Biglow site. The data and models used for the Biglow Solar burn probability analysis were developed by Oregon State University, the Oregon Department of Forestry, the Washington Department of Natural Resources, the U.S. Forest Service, the U.S. Bureau of Land Management, and Pyrologix, a company that supports wildfire mitigation. This collaborative effort described in "PNW Quantitative Wildfire Risk Assessment Methods" McEvoy, Dunn, and Rickert 2023[1]). is considered sufficient for developing accurate burn probability analyses.

e. Battery Energy Storage System Fire Safety Design and Risk Minimization (WF-05)

We appreciate your detailed recommendations regarding BESS design criteria to minimize fire risk. Public safety and wildfire risk reduction are central considerations in the design of the Biglow Solar facility, including the BESS.

Consistent with the EFSC Wildfire Prevention and Risk Mitigation, Public Services, and Soil Protection standards, the Proposed Order requires that facility components be designed,

[1] McEvoy, A., C. Dunn, and I. Rickert. 2023. PNW Quantitative Wildfire Risk Assessment Methods. Unpublished Manuscript. Available online at the website https://oe.oregonexplorer.info/externalcontent/wildfire/PNW_QWRA_2023Methods.pdf.

constructed, and operated to protect public health, safety, soils, and nearby agricultural lands.

We note that the design of all Solar Components and the proposed BESS incorporates multiple layers of engineered fire prevention and containment protections, including:

- BESS enclosures are manufactured to meet applicable building, electrical, and fire code standards, including resistance to environmental stressors. The centralized BESS yard layout further reduces exposure to potential turbine debris compared to dispersed configurations and site design maintains appropriate setbacks from turbines (520 feet).
- Each BESS unit includes thermal sensors, continuous monitoring, alarm systems, and automatic shutdown capabilities. These systems are designed to detect overheating or abnormal operating conditions early and initiate protective measures. The system is UL 9540A tested, meaning it has undergone rigorous fire propagation testing under nationally recognized safety standards.
- BESS will be housed in enclosed, containerized units located within a centralized BESS yard. Each unit includes internal separation and dedicated monitoring systems designed to detect abnormal conditions and isolate potential thermal events before propagation. The containerized configuration localizes any potential incident within an individual unit.

The wildfire mitigation measures outlined in the Construction and Operational WMPs, as well as the vegetation management measures outlined in the Comprehensive Solar Revegetation and Soil Management Plan and the enforceable O&M Plan requirements, and the engineered safety features incorporated into the BESS design, are intended to protect nearby homes, agricultural lands, and natural areas in Sherman County, where dry vegetation, high summer temperatures, and windy conditions increase fire risk.

In Proposed Order Section III.N.2, ODOE recommends that EFSC find that these plans sufficiently characterize wildfire risk within the analysis area using current data from reputable sources and that the facility components will be designed, constructed, and operated in compliance with wildfire mitigation plans.

Your comments related to fire risk, while relevant under the EFSC Wildfire Prevention and Risk Mitigation Standard, the EFSC Land Use Standard, and the EFSC Public Services Standard, are addressed by the Proposed Order and its recommended plans and conditions. We hope these responses help alleviate your concerns related to wildfire risk because it has been the subject of much discussion, input, and scrutiny throughout the EFSC review process.

3. Land Use

PGE recognizes your concern regarding the conversion of agricultural lands to renewable energy development.

a. *Loss of Agricultural Land*

With respect to the first concern, we hope the findings from the Agricultural and Fiscal Impact Analysis (AIA) included as BCWF RFA4 Attachment K-2 and the Community Investment Plan (Proposed Order, Attachment E), help alleviate these concerns. The AIA quantifies direct, indirect, and induced impacts from removing land from agricultural production, and then the CIP proposes mitigation measures to offset impacts. The AIA demonstrates that land removed from agricultural production by Biglow Solar represents 0.6 percent and 1 percent of the average annual acres of winter wheat harvested in Sherman County and Oregon, respectively. The CIP

incorporates many ideas provided by the community, including yours, that direct mitigation dollars to help fund important projects that benefit the local agricultural economy and offset impacts.

In addition, because issues relating to agricultural land supply, tenant farming, and agricultural impacts were raised in the record by your family, PGE and BN acknowledge that land ownership and agricultural operations are not always the same, and that project impacts may differ between landowners and tenant operators. BN worked closely with both the landowner and the tenant farmer to address the early conclusion of the existing lease. The parties reached a mutually agreed-upon lease termination arrangement.

The negotiated compensation reflects a private resolution between the parties and considered the remaining lease term, anticipated agricultural use, and other relevant factors. The agreed-upon amount was intended to provide substantial consideration in excess of several years of projected farming revenue, mitigating potential losses while allowing the farmer to continue agricultural operations elsewhere.

b. Wildfire Risk to Agricultural Neighbors (LU-07)

We feel it necessary to document for the record that PGE and BN have agreed to honor your request to impose a half-mile setback from your property line, which goes above and beyond any setback standard in code. This request was honored in response to concerns about wildfire mitigation, along with visibility of the facility from your property. As committed previously, this Micrositing Corridor setback will be included in the Biglow Solar final design and is memorialized by the First Amendment to Option and Land Lease with John Scharf.

Further, as discussed during the public hearing, liability matters are not within the jurisdiction of EFSC; and therefore, comments regarding liability do not address a Council Standard.

Your comments related to land use, while relevant under the EFSC Land Use Standard, are already addressed by the Proposed Order and its recommended plans and conditions, or by the private agreements already reached by your family.

4. Fish and Wildlife Habitat (FW-01)

Your comment letter submitted January 1, 2026, expresses concern that some wildlife species were not addressed in BCWF RFA 4 Exhibit P. The analysis in Exhibit P focuses on impacts to wildlife habitat, and the analysis in Exhibit Q focuses on threatened and endangered species as required by the following OARs governing issuance of site certificates by the Council.

OAR 345-022-0060 requires that in order for the Council to issue a site certificate, "the Council must find that the design, construction and operation of the facility, taking into account mitigation, are consistent with the general fish and wildlife habitat mitigation goals and standards of OAR 635-415-0025 (Implementation of Department Habitat Mitigation Recommendations) (1) through (6) in effect as of February 24, 2017." OAR 345-022-0070 requires that in order for the Council to issue a site certificate, they must find (after consultation with the Oregon Department of Agriculture and/or Oregon Fish and Wildlife Commission) that the design, construction, and operation of the proposed facility, taking into account mitigation, are not likely to cause a significant reduction in the likelihood of survival or recovery of state-listed threatened or endangered species. The analysis in Exhibit Q determined that no state listed or candidate species are expected to be affected by the Biglow Solar Components.

The Biglow Solar Components have been designed to avoid many habitat impacts. The Draft Habitat Mitigation Plan included in Proposed Order (Attachment F) addresses the potential temporary and permanent impacts to wildlife habitat from the Biglow Solar Components that cannot be avoided and establishes a habitat mitigation area (HMA) adjacent to the Carty Generating Facility in Morrow County. PGE discussed the location of the HMA with the Oregon Department of Fish and Wildlife and received assurance that the mitigation goals for in-kind and in-proximity habitat can be met.

Your comments, while relevant under the EFSC Fish and Wildlife Habitat and Threatened and Endangered Species standards, are already addressed by the Proposed Order and its recommended plans and conditions.

5. Vegetation Management and Soil Protection (SP-01)

Your comment letter submitted on January 29, 2026, expresses concern about soil and vegetation quality at the end of the solar facility's life. Tetra Tech, on behalf of PGE and BN, conducted a literature review of the effects of solar energy facility development on vegetation and soils, focusing on impacts experienced in arid grassland and shrubland-type environments compared to preexisting agricultural land use. The resulting memo and copies of the reviewed publications are included as an attachment to this letter (Attachment B) and outline benefits such as microhabitats around solar panels with lower air temperatures and evapotranspiration rates, higher soil water content, and additional surface roughness that slows wind speeds and protects against erosion. Planting native vegetation with deeper roots around the panels protects soil from erosion and allows nutrients to be cycled into the soils to greater depths. This improves soil structure, soil organic matter content, nutrient levels, and subsequently, the ability of the soil to sequester carbon. Any negative effects from the solar panels, as outlined in the memo, would be addressed through mitigation actions outlined in the Comprehensive Solar Revegetation and Soil Management Plan.

Your comments, while relevant under the EFSC Soil Protection Standard, are already addressed by the Proposed Order and its recommended plans and conditions. It is our position that none of your comments under the EFSC Soil Protection Standard rise to the level of requiring modifications to the Proposed Order.

6. Good-Faith Participation and Record of Outreach

PGE and BN have made extensive, sustained efforts over multiple years to engage with you directly, respond to questions, and provide access to project information and technical resources. Separate and apart from the RFA 4 amendment process, the Operations Manager of the existing BCWF facility has also maintained communication with you regarding operational and maintenance concerns, ensuring that your feedback was heard and addressed where appropriate.

Since fall of 2024, BN has dedicated significant time and resources to supporting a constructive relationship with you. These efforts have included repeated meetings, phone calls, written correspondence, and the availability of subject matter experts to address your specific concerns, including fire-safety engineers, agricultural mitigation specialists, and project design personnel. We also provided written follow-up and technical materials when you were unable to attend scheduled discussions. We recognize that meaningful engagement and thoughtful project refinement do not occur overnight; accommodations require study, engineering review, coordination with landowners, and regulatory alignment. Nevertheless, we have consistently

worked to respond to your concerns in a deliberate and substantive manner.

In addition to studies required by EFSC rules, BN voluntarily elected to prepare detailed visual simulations from your residence and from specific viewpoints you identified as being of greatest interest to you. These simulations were not required under the EFSC rules or any applicable Site Certificate condition. BN undertook this additional effort solely to provide you with site-specific, location-based information regarding potential visual impacts and to ensure that your concerns could be evaluated using accurate, project-specific renderings rather than generalized assumptions. This work reflects our commitment to transparency and good-faith engagement beyond what is required by the regulatory process.

We are committed to continuing to work with you and your family constructively. Given the accommodations implemented and the enhanced regulatory requirements included in the Proposed Order, we believe the record demonstrates that substantial and meaningful efforts have been made to address the concerns raised.

Please reach out if you have questions or would like to discuss further. We are committed to continuous engagement of the community and neighbors as this project moves forward.

Sincerely,

Dan Wilson

Project Description

Project Description

Biglow Solar + Storage Project Overview

OVERVIEW
PGE and BrightNight have partnered to bring a solar and storage project to the existing Biglow Canyon Windfarm in Sherman County, Oregon.

CAPACITY
385-Megawatts in two phases. Today, we're discussing phase 1 (125 MW PV and 125 MW BESS).

FOOTPRINT
Study area is 3,980 acres. Actual project footprint is ~676 acres.

INTERCONNECTION
Utilizing the existing Biglow Canyon Substation. Ideal optimization of existing infrastructure to reduce project impact.

PERMITTING
Currently moving through the Oregon EFSC process.

Tax Revenue
At least $40,000,000 in tax revenue generated over the life of the project.

Schedule Overview

2024

April-Sept

- Survey Complete (cultural resources, habitat, raptor, wetlands, botanical)
- Meetings with community leaders
- Initial tribal outreach

2025

April

- Application for Amendment for existing EFSC Site Certificated deemed published and complete by ODOE

July

- Preliminary layout
- Technology selection
- Agricultural mitigation meetings

August

- Sponsorship of the Sherman County Fair
- Open house, Aug. 19

September

- Anticipate completing EFSC application submission

November

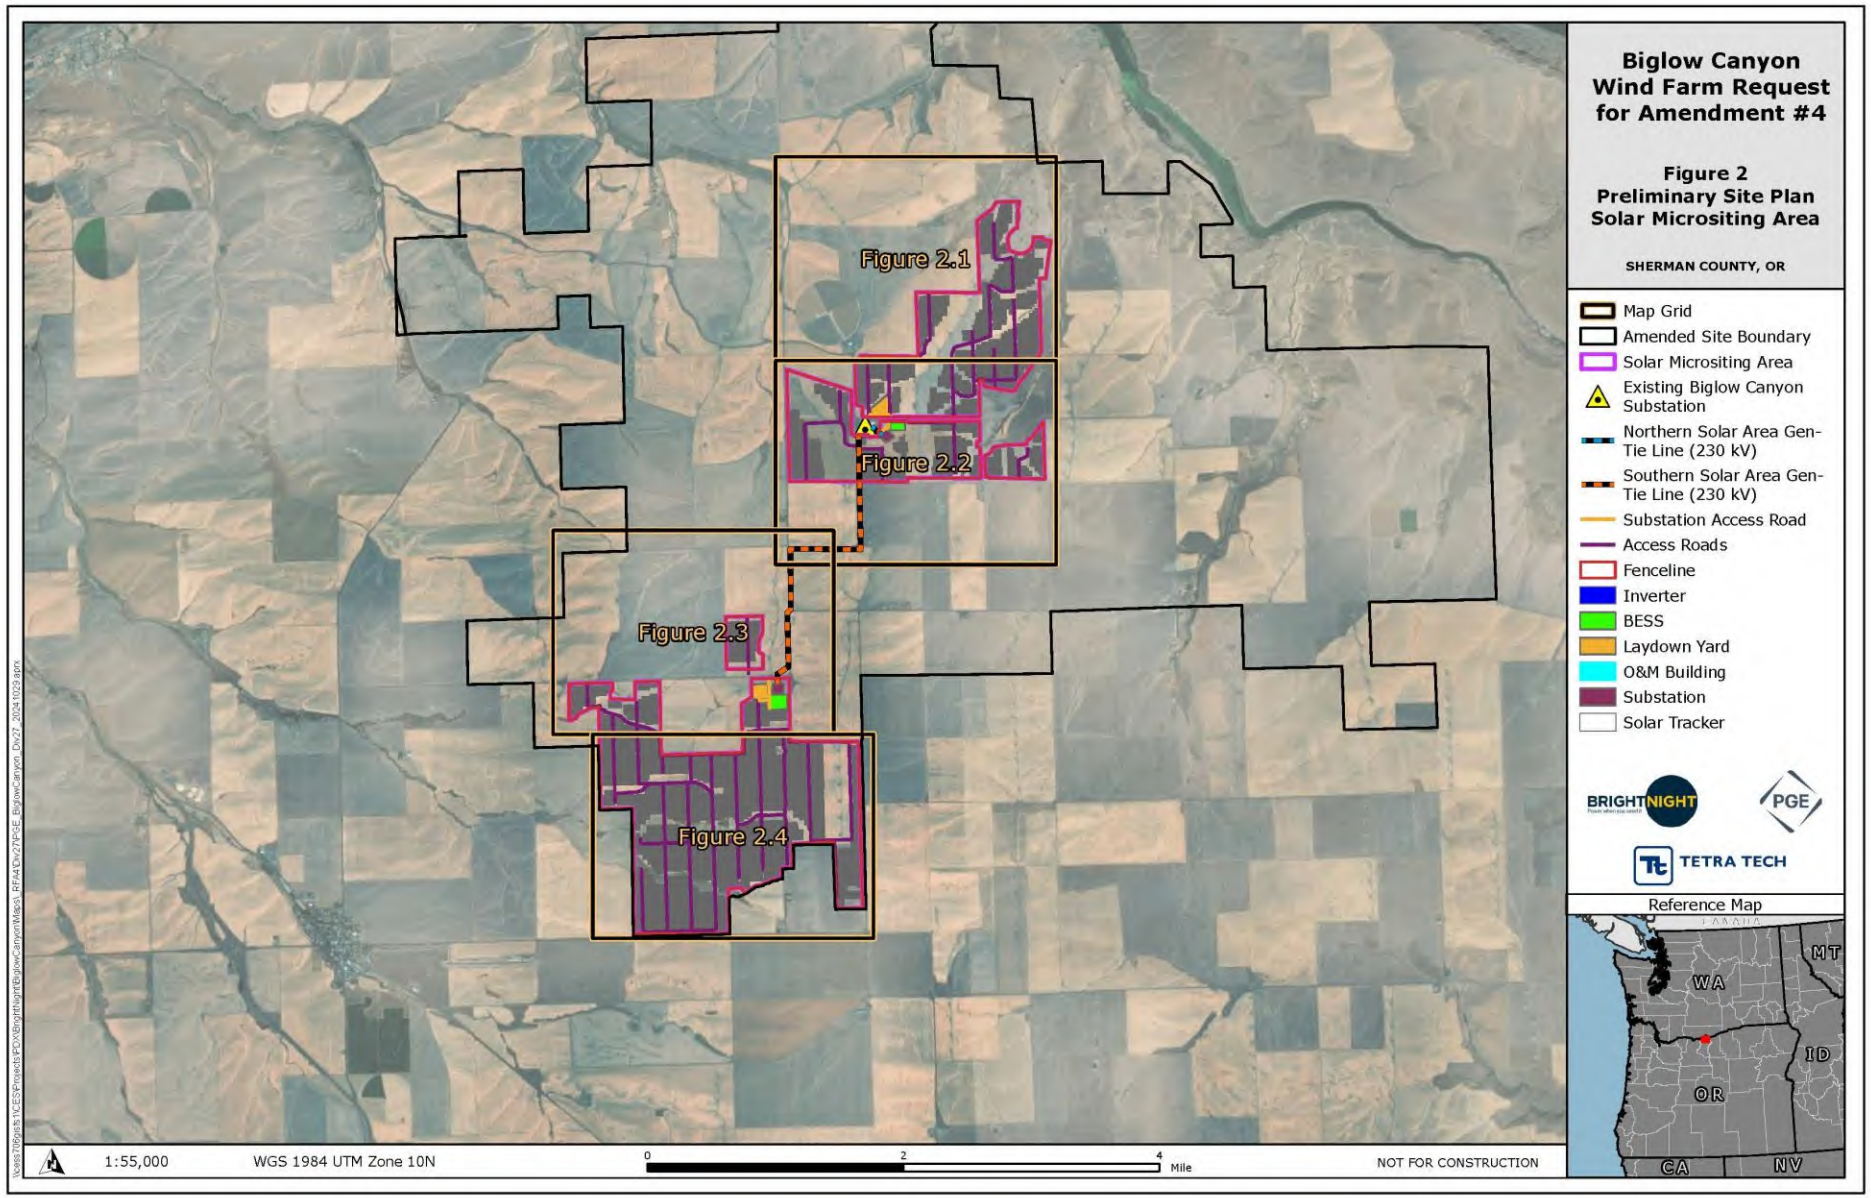
- EFSC issues "draft proposed order," tentative hearing date set

2026

January

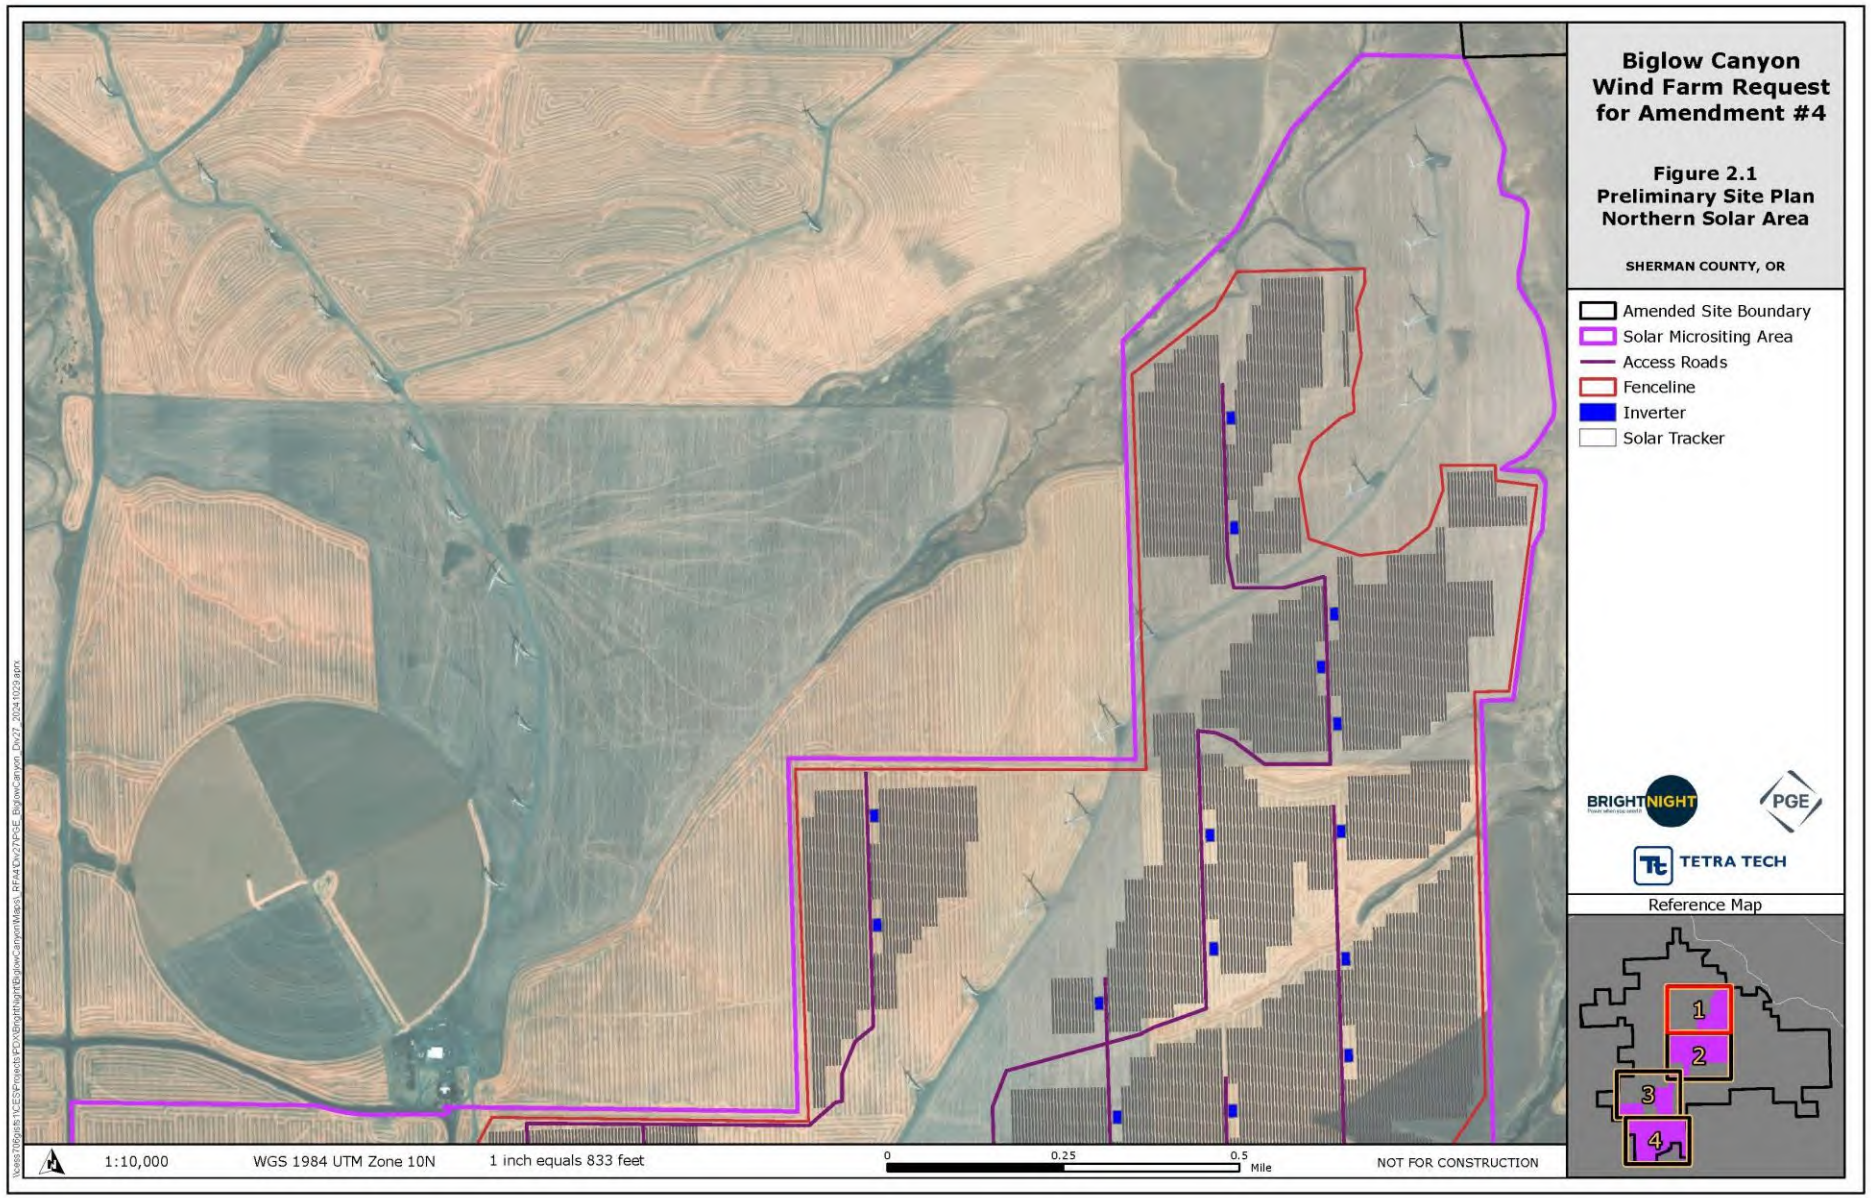
- Council review and determination

Q2



- Construction of phase 1

2027



Q4

- Anticipated construction of phase 2

Fire Prevention

BrightNight plans to use the "Tesla Megapack" battery system at the Biglow Solar and Storage Project. This industry-leading equipment features exceptional safety and prevention technology:

Noise

The Megapack is self-contained and operational noise levels are designed to minimize noise pollution. The Greenwater project will abide by all local noise ordinances.

Emissions

In the unlikely event of a fire, emissions are extremely limited. Any emissions would originate from the plastic enclosures, not the batteries. Concentrations are so small there would would be no negative impact to air quality in the surrounding area

Proactive Fire Control

Megapack is designed to prevent battery fires and be resilient if they occur. Fires are extremely rare. Testing has shown that if one occurs, Megapack safety systems can control and contain a fire within the unit.

Containment

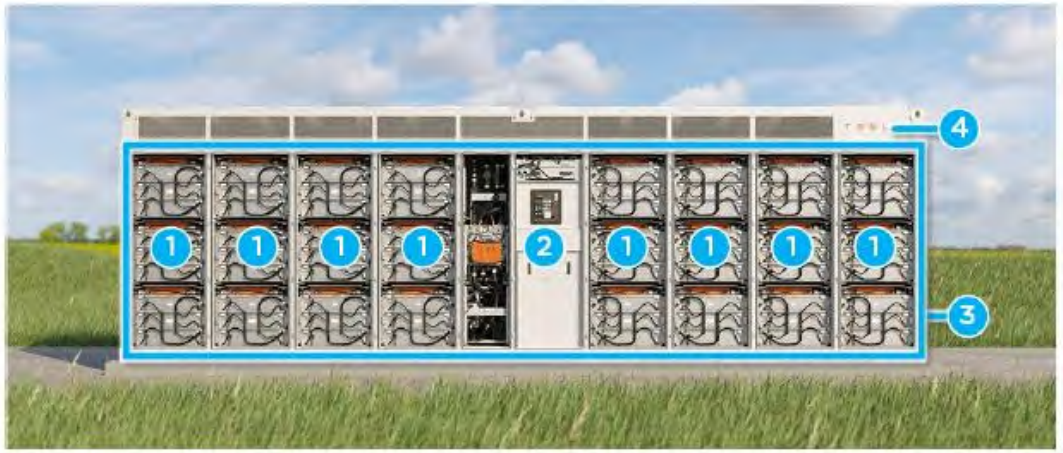
Each Megapack unit is self-contained. This important safety feature helps prevent potential soil or water contamination and prevents the spread of an unlikely fire event.

Water Runoff

Megapacks are designed to make it difficult for water to come in contact with the enclosed battery cells.

Lithium Batteries

Tesla Megapack Fire Protection Systems



BESS projects are safe for the environment. Self contained systems with no emissions during normal operation.

24/7 Monitoring. Megapack installations are remotely monitored by Tesla 24/7, allowing for early detection, diagnosis and troubleshooting of system errors while providing live support to first responders when needed.

Proactive Fire Control. Megapack is designed to prevent battery fires and be resilient if they occur. Fires are extremely rare. Testing shows that if one occurs, Megapack safety systems can control and contain a fire within the unit. Typically contained to a single module with no visible flames on the exterior.

Recyclable at End of Life. At the end of the system's lifetime BrighNight will safely remove the battery enclosures and recycle the majority of components.

1. Battery modules with active and passive fuses – externally serviceable
2. Touch-safe Customer Interface Bay
3. Non-walk-in IP66 enclosure and deflagration mitigation
4. Thermal roof with overpressure vents

UL Listed Equipment. Equipment is fully test and listed by the UL testing company for the products in your house.

Fire Event Gas Byproducts. Gases resulting from a Megapack fire are similar to those of a typical structure fire: hydrogen, carbon dioxide, carbon monoxide and methane. Expected fire size is less than a house or vehicle fire.

Fire Event Water Runoff. Megapack units are designed to make it difficult for water to come in contact with the enclosed battery cells. Fire water runoff testing has shown no harmful levels of contaminants. (Note: Tesla's Emergency Response Guide recommends no direct water application to a Megapack fire.)

Attachment B: Memo – Effects of Solar Energy Development on Vegetation and Soils

TETRA TECH

Memo

To:	Kathleen Campanella
Cc:	Maribeth Sawchuk
From:	Anjali Manoj, GIT (Tetra Tech); Kiana Ziola (Tetra Tech)
Date:	July 2, 2025
Subject:	Effects of Solar Energy Facilities Development on Vegetation and Soils

Several research publications were reviewed to determine the impacts of the development of solar energy facilities to the vegetation and soils at these sites. A specific emphasis was given to impacts experienced in arid grassland and shrubland type environments and the impacts were primarily compared to a pre-existing agricultural land use context as these are the typical scenarios applicable to the most solar energy facilities in Washington and Oregon.

Per Natural Resource Conservation Service published data about soil health in the Inland Northwest, in areas dominated by agriculture, especially monoculture crops like wheat, the soils typically have low organic matter, are depleted of nutrients, and have reduced water retention capacity due to the deteriorated soil structure (NRCS 2025). Repeated tillage combined with the shallow rooting depth of crops like wheat when compared to native plants often results in highly compacted layers at the tillage depth and interruptions to natural nutrient cycling processes. These are results Tetra Tech has consistently seen during soil monitoring at various renewable energy sites across eastern Washington and Oregon. The dominant monoculture crops in these regions also implies reduced vegetation diversity as compared to the native grassland and shrubland ecosystems that historically stood in the place of these agricultural lands. Therefore, multifunctional land uses such as the conversion to solar energy facilities have the potential to improve the provision of a variety of ecosystem services (Walston et al, 2021). This is especially true when the solar energy infrastructure in these facilities is interspersed with native vegetation between the photovoltaic (PV) arrays.

In the case of when pre-existing agricultural lands are converted to solar energy facilities with native grassland and shrubland vegetation interspersed, most research indicate that vegetation and soils improve on numerous metrics primarily due to the effect of the PV panels. PV panels favor the creation of heterogeneous microhabitats with lower air temperatures, lower evapotranspiration rates, and higher soil water content as a result of shading. Additionally, the PV panels create surface roughness that slow down wind speed and therefore add protection to vulnerable soils from wind erosion. These conditions can be beneficial to native plants that are seeded to establish in between the PV panels as they provide a better scenario for plant growth, especially in the initial stages of the vegetation efforts (Liu et al, 2019). When native vegetation establishes, the roots penetrate deeper into the soil as compared to crops like wheat. This serves to protect the soils better from erosion by wind and water and allows nutrients to be cycled in the soils to greater depths. Native grasslands and shrublands also feature increased litter that is protected from wind erosion. This further helps in improving soil structure, soil organic matter content, nutrient levels, and subsequently, the ability of the soil to sequester carbon (Liu et al, 2019; Lambert et al, 2021). The increased biodiversity through the re-establishment of native grassland and shrubland vegetation provides some landscape level benefits as well including improved pollinator supply which can benefit agriculture in the surrounding areas (Walston et al, 2019).

Research also points to how the development of solar energy facilities can have some disadvantages. For vegetation seeking to establish under or within the shade radius of the PV panels, the PV panels will intercept sunlight and impact the amount of solar radiation available to plants for photosynthesis in these areas (Sarr et al, 2023). As a result, vegetation communities may struggle to take hold and establish around the panels. The consequence of this is that the

growth of dominant plant species may be inhibited while subdominant species and weeds may take over (Gómez-Catasús et al, 2024). Another likely negative effect of the PV panels noted by some research is the alteration of the local distribution of precipitation. During precipitation, the areas under the panel receive lesser water inputs while areas along the edges of the panels may receive much high-water inputs from the runoff of the PV panels. This effect is only in the period immediately post precipitation and eventually stabilizes between all areas around the panels as the excess water received in the runoff areas of the panels is made up for by the decreased water loss from evaporation experienced under the panels from shading (Gómez-Catasús et al, 2024). Another concern from the development of solar energy facilities is compaction of soils, especially during construction. This is a well-known potential impact in anticipation of which several best management practices, monitoring programs, and adaptive management measures are designed and implemented under the guidance of appropriate authorities ahead of beginning any construction activities of these facilities. Ultimately, the potential disadvantages posed by the development of solar facilities can be mitigated and prevented by a large extent. The ability of the development of solar energy facilities to ameliorate vegetation and soil conditions is dependent on the successful implementation of revegetation efforts post the development of solar energy facilities combined with effective soil protection and reclamation measures.

While the points noted above are primarily investigating the case of agricultural fields that are converted to solar energy facilities with native grasslands and/shrublands interspersed, they are similarly applicable to the case of agricultural fields that are converted to solar energy facilities with agriculture interspersed (Walston et al, 2021). Apart from the shading effect of panels reducing the available area for crop production, there are no significant detriments noted to the crops or the soil from solar energy facilities (Sarr et al, 2023). It is important to note however that the benefits to vegetation and soils noted above will be seen to a much smaller degree due to the nature of crop plants as opposed to native vegetation (Walston et al, 2021).

Overall, research indicates that the development of solar energy facilities serves a net benefit effect to vegetation, soils, and in turn, the ecosystem in the long term by providing an opportunity for the rehabilitation of soils and vegetation that have been affected by agriculture-related interruptions to natural nutrient cycling. When the energy facilities are eventually decommissioned, the improved vegetation communities and soil quality can be a great benefit to continue the establishment of the native grasslands and shrublands or to return the land to agriculture in the future, should the need arise.

ABSTRACT

The increasing pressure on land resources for food and energy production along with efforts to maintain natural systems necessitates the development of compatible land uses that maximize the co-benefits of multiple ecosystem services. One such land sharing opportunity is the restoration and management of native grassland vegetation beneath ground-mounted solar energy facilities, which can both protect biodiversity and restore related ecosystem services. In this paper, we applied the InVEST modeling framework to investigate the potential response of four ecosystem services (carbon storage, pollinator supply, sediment retention, and water retention) to native grassland habitat restoration at 30 solar facilities across the Midwest United States. Compared to pre-solar agricultural land uses, solar-native grassland habitat produced a 3-fold increase in pollinator supply and a 65% increase in carbon storage potential. We also observed increases in sediment and water retention of over 95% and 19%, respectively. We applied these results to project the potential benefits of adoption of native grassland management practices in current and future solar energy buildout scenarios. Our study demonstrates how multifunctional land uses in agriculture-dominated landscapes may improve the provision of a variety of ecosystem services and improve the landscape compatibility of renewable energy and food production.

1. Introduction

Solar photovoltaic (PV) energy technologies have exponentially increased across the globe over the past decade (Kabir et al., 2018; Irsyad et al., 2019). Currently, there are over 33 gigawatts (GW) of ground-based large-scale (>1 MW) solar PV energy production in the U.S. (EIA, 2019a), representing about 1.5% of total U.S. electricity generation in 2018 (EIA, 2019b). The proliferation of large-scale solar energy developments is expected to continue across the U.S. over the next decade. For example, the U.S. Department of Energy's National Renewable Energy Laboratory, through its Standard Scenarios Report, estimates around 200 GW of installed electric capacity among ground-mounted solar facilities by 2040 under its Mid-Case scenario, and more than 500 GW of ground-mounted solar facilities by 2040 under its Low-PV Cost scenario (Cole et al., 2019). Like other forms of energy development, land use represents a major challenge for future solar energy deployment. Ground-based solar energy developments require between 2.5 and 3.5 ha per megawatt (MW) (Ong et al., 2013; Hernandez et al., 2014), and approximately 7500 km^2 of total land will be needed to meet 2030 projected solar energy production (Hartmann et al., 2016), roughly the combined size of the states of Delaware and Rhode Island.

Given their large land requirements, questions about the sustainability of solar energy developments have emerged in terms of their compatibility with other land uses such as agriculture (Moore-O'Leary et al., 2017; Hernandez et al., 2019). Ground-based solar energy developments are increasing in agricultural landscapes, due in large part to the siting of utility-scale solar energy developments on former agricultural fields (Adelaja et al., 2010; Adeh et al., 2019). Croplands are generally flat, open, and relatively undeveloped, making them ideal locations for solar energy development (Adeh et al., 2019). This pattern of conversion from agriculture to solar energy development can represent a land use tradeoff between food production and renewable energy production (e.g., Krishnan and Pearce, 2018). As the pressure intensifies on land resources for energy and food production, greater emphasis has been placed on solutions that maximize mutual benefits of multiple

ecosystem services. Recent approaches have suggested the integration of solar energy with food production, biodiversity conservation, and other ecosystem services (i.e., the energy-food-ecology nexus; Moore-O'Leary et al., 2017; Hernandez et al., 2019). For example, the co-location of solar energy and agriculture, often termed as "agrivoltaic systems", could improve the land-use potential of solar sites for energy and food production (Ravi et al., 2016; Dinesh and Pearce, 2016; Hoffacker et al., 2017; Barron-Gafford et al., 2019). In one study, Barron-Gafford et al. (2019) found that shading by solar PV arrays benefitted the production of crops such as Chiltepin peppers (*Capsicum annuum var. glabriusculum*), jalapenos (*C. annuum* var. *annuum*), and tomatoes (*Solanum lycopersicum var. cerasiforme*) by increasing yields and reducing water requirements while also creating cooler microclimate conditions that improved solar energy production.

Other research surrounding the energy-food-ecology nexus of solar energy has focused on the restoration of native grassland vegetation at ground-mounted solar facilities ("solar-native vegetation") to improve biodiversity and other ecosystem services such as pollination of adjacent croplands (Moore-O'Leary et al., 2017; Walston et al., 2018; Hernandez et al., 2019). In the United States, this approach has focused on vegetation management efforts at solar facilities aimed at establishing native grassland vegetation, such as milkweed (*Asclepias* spp.), native forbs and wildflowers, and other pollinator-friendly vegetation, either among the solar PV arrays or elsewhere within the solar facility footprint area, that attract and support native insect pollinators and other beneficial insect predators by providing food resources, refugia, and nesting habitat. Highlighting the potential significance of this approach, recent research found that over 3500 km^2 of agricultural land near existing solar energy facilities in the U.S. may benefit from increased pollination services through the establishment of solar-native vegetation (Walston et al., 2018).

Conventional ground management approaches at solar facilities often involve the establishment and management of low-growing turfgrass (Walston et al., 2018). While turfgrass provides some ecosystem service value for biodiversity and soil and water control, shifting to native grassland management practices at these locations has the potential to improve the ecosystem services potential of solar energy facilities. Compared to conventional turfgrass approaches, native grassland vegetation may improve ecosystem services related to biodiversity, carbon storage, water conservation, soil retention, and pollination of nearby croplands. Favorable microclimate conditions created by solar PV arrays, such as lower temperatures and greater soil moisture, can improve the performance of native grasses, which increases aboveground biomass and related carbon sequestration (Armstrong et al., 2016; Adeh et al., 2018). In addition, native grasses and forbs typically have deeper root systems than row crop agriculture and turfgrass (Schenk and Jackson, 2002), with root depths of some native grassland species exceeding 2–5 m (Packard and Mutel, 1997). Deeper root systems create the potential for improved soil stabilization and reduced water runoff (Hernandez-Santana et al., 2013). To date, however, these solar-native vegetation ecosystem service benefits have not been adequately quantified or evaluated in a common framework that allows for an understanding of a suite of ecosystem services. Thus, to build upon the previous efforts to understand the ecosystem service benefits of solar-native vegetation, this paper focuses on modeling the potential supply of ecosystem services resulting from different vegetation management approaches at solar energy facilities. Specifically, we were interested in addressing the following question: *What are the multiple ecosystem service benefits of solar-native vegetation compared to pre-existing land uses and other types of vegetation management practices at solar facilities*? To address this question, we conducted a geospatial land use change assessment for solar energy facilities in the Midwest and we developed spatially-explicit models at a regional scale aimed at quantifying differences in the following ecosystem services associated with solar-vegetation management options: pollinator supply, carbon storage, soil retention, and water yield. We then project these results to examine ecosystem service implications of future solar energy development within the region.

2. Methods

2.1. Study area

We examined ecosystem services associated with vegetation management practices at solar energy facilities within the Midwestern region of the United States (Fig. 1). This region is approximately 1.1 million km^2 in size and includes the states of Illinois, Indiana, Iowa, Michigan, Minnesota, Missouri, and Wisconsin. The predominant land use in this region is agriculture (37% of the study area), followed by forest (33%) and grasslands and other herbaceous land cover types (17%). The climate is humid temperate, with an average annual precipitation of 725 to 1100 mm (USDA, 2019). Average annual minimum and maximum temperatures in the region are −9 degrees Celsius (°C) and 29 °C, respectively (USDA, 2019).

Euro-American settlement and associated agricultural intensification has resulted in the decline of the region's grasslands, a diverse vegetation system that was much more dominant and widespread throughout the region prior to the mid-1800s. For example, over 99% of the tallgrass prairie in Illinois, Indiana, Iowa, Minnesota, and Missouri have been lost primarily due to agricultural expansion (Samson and Knopf, 1994). As such, many of the current terrestrial ecological restoration objectives within the region focus on restoration of native grassland and prairie systems. For solar sites in the Midwest, increasing emphasis has been placed on native grassland restoration among the PV arrays (Clean Energy States Alliance, 2020), which is a more compatible habitat type for solar energy development than other habitat types such as forests or wetlands.

2.2. Identification of solar energy facilities and data preparation

We identified the location of large-scale ground-based solar energy facilities (>1 MW) from the U.S. Energy Information Administration (EIA) for the year 2018 (EIA, 2019). The EIA reports generator-level specific information on electricity production facilities, including latitude and longitude information for facility locations and nameplate electricity capacity (MW). We queried the EIA database to only those sectors that were utility or industrial ground-based facilities (sectors 1 and 2). By doing so, we omitted large commercial rooftop facilities from our study. We then used a Geographic Information System (GIS; ArcGIS version 10.6.1) to map the approximate point location of each facility using the latitude and longitude coordinates reported by the EIA. We overlaid these points with the latest online World Imagery basemap within ArcGIS (ESRI, 2019) and digitized the footprint boundaries of all solar sites observable in the imagery. Solar facility polygons were drawn to include the PV panel area plus other areas observable within the fenced area of the facility (e.g., disturbed soil, laydown areas, operations facilities). Most of the World Imagery available for the region was obtained in 2018. We then calculated the size (ha) of each digitized solar facility's footprint polygon. For these facilities, we correlated facility electric capacity (MW) and footprint size (ha) and we used this relationship to estimate the footprint size for solar facilities that were not observed or incomplete in the satellite imagery. The 2018 list of all solar energy facilities in the Midwest, along with corresponding footprint sizes, is provided in Supplement 1.

We conducted a land use change assessment to determine what percentage of solar facilities in the Midwest were developed on former agricultural fields or other land use-land cover (LULC) types. We performed this assessment only for those solar facility footprints that could be delineated in a GIS. Because large-scale solar energy development largely did not appear in the Midwest until 2012, we used 2010 LANDFIRE Existing Vegetation Types (http://www.landfire.gov/evt.php) as the pre-solar land use dataset and determined the composition

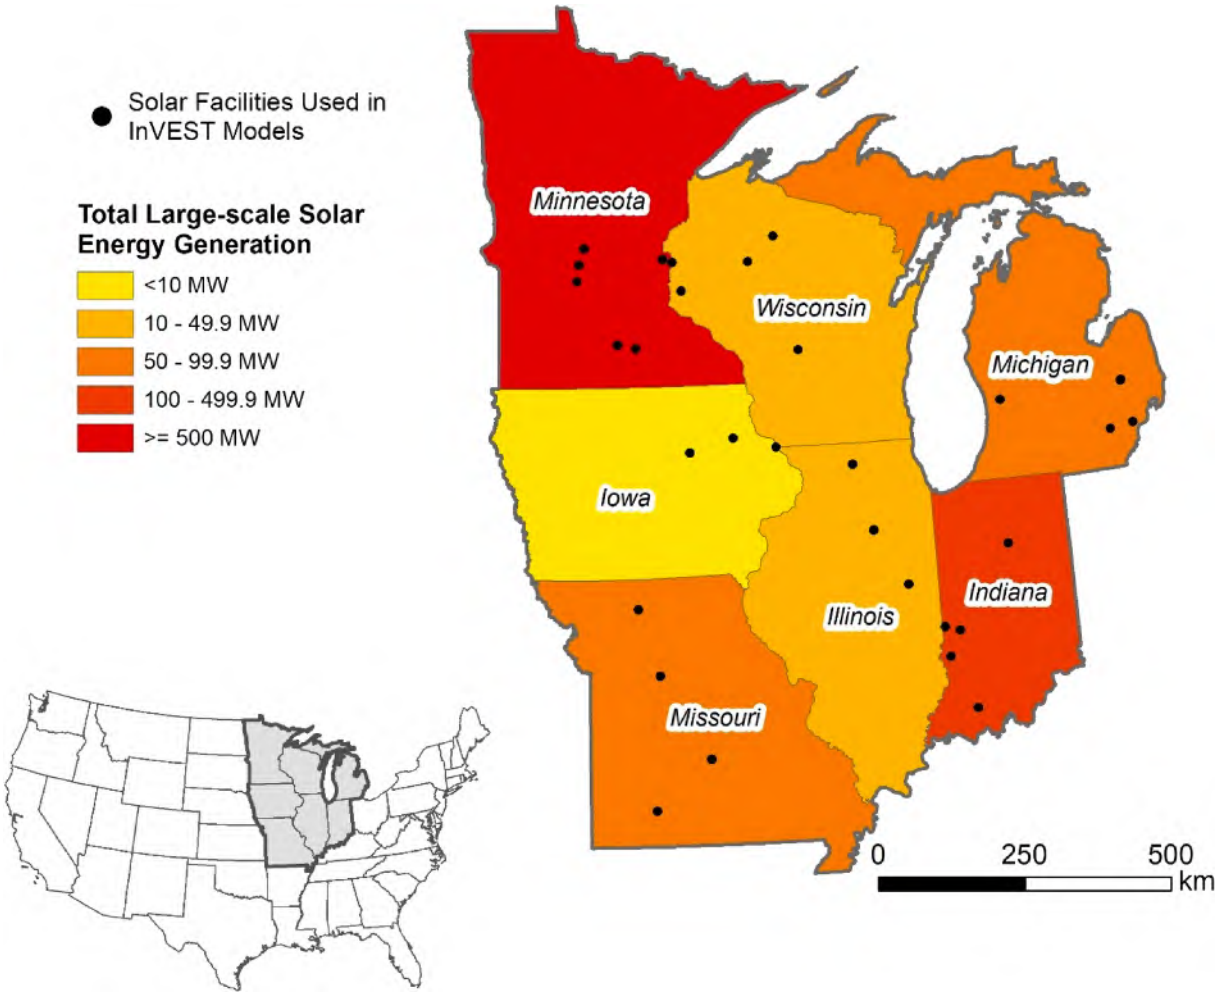

Fig. 1. Total 2018 large-scale (>1 MW) solar energy generation in States of the Midwest region of the United States (source: EIA, 2019). Locations of the thirty solar energy facilities used in InVEST modeling are shown in black.

of 2010 land use types intersecting the solar facility footprints as the measure of LULC change (see Supplement 1).

2.3. Scenarios

To determine the ecosystem services among vegetation management activities at mapped solar energy facilities, we designed three land use scenarios for the solar energy facility footprints: an agriculture scenario (the baseline "pre-solar development" land use) and two solar energy development scenarios – a solar-turfgrass scenario and a solar-native grassland scenario (Fig. 2). Because we assumed the majority of solar facilities in the region were previously under corn-soybean agricultural production (Supplement 1), we replaced all land uses in the solar footprint polygons with agriculture to represent the pre-solar land use. We considered this scenario to be the baseline scenario for comparison. The second scenario we evaluated was a solar-turfgrass vegetation scenario in which we assumed the sodding of cool-season turfgrass within the solar facility. This scenario also involves regular vegetation maintenance at the solar facility such as active mowing and herbicide applications to minimize or prohibit the growth of vegetation (<0.3 m high) within the solar facility footprint. Turfgrass is a common vegetation management practice at solar facilities and this scenario was considered to be the business as usual ("BAU") scenario for operating solar facilities. The third scenario we evaluated was a solar-native grassland scenario in which we assumed the intentional establishment of native prairie grasses and forbs in the solar facility footprint that provide forage and nesting habitat for native insect pollinators. Compared to the turfgrass scenario, the solar-native grassland scenario involves management activities that allow the vegetation to flower and reach heights up to 1 m within the solar PV arrays (the maximum height typically allowed at solar PV arrays to avoid shading of the panels). Because native grasses and forbs typically have deeper root systems than turfgrass (Schenk and Jackson, 2002), we assumed greater above- and below-ground vegetation biomass under the solar-native grassland scenario compared to the solar-turfgrass scenario.

2.4. Modeling framework

We used a multiple service model called Integrated Valuation of Environmental Services and Tradeoffs (InVEST, version 3.6; Sharp et al., 2018) to evaluate ecosystem services under each of the three land use scenarios at the Midwest solar energy facilities. The InVEST suite of tools has been developed to assist decision makers in comparing the impacts of different land use scenarios on the provision of ecosystem services. To our knowledge, this is the first application of InVEST to examine ecosystem service response to solar energy land uses. We used the following four existing InVEST models: Pollinator Model (for pollinator habitat quality), Carbon Storage Model, Sediment Delivery Ratio (SDR) Model (for soil retention), and Water Yield Model (for water retention). A detailed description of our modeling methods and parameters can be found in Supplement 2. Each of these InVEST models incorporate spatial datasets on land use-land cover (LULC) and some of them use elevation,

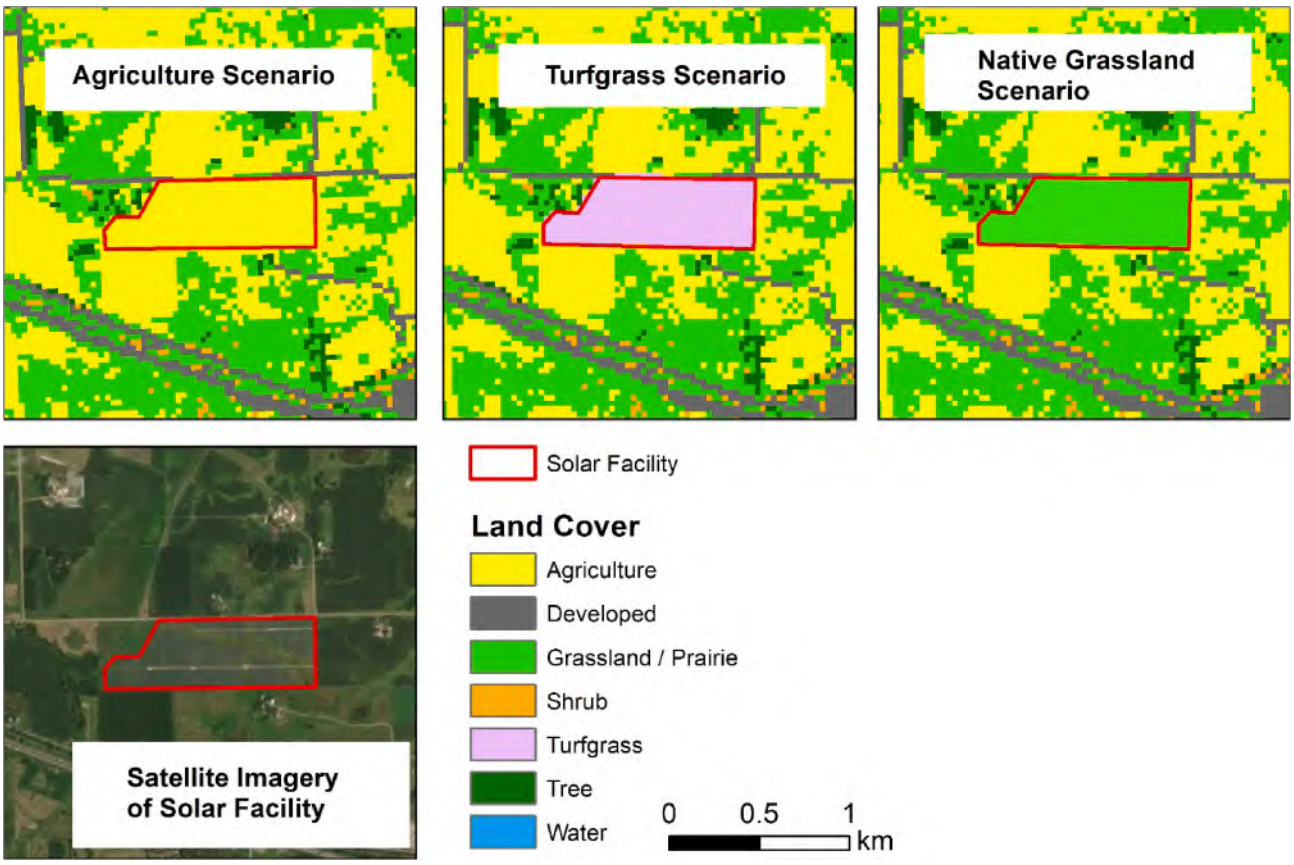

Fig. 2. Vegetation scenarios evaluated in this study. The agriculture scenario represents the pre-solar land use.

rainfall, and soil and vegetation properties, along with tabular biophysical parameters, to conduct spatially-explicit assessments of ecosystem services. The spatial datasets used in the models are also described in Supplement 2.

For this LULC dataset, we used a 30 m raster dataset of vegetated land cover from the 2014 LandFire Program (Existing Vegetation Types; http://www.landfire.gov/evt.php). We initially summarized the LULC map across the entire Midwest region into seven broad LULC classifications based on vegetation life form: developed, agriculture, barren or sparsely vegetated, grassland, shrubland, forested, and water and wetlands. We then updated the LULC map to create an eighth LULC classification representing solar energy facility developments using the footprint polygons delineated from satellite imagery. We selected a total of 30 solar facility footprint polygons, with a minimum of 3 footprints in each state, to update the LULC raster dataset (Fig. 1). This LULC update was performed by overlaying the facility footprint polygons on the initial LULC map and reclassifying the underlying pixels of the LULC map to a unique solar-specific LULC code.

All of the InVEST models also require tabular biophysical parameters to relate land cover types from the LULC map to the individual ecosystem service processes. We reviewed the existing literature to identify studies utilizing these InVEST models in the United States to parameterize each model. Surrogate vegetation and LULC types were used to identify the biophysical parameters to include in each scenario (Table 1).

We used the surrogate LULC types to review existing literature from previous InVEST modeling studies in the United States and summarize the biophysical parameters for each model (Table 2). We ran each model using upper- and lower-bound parameter values based on the 25% and 75% quartile range of values reported in the literature. We used this range to estimate the uncertainty in models and we used the midpoint (average) values in comparing ecosystem services across scenarios. For

Table 1
Land use-land cover (LULC) surrogates for the three land use scenarios modeled in this study.

Scenario	Surrogate LULC types
Agriculture (baseline pre-solar land use)	Row crop agriculture LULC types (e.g., corn-soybeans).
Solar-turfgrass	Residential, suburban, and turfgrass LULC types.
Solar-native grassland	Native grassland and prairie LULC types.

all ecosystem service estimates, we focused on the change in the service delivery for the solar-native grassland scenario compared with the solar-turfgrass scenario and the baseline agriculture scenario. For each scenario, we assumed the surrogate vegetation (Table 1) was consistently and uniformly distributed across all solar facilities. We were not able to use InVEST to model the effect of solar panels on these ecosystem services so we assumed this effect to be constant across all three land use scenarios.

The InVEST Carbon Storage Model is a carbon stock estimation model that is explicitly connected to land cover type. This model calculates total carbon storage (Mg C/ha) for each land cover type based on the aggregation of four carbon pools: aboveground carbon density, belowground carbon density, soil organic carbon density, and dead organic matter carbon density (Sharp et al., 2018). We used this model to examine differences in total carbon storage associated with each scenario.

The InVEST Pollinator Model was designed to model and map patterns of pollinator habitat quality and potential pollination service values across landscapes (Sharp et al., 2018). This model utilizes information on floral resource availability (associated with each LULC type), along with tabular inputs on nesting and foraging parameters for individual pollinator species or species groups, to estimate the supply,

abundance, and service value of insect pollinators across the landscape. In this study, we used the pollinator supply InVEST output to assess the ability of each scenario vegetation type to support insect pollinators. As described by the InVEST model (Sharp et al., 2018), pollinator supply is a unitless index (between 0 and 1) indicating where pollinators originate on the landscape. For the purpose of comparing the different vegetation scenarios, we used native bumblebees (Family Apidae) and native sweat bees (Family Halictidae) as the modeled guilds (Supplement 2).

The InVEST Sediment Delivery Ratio (SDR) Model estimates the overland movement of sediment based on topography, climate, soil, and land cover properties. The SDR model is a spatially-explicit model working at the spatial resolution of the input digital elevation model raster (Sharp et al., 2018). For each pixel, the model computes the amount of annual soil loss from that pixel based on a revised Universal Soil Loss Equation (USLE). It then calculates the SDR, which is the proportion of soil loss that reaches the catchment. Finally, the model uses the USLE and SDR to calculate erosion as total catchment sediment export (tons/ha). Inputs for the SDR model include raster maps for LULC, elevation, rainfall, and soil erodibility, along with tabular biophysical attributes related to sediment retention based on land cover type (Supplement 2). We used this model to estimate the amount of surface soil erosion associated with each vegetation scenario. Because sediment erosion represents a negative impact on the landscape, we considered erosion to be the inverse of a positive ecosystem service – soil retention, or the ability of a modeled vegetation type to retain soil.

The InVEST Water Yield Model calculates the net water yield at pixel-based and watershed scales based on the difference between precipitation and actual evapotranspiration. Actual evapotranspiration is a function of reference evapotranspiration, root restricting layer depth, plant available water content, and land cover type (Sharp et al., 2018). Following the methods described by Bai et al. (2019), we used the Water Yield model as an interim step in quantifying water retention: the ability of the modeled land cover type to intercept water from runoff. Water retention is calculated by subtracting runoff from water yield as follows:

$$WR_{ij} = WY_{ij} - Runoff_{ij}$$

where WR_i is the annual water retention (mm/yr) for pixel i on LULC type j, WY_{ij} is the annual water yield (mm/yr) for pixel i on LULC type j (calculated from InVEST), and $Runoff_{ij}$ is the annual surface runoff (mm/yr) for pixel i on LULC type j. Runoff is a product of annual precipitation and a runoff coefficient for each LULC type based on slope and soil type (Supplement 2). Because most solar energy developments are constructed on low slopes (<10%; Hartmann et al., 2016) and most agricultural areas in the region are loamy soils (Hollinger, 1995), we calculated LULC-specific erosion coefficients based on assumed slope of <10% and loamy soil properties.

2.5. Synthesis

We compared the output from the four InVEST models among the three vegetation scenarios. These comparisons were made on a unit-area basis for the 30 modeled solar energy developments and projected to the current amount of large-scale solar energy development in the Midwest region. We also explored the future potential for these ecosystem services by projecting these results to a future solar energy development scenario. Based on solar energy targets identified from state legislation and energy websites (e.g., Illinois Future Energy Jobs Act [S.B. 2814, 2016]; SEIA, 2019; MISO, 2019), we estimated the total foreseeable potential large-scale solar energy development within the Midwest region in the next 10–15 years (2030–2034). Using a solar land use-MW relationship calculated from delineated existing solar footprints in the region (Supplement 1), we estimated the future aggregate solar footprint size and projected our InVEST model results to this scenario.

3. Results

3.1. Solar energy development

We identified 276 large-scale solar facilities in the Midwest region that were operating in 2018, representing a total nameplate electricity capacity of 1183.8 MW (Supplement 1). The state of Minnesota contained most of the region's solar energy development both in terms of the number of facilities and total electricity capacity (Fig. 1; Table 3). Approximately 59% of the solar facilities and over 62% of the region's solar electricity capacity occurred in Minnesota. The state of Iowa contained the fewest number of solar facilities (n = 5) and the lowest amount of large-scale solar electricity generation (9.2 MW).

We identified and mapped the facility footprints of 192 solar facilities from the ESRI World Imagery. The remaining 84 solar facilities were either incomplete or not yet constructed at the time the satellite imagery was collected. We determined a land use-MW relationship of 3.0 ha per MW for all 192 delineated solar facilities (Supplement 1) and applied this relationship to estimate the footprint sizes for the remaining 84 solar facilities. Using the GIS-derived and estimated solar footprint sizes, we determined the total current footprint size among all solar facilities in the Midwest to be approximately 3416 ha (34.2 km^2).

Table 3
Summary of current (2018) large-scale solar energy development in the Midwest region.[a]

State	Current number of solar facilities	Current total nameplate capacity (MW)	Total current estimated footprint size (ha)[b]
Illinois	6	38.5	86.7
Indiana	60	214.3	574.2
Iowa	5	9.2	15.9
Michigan	13	98.3	250.1
Minnesota	163	741.5	2252.7
Missouri	17	61.1	173.2
Wisconsin	14	20.9	63.2
Regional total	276	1183.8	3416.0

[a] Sources: Data for 2018 solar facility development obtained from EIA (2019).
[b] Estimated total footprint size was based on solar footprint polygons digitized in GIS (for those facilities that could be mapped and located with satellite imagery) a land use relationship of 3.0 ha per MW of nameplate capacity for those facilities that could not be located within satellite imagery (Supplement 1).

Page 1166 of 1567

We determined the pre-solar construction land uses by identifying and quantifying the amount of 2010 LULC types within the 192 delineated solar facility footprints. By far, the dominant pre-construction LULC type converted to solar energy was row crop agriculture, comprising 70% of the 2010 LULC types within the solar footprint polygons (Supplement 1). This represents a conversion of approximately 2391 ha (23.9 km^2) of row crop agriculture to current ground-based solar energy development. Other forms of LULC conversion included developed areas (15.0%, 512.4 ha), pasture and hay fields (5.4%, 184.5 ha), and forest and riparian areas (4.5%, 153.7 ha).

3.2. InVEST model results

Ecosystem service model results for the 30 Midwest solar facilities, averaged by state, are presented in Table 4 (see Supplement 2 for more detailed results). Differences in modeled ecosystem service results among scenarios were primarily related to LULC changes. We used the variability in reported biophysical parameter values (Table 2) to calculate the range (and midpoint average) of ecosystem service results under each scenario. We found the patterns of ecosystem service provision among scenarios were consistent for the entire Midwest (Fig. 3). For example, the solar-native grassland scenario retained more water than the solar-turfgrass scenario, which retained more water than the agriculture scenario (solar-native grassland > solar-turfgrass > agriculture). We therefore present remaining results using the regional averages of modeled ecosystem services.

Carbon Storage. On average for the entire Midwest region, the solar-native grassland scenario had a potential carbon storage capacity of 129.3 Mg C/ha, which was 65% and 35% greater than the agriculture and solar-turfgrass scenarios, respectively (Table 4; Fig. 3).

Pollinator Supply. On average, the solar-native grassland scenario improved pollinator supply by 3-fold and 30% compared to the agriculture and solar-turfgrass scenarios, respectively (Table 4; Fig. 3).

Sediment Export. On average, sediment export under the solar-native grassland scenario was 0.007 tons/ha/year, which was a reduction of over 95% and 77% compared to the agriculture and solar-turfgrass scenarios, respectively (Table 4; Fig. 3).

Water Retention. On average, water retention under the solar-native grassland scenario was 885.0 mm/yr, which was 19% and 9.5% greater than the agriculture and solar-turfgrass scenarios, respectively (Table 4; Fig. 3).

Table 4
State and Midwest regional average ecosystem service results.

State	Agriculture scenario	Turfgrass scenario	Native grassland scenario
Carbon storage (Mg C*ha^{-1})			
All States	78.3	95.7	129.3
Pollinator supply (unitless index)			
Illinois	0.032	0.071	0.094
Indiana	0.032	0.072	0.094
Iowa	0.032	0.074	0.093
Michigan	0.032	0.076	0.095
Minnesota	0.033	0.074	0.098
Missouri	0.034	0.076	0.101
Wisconsin	0.034	0.079	0.100
Regional average	0.033	0.074	0.096
Sediment export (tons*ha^{-1}*yr^{-1})			
Illinois	7.084	0.536	0.131
Indiana	2.935	0.237	0.062
Iowa	2.165	0.168	0.041
Michigan	0.837	0.065	0.017
Minnesota	3.449	0.258	0.063
Missouri	10.252	1.061	0.263
Wisconsin	0.528	0.039	0.009
Regional average	0.327	0.030	0.007
Water retention (mm*ha^{-1}*yr^{-1})			
Illinois	832.3	910.0	1007.4
Indiana	740.3	812.6	900.1
Iowa	666.8	725.0	791.5
Michigan	733.0	783.2	842.4
Minnesota	748.3	803.2	869.3
Missouri	748.9	820.5	907.3
Wisconsin	762.2	824.7	904.1
Regional average	744.3	808.0	885.0

3.3. Projections to current and future energy scenarios

Using the Midwest regional averages for all calculations, the solar-native grassland scenario for all existing solar facilities (3416 ha) had the potential above- and below-ground carbon storage capacity of 267,473 Mg C, which was 174,216 Mg and 114,778 Mg greater than the agriculture and solar-turfgrass scenarios, respectively (Table 5). The solar-native grassland scenario conserved over 1000 tons more sediment from erosion than the agriculture scenario and 79 tons more sediment than the solar-turfgrass scenario. For existing solar energy developments, the solar-native grassland scenario retained over 4,800,000 m^3 and 2,600,000 m^3 more water than the agriculture and solar-turfgrass scenarios, respectively (Table 5). Because InVEST calculates pollinator supply as a unitless index value, we did not make future projections for pollinator habitat quality.

Based on solar energy targets identified from state legislation and energy websites (e.g., Illinois Future Energy Jobs Act [S.B. 2814, 2016]; SEIA, 2019; MISO, 2019), we conservatively estimated the amount of large-scale solar energy development for a future 2030–2034 time period to be approximately 10,000 MW (10 GW). This represents about 5% of the national 2030 goal for ground-mounted solar set forth by the U.S. Department of Energy (U.S. Department of Energy, 2012). Several Midwestern states such as Minnesota, Illinois, Indiana, and Wisconsin already have a queue of expected solar projects that would collectively reach this level of development in the next 5 years. Based on our calculated regional solar land use estimate of 3.0 ha per MW (Supplement 1), we estimated this future regional solar development footprint to occupy approximately 30,000 ha (300 km^2). If all solar facilities incorporated native grassland vegetation management strategies under this future energy scenario, the total above- and below-ground carbon storage potential of these facilities could exceed 3,800,000 Mg C, which would represent 1,500,000 Mg C and 1000,000 Mg C greater storage potential than agriculture and solar-turfgrass scenarios, respectively (Table 5). Under this future energy scenario, region-wide adoption of solar-native grassland management strategies has the potential to conserve over 9000 tons of sediment loss from erosion annually and retain over 40,000,000 m^3 of water from runoff annually (Table 5).

4. Discussion

Ecosystem services of vegetation management options at solar energy facilities are an emerging field of study. Our study demonstrates how multifunctional land uses in agricultural-dominated landscapes have the potential to improve the provision of a variety of ecosystem services. Numerous studies have demonstrated the effectiveness of native grassland restoration in agricultural landscapes in conserving insect pollinators and restoring important ecosystem services (e.g., Hernandez-Santana et al., 2013; Blaauw and Isaacs, 2014; Schulte et al., 2017). While field studies at solar facilities are currently under way to measure the ecosystem services of different vegetation management options, it will take several years for these field data to become available. To obtain initial estimates, we focused on examining the potential ecosystem services in a spatially-explicit manner using secondary data sources and scaled our model results to regional estimates. Our models included input parameters from previous studies in the U.S. that evaluated ecosystem service tradeoffs among various land uses, including

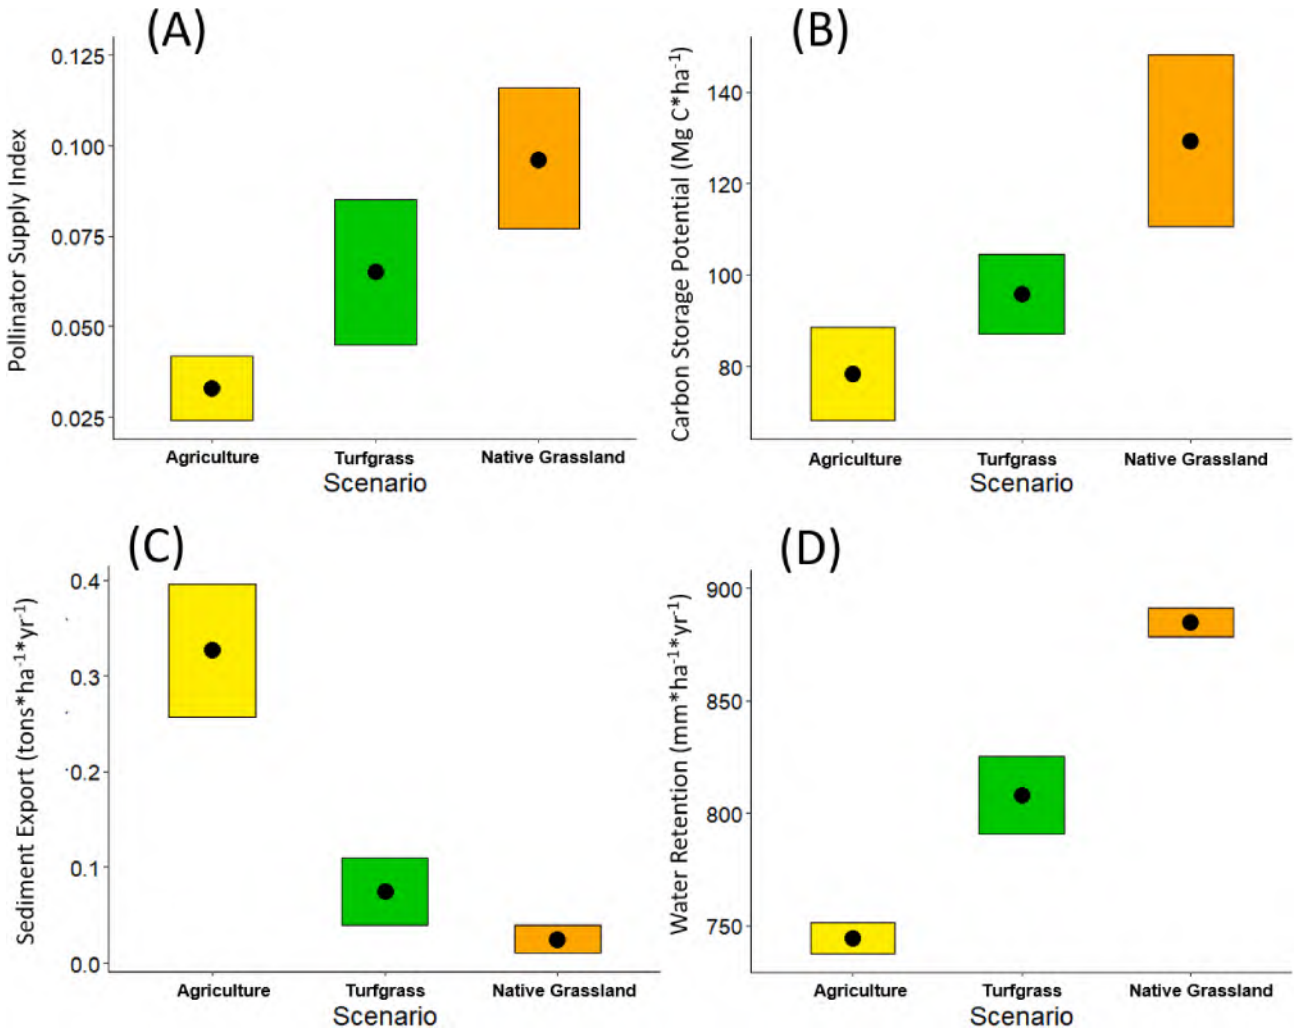

Fig. 3. Average ecosystem service values for the thirty Midwest solar facilities modeled with InVEST: (A) pollinator supply, (B) carbon storage, (C) sediment export, and (D) water retention. Tiles represent the upper- and lower-bound estimates based on the 25% and 75% quartiles. Points represent the midpoint average values.

Current	25,425,300	27,601,300	30,231,600
Future	223,290,000	242,400,000	265,500,000

[a] Current time period refers to existing solar energy facilities in the Midwest as of 2018 (1.2 total GW), with a total estimated footprint size of 3416 ha (34.2 km^2) (EIA, 2019). Future time period refers to a future solar energy development scenario (10 GW), with an estimated footprint size of 30,000 ha (300 km^2).

our land use surrogates (agriculture, native grassland and prairie, and turfgrass/suburban land use types). This approach allowed us to examine the potential tradeoffs in vegetation management land uses at solar energy facilities.

There is ample research supporting the InVEST ecosystem service model parameters and output related to our surrogate land cover types (see Table 2 and Supplemental 2). For example, in a study of land use impacts on ecosystem services in Minnesota, Johnson et al. (2012) examined tradeoffs in total carbon storage using estimates of 108 Mg C * ha^{-1}, 100 Mg C * ha^{-1}, and 67.7 Mg C * ha^{-1} for native grassland, developed, and agricultural land use types, respectively. In Wisconsin, Meehan et al. (2013) used the InVEST pollinator model with biophysical parameters similar to ours to associate pollinator habitat with LULC types. They found that switching from annual row crop agriculture (corn) to perennial grasses in Wisconsin would increase pollinator abundance by an average of 11%. In Iowa, Schulte et al. (2017) discovered that prairie strips in corn-soybean dominated agricultural settings reduced total water runoff from catchments by 37%, resulting in the retention of 20 times more soil as compared to an agricultural baseline scenario.

As expected, our models suggest that solar-native grassland improves habitat for local insect pollinators. Overall, we detected a 3-fold increase in pollinator supply under the solar-native grassland scenario compared to the pre-solar development land use scenario (agriculture) and a 30% increase in pollinator supply compared to the solar-turfgrass scenario. The implementation of pollinator-friendly vegetation at current and future solar energy facilities has the potential to benefit biodiversity by providing habitat for insect pollinators and other wildlife (e.g., birds; Clean Energy States Alliance, 2020). In addition, increased abundance and diversity of native pollinators associated with solar-native grassland could improve the services these organisms provide for pollination of

nearby agriculture. A number of studies have found direct correlations between pollinator habitat enhancements in agricultural settings and improved agricultural production associated with beneficial increases in pollinator services (Blaauw and Isaacs, 2014; Pywell et al., 2015; Venturini et al., 2017). In the Midwest, dominant crops such as soybeans may benefit from the presence of native pollinators. For example, pollinator habitat enhancement around soybean fields in Ohio increased native pollinator visitation to soybean flowers and increased soybean yields by up to 23% (Cunningham-Minnick et al., 2019). There are nearly 400 km^2 of soybean fields within 1.5 km of existing solar facilities across the seven Midwest states in this study (Walston et al., 2018), highlighting the potential agricultural pollinator service implications of solar-native grassland.

Compared to baseline agricultural land uses, our models suggest that solar-native grassland has the potential to increase the total carbon storage capacity of all current and future solar energy sites in the Midwest by over 170,000 Mg C and 1,500,000 Mg C, respectively. Putting these estimates into context, compared to the agricultural baseline scenario, the potential total future solar-native grassland carbon storage benefit is equivalent to offsetting the CO_2 emissions from over 5000 GWh of electricity generated from coal-fired power plants (World Nuclear Association, 2011). There are also future implications of solar-native grassland for sediment and water retention. The future solar-native grassland scenario has the potential to reduce over 9000 tons of sediment loss as a result of surface erosion annually and retain over 40,000,000 m^3 of surface water runoff annually from future solar sites. These increases in ecosystem services are equivalent to offsetting the amount of erosion and runoff of over 1000 ha (10 km^2) of row crop agriculture in the Midwest annually (NRCS, 2010).

It is important to clarify that the full ecosystem service benefits modeled in our study may not be immediately observed after the establishment of solar-native grassland. Rather, ecosystem services may gradually increase over time as the native grassland community matures. For example, soil organic carbon accumulates at former row-crop agricultural fields that have been restored to native prairie grasses at a rate of approximately 0.68 Mg C*ha^{-1}*yr^{-1} (McLauchlan et al., 2006). At this rate, an average 10 MW solar facility (30 ha) situated on land formerly used for agriculture that has been planted with native grassland vegetation will accumulate over 200 Mg of soil organic carbon after 10 years of operation. Over the timeframe of a solar energy facility lease period (which may be 20–30 years), therefore, we expect the site's ecosystem service potential to increase and more closely resemble modeled outcomes. Nevertheless, some ecosystem service benefits of solar-native grassland may be more quickly realized. For example, in as little as 3 years post-seeding, newly established native grasslands in Iowa are capable of reducing erosion and runoff in agricultural landscapes (Hernandez-Santana et al., 2013). In another study in Michigan, the establishment of native wildflowers in agricultural systems doubled the abundance of native bees and increased their visitation to nearby blueberry crops by 25% in less than 3 years after wildflower planting (Blaauw and Isaacs, 2014).

Our study focused on comparing the potential ecosystem services of different land management scenarios at solar energy facilities. We recognize some practical considerations in our study that warrant further investigation. First, the InVEST models we used have unique assumptions that relate land use classifications to ecosystem services (Sharp et al., 2018). Therefore, our modeling results were limited by the accuracy of the 30 m land use raster dataset we used and the general ecosystem service relationships that have been developed for those land use classifications. Second, our models did not incorporate sensitivity analyses or field-based validation efforts with primary data collected at solar facilities. Instead, we focused on examining a range of possible ecosystem service outcomes based on secondary sources of data from previous InVEST studies that examined surrogate land use types. This approach allowed us to understand the uncertainty in model results and we used average values to compare scenarios. Validation of our models consisted of comparisons to other InVEST studies that evaluated our land use surrogates. As discussed above, the relative differences in our model results were consistent with these previous studies. Third, we were not able to measure how solar panels may influence the modeled ecosystem services so we assumed the influence of solar panels to be constant. However, the presence of solar panels may influence ecosystem processes. For example, soil evapotranspiration processes may decline by 10–30% under solar panels compared to open sites (Marrou et al., 2013). For these reasons, greater emphasis should be placed on interpreting the relative implications of our results rather than the actual ecosystem service value calculations. Additional work is needed to collect the primary data on ecosystem services at solar energy facilities, collect data on the temporal patterns of these ecosystem services in relation to habitat establishment, and examine the effects of solar panels on processes such as runoff, erosion, and carbon storage.

5. Conclusions

The establishment of native grassland vegetation at solar energy facilities is a strategic land use practice to improve the landscape compatibility of solar energy development (Walston et al., 2018; Hernandez et al., 2019). Recent attention on this strategy from the solar industry, natural resource agencies, conservation organizations, and state governments underscores the amount of multidisciplinary coordination involved in implementing solar-native grassland (EPRI, 2019; Clean Energy States Alliance, 2020). In regions where native grasslands have been lost to other human activities such as agriculture, native grassland restoration at solar energy facilities represents a win-win solution for energy and the environment through the improved ecosystem services provided by the native habitat that may encourage future solar energy adoption. While several states have passed legislation and scorecards to guide the implementation of solar-native vegetation habitat standards, decisions regarding establishment of solar-native grassland also consider the costs of particular seed mixes and costs of seedling establishment, vegetation height restrictions, and long-term maintenance needs (Clean Energy States Alliance, 2020).

This paper is the first to compare the potential ecosystem services related to vegetation management practices at solar energy facilities. Since none of the calculated ecosystem service benefits of solar-native grassland accrue solely to the solar industry or any other group of stakeholders, the calculated values may be better considered as benefits for society-as-a-whole. These findings may be used to build cooperative relationships between the solar industry and surrounding communities to better integrate solar energy into agricultural landscapes. We focused on the potential non-monetary aspects of these ecosystem services in this study. Additional work is needed to collect the primary data that would support economic evaluations to inform solar-native grassland business decisions for the solar industry and quantify the economic benefits of services provided to nearby farmers, landowners, and other stakeholders.

Abstract

The arid sandy areas have great potential for producing solar power, and a large number of solar photovoltaic (PV) power (SPP) stations have been set-up in these regions across the world. Construction of SPP at large scale certainly changes the land surface with consequences on the local ecosystem. However, few studies have focused on these impacts. This study explored the influence of SPP on vegetation by modifying microhabitats. The soil water content (SWC), evaporation, photosynthetically active radiation (PAR), soil and air temperature (AT), vegetation coverage, biomass, and species richness were measured under different positions of the SPP and outside. The results showed that SWC in the station was much higher than that observed outside the SPP, and the evaporation in the SPP was lower than outside ($P < .05$). The PAR below the PV panel line zone is much lower than the interval (IT) zone. The surface coverage, biomass, and species richness were significantly higher in the SPP than outside the IT zone and outside the SPP ($P < .05$). The AT under the panel was 1.67 times lower than above during the plant growing season. The microhabitat index has a high correlation with biomass, coverage, and species richness. PV panels could impact microhabitat in arid sandy areas and accelerate vegetation recovery progress and quality. The SPP construction would not only supply clean energy but also bring unintended ecological benefits in the future.

1 | INTRODUCTION

Fossil fuels, such as coal, oil, and natural gas, dominate worldwide electricity generation, as well as transportation, heating, and industrial energy demands since the 20th century. This dependence on fossil fuels deepens the impact of global warming and boosts climate change risks. Compared with fossil fuels and other energy sources, such as nuclear power, renewable energy sources, such as solar and wind power, provide viable options for energy supply because of their abundant provision and wide availability on earth (Barthelmie et al., 2014; Miller, Gans, & Kleidon, 2011; MacDonald et al., 2016). Related to multiple climate benefits and sustainable development, renewable energy sources have been widely embraced as a primary solution to the current challenges of global energy demand, climate change, and environmental and societal sustainability (Dincer, 2000; Panwar, Kaushik, & Kothari, 2011). Solar energy is considered as one of the

Yu Liu and Rui-Qi Zhang contributed equally to this work and are co-first authors.

most promising alternatives due to its characteristics: inexhaustible, carbon-emission free, and nongenerating liquid or solid waste products (Ito et al., 2003; Tsoutsos, Frantzeskaki, & Gekas, 2005; Ahmed, Al Amin, Hasanuzzaman, & Saidur, 2013; Solangi, Islam, Saidur, Rahim, & Fayaz, 2011). By using solar photovoltaic (PV) panels, solar energy could be translated to electricity and grid connected though PV power stations (Singh, 2013; Sahu, 2016). The solar energy market has got extensive attention from worldwide governments (Creutzig, 2017). Updated to 2017, the total global PV installed capacity already reached 404.5 GW, nearly 225-times higher than the capacity in 2000 (1.8 GW). In 2017, China had installed 53.3% of the world's solar capacity, with an increase of 52.8 GW to its capacity in 2016 (Europe Solar Power, 2018). The United States was the world's second largest PV market and increased 10.6 GW compared with its capacity in 2017. In the same year, Japan holds 12.2% of the global share, whereas Germany took up to 10.6% (Europe Solar Power, 2018). Thus, the PV industry has become a fast-growing industry that has gradually developed a huge market worldwide.

The PV installed capacity of Africa and the Middle East region has also developed very strongly due to their high solar radiation potential. The regional radiation potential values are the most significant data for locating solar power stations (Janke et al., 2010; Sánchez-Lozano, Teruel-Solano, Soto-Elvira, & García-Cascales, 2013; Jahangiri, Ghaderi, Haghani, & Nematollahi, 2016). Other semiarid and arid areas of the world, such as Nevada (USA), Baja California (Mexico), Atacama (Chile), Southern Spain (Organization for Economic Cooperation and Development—Europe), Empty Quarter (Arabian Peninsula), Gobi (China and Russia), Rajasthan (India), Sahara (North Africa), Kalahari (South Africa), and Great Victoria, Gibson, and Tanami (Australia), have a great potential for installing large-scale PV power stations due to the combined conditions of a large amount of available land and areas with high air optical quality (Ito et al., 2003; Muneer, Asif, & Kubie, 2003).

In the latest years, the Chinese Government has prompted plenty of efforts to maintain and develop the solar industry. The solar recourses are unevenly distributed throughout China, which decreases from northwest to southeast. The provinces located in the northwestern part, such as Xizang, Qinghai, Gansu, Xinjiang, and Ningxia concentrate most of the solar energy and thus are considered as the future energy base of China (Wu et al., 2014). Due to the low density of solar energy in nature, and the current transfer efficiency of the solar PV power (SPP; Ito et al., 2003), the solar PV stations need a large land area to install PV panels. Compared with the densely populated and land-scary east part of China, the northwest region of the Country is highly suited to install solar electric stations when considering both land use efficiency and solar energy distribution. Nonetheless, most parts of these regions are plateauing and desert, such as the Gobi and the steppes, which have the most sensitive ecological vulnerability in the whole state (Du, Zuo, Li, Wang, & Xue, 2019). SPP construction would cause significant soil surface disturbances that increase the risk of land degradation of the fragile arid ecosystem.

Some studies have evaluated the environmental impacts of the SPPs during their life cycle, including metrics about the energy payback time and greenhouse gases emissions (Northrup & Wittemyer, 2013). Emissions reduction and health benefits brought by the SPP's establishment are not open to question (Hosenuzzaman et al., 2015). Visual impacts, air pollution, and natural resource depletion associated with the installation of PV panels were also evaluated (Tsoutsos, Frantzeskaki, & Gekas, 2005). Some researchers have mentioned that SPP could impact and modify landscape during their construction through activities, such as earth movement and by equipment and facilities transportation (Tsoutsos, Frantzeskaki, & Gekas, 2005, Hernandez, Hoffacker, & Field, 2015). Besides, Wu et al. (2014) reported that large-scale concentrated solar power plants in Northwest China had huge and positive influences on the ecological environment, especially in alleviating soil erosion. The ecological impacts of PV panels are often assumed to be negligible, and thus, few studies in the literature investigate the influence of SPP's establishment on the local sandy ecosystem. Besides, many of these effects are hypothesized with little peer-reviewed evidence (Northrup & Wittemyer, 2013). Li et al. (2018) used a climate model with dynamic vegetation to estimate the unintended climate consequences led by large-scale installations of wind and solar farms. These studies indicated that the effects of large-scale solar farms are consistently conducted with significant locally, and further studies are required to assess the impacts of smaller solar farms installed at specific locations (Li et al., 2018). Nevertheless, the environmental and ecological impacts of PV panels are still unresolved questions. The previously available studies about PV panels have not dealt in detail with the impacts on ecological effects in the arid sandy ecosystem.

The study aim is to highlight both the ecological effects and the vegetation changes brought by SPP installed in an arid and sandy landscape of Western China. The SPP located in Yinchuan City was chosen for this study because it is located on the border of the Mu Us Desert. This is a transitional region and is highly sensitive to human activities, such as land use changes (Cao, Yu, Georgescu, Han, & Wu, 2015), and natural factors (Liang et al., 2016). The main contribution of this study is the quantification of the effects of the PV panel establishment on the soil water content (SWC), evaporation, soil and air temperature (AT), surface coverage, biomass, and species richness. The results of this study will enable to ascertain the ecological significance of solar PV station in arid and sandy regions.

2 | MATERIALS AND METHODS

2.1 | Study sites

This study was carried out in the SPP (38°31′57″N, 106°36′47″E; 1,222 m a.s.l.) constructed near Yinchuan City, at Xingqing District (Figure 1a). This area is located in the southwest border of the Mu Us Desert, in the Ningxia Hui Autonomous Region, China. The study area is part of the wind erosion zone, and it has a moderate temperate continental monsoon climate. The average annual precipitation is ~200 mm, and the annual evaporation is ~2,250 mm. The mean annual temperature is 8.4°C. The annual hours of sunshine are 3,075.5 hr, and the mean annual frost-free period is ~160 days. The most

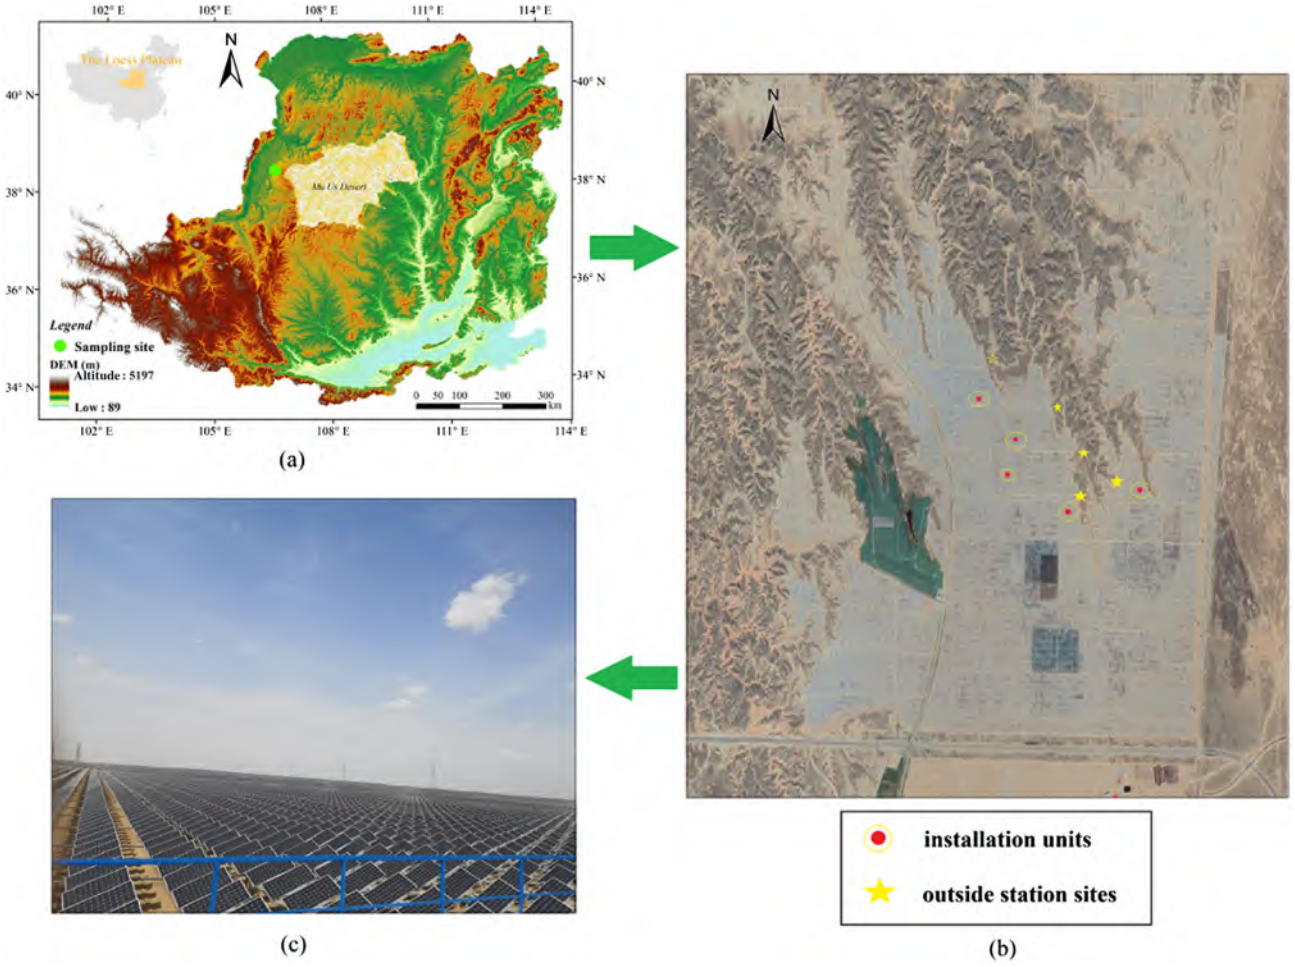

FIGURE 1 (a) The lactation of Baofeng solar photovoltaic (PV) power station. (b) The ichnography of Baofeng solar PV power station and the experiment sites. (c) The large-scale view of the solar PV panels constructed in the arid area. DEM, digital elevation model [Colour figure can be viewed at wileyonlinelibrary.com]

maximum wind frequency is the west wind. The annual daily maximum wind speed (>5 m s^{-1}) days were 167 days in the region. The region's annual solar radiation value could reach 5,600 MJ m^{-2}. The soil type is light sierozem. Natural vegetation is scarce without the presence of forest. Dominant plant species in this area are mainly psammophytic shrubs and herbaceous plants, including *Halogeton arachnoideus*, *Artemisia scoparia*, *Artemisia ordosica*, and *Artemisia sphaerocephala*. All the experiments were conducted in the Baofeng SPP station, which was constructed in 2016. This station occupies an area of about 15.33 km^2 and has an installed capacity of 640 MW.

2.2 | Field experiments

The PV power station was constructed by a vast installation unit, which is 7-m long in the east–west direction, 6.8-m width in the south–north direction, and 2.15-m height above the ground. The PV panels in the installation unit were controlled by an automatic optical tracking system (single axis), which can rotate in the east–west direction. The schematic diagram of the installation unit is shown in Figure 2c–e. We defined three kinds of districts in this study. In one installation unit, the area district vertically below the PV panel line (axis horizontality) in south–north direction was defined as the below line (BL) zone, and the area district between two PV panel lines was defined as the interval (IT) zone. The area district 30 m nearby solar power station was defined as the outside (OS) zone. We randomly selected five installation units in the SPP to stand for the BL zone (5 points) and the IT zone (5 points), and the other 5 points around the SPP stands for the OS zone. All 15 points are shown in Figure 1b. The vegetation in and around SPP is natural growing without any type of grazing (Figure 2a,b). Microhabitat indicators such as soil moisture, soil temperature (ST), evaporation, and photosynthetically active radiation (PAR) were measured in each zone. The AT above and below the PV panel was monitored by temperature sensors throughout the year. An intensive field study was conducted to examine the aboveground biomass, vegetation coverage, and plant species in the three zones. All soil and plant samples were collected from July 23 to 27, 2018.

2.3 | Sampling and measurements

A dual-range digital thermometer (OS542, OMEGA, USA) was used to measure the ST at every point. ST was measured three times every

1099145x, 2019, 18, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ldr.3408 by University Of Arizona Library, Wiley Online Library on [01/07/2025]. FIGURE 2 (a, b) The vegetation conditions inside and outside the photovoltaic (PV) power station. (c) Example of outside (OS) station zone. (d) The front view (in south–north direction) of an installation unit; (e) the top view of an installation unit. (f) The size of one PV panel. The area district vertically below the PV panel line (axis horizontality) in south–north direction was defined as the below line (BL) zone (orange strip), and the area district between two PV panel lines was defined as the interval (IT) zone (green strip). The area district 30 m nearby solar power station was defined as the outside (OS) zone [Colour figure can be viewed at wileyonlinelibrary.com]

2 hr from 10:00 a.m. to 6:00 p.m. at each point (same location). The position to measure ST is randomly selected at each point about 5-cm height above the ground. The ST of each zone is the average value of 5 points in 6 hr. PAR was also measured three times every 2 hr from 10:00 a.m. to 6:00 p.m. at each point (same location). PAR was measured randomly by a canopy effective radiation recorder (ECA-GG01, Beijing ECOA Company, China) under the vegetation canopy (10 cm above the ground) in the three zones. The average value in 6 hr of 5 points for each zone stands for the PAR of the three zones.

The AT above (10 cm above the panel) and under (100 cm above the ground) the PV panels were monitored with a temperature sensor (S-THB-M002, HOBO, USA) from August 2017 to July 2018. The sensor reads the AT every 5 min. After outliers rejection, we group the AT value in 24 hr day^{-1} and use the daily mean temperature to calculate monthly mean AT. Temperature variation is observed in July 2018. Temperature variation is the difference value of AT above panel and under the panel in 24 hr (the average AT value in 24 hr of July 2018).

Three culture dishes (internal diameter of 150 mm) were utilized as evaporation pan to measure the evaporation of two consecutive days at each point: July 24 and 25. The position of dishes is randomly selected at each point. The culture dishes were filled with water and weighed twice: just before installing and then 24 hr later. The evaporation capacity (*EC*; mm) was calculated as follows:

$$EC = (W_1 - W_2)\rho_w / S_b, \quad (1)$$

where W_2 (g) is the weight of the dish with the remaining water after 24 hr, W_1 (g) is the weight of the dish with the water when it was settled, ρ_w is 1 g cm^{-3}, and S_b is the base area of the standard small evaporation pan (r = 10 cm).

The gravimetric SWC (%) of the 0- to 100-cm soil depth range was measured every 10-cm soil layer by a 4-cm diameter and 20-cm height soil auger at each point. Soil samples were collected in a 1.0m × 1.0m quadrat at each point. A total of 150 soil samples were taken in the three zones. The soil samples were stored in aluminum specimen boxes and weighed immediately after collection (using an electronic balance) and then weighed again after the samples were dried at 105°C for 24 hr. The SWC of each soil layer was calculated as follows:

$$SWC_i = (m_{i1} - m_{i2})/m_2\, 100\%, \quad (2)$$

1099145x, 2019, 18, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ldr.3408 by University Of Arizona Library, Wiley Online Library on [01/07/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

where m_1 (g) is the soil sample weight after collection, and m_2 (g) is the weight of the dried soil samples. i is the number of the soil layer, i = 1, 2, 3, ..., 10.

Mean SWC of 0–100 cm (%) was calculated below:

$$SWC = (SWC_1 + SWC_2 + SWC_3 + \ldots + SWC_{10})/10. \quad (3)$$

Plant coverage and species richness were estimated by using five quadrats of 1.0m × 1.0 m. The position of quadrats was randomly selected in each point. All the aboveground plant parts were collected and dried at 75°C for 72 hr in each quadrat, and then the dry mass in each quadrat was weighed. The average value of the dry mass represents the biomass of vegetation in the three zones. The number of species and vegetation coverage was estimated at each quadrat, and the species richness and vegetation coverage of each zone were calculated as the mean value of species number and vegetation coverage obtained in the five quadrats.

2.4 | Data preprocessing and statistical analyses

All data preprocessing was performed using Excel 2013 worksheet software (Microsoft Office Suite, USA). The one-way analysis of variance, Pearson correlation analysis, and the tests of significance were conducted by using SPSS 22.0 software (IBM, Montauk, NY, USA). Significant differences were determined at a significance level of .05. The figures were plotted by using SIGMAPLOT 12.5 software (Systat Software Inc., San Jose, CA, USA), and the table was produced with Excel 2016.

3 | RESULTS

3.1 | Effects of solar PV panels on surface microhabitats

The results showed clear differences in the SWC, evaporation, soil temperature (ST), and PAR between the BL, IT, and OS zones. One the one hand, the spatial pattern of SWC in 0- to 100-cm depth of the three zones was all decreased with increasing soil depth (Figure 3a). However, SWC in the OS zone was always lower than the values in the BL and IT zones considering within 100-cm soil layer. ST has the highest value (33.4°C) in the OS zone, whereas the BL zone had the lowest (30.2°C). The ST of the IT and OS zones is about 3°C higher than the BL zone (Figure 3c). The evaporation and PAR of the three zones were depicted in Figure 3b,d. The evaporation in the OS zone was significantly higher than in the other two zones in the SPP (P < .05), which was two times higher than the BL zone and 1.5 times higher than the IT zone, whereas inside SPP, the evaporation of the IT

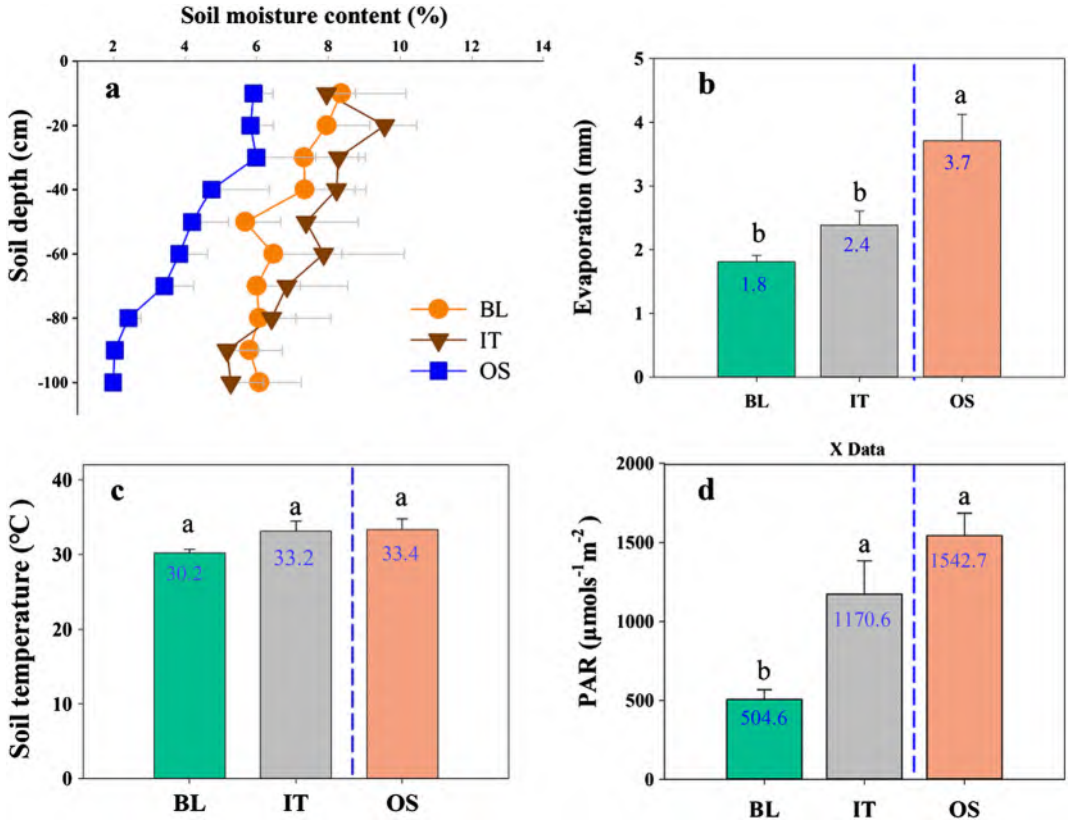

FIGURE 3 Soil moisture (0–100 cm in depth), soil temperature, evaporation, and photosynthetically active radiation (PAR) in the area district vertically below the photovoltaic panel line (axis horizontality) in south–north direction (BL), area district between two photovoltaic panel lines (IT), and area district 30 m nearby solar power station (OS) zones. Means with different letters are significantly different (P < .05) between the three zones. The error bars indicate standard errors [Colour figure can be viewed at wileyonlinelibrary.com]

1099145x, 2019, 18, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ldr.3408 by University Of Arizona Library, Wiley Online Library on [01/07/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

zone was 33% higher than the evaporation in the BL zone. Concerning PAR, the highest to lowest PAR values of the three zones was OS > IT > BL. The PAR of the BL zone was significantly lower than the other two zones ($P < .05$): 56.9% and 67.4% lower than in the IT and OS zones, respectively. Besides, the PAR in the OS zone is higher than the IT zone, but between them, there was no significant difference ($P > .05$).

The monthly average AT above the PV panel mirrored the trend of the AT under the panels: In both cases, AT started rising in February and reached the peak values in July (Figure 4a). Between September and November, the AT above and under the PV panel showed little difference. However, during the remaining 9 months, the monthly average AT of above panel was higher than under the panel. During the plant growing season (from April to August), above the panel's average AT of growing season was 36.21°C, whereas under the panel, the average temperature was only of 21.78°C. AT above the panel was ~1.67 times higher than that under the panel during the growing seasons. This AT above and under the PV panel also changed within a day (Figure 3b). We pick July 2018 to observe the daily AT difference between above and under the PV panel. From 12:00 p.m. to 6:00 p.m., AT was strongly reduced by PV panels. During these 6 hr, the temperature variation was above the mean AT variation estimated for the 24-hr period (19.27°C) and reached the biggest temperature variation time period within 1 day.

3.2 | Effects of solar PV panels on vegetation recovery

The biomass and surface coverage in the BL and IT zones were higher than the values in the OS zone (Figure 5a,b). The biomass of the BL and IT zones was 30 and 15.4-times higher than that in the OS zone, whereas the surface coverage was 6.8 and 6.2 times higher than in the OS zone, respectively ($P < .05$). Inside the solar station, the BL and IT zones did not have significant differences in the coverage ($P > .05$), whereas the biomass in the BL zone was nearly 2-times higher than in the IT zone ($P < .05$). The species richness of the three zones showed clear differences between the areas inside and outside the SPP (Figure 5c). The IT zone presented the highest species richness (5.5), the BL zone showed intermediate values (4.5), and the OS zone had the lowest values (2.6). There was no significant difference between the two zones inside the SPP; however, both the BL and IT zones had significant differences ($P < .05$) compared with the OS zone in species richness.

3.3 | The correlation between microclimate and vegetation

The results of correlation analysis for the ecological and vegetation indices are set out in Table 1. The correlation between biomass and ST, evaporation, and SWC was significant ($P < .05$). Besides, biomass between PAR was highly significant ($P < .01$), and its coefficient of correlation was more than −.76. Coverage also had a highly significant correlation with evaporation, PAR, and SWC ($P < .01$). Species richness had a significant correlation with SWC ($P < .05$) and a highly significant correlation with PAR ($P < .01$), and its coefficient of correlation reached −.81. We also concluded that evaporation was negatively correlated with coverage and biomass; SWC was positively correlated with coverage, biomass, and species richness, whereas PAR was negatively correlated with coverage, biomass, and species richness; and ST was also negatively correlated with biomass.

4 | DISCUSSION

Large-scale SPP has been mainly installed in the areas that have minimal competition for land surface against natural and other human land uses, such as deserts like the Gobi, and steppes (Hernandez, Hoffacker, Murphy-Mariscal, Wu, & Allen, 2015). These regions are sensitive to environmental changes where wind erosion might be intensified and sandstorm probability could be increased due to land use changes. Multiple environment impacts may change a lot during

TABLE 1 Pearson correlations between the microhabitat and vegetation indices

Variation	ST (°C)	Evaporation (mm)	PAR (μ $mols^{-1}$ m^{-2})	SWC (%)	Coverage (%)	Biomass (g m^{-2})	Species richness
ST	1.00	0.10	0.71**	−0.04	−0.36	−0.56*	−0.19
Evaporation		1.00	0.36	−0.60*	−0.79**	−0.74*	−0.50
PAR			1.00	0.33	−0.65**	−0.76**	−0.81**
SWC				1.00	0.72**	0.53*	0.62*
Coverage					1.00	0.86**	0.78**
Biomass						1.00	0.45
Species richness							1.00

Note. Microhabitat indices include soil temperature (ST), evaporation, photosynthetically active radiation (PAR), and mean soil water content of 0- to 100-cm soil layer (SWC). Vegetation indices include coverage, biomass, and species richness.

*Correlation is significant at 0.05 level.

**Correlation is significant at 0.01 level.

the SPP's life cycle, especially during the beginning stage. Our study indicates that the existence of SPP would influence the local environmental and ecological status quo. The panels created a heterogeneous radiation habitat and covered ground owing to the fluctuant shading, thus leading a changing energy cycle (Cossu et al., 2014). The changing of the energy cycle led to the variation of the environmental factors. Previous studies have shown that PV panels of large-scale solar farms in the Sahara directly reduced the surface albedo, creating positive albedo–precipitation–vegetation feedback, which triggered an increasing temperature and precipitation (Li et al., 2018). On a smaller scale, this study has shown that the presence of PV panels changed the microhabitat factors in different ways. PV panels convert solar radiation into electricity (Lewis et al., 2006), according to the law of conservation of energy, and the land surface under the power station would receive less radiation than the uncover land (Zhou et al., 2012). Besides, the vegetation coverage in the SPP is much higher than the outside, which further reduced the solar radiation reaching the surface. Hence, the PAR in the station was significantly lower than the PAR outside the station, especially in the BL zone.

ST changed in a quite different way due to the influence of the PV panels, and the ST of the BL zone is still 3°C lower than the IT and OS zones, which was still influenced by the PV panel (Figure 2c). The AT under the panels differed from the AT above the PV panels. AT under the panels was suitable for plants during their growing season. From April to August, the average temperature of the panel was only 21.78°C. A likely explanation is that the radiative balance was modified by the panel shelter, the panels directly decrease solar energy transfer of heat energy through electricity converting and shading

1099145x, 2019, 18, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ldr.3408 by University Of Arizona Library, Wiley Online Library on [01/07/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

effect, which provided an open structure with sufficient air circulation (Marrou, Dufour, & Wery, 2013). Plants in arid sandy areas always facing heat stress conditions and in most cases leaves are dried during the growing season. High temperatures could cause serious physiological injuries to plants, such as scorching of leaves and stems, leaf abscission, and senescence (Wahid, Gelani, Ashraf, & Foolad, 2007). Moreover, high temperatures could affect the shoot net assimilation rates that reduce the plant growth, which consequently leads to a decrease in the total dry weight of the plant (Bita & Gerats, 2013). The results of this study showed that PV panels could effectively reduce the temperature during both the growing season and the hottest time of the day, which could to some extent let plants alleviate heat stress and prevent plant productivity decrease.

The water condition was also influenced by the PV panels. The SWC in the SPP was higher than in the area out of it, whereas evaporation just showed the opposite trend. SWC is only recharged by rainfall in the study region. However, the PV panel has changed this process in two aspects. For one thing, the panels directly intercepted part of the precipitation, which could vertically fall into the BL zone without panels. Besides, rainfall could be temporally stored in the panels, and then due to its inclination, the rainfall would redistribute to the soil surface (Armstrong, Waldron, Whitaker, & Ostle, 2014). Thus, SWC in the IT zone was slightly higher than in the BL zone (Figure 2a). The shading effect of the panels explained the significantly lower evaporation that was observed in the SPP (Figure 2b). These results agreed with the study of Marrou, Guilioni, Dufour, Dupraz, and Wery (2013) who found that the shadow of the panels could save up to 14–29% of evapotranspired water in vegetable crops. Furthermore, the shading effects can increase the sensible heat flux of the ground layer, encouraging a decrease of the latent heat flux and soil heat flux, thus limiting evaporation (Coutts, Daly, Beringer, & Tapper, 2013). All these effects caused the observed heterogeneity of SWC distribution. SPPs are usually located in areas that lack water and accompanied by high potential evaporation. Through Pearson correlation analysis, it was shown that there was a high correlation between vegetation coverage, SWC, and evaporation ($P < 0.01$), and its coefficient of correlation was more than 0.72 and −0.79, respectively. Plants that grow in arid areas are highly affected by both temperature (Beedlow, Lee, Tingey, Waschmann, & Burdick, 2013) and water availability (Zhou, Zhang, Ji, Downing, & Serpe, 2011). When vegetation is facing prolonged drought stress, SWC would strongly control the spatiotemporal patterns of biomass (Kammann, Linsel, Gößling, & Koyro, 2011). In water-limited areas, water is the foundation of vegetation planting (Kammann, Linsel, Gößling, & Koyro, 2011). Besides, good water conditions have positive effects on juvenile crop stages, which is vital to vegetation establishment (Marrou, Dufour, & Wery, 2013). The mean vegetation fractional coverage in middle Asia, where Northwestern China is included, ranges from 3% to 33% (Zhang et al., 2016). In our study, we found that the vegetation coverage of the OS zone was 13.4%, just among the average level of coverage. However, the vegetation coverage in the SPP was about 85% lower than that of the BL zone (93.5%), which is a value much higher than the average level of vegetation coverage at a regional scale. At the same time, the biomass and species richness were significantly higher in the SPP than in the area outside. The construction of SPP destroyed the low coverage of natural vegetation; however, after 2 years (2016–2018) of recovery, significant differences in vegetation characteristics had already shown. The vegetation in the SPP had shown a better recovery in terms of quality and speed, which got highly correlation with microhabitat indices SWC and evaporation. This study has indicated that SPP can provide a better water condition for plant growth in arid sandy ecosystems. Under the context of global warming and water resource shortage, the effects of panels could maintain a relatively higher SWC in the soil and lower evaporation, leaving more water for plant growth, and thus facilitate the destroyed vegetation recovery or improve the vegetation coverage in sandy areas. These benefits provide a consistent advantage in the near future.

Prior studies focused on dryland and desert ecosystems have noted the importance of vegetation coverage and biomass to provide important ecological services such as soil protection and animal feeding (Jiang, Liu, Zhang, Zhang, & Wang, 2019). The soil erosion process is influenced by natural and human factors, and thus, it has a close-fitting connection with climate conditions, such as precipitation and temperature, ground cover (e.g., vegetation cover), and land uses (Li et al., 2017; Wei et al., 2017). The ultimate means to combat desertification and protect soil from wind erosion is vegetation construction (Su et al., 2007). Vegetation cover has a lower and upper threshold for controlling wind erosion. A plant coverage lower than 10% has little ability to reduce wind velocity at the soil surface, whereas the effect of vegetation on reducing wind erosion has basically reached the maximum when plant cover is ~40% or above (Jiang, Liu, Zhang, Zhang, & Wang, 2019). This study has indicated that PV panels favored the development of a microhabitat with lower evaporation and higher SWC, moderate temperature, and PAR, which enabled vegetation development with high coverage, biomass, and biodiversity in SPP. The average vegetation coverage in the SPP was 90.5%, which could effectively destroy the wind–sand flow structure. Meanwhile, the PV panels covered more land, modifying the land surface properties, in particular, increasing the surface roughness, which could slow down wind speed. In these two aspects, wind erosion could be efficiently reduced and controlled. Moreover, the higher biomass in the station could let more litter get into the soil, which provides nutrition and improves the soil structure (Jia, Huang, Miao, Lu, Li, Liu, Shen, He, & Wu, 2018; Jia, Liu, He, Miao, Huang, Zheng, Han, & Wu, 2018) that enhances the soil water holding capacity. Meanwhile, the observed better soil water conditions could provide a better scenario for the plant growth, higher biomass production, and total coverage. These changes created positive vegetation–water feedback associated with the other influence brought by SPP. Altogether, these results reflected that the establishment of SPP enhances the resistance capacity of an area against wind erosion and has positive ecological effects under adverse climatic conditions. SPP's installation in arid sandy areas could provide not only electricity energy but also huge ecological benefits brought by a good vegetation condition, which could help other researchers and policy-makers to pay more attention to the ecological benefits besides the economic profits. Our study was just a primary

1099145x, 2019, 18, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ldr.3408 by University Of Arizona Library, Wiley Online Library on [01/07/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

research of the PV panel's ecological effects, and further studies will be needed in more sites to gather large datasets that can support sound conclusions.

5 | CONCLUSIONS

SPP in arid areas could perpetuate the efficient use of regional solar recourses and bring both economic and ecological benefits. SPP installation had a big influence on the surface microhabitat in the arid sandy ecosystem of Western China. Higher SWC and lower evaporation constitute better water conditions, which were the key factors of improving the ecological environment in the sandy areas. Moreover, the PV panels could relieve heat stress by adjusting the air and ground temperature during the plants' growing season. This hydrological process and the modified temperature conditions supported the plant growth and thus accelerated vegetation recovery. After 2 years (2016–2018) of recovery, vegetation coverage in the station reached a very high value (90.5%), which could provide effective protection to soil against wind erosion. Furthermore, biomass and species diversity increased owing to the combined influences of the PV panels. Therefore, PV panels made the surface microhabitats different to some extent, and positive vegetation–microhabitat feedback thus could promote the ecological restoration in the arid sandy region.

ACKNOWLEDGMENTS

This study was funded by the project of the National Natural Science Foundation of China (NSFC 41722107), the Light of West China Program of the Chinese Academy of Sciences (XAB2015A04 and XAB2018B09), and the Youth Talent Plan Foundation of the Northwest A&F University (2452018025). We thank the editor and anonymous reviewers for their constructive comments and suggestions on this manuscript.

Abstract

Solar photovoltaic (PV) has become the second renewable energy source, giving rise to potential conflicts with biodiversity conservation. However, the information available about the impacts and mitigation measures of solar PV energy is scarce and scattered, and a rigorous and comprehensive review on the topic is lacking. Here, we review the state of knowledge on its impacts and mitigation measures and identify main knowledge gaps. For that, we reviewed more than 2000 articles, out of which only 180 assessed the impacts of solar PV ($N = 138$) and/or propose mitigation measures (65). Even though Asia and Europe head the list of regions with the highest PV installed capacity (59% and 22%, respectively), a large portion of the existing knowledge is drawn from North American environmental contexts (48% of the studies), specifically from deserts (41%). Impacts were addressed on plants (26%), arthropods (14%), birds (10%), microorganisms (10%), reptiles (7%), mammals (4%), and bats (1%), but also on abiotic factors (e.g., humidity and temperature; 20%) and ecosystem services (3%). Most studies addressed the impact of PV on habitat alteration at landscape (33%) and microhabitat scale (20%), and on microclimate at microhabitat scale (17%), but other topics have been scarcely addressed (e.g., impact on microclimate at landscape scale or the potential of agrivoltaic systems). Lastly, 53% of the studies employed a single PV facility, and preconstruction situations were rarely reported (8%). There is a strong environmental context bias in the current understanding of PV impacts, which might not be extrapolable to other environmental situations like farmlands, where most of the solar PV capacity is being installed. Moreover, standardized and robust sampling designs are lacking to address cumulative, long-term, and long-scale impacts and produce comparable findings across contexts. Given the lack of empirical evidence and the irrepressible development of PV energy, it is advisable to apply an iterative monitoring and adaptive process

to guarantee a safe energy transition. This review may provide useful guidance on prioritizing research efforts for a smooth shift to renewable energy.

1 | INTRODUCTION

Renewable energy is expanding rapidly, reaching an installed global energy capacity of around 3400 GW in 2022 (EI, 2023). These trends are expected to accelerate in the coming years, as an increase of about 1400 GW is forecasted by 2027 (IEA, 2023). The main driving force of this development has been the need to meet the increase in energy demand of a growing human population while meeting the goals set by the Paris Agreement to reduce carbon emissions and mitigate the impacts of climate change (IPCC, 2023; UNFCCC, 2015). Solar photovoltaic (PV) has recently experienced the most notable increase among all renewable energies (Figure 1) (Ritchie et al., 2023) and is projected to surpass natural gas and coal by 2026 and 2027, respectively, becoming the largest energy source (EI, 2023). Nowadays, Asia has the largest installed capacity of PV in the world (618.8 GW in 2022), followed by Europe (227.3), North America (128.9), South America (32.7), Oceania (27.4), and Africa (11.6) (Figure 1), with China (392.4 GW), United States (111.5), and Japan (78.8) being the top three countries (EI, 2023; Ritchie et al., 2023).

PV production costs have decreased rapidly, emerging as one of the most cost-effective technologies for generating electricity worldwide and one of the most promising potentials for mitigating climate change (IPCC, 2022). The establishment of large-scale PV projects comes with a wide range of environmental consequences, including pollution, erosion, and the occupation of land, which stands out as a prominent concern due to the impacts it triggers on biodiversity (Hernandez, Easter, et al., 2014). The viability of PV projects depends on multiple factors (economic, social, technical, and environmental; Wang et al., 2009), and current site planning is often guided by cost–benefit analysis, prioritizing cheap lands close to the transmission network, in detriment of environmental and landscape attributes in some cases, such as seminatural and agricultural habitats in Japan and Korea (Kim et al., 2021). Indeed, a large portion of PV facilities has been installed in agricultural lands, followed by natural and seminatural habitats (Kim et al., 2021; Kruitwagen et al., 2021; Ortiz et al., 2022)—especially arid lands and grasslands—and a clear overlap exists with important conservation areas (Kiesecker et al., 2019; Pérez-García et al., 2022), with the largest conflict occurring in Eastern Asia, Western Europe, and North America (Rehbein et al., 2020). This fact, together with the forecasted increase on PV (EI, 2023), raises concerns about potential conflicts between PV development and biodiversity conservation goals. The current challenge is that the assessment of environmental impacts and the implementation of measures to minimize them keep up with the fast rate of solar PV development for a sustainable energy transition that integrates biodiversity conservation.

The information available about the impacts and mitigation measures of PV energy is scarce and scattered, and some of the potential impacts described are based on hypotheses with little evidence support or on extrapolation from other human infrastructures (Lafitte et al., 2022). Although previous studies have attempted to compile the available information, most have a strong focus on specific contexts (e.g., deserts in the United States; Cypher et al., 2021; Hernandez, Easter, et al., 2014; Lovich & Ennen, 2011) and/or impacts (e.g., collision with PV panels; Kosciuch et al., 2020; Smallwood, 2022; Walston et al., 2016) and thus, a rigorous and comprehensive overall review is lacking. The aim of this study is to review the state of knowledge about impacts and mitigation measures of PV energy on wildlife and ecosystems and to identify the methodological limitations and knowledge gaps where future research efforts should be invested. For that, we reviewed research articles published in peer-reviewed scientific journals, identifying the geographic location, study contexts, ecosystem components, and impacts covered to get a thorough view on the knowledge and claims about PV impacts. Moreover, we assessed whether the number of research studies by world regions has been proportional to the expansion of PV energy to detect where PV development has surpassed the pace of research progress, posing a greater risk to the preservation of biodiversity. The results of this work will help to gain insight into the impacts of PV energy, as well as to guide future research efforts prioritizing knowledge gaps.

2 | METHODS

Following the practical guide for systematic searching and study screening for literature reviews suggested by Foo et al. (2021), we conducted a rapid evidence assessment

1755263x, 2024, 4, Downloaded from https://conbio.onlinelibrary.wiley.com/doi/10.1111/conl.13025, Wiley Online Library on [01/07/2025]. FIGURE 1 Installed global renewable energy capacity by technology from 2000 to 2022 (top) and solar photovoltaic (PV) cumulative capacity from 2000 to 2022 per continent (bottom). *Source*: EI (2023) and Ritchie et al. (2023).

(REA) in September 2023 using all databases in ISI Web of Science (WOS). This REA followed the following steps:

- Search of research articles based on explicit evidence search criteria (see below);
- Systematically collecting data;
- Synthesizing the data.

This was supplemented by searching reference lists and citations of included studies and relevant reviews. Our search was limited to title, abstract, and keywords, and included the following terms: ("photovoltaic energ*" OR "photovoltaic panel*" OR "solar array*" OR "solar development" OR "solar energ*" OR "solar facilit*" OR "solar farm*" OR "solar installation*" OR "solar panel*" OR "solar park*" OR "solar plant*" OR "solar power" OR "utility-scale solar") AND ("*diversity" OR "ecosystem*" OR "*habitat*" OR "wild*"). From the search terms and resulting number of articles in WOS, we excluded records that did not directly address the impacts of PV energy. Although the review was focused on PV energy, we also kept those studies addressing the impacts of concentrating solar energy (CSP) when impacts could be relevant or comparable to PV energy. We only kept those articles based on

1755263x, 2024, 4, Downloaded from https://conbio.onlinelibrary.wiley.com/doi/10.1111/conl.13025, Wiley Online Library on [01/07/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

empirical data and removed perspective and policy pieces. The remaining articles were assessed for relevant information and characterized according to broad category classes (Table 1).

First, we divided the articles into the main topics addressed in this review: impact on biodiversity, mitigation of biodiversity impacts, or both. In studies evaluating mitigation measures, we specified the level within the mitigation hierarchy (i.e., avoidance, minimization or compensation of impacts), and we briefly described the mitigation measured applied. To evaluate the environmental contexts underlying current knowledge on impact and mitigation measures of PV energy, we noted the studied topic as well as the geographic location (continent and country), climate (according to Köppen climate classification system), study context (e.g., habitat) covered by each study, and the targeted ecosystem components (biotic or abiotic factors and ecosystem services). Lastly, to assess the methodological limitations of current research, we noted the scale of the studies (whether they covered one or more PV facilities), the study design employed (before-after-control-impact [BACI]; control-impact [CI]; impact [I]; before-after [BA]; Table 1). Further explanation of the compiled information can be found in Table 1.

3 | RESULTS AND DISCUSSION

3.1 | Mismatch between PV deployment and impact research

We found 180 articles assessing the impacts of PV energy on biodiversity (N = 138) and/or proposing mitigation measures (65) (Table S1). These references can be consulted at the "Observatory of Scientific Literature Related to Photovoltaic Solar Energy and Biodiversity", published and updated by the Steppe-Forward Chair. The number of studies has increased significantly from 2015 onwards, with a notable increase from 2022 in Asian and European countries (Figure 2).

Most of the research has been carried out in North America (N = 75; 48.1% of the studies)—with the United States (73, 46.8%) being the main contributor—followed by Europe (34, 21.8%), Asia (26, 16.7%), Africa (6, 3.8%), South America (3, 1.9%), Antarctica, and Oceania (1, 0.6%; Figures 2 and 3). Therefore, even though Asia and Europe head the list of regions with the highest PV installed capacity (59.1% and 21.7%, respectively), a large proportion of the existing knowledge is drawn from North American contexts, which only hold the 12.3% of PV energy installed worldwide (Figures 2 and 3).

Of the empirical studies with specific information on the covered habitats (N = 92), 38 (41.3%) were carried out

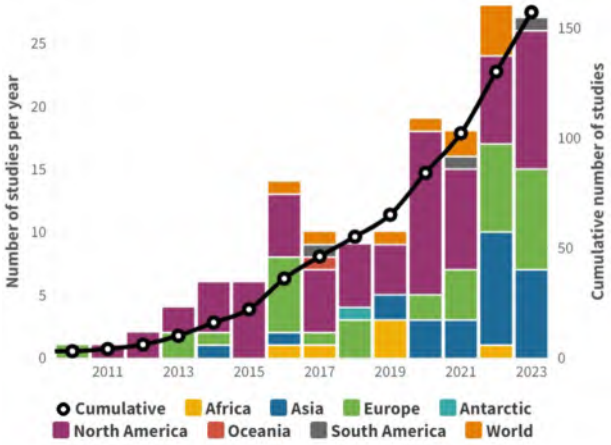

FIGURE 2 Number of studies reviewed assessing the impacts of photovoltaic (PV) energy or measures to minimize them from 2010 to September 2023 per region. Studies carried out under lab conditions (1) and reviews on specific impacts without a geographic focus (23) were removed, totaling 156 articles. "World" refers to studies carried out at global scale.

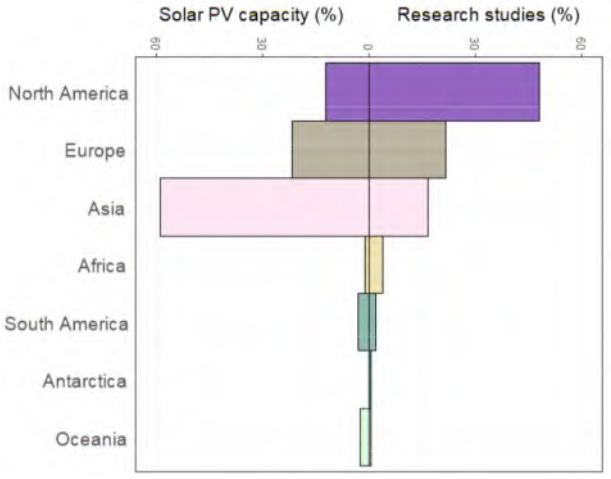

FIGURE 3 Proportion of research studies assessing the impacts of photovoltaic (PV) energy or measures to minimize them (right) and of cumulative installed capacity (left) per region. The percentage of studies is calculated from a total of 156, after removing those carried out under lab conditions (1) and reviews on specific impacts without a geographic focus (23).

in desert ecosystems, 20 in agroecosystems (21.7%; vineyards, abandoned or active fields, and pasturelands), 17 in grasslands (18.5%), and eight in urban environments (8.7%; quarries and waste dumps). Forest, shrubland, and tundra habitats were represented by no more than five studies (<5.5%), and nine studies (9.8%) were experimental tests. A high proportion of studies focused on abiotic factors (e.g., microclimate and soil properties; N = 27 out of 132 empirical studies, 20.4%) and to a lesser extent on ecosystem services (N = 4, 3.0%), whereas most studies

Summary of results		

Note: Wherever applicable, the categories defined for each parameter are specified, as well as a brief explanation. We highlight with an asterisk the fields that were duplicated in case a study addressed more than one topic, ecosystem component, or study context. Lastly, we indicate between brackets the number of studies under each category, considering only the articles incorporated in this study.

Abbreviation: PV, photovoltaic.

[a]The "lake-effect" hypothesis suggests that waterbirds and aquatic insects mistake solar arrays for water bodies, colliding with the infrastructure as they attempt to land. This could either result in direct mortality or leave individuals injured or stranded. See the main text for more information.

addressed biotic components ($N = 80$, 60.6%). Plants were the most studied group ($N = 35$, 26.5%), followed by arthropods ($N = 19$, 14.4%), birds and microorganisms ($N = 13$, 9.8%), reptiles ($N = 9$, 6.8%), mammals ($N = 5$, 3.8%), and bats ($N = 2$, 1.5%). When we cross-reference this information, we observe that the knowledge about the different ecosystem components is not evenly based in all habitats or study contexts. For instance, most information for reptiles comes from deserts, but information for mammals in this ecosystem is lacking as well as for arthropods in grasslands (Figure 4). Similarly, little information is available on bats, and knowledge on aquatic arthropods is mainly drawn from experimental assays.

Most studies addressed the impact of PV energy on habitat loss or alteration at both landscape ($N = 43$, 32.6% of the 132 empirical studies) and microhabitat scales ($N = 27$, 20.4%), and on microclimate at microhabitat scale ($N = 23$, 17.4%) (Figure 5). Furthermore, a high proportion of studies addressed land-use planning, aiming to identify compatible areas for PV development and biodiversity conservation ($N = 25$, 18.9%). As the number of studies per topic decreases, the context bias in current knowledge becomes more evident. For example, most studies addressing the impact of PV energy on collision rates and microclimate at landscape scale have mainly been carried out in deserts and arid climates, and little knowledge exists about the potential of agrivoltaic systems (Figure 5). Moreover, the lake effect hypothesis has been tested mainly under experimental conditions. Regarding methodological aspects, a total of 56 studies (53.3% out of 105 empirical studies with this methodological information) were focused on a single PV facility or experimental array, and 49 studies (46.7%) were based on more than one. Only two (1.9%) studies used a BACI design and seven (6.7%) used a BA design.

3.2 | Impacts of PV energy

The available information to date on the potential impacts of PV energy on biodiversity is summarized in Figure 6. As highlighted in Figure 5, some of these impacts have been addressed in specific environmental contexts and climates (e.g., heat island effect) and should therefore be treated with caution.

3.3 | Impacts on microclimate and soil properties

There is a lack of research on the microclimate impacts of PV energy, and current knowledge is mainly based on

1755263x, 2024, 4, Downloaded from https://conbio.onlinelibrary.wiley.com/doi/10.1111/conl.13025, Wiley Online Library on [01/07/2025]. FIGURE 4 Study contexts (left-hand side) and ecosystem components (abiotic, biotic, and ecosystem services; right-hand side) covered in the research literature on the impacts of photovoltaic (PV) energy or measures to minimize them. Colored bands indicate relationships between them. Some investigations cover more than one ecosystem component or study context.

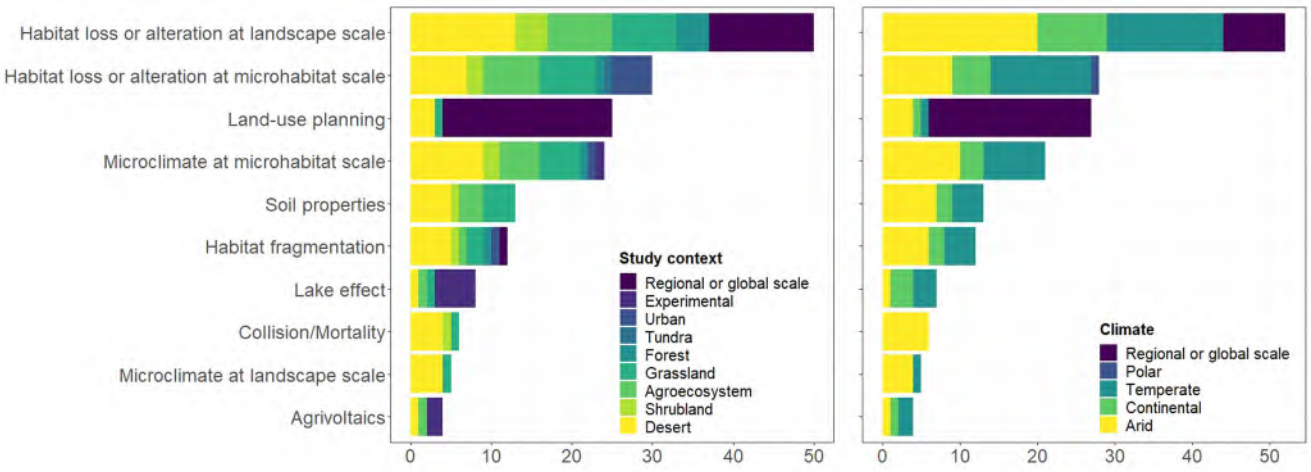

FIGURE 5 Topics addressed in the literature according to study contexts (left) and climates (right).

arid climates (Figure 5). In this climate contexts, PV facilities can alter the energy balance of short- and long-wave radiation by the introduction of darker and less reflective surfaces, which reduce albedo and increase the absorbed solar insolation (Barron-Gafford et al., 2016). Besides, vegetation removal reduces heat dissipation through transpiration and enhances heat gain and storage in soils, energy that will be later re-radiated in the form of heat (Barron-Gafford et al., 2016). Consequently, nighttime temperatures within PV facilities rise 3–4°C compared to surrounding (dryland) ecosystems, thereby inducing a "Heat Island" effect (Barron-Gafford et al., 2016). At a finer

1755263x, 2024, 4, Downloaded from https://conbio.onlinelibrary.wiley.com/doi/10.1111/conl.13025, Wiley Online Library on [01/07/2025]. FIGURE 6 Impacts of photovoltaic (PV) energy at landscape (left) and microhabitat (right) scale. At landscape scale, PV facilities produce habitat loss and fragmentation, and alter the microclimate by inducing a heat island effect at nighttime, at least in arid and temperate climates (see Figure 5). At microhabitat scale, PV panels alter the physical and chemical properties of soils and create novel shade, runoff, and radiation exposure gradients, altering microclimate and ultimately microsite habitat conditions. Given that temperature, water, and light are three key determinants for plant growth, novel conditions trigger a cascade of processes that impact on the plant community, but it can also result on habitat alteration for myriad of taxa (microorganisms, pollinators, birds, bats, and mammals). Lastly, mortality of volant wildlife through collision with PV panels or associated power lines is one of the most recorded PV impacts.

scale, PV panels intercept sunlight, reducing photosynthetically active radiation and creating novel shade conditions underneath (Tanner, Moore-O'Leary, et al., 2020; Wu et al., 2022), thereby decreasing air, surface, and soil temperature and variation as compared to the interval (IT) zone (i.e., area between panel arrays) and control sites during warm seasons (Armstrong et al., 2016; Lambert et al., 2021; Liu et al., 2019; Suuronen et al., 2017; Tsafack et al., 2022). However, this pattern is reversed during nighttime and in cold seasons, partly due to the inhibition of dew formation (Marrou, Guilioni, et al., 2013) and/or to the heat re-radiated from the soil and trapped under PV arrays (Barron-Gafford et al., 2016). Panels also alter the local distribution of precipitation, reducing water inputs below the panels but increasing them in the edge via storm runoff of PV panels. Even though humidity and soil moisture might be higher in runoff areas immediately after rainfall (Moscatelli et al., 2022; Tanner, Moore-O'Leary, et al., 2020), the shielding effect of PV panels reduces water loss by evaporation (Liu et al., 2019, 2022) and evapotranspiration (Marrou, Dufour, et al., 2013), ultimately increasing soil moisture (Suuronen et al., 2017) or smoothing the differences with the IT, runoff, and control sites (Choi et al., 2020). Other factors such as air circulation and turbulence, soil properties, and PV systems (e.g., tracking vs. fixed panels) might shift these microclimate patterns (Moscatelli et al., 2022; Suuronen et al., 2017; Yuan et al., 2022; Yue et al., 2021). More studies are needed to confirm whether these effects can be extrapolated to other environmental contexts and climates.

PV construction can also alter the physical and chemical soil properties, but these effects are highly dependent on land-use history, vegetation management, and control sites used in the comparison. Physical soil quality is degraded after PV installation since it reduces soil aggregate stability, a key factor of soil functioning (Lambert et al., 2021). Chemical soil quality also seems to be degraded in PV facilities (decreased in organic carbon, total carbon, and total nitrogen) as compared to seminatural habitats, but it is similar to that observed in other anthropogenic soils (e.g., abandoned vineyards) (Choi et al., 2020; Lambert et al., 2021). However, other studies have reported higher nitrogen and carbon values in IT soils than under PV panels or arable control sites (Moscatelli et al., 2022) and higher

1755263x, 2024, 4, Downloaded from https://conbio.onlinelibrary.wiley.com/doi/10.1111/conl.13025, Wiley Online Library on [01/07/2025]. electrical conductivity, phosphorus, potassium, soil organic matter, and fast-acting potassium in vegetated PV parks compared to bare land controls (Bai et al., 2022; Yuan et al., 2022). Similarly, another study observed that phosphorus, potassium, nitrate nitrogen, and soil pH increased 6 years after PV installation (Liu et al., 2022). Further research is needed to understand the mechanisms underlying these changes on soil properties.

3.4 | Habitat fragmentation, loss, or alteration

Habitat destruction and/or alteration occur at both broad scale (i.e., landscape) and fine scale (i.e., microhabitat). The physical onsite footprint and spacing of PV has been estimated at 1 ha for a 0.12–0.83 MW/ha (Grippo et al., 2015; Hernandez, Hoffacker, et al., 2014; Wu et al., 2014). At landscape scale, habitat loss due to PV construction has been described to be a threat for several taxonomic groups such as reptiles (Averill-Murray et al., 2013), arthropods (McCoshum & Geber, 2020), bats (Szabadi et al., 2023), and birds (Haga et al., 2020). In terrestrial animals, it can also impact broad-scale ecological processes such as daily, seasonal, and migratory movements through the creation of connectivity barriers (i.e., non-permeable perimetral fencing) (Averill-Leskova et al., 2022; Murray et al., 2013; Sawyer et al., 2022). At finer scale, PV panels per se represent a harsh environment, which can be colonized by a highly diverse microbial community composed of drought-, heat-, and radiation-adapted species (Moura et al., 2021; Tanner et al., 2018; Tanner, Molina-Menor, et al., 2020). Moreover, PV panels create novel shade and moisture gradients (see above), ultimately altering microsite habitat conditions with both winner and loser species resulting from the new PV ecosystem. The diversity and activity of soil fungi and prokaryotes seem to be higher in PV parks, especially in runoff areas, than in bare ground and arable controls (Bai et al., 2022; Moscatelli et al., 2022), and soil extracellular enzyme activity, an indicator of microbial function capacity, might increase after installation (Liu et al., 2022). However, soil archaea community structure and diversity does not differ between PV soils and adjacent deserts (Yuan et al., 2022). Future research should deepen on the impact of PV construction across the microclimate-soil-microorganism system due to its role in biological processes and ecosystem functioning (Bai et al., 2022).

PV panels can also impact on the plant community, although the responses might vary between habitats, seasons, and species, let alone vegetation management strategies (Tanner et al., 2021; Tanner, Moore-O'Leary, et al., 2020). In hydric stressful climates, PV panels could soften the harsh environmental conditions and alleviate heat stress, thereby increasing seed bank survival and aboveground plant productivity and diversity (Liu et al., 2019; Tanner, Moore-O'Leary, et al., 2020). However, the opposite effect might be found in communities that benefit from rainfall and sun exposure, reaching the lowest rates of photosynthesis and plant biomass under PV panels and their maximum productivity and diversity values at the runoff or IT zones (Bai et al., 2022; Moscatelli et al., 2022; Tanner et al., 2021). Overall, plant community composition might change by inhibiting the growth of dominant species and leaving room for subdominant ones (Bai et al., 2022; Uldrijan et al., 2022). Moving up the trophic chain, we find that arthropod pollinators use IT and under-panel habitats interchangeably, even though abundance and diversity tend to be lower under PV panels (Graham et al., 2021). Other authors have found that induced changes on the plant community and microclimate, together with targeted management measures (see *Mitigation hierarchy* below), might convert PV installations on invertebrate refuges (Jeal, Perold, Seymour, et al., 2019; Suuronen et al., 2017).

Overall, both habitat destruction (landscape) and the alteration of the abiotic conditions (microhabitat) result in habitat modification, loss and/or fragmentation for myriad of species (McClung et al., 2019). These changes combined with displacement due to visual or noise disturbances, might trigger behavioral responses (i.e., perception and habitat-use; Chock et al., 2021), ultimately resulting in population-level impacts across many taxa (Smallwood, 2022). A lower bat activity (Szabadi et al., 2023; Tinsley et al., 2023) and bird diversity and/or density has been found within PV parks (DeVault et al., 2014; Jeal, Perold, Ralston-Paton, et al., 2019; Visser et al., 2019), but no differences have been observed on bird reproductive success (Kitazawa et al., 2019). Conversely, PV panels might provide perches and thermal refuges that would be otherwise limited in specific contexts (e.g., deserts), or they could even offer foraging, roosting, sheltering, and nesting habitats (DeVault et al., 2014; Gerringer et al., 2022; Nordberg et al., 2021; Visser et al., 2019). Further research is needed to understand the consequences of habitat alteration following PV installation on wildlife habitat-use patterns and populations.

3.5 | Wildlife mortality

Direct mortality of flying wildlife (bats, birds, and aquatic insects) through collision with PV panels and other infrastructures (i.e., power lines and perimetral fences) is one of the most addressed impacts of PV energy, but most information comes from unpublished reports that employ non-standardized methodologies (Smallwood, 2022). Bird mortality rates at PV projects have been estimated between

1755263x, 2024, 4, Downloaded from https://conbio.onlinelibrary.wiley.com/doi/10.1111/conl.13025, Wiley Online Library on [01/07/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

2.49 and 10.7 fatalities/MW/year (Kosciuch et al., 2020; Visser et al., 2019; Walston et al., 2016). A recent work provides more accurate estimates by adjusting the results of previous reports performed from 1982 to 2018 for the effect of body size on carcass detectability, obtaining a mortality rate of 11.61 (95% CI = 8.37–17.56) bird fatalities/MW/year and 0.06 (95% CI = 0.01–0.1) bats/MW/year at 11 PV projects (Smallwood, 2022), considering only collision with PV panels and ignoring other sources of mortality (i.e., power lines and perimetral fences). Future studies should account for other sources of bias on carcass counts, such as carcass disappearance due to decomposition or removal by scavengers, in order to obtain more accurate quantifications of mortality (see for example Gómez-Catasús et al., 2021). Moreover, mortality estimates alone do not say much about their ecological and conservation significance, which depends on their larger-scale, population-level consequences, which are influenced by population descriptors (i.e., size and trends) and life-history traits (e.g., pace of life and reproductive strategy). A recent study found that of 23 priority species colliding at wind and solar facilities, 11 (48%) were vulnerable to population-level effects (Katzner et al., 2020), especially non-local, nocturnal migrant species.

Information on the factors influencing collision risk and fatality estimates is scarce. In relation to species-specific factors, songbirds (Passeriformes), pigeons, and doves (Columbiformes) seem to suffer the highest mortality rates (Kosciuch et al., 2020; Smallwood, 2022). These species groups are generally abundant in the studied regions, and they share several traits (e.g., ground dwelling and inhabit anthropogenic landscapes). Migratory and aquatic birds also suffer high collision rates, although their contribution to mortality rates seem to vary with the occurrence of water bodies, wintering grounds and migration routes in the surroundings, suggesting that their collision risk is context-dependent (Walston et al., 2016; Kosciuch et al., 2020). Moreover, collision rates vary with phenology, being more frequent in fall and winter, coinciding with the higher abundance of birds following the breeding season and with migratory movements to the wintering grounds (Kosciuch et al., 2020). We found no studies evaluating the effect of site descriptor factors on fatality rates, and only one study addressed PV park attributes, showing a negative effect of PV capacity (Kosciuch et al., 2020).

The mechanisms underlying collision events are poorly understood. The most discussed hypothesis is that aquatic insects might mistake solar panels as natural water bodies (i.e. "lake effect" hypothesis) due to polarization of light reflected, which they used to locate water bodies for egg-laying (Horváth et al., 2010), turning into ecological traps (Horváth et al., 2009, 2010). More recently, it has been observed that solar panels can polarize not only visible light (390–700 nm), but also ultraviolet light (<380 nm), which is also a cue used in habitat selection for some aquatic insects (Fraleigh et al., 2021). Although the "lake effect" hypothesis has been widely exposed as a potential mechanism underpinning also bird and bat collisions (PV panels might provide analogous reflections of echolocation calls than water bodies; Greif & Siemers, 2010; Russo et al., 2012), there is little evidence proving this causal factor. Other potential explanation widely discussed is that insectivorous wildlife might be attracted to PV panels due to the higher abundance of insect prey (Diehl et al., 2016; Horváth et al., 2010), being stranded, injured, or killed at solar panels (Smith & Dwyer, 2016), but we have found no evidence for this hypothesis either. Further research is needed to test these hypotheses and to understand how these organisms perceive solar energy infrastructures.

3.6 | Mitigation hierarchy: From prevention to compensation

The implementation of PV facilities must follow the mitigation hierarchy procedure to avoid, reduce, and ultimately offset its negative impacts on wildlife. First, proactive land-use planning is essential, considering ecological and conservation attributes in deciding project locations that secure wildlife habitat preservation as well as the maintenance of other important land-uses such as agricultural land (Hermoso et al., 2023). Land sparing (i.e., the promotion of PV sprawl in urban areas or degraded lands) has been proposed as an alternative to mitigate habitat loss and soil degradation in natural and semi-natural habitats (DeVault et al., 2014; Hernandez et al., 2015; Kim et al., 2021; Lambert et al., 2021) rather than PV construction in remote areas, which requires additional transmission infrastructure with further impacts on biodiversity (Biasotto & Kindel, 2018).

In a second step, PV projects should contemplate minimization measures for those impacts that are unavoidable. The concept of *conservoltaic* consists on the combination of PV energy production and biodiversity conservation (Nordberg & Schwarzkopf, 2023). For instance, lessening vegetation disturbance during construction or the application of habitat restoration practices might help to combat desertification (Xia et al., 2022), alleviate soil degradation (Ormeño et al., 2016), or minimize habitat loss (Armstrong, Kulikowski, et al., 2021; Cypher et al., 2021; Gerringer et al., 2022), and targeted vegetation management during operation can create habitat islands for wildlife (Blaydes et al., 2021, 2022; Guiller et al., 2017). The installation of permeable security fencing or the translocation of sensitive species outside the project's footprint are other potential mitigation measures (Agha et al., 2020; Brand et al.,

1755263x, 2024, 4, Downloaded from https://conbio.onlinelibrary.wiley.com/doi/10.1111/conl.13025, Wiley Online Library on [01/07/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

2016; Cypher et al., 2021). Another emerged land sharing strategy is the co-location of PV energy with agricultural practices, such as crop cultivation or animal husbandry (so-called "*agrivoltaic systems*"), which promises to maximize food and energy production while minimizing the impacts on ecosystems (e.g., water use efficiency and erosion prevention; Barron-Gafford et al., 2019; Hernandez et al., 2019; Vaverková et al., 2022), even increasing PV panel efficiency through dust accumulation and cooling (Hernandez et al., 2019; Nordberg et al., 2021). However, the potential of this land sharing strategy to mitigate impacts on biodiversity and to be considered within the mitigation hierarchy deserves more attention. Overall, if properly managed, PV farms have the potential to promote important ecosystem services (e.g., carbon storage and biological pest control; Armstrong, Brown, et al., 2021; Barron-Gafford et al., 2019; Randle-Boggis et al., 2020; Semeraro et al., 2018; Walston et al., 2018, 2021, 2022) and even to enhance or restore previous ecosystem goods and services in degraded lands (Hernandez et al., 2019). However, further research is needed to empirically test these potential synergies and to verify whether they are generalizable or not to all climatic-environmental contexts (Figure 5).

Mortality due to collision (both with power lines and PV panels) is another impact to mitigate in PV facilities. First, the widely known power line collision mitigation measures should be implemented (Bernardino et al., 2018). On the other hand, PV panel collision mitigation has been studied in aquatic invertebrates, suggesting that specific panel designs might be effective tools to disarm the panel-induced ecological trap (e.g., employment of a white, non-polarizing gridding; Black & Robertson, 2020; Horváth et al., 2010) and matte colors or anti-reflective coatings (Száz et al., 2016; Horváth et al., 2020; but see Blaho et al. [2014]). Further research is needed to find effective tools that mitigate collision impacts across taxa. Finally, offsite compensatory mitigation is employed as last resort to offset for unavoidable impacts, including land acquisition and the restoration of off-site habitats. We have not found any reference evaluating the effectiveness of these measures in PV facilities specific contexts, but it is recommended to use the available scientific knowledge on similar conservation strategies so that they can be conveniently designed and implemented, always supported by a monitoring of their effectiveness to achieve adaptive management.

3.7 | Conclusions and research gaps

Research on PV impacts on biodiversity have not increased proportionally to its development, with a significant knowledge deficit compared to other currently less widespread energies, such as wind energy (e.g., Marques et al., 2014; Nazir et al., 2020; Peste et al., 2015; Powlesland, 2009; Wang et al., 2015; Wang & Wang, 2015). Besides, there is a notable decoupling between PV development and progress of research on its impacts by region: although PV capacity is concentrated in Asia and Europe (ca. 59% and 22%, respectively), where the greatest conflicts with conservation areas occur (Rehbein et al., 2020), most of the knowledge on PV impacts comes from North American contexts (48%). This inevitably leads to a bias in the current knowledge about PV impacts (41% in deserts), which might not be extrapolated to other environments like farmland, where most of the PV capacity is sited (Kruitwagen et al., 2021). We detail below the *main conclusions drawn* and the *knowledge gaps* where research efforts should be invested so that biodiversity conservation can keep up with the accelerating development of this renewable energy:

- **Adaptive, collaborative strategies to avoid and compensate PV impacts.**
  The urgent call to combat the impacts of climate change makes the advance of PV energy inevitable. However, given the lack of empirical evidence found in this review for some PV impacts and mitigation measures (see Figure 5), the development of PV should be accompanied by adaptive planning and management, applying an iterative process where every new facility is accompanied by extensive monitoring, contributing for the acquisition of new knowledge that will be applied in future installations in close collaboration with stakeholders (Köppel et al., 2014). Further research is needed on: 1) wildlife use of PV facilities; 2) the impacts of specific configurations (e.g., landscape context); and 3) the effectiveness of management and mitigation/compensation schemes applied within and outside the PV facilities to maximize the benefits on biodiversity and ecosystem services. This knowledge is essential to identify optimal locations and land sharing opportunities of 'conservoltaic' systems (Nordberg & Schwarzkopf 2023). Lastly, the increasing efficiency of PV panels allows foreseeing an optimization of land surface occupied by facilities.
- **Need for diversification of environmental contexts and ecosystem components.**
  Most information available on the impacts of PV comes from desert ecosystems (41%), but there is a lack of research in grasslands and farmland. Moreover, only 80 studies reviewed have focused on specific species or groups of species, even in regions with good scientific knowledge of species ecology and threats like the EU where 76 species (mainly birds and reptiles; 48%

1755263x, 2024, 4, Downloaded from https://conbio.onlinelibrary.wiley.com/doi/10.1111/conl.13025, Wiley Online Library on [01/07/2025]. and 38%, respectively) included in the Birds and Habitat Directives are reported threatened by solar power development (European Environment Agency, 2023). Given that most PV impacts are context-dependent, future research efforts should be invested in those contexts and ecosystem components for which the greatest knowledge gaps have been found (e.g., microclimate impacts on agroecosystems, grasslands, or shrublands in continental climates or the effectiveness of agrivoltaics in arid and continental climates; Figure 5), diversifying environmental conditions and prioritizing those species that are more threatened by PV development.

- **Lack of standardized and robust sampling designs**. A large portion of the studies were carried out on a single PV project (53%), and preconstruction estimation of baseline situations was rarely reported (8%), with only two studies employing a strict BACI framework. There is a need to use comprehensive BACI designs that provide critical information on the direct responses of sensitive wildlife, including a large number of years and facilities (i.e., long-term and large-scale studies) as well as preconstruction and control-site data for interpreting postconstruction changes. Moreover, the employment of standardized protocols—especially for collision studies—would allow findings to be comparable across contexts, opening the way to more robust and generalizable conclusions (Conkling et al., 2021).
- **Lack of knowledge regarding the cumulative and synergistic ecological impacts.** Recent studies have proven that medium-sized PV plants result in higher loss of seminatural habitats than large-sized PV plants, probably due to more strict environmental impact assessment on mega-solar PV facilities, which might lead to the fragmentation of large projects (Kim et al., 2021). The scattered distribution of small facilities might result in a high cumulative environmental impact that would not be detected by independent assessments, supporting the need for cumulative and synergistic environmental impact assessments (Serrano et al., 2020).
- **Disentangling the mechanisms underlying wildlife collision with PV panels is mandatory to design effective mitigation measures.** There is an urgent need to identify the species (e.g., morphological and local abundance), site (e.g., landscape context), and PV facility (e.g., size) specific factors determining collision events to improve our understanding of this process and properly design mitigation measures. In addition, more research is needed to understand how species perceive PV facilities in relation to surrounding landscape elements and the mechanisms underpinning maladaptive behaviors such as the attraction to PV panels suffered by some taxonomic groups (Chock et al., 2021). Lastly, to properly disentangle these mechanisms, an accurate quantification of casualty estimates is mandatory, which should be corrected by all bias sources when counting carcasses, including imperfect detection and carcass disappearance due to decomposition or removal by scavengers, as well as the underlying potential factors influencing these bias sources (e.g., vegetation structure, carcass age, carcass size, and observer) (see Gómez-Catasús et al. [2021] for an example with power lines).

ACKNOWLEDGMENTS

We thank Gerald Puig for his help with the design of the graphical abstract summarizing the impacts of PV energy. We are also grateful to Núria Pou and Anna Farràs who were in charge of elaborating the "Observatory of Scientific Literature Related to Photovoltaic Solar Energy and Biodiversity". This research is a contribution to the Steppe-Forward Chair (UAM-CTFC-TotalEnergies). Julia Gómez-Catasús was funded by the Steppe-Forward chair (UAM-CTFC-TotalEnergies) and a Margarita Salas postdoctoral fellowship (CA4/RSUE/2022-00205) provided by the Spanish Ministry of Universities and Universidad Autónoma de Madrid (Spain).

CONFLICT OF INTEREST STATEMENT

The authors declare no conflicts of interest.

DATA AVAILABILITY STATEMENT

The dataset and all code for figures and analyses in this manuscript will be archived on a public repository such as Github.

Abstract: Agrivoltaic systems, which consist of the combination of energy production by means of photovoltaic systems and agricultural production in the same area, have emerged as a promising solution to the constraints related to the reduction in cultivated areas due to solar panels used in agricultural production systems. They also enable optimization of land use and reduction in conflicts over land access, in order to meet the increasing demand for agricultural products and energy resulting from rapid population growth. However, the selected installation configurations, such as elevation, spacing, tilt, and choice of panel technology used, can have a negative impact on agricultural and/or energy production. Thus, this paper addresses the need for a review that provides a clear explanation of agrivoltaics, including the factors that impact agricultural and energy production in agrivoltaic systems, types of panel configurations and technologies to optimize these systems, and a synthesis of modelling studies which have already been conducted in this area. Several studies have been carried out in this field to find the appropriate mounting height and spacing of the solar panels that optimize crop yields, as this later can be reduced by the shade created with the solar panels on the plants. It was reported that yields have been reduced by 62% to 3% for more than 80% of the tested crops. To this end, an optimization model can be developed to determine the optimal elevation, spacing, and tilt angle of the solar panels. This model would take into account factors that influence crop growth and yield, as well as factors that affect the performance of the photovoltaic system, with the goal of maximizing both crop yield and energy production.

1. Introduction

Of all natural resources, water, energy, and food are the most essential to sustain life on earth [1,2]. Water, energy, and food share common challenges of limited accessibility, increasing global demand, and sustainability constraints [3]. Moreover, these essential resources are expected to face a significant surge in demand due to rapid population growth, in order to meet the basic needs of the population [4]. Indeed, according to UN projections, the world's population will increase from 8.5 billion in 2030 to 9.7 billion in 2050 and reach about 10.4 billion in the 2080s [5]. Moreover, according to the FAO [6], agricultural production will have to be doubled to meet demand in developing countries, while these countries will have to face constraints related to increased competition for access to water and energy and the impacts of climate change. To this end, it has been predicted that production needs to be increased by 60% [7] or even doubled to meet the

population's needs in the face of population growth and changing diets [8]. The major constraints to agricultural development are related to access to water and energy for irrigation. Irrigation is the controlled delivery of water for agriculture through artificial systems to meet water needs not met by rainfall for crop growth and development [9]. Sophisticated and water-efficient irrigation techniques have significantly increased energy requirements. The energy cost required to operate these systems compromises the viability of many irrigation networks [10]. To this end, new perspectives have emerged, namely the use of renewable energy in irrigation systems as an alternative to pumping systems powered by fossil fuels [11,12], bearing in mind that the high cost of fuels and the lack of electricity, especially in rural areas, are factors that negatively affect the functioning of irrigation systems [13]. Solar PV panels are utilized due to their environmental benefits, cost-effectiveness, and ability to address issues of fossil fuel scarcity and unavailability in certain regions. The energy sector has seen significant and accelerated progress in terms of innovations observed with the use of renewable energy. A total of 20% of global energy consumption in the world comes from renewables, and about 30% of investment in renewables is in wind power and 60% in solar power [14].

Solar photovoltaic energy has emerged as an environmentally friendly and economically viable alternative with lower energy costs [9,13]. In addition, photovoltaic panels are among the leading renewable energy technologies in the world and have seen continuous decrease in costs over the years. It is predicted that 25% of the electricity needed in 2050 will come from solar PV, with a reduction of 4.9 Gt of CO_2 corresponding to a 21% decrease in emissions in the energy sector [15].

Nevertheless, using solar panels to pump water for irrigation can significantly reduce cultivated areas due to the space occupied by the solar panels [16]. One solution to this problem is, therefore, the adoption of agrivoltaic systems. These dual-use systems involve raising the PV panels to use the space under the panels for agricultural purposes [17]. Thus, this system reduces the issue of conflicts regarding land access [18,19]. Agrivoltaics can also significantly reduce the constraints on access to electricity for populations. According to Jamil et al. [20], agrivoltaic practices on only 1% of cultivated land can satisfy the energy demands of at least one-quarter of the population in Canada. However, solar panels installed in an area can impact microclimate, temperature, and solar radiation distribution, water, biodiversity, air quality, and ecosystem-energy balances [21,22]. Given the impact of solar panels on crops, several studies have investigated the optimal panel layout to maximize crop production in the presence of the panels. These studies have mainly focused on determining the height and spacing of the panels to create a suitable environment for crops under the panels. However, these arrangements were determined through studies that primarily focused on the irradiation received under the PV array and the resulting shading on the crops, with specific arrangements being tested [23–25]. Other studies have examined panel orientation through field experiments [26]. Kim et al. [27] worked on modeling the hybrid performance of an agrivoltaic system in South Korea. Their model focused on the variation of the amount of electricity generated and the crop yield obtained based on the incident radiation, as well as the impact of atmospheric conditions on the radiation. Three different shading ratios were tested to compare the levels of shading (21.3%, 25.6%, and 32%), with the shading ratio calculated as the panel area divided by the system area. A height of 5.42 m was used for all three tests and the shading rate was based on the density of the modules. However, there is still limited research and decision-making tools to determine the appropriate configuration for the crop being grown. Thus, modeling studies to determine the optimal height, spacing, and inclination of the panels to maximize growth and development for a given crop and the performance of the panels would help users to find the right configuration.

In order to achieve our purpose, this review focuses on a clear explanation of agrivoltaic systems and the functioning of its different components, as well as the factors that affect each of them. We believe that a large literature review will allow us to identify the most important parameters to consider for the design of the optimization model. The present paper will also summarize the studies carried out on the possible configurations of agrivoltaic systems, as well as the overall successes and failures of the arrangements and orientation.

2. Definition and Terminology

An agrivoltaic practice is a concept that originated in 1980 [23]. It is defined as a land-use concept that directly integrates solar energy production and agricultural activities, which are practiced under the photovoltaic field installation, both of which are highly dependent on sunlight [28]. Agrivoltaics has several names that vary according to region and application, such as "dual-use", "co-location", "agri-PV", "agri-solar", "solar sharing", "pollinator-friendly solar", etc. [29]. Indeed, it is a symbiotic relationship in which both activities interact directly and benefit from this co-location [30]. This practice leads to synergies by optimizing the potential offered by both production systems [31], especially in agroforestry systems [32].

Agrivoltaic practices can be carried out in different ways depending on the activities carried out by the population in a given area (Figure 1). Agrivoltaic applications represent the combination of energy production with (i) agricultural production in the field or (ii) agricultural production in greenhouses or livestock rearing, or (iii) provision of ecosystem services through vegetation management or (iv) different agricultural practices combined [29].

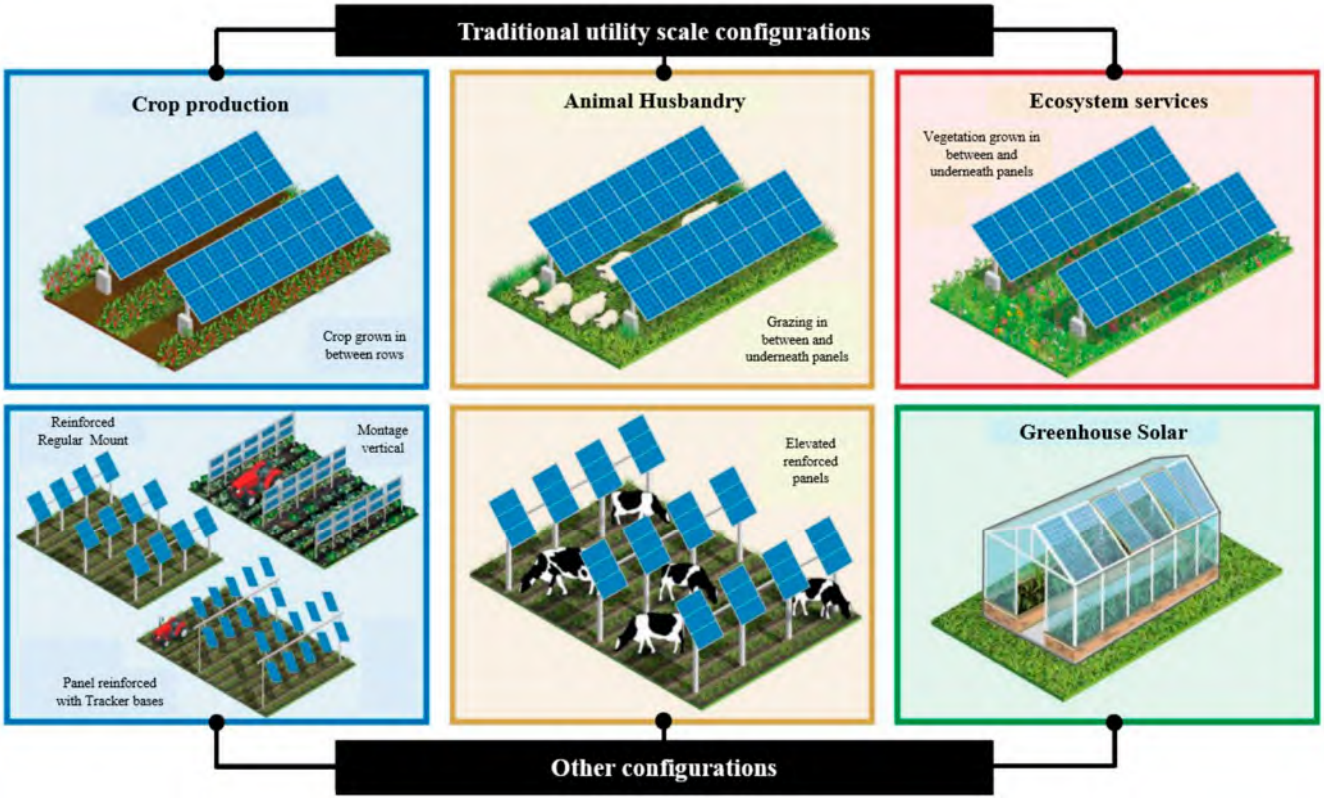

Figure 1. The different agrivoltaic systems [29].

Agrivoltaic technology has an important role in strengthening the water–energy–food relationship [33], given the increasing future need for energy and food production in the face of population demand [34]. Indeed, one of the constraints on the development of PV systems is the increased competition for land due to high population growth and rising food demand [35]. Although land resources are limited, the need for energy and food is increasing, leading to increased competition for land between the two sectors. In response to this growing competition, agrivoltaics was conceived to keep the two activities in balance [36]. Due to their dual use, agrivoltaics would mitigate competition for space and offers the possibility to install large PV systems, while keeping the land accessible for food production [37]. Thus, agrivoltaics system reduces land constraints concerning the placement of solar PV plants for electricity generation [38]. Moreover, this system has proven to be a particularly effective way to increase land use efficiency [32]. Land use efficiency is determined by the so-called parameter Land Equivalence Ratio (LER). The method of measuring land use in integrated agricultural and electricity production systems was originally derived from the intercropping method applied in the farming sector to increase land yield and total income [39]. The LER is a function of the area of the PV system and the total area needed to meet the agricultural and electricity production of the system [40]. Agrivoltaic systems can increase overall land productivity by 35–73%, thus they avoid using land solely for energy production at the expense of agricultural production [41]. According to Lee et al. [42] and Weselek et al. [31], agrivoltaics can increase land productivity by 60–70%, and for Dinesh and Pearce [38], it can increase the economic value of land by more than 30% by minimizing yield losses due to shading effects through appropriate crop selection. According to Trommsdorff et al. [43], land use efficiency varies depending on time and climate. In 2017, the Land Equivalence Ratio (LER) in Germany indicated an increase in land productivity from 56% to 70%, and this value reached 90% during the dry and hot summer of 2018. Abidin et al. [39] reported that applying agrivoltaics to less than 1% of the world's cultivated land could offset the global energy demand. Although agrivoltaics may reduce the efficiency of electricity generation or agriculture when viewed in isolation, studies have shown that the synergy between the two activities can lead to increased overall efficiency. For example, the combination of two hectares of land (1 ha of crops and 1 ha of solar panels each considered individually) corresponds to 100% of crops and 100% of solar energy. However, the use of agrivoltaics in two hectares of land corresponds to 160% cultivation and 160% energy (i.e., 80% of crop and 80% of energy in only 1 ha of land) [39].

As reported by Trommsdorff et al. [43], Formula 1 is used to calculate LER. However, Formula (2) can be used to take into account the high land loss due to the surface occupied by the mounting structure of the solar PV panels.

$$LER = \frac{Yeild_x(dual)}{Yeild_x(mono)} + \frac{Yeild_y(dual)}{Yeild_y(mono)} \quad (1)$$

$$LER = \frac{Yeild_x(dual)}{Yeild_x(mono)} + \frac{Yeild_y(dual)}{Yeild_y(mono)} - 8.3\% \quad (2)$$

x is the cultivated crop and y is the electricity.

3. Solar Panel Installation Techniques to Optimize Agrivoltaic Systems

3.1. Classification of the Different Agrivoltaic Installations

The module configurations in agrivoltaic systems can be categorized into elevated and inter-row systems. The modules are installed above the crop at more than 1.8 m in elevated systems. Growing crops under elevated solar panel installations typically leads to a decrease in the amount of solar radiation they receive, which can cause shading and reduced exposure to sunlight. The main crops used in this type of agrivoltaic system are grapes, small fruit trees, and delicate vegetables. In contrast, inter-row PV systems are systems in which agricultural production is usually carried out in the space between the rows of

panels. The distance between two consecutive rows of the panels can be considerable in this type of installation to facilitate the passage of large agricultural machinery. The most common crops in inter-row solar systems are grasses, hardy vegetables, and higher-value horticultural crops [29]. The different configurations are established to compare their impact on the level of shading created by the panels and their consequences on crop yields to determine the optimal density for an agrivoltaic installation [44]. Another way to increase the efficiency of a PV system is to install double-sided PV panels [45]. Figure 2 summaries the different configurations.

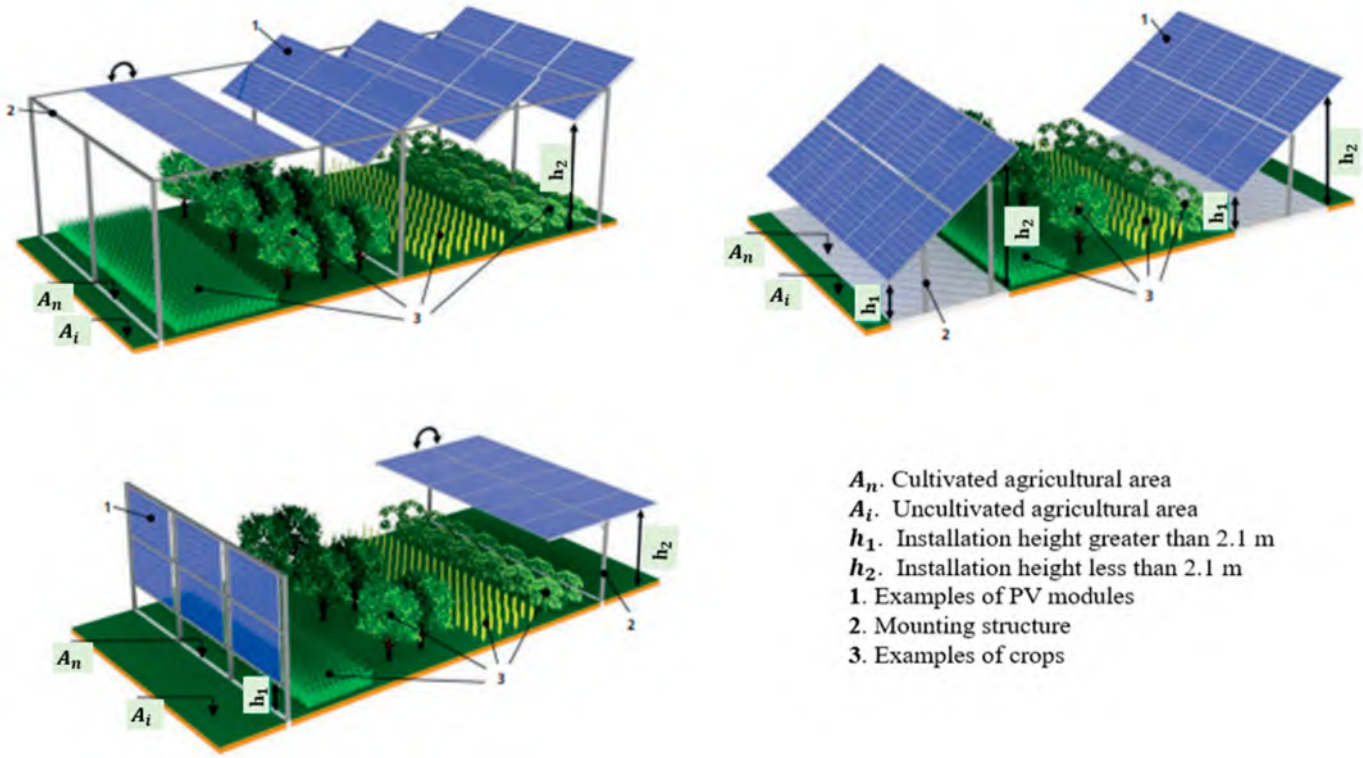

Figure 2. Overview of different configurations of agrivoltaic installations [44].

Several configurations and technologies have been developed and tested to optimize production in agrivoltaic systems. Therefore, the installation must meet the requirements of both the crop and the photovoltaic panels, which can be achieved by using optimal panel spacing and installation height that also allows the passage of agricultural machinery and appropriate panel technology [44]. Macknick et al. [46] have identified three types of approaches for the implementation of agrivoltaic systems: (i) the energy production approach, which focuses on optimizing the solar energy produced (thus minimizing changes in standard solar development practices), while cultivating between and/or under the panels, (ii) the agricultural production approach which focuses on optimizing biomass production (minimizing changes in existing vegetation management activities), while taking energy production into account, and (iii) the integrated agricultural and energy production approach (incorporating vegetation and energy priorities into system design).

These approaches are based on implementing one of the two installation techniques: open agrivoltaic systems, in which the PV module are installed at the ground level via support, and closed agrivoltaic systems, in which the modules are installed on greenhouses, thus serving as a cover [44]. However, only open agrivoltaic systems are considered in this paper. For this purpose, a general classification of the different agrivoltaic systems is proposed in Figure 3.

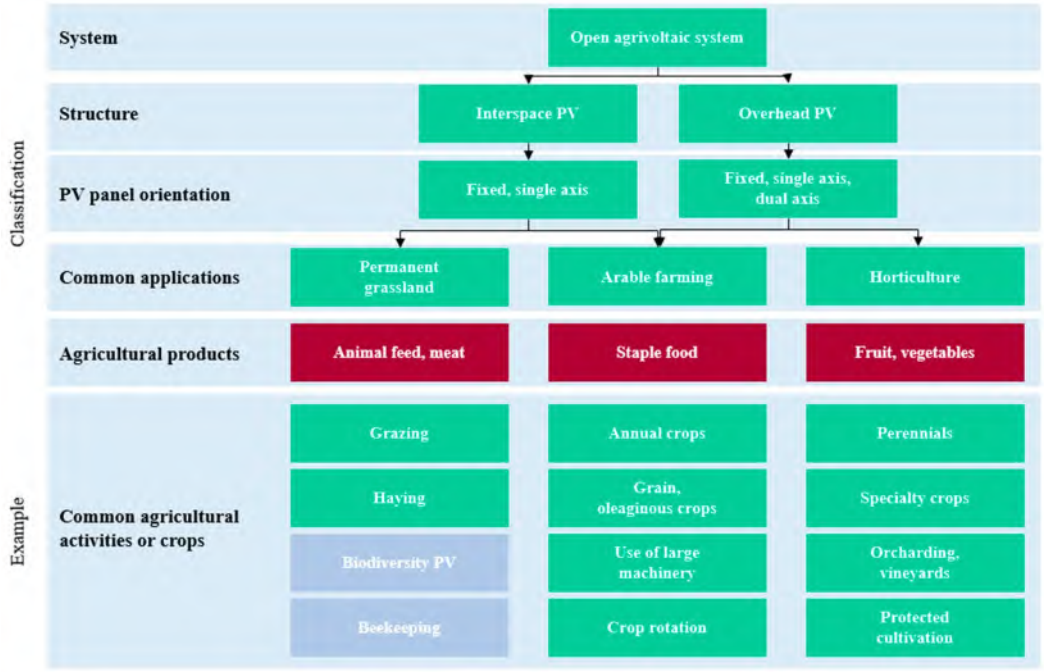

Figure 3. Summary of different agrivoltaic field systems [44,47].

3.2. Installation Techniques to Optimize the Agrivoltaic System

3.2.1. Mounting Height or Overhead of Agrivoltaic Systems Installation

The first agrivoltaic installation in the world was developed by Goetzberger and Zastrow at the Fraunhofer Institute (Germany) in 1980. It employed a height of 2 m and a spacing of 6 m between panel rows [23]. Since then, several studies have been carried out to determine the optimal elevation and spacing of solar photovoltaic modules to maximize energy and agricultural production. The ability of crops to grow and develop underneath PV modules raises structural issues in the case of aerial systems [44]. The height of the panels is an essential factor in the success of the various agrivoltaic practices. However, there are no recommendations for the panels' ideal height for an agrivoltaic installation. The height of the PV panels depends on several factors, including the geographical location of the site, the crop to be cultivated, the soil types, and financial resources. Thus, the height of the panels defines the crop to be grown on the site, the location of the crops in the systems (between the rows of panels or under the PV panels), and the equipment that can be used. Moreso, the solar panels installed in the agrivoltaic systems can have different configurations depending on the climate and soil to protect the structures from certain climatic hazards, namely high winds and freezing. For this purpose, a height of 1.8 m of the tubes supporting the PV panels is considered the minimum viable height for vegetable production under the panels. However, a tube height of 2.4 m is preferable for crops. This is because crops are grown between rows of panels at heights below 1.8 m, except for low-lying crops that appreciate shade. The elevation of the modules promotes a more even distribution of sunlight under the solar PV panels. In addition, these higher installations also allow the movement of equipment and people under the modules [29].

According to Trommsdorff et al. [44], overhead systems should be mounted at a minimum height of 2.1 m from the ground. In 2004, agrivoltaic systems started to be installed in Japan with installation heights of 3 m [31]. Dupraz et al. [24] used a 4 m elevation to assess the impact of this configuration on crop yields at Montpellier in 2010. This height was chosen to ensure access to large agricultural machinery on the site. In Germany, the impact of shading of the panels on crops was studied in 2016 by installing the PV panels at a distance of 5 m from the ground. In the USA, a 3.3 m high system was installed over the same period to assess the impact of agrivoltaic systems in arid environments [33]. Kim et al. [48] investigated the effect of agrivoltaic systems in South Korea using an

elevation of 5.2 m. Several studies were undertaken involving a range of configurations of agrivoltaic systems on different crops [28,38,49–59]. In addition, standard heights of solar panels can be used for sheep grazing whereas higher panel heights are required for cattle grazing [29]. Figure 4 gives two example of elevated agrivoltaic installation.

Figure 4. (**a**) Panels installed at the height of 4 m in Montpellier © Dupraz, (**b**) Panels installed at the height of 5 m in Germany © Fraunhofer ISE [33].

For traditional industrial-scale solar installations, minimal spacing is required between rows to avoid the shading of one onto another, but spacing between PV modules of a same row is not necessary. For an open agrivoltaic system, the spacing between rows on the one hand and the spacing between modules in the same row on the other hand must be carefully determined according to the type of crop. A wide panel spacing increases the capacity and uniformity of solar radiation penetration to the crop, thus reducing the impact of shading from the panels. Spacings tested ranged from 0.2 m [29] to 6.4 m [50]. A typical image concerning the spacing between modules is depicted on Figure 5. The spacing between rows of panels increases the efficiency of elevated agrivoltaic systems (Figure 6). In addition to enhancing the uniformity of solar radiation distribution to the crops, this configuration also increases the number of crop rows under the panels, facilitates the movement of large farm machinery, and increases the space available for farm workers. The spacing between rows in the aerial systems tested in the field ranged from 0.71 m [55] to 9.5 m [58].

Figure 5. Panels spacing for an experiment in the USA [29].

Figure 6. Spacing between rows of panels allowing movement of farm machinery under the PV panels © Fraunhofer ISE [44].

Another method of optimizing elevated agrivoltaic systems is to use an optimal tilt angle and orientation to increase the yield of the solar panels and the crops grown under them (Figure 7). Various tilts and orientations have been tested for different locations for fixed installations. According to Trommsdorff et al. [44], solar tracking modules allow for more flexible light management under the panels. The process of tracking PV systems involves installing a mechanical system that can adjust the orientation and tilt of the modules at different times of the day, with the goal of optimizing energy production. Two categories of solar tracking systems are used: single-axis trackers and dual-axis trackers. In the first configuration, the PV module array tracks the sun horizontally according to its angle of incidence (altitude) or vertically according to its orbit (azimuth). The second configuration combines the two, producing a more significant amount of energy. These mobile systems optimize crop yields through greater light availability during critical growth periods. In addition, the flexibility of the tilt angle provides constructive protection against hail or extreme radiation by adjusting their orientation as required.

(**a**) (**b**)

Figure 7. (**a**) Single-axis solar tracker module [44] and (**b**) dual-axis solar tracker module [60].

One of the main constraints of installing aerial agrivoltaic systems is the high investment and maintenance cost. The wide spacing of the panels can create favorable conditions for crop growth and development, but it leads to a reduction in energy density due to the reduced number of panels installed on the plot. Also, the spacing between rows of panels can increase the investment cost in areas with high land costs and limited land availability [29]. However, these systems face shading constraints [33], so these installations are favorable for viticulture. Moreover, dual-axis systems with large arrays of PV modules can

create shading under the panels, while other parts of the ground surface receive maximum sunlight [44].

3.2.2. Vertically Mounted Agrivoltaic Systems

The mounting of solar panels vertically to the ground is also a method of optimizing agrivoltaic systems (Figure 8). It consists of an installation technique in which the modules are oriented in the east–west direction, which has proved to be more efficient for permanent crops, or in the north–south direction, where energy production is a priority [61]. These systems require a significant distance between consecutive rows of vertical supports. For example, [62] studied vertical arrays using a 10 m spacing between the rows. A report by [26] showed that the yield of oats and potatoes decreased by 50% when the distance between rows was decreased in length from 20 to 5 m. In addition, [26] reported that 10% of the land near the panels does not have to be cultivated and can be used as ecological zones. Bifacial panels are widely used in these systems.

Figure 8. Vertical agrivoltaic installation with bifacial modules in Sued [62].

Vertical panels are favorable to crops as they allow a homogeneous distribution of sunlight, facilitate farm machinery movement, cleaning of solar panels, and access to crop rainwater. It is more economical, as it reduces the support cost, which is lower than that of aerial systems [39]. However, according to Katsikogiannis et al. [61], the constraint of its usage is the reduction in the electrical energy produced. Indeed, these systems allow for a 50% increase in LER and for a 33% reduction in electrical production compared to conventional single PV systems. According to Reagan and Kurtz [63], electrical production can be increased by 10–20% compared to traditional techniques by using a 2 m spacing between the supports, which results in a substantial reduction in crop yield [26].

Table 1 gives the strengths and weaknesses of the different installations.

Table 1. Summary of the strengths and weaknesses of the different installations.

Type of Installation	Strengths	Weakness
Inter-row systems	• Considerable space in this type of installation facilitates the passage of large agricultural machinery • Low investment cost	• Crop yield reduction due to uncultivated space

Table 1. *Cont.*

Type of Installation	Strengths	Weakness
Elevated systems with spacing between rows of panels	• Spacing between rows of panels and between panels enhance the uniformity of solar radiation • Can create crop protection in temperate zones • Crops under panels increase crop yields • Facilitates the movement of large farm machinery • Increases the space available for farm workers	• High investment and maintenance cost • Can create a shadow under the panels • Reduction in energy density due to the reduced number of panels installed
Tracking systems	• Greater light availability during critical growth periods • Constructive protection against hail or extreme radiation	• High investment and maintenance cost • Dual-axis systems with large arrays of PV modules can create irregular distribution of light to crops
Vertical mounting systems	• Homogeneous distribution of sunlight • Facilitate farm machinery movement • Cleaning of solar panels • Access to crop rainwater • Reduced cost of the installation structure • Increased electricity production for small distances between installation structures	• Reduction in agricultural production for small distances between installation structures (2 m) • Reduction in electricity production for large distances between the installation structures (20 m)

4. Factors Affecting the Operation of Photovoltaic Systems

Agrivoltaics relies mainly on the distribution of sunlight for photovoltaic energy production and photosynthesis. Therefore, the solar radiation spectrum is shared between the solar panels and the crops underneath [34]. Indeed, the principle of photovoltaics is the conversion of sunlight into direct current electricity. This production of electrical energy is the result of the absorption of photons from photovoltaic cells exposed to the sun, which in turn release free electrons to produce electrical energy [64–68]. Furthermore, the solar cell is the main component of the solar photovoltaic system [69].

Solar cells can be grouped into four generations based on the specific constituent elements and their periods. The first generation of PV cells is based on silicon wafer technology, including monocrystalline and polycrystalline cells [70]. The cells have an efficiency of between 18% and 20%, depending on the quality of the silicon used. However, according to Blakers et al. [71], the maximum efficiency reported for polycrystalline silicon cells could be as high as 26–27%. The theoretical maximum efficiency of monojunction silicon cells is around 30% and is called the Shockley–Queisser limit. The basic structure of these cells usually consists of a glass front and back cover, encapsulation layers, a solar cell matrix, and solder joints to electrically connect the individual cells [72]. Second-generation solar cells are thin-film cells that have a reduced maximum thickness of a few nanometers or tens of micrometers, compared to first-generation cells. This reduction in thickness helps to decrease the material usage and cost of silicon solar cells. These cells are made of two heterojunction layers squeezed between two contact layers. Efficiencies of 22.6% have been achieved with cadmium telluride (CdTe) thin films [73]. Third-generation cells consist of dye-sensitized solar cells (DSSCs), perovskite, and organic solar cells. DSSCs are limited by the synthesis of organic dyes and their chemical stability. For this reason, perovskite has been used as an alternative to DSSCs, and more than 21% efficiencies have been achieved in a very small area. The fourth-generation tandem solar cells are made of composite materials, consisting of polymers mixed with nanoparticles to have the properties of a single absorbing layer. The tandem solar cell is characterized by a top and bottom solar cell and an intermediate buffer layer. The upper GaAs cells absorb solar radiation, which is then transmitted to the Si of the lower cells [74]. The electrodes extract the generated charge carriers, and a photo-current flows through the thin buffer layer between the two solar cells [75]. The four generations mentioned are shown in Figure 9.

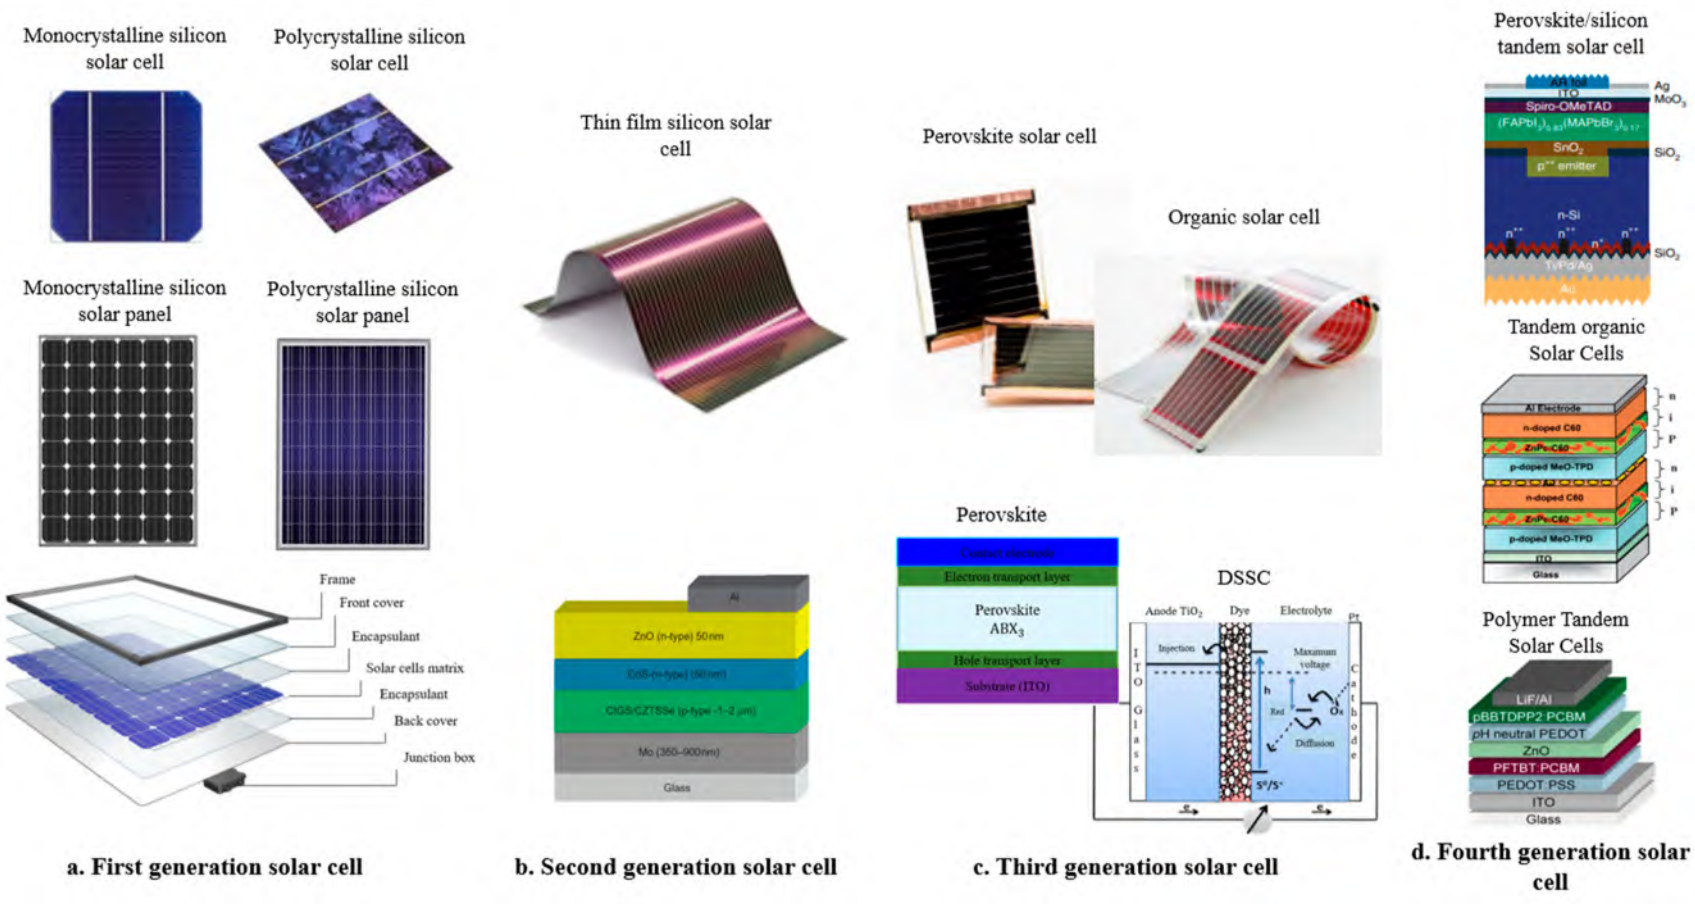

Figure 9. The four different generations of solar cells and their structures [74,76–80].

First-generation solar cells, namely monocrystalline and polycrystalline silicon-based cells, are the most commonly available in the commercial world [74]. According to Zhang et al. [76] and Rabanal-Arabach [77], 80–85% of the panels on the market belong to silicon technology.

In temperate regions with much sunshine, solar radiation is often too intense for some crops, especially in the summer. Shading screens are often installed in the systems to reduce the intensity of this radiation. These are semi-transparent solar panels [28,81,82]. Indeed, different opaque, transparent, and semi-transparent technologies are used in agrivoltaic systems and lead to different changes in sunlight availability throughout the day [29]. Bifacial panels are also widely used in agrivoltaic systems, as they use the light from the ground side (opposite side of the module) to generate electricity. Depending on the level of radiation on the back side, this can increase electricity production by up to 25% [44]. Agrivoltaic systems must be designed to grow appropriate vegetation depending on the available solar energy, soil, ambient climate, and other conditions. Therefore, the optimal conditions in agrivoltaic systems should be specific to the area where the system is implemented.

The PV module energy production mainly depends on the cells' temperature and the solar radiation. These parameters are related to the following factors: azimuth, tilt, latitude, solar declination, the slope, vertical shadow angle, hourly angle, zenith angle, elevation height, presence of vegetation at the bottom of the panels. The performance of a solar panel is determined by the amount of solar radiation it receives, whereas the temperature can create power losses (high temperature) or enhance the power (low temperature). The amount of solar radiation that the PV array receives changes depending on the geographical location, the sun's movement, the climatic conditions of the area, and the orientation of the panels [83]. Ideally, a photovoltaic installation should have the incident solar flux perpendicular to the array surface to maximize the panels' energy potential [84,85]. Thus, the optimal orientation must be determined due to the perpetual movements of the sun.

The orientation of the panels is determined through two parameters i.e., the azimuth and the tilt. The movement of the sun is a function of its elevation which depends on two parameters, namely the latitude and the solar declination. Furthermore, according to Jafarkazemi and Saadabadi [86], the azimuth angle of the surface, latitude, time of day, slope or tilt angle, day of the year, and incident radiation angle determine the amount of solar radiation received by the PV panels installed on a given area (Figure 10).

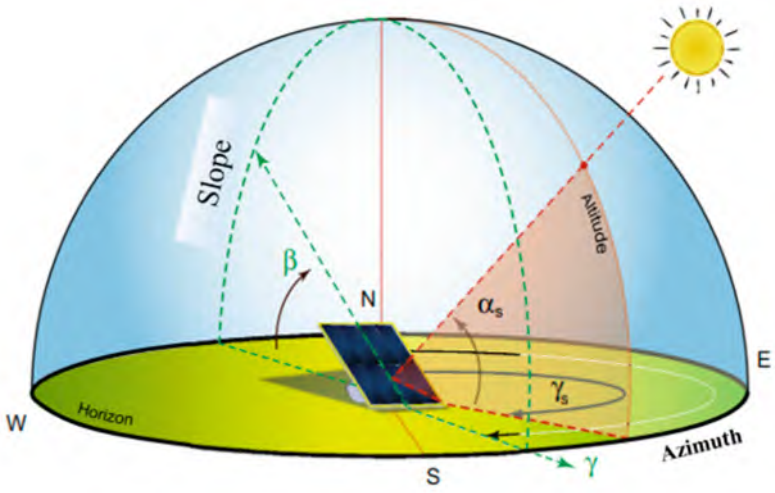

Figure 10. Factors affecting the performance of solar PV panels [87].

In particular, the electrical energy resulting from the transformation of the solar energy absorbed by the panels is strictly related to the slope (the tilt angle) and the azimuth angle [88]. The tilt angle (elevation angle) represents the angle formed by the horizontal

plane of the installation and the PV panels for a fixed structure [85,89]. A change in the tilt angle simultaneously leads to a change in the amount of radiation reaching the surface of the PV panels [89]. However, as a general rule, the tilt angle for a PV array installation is nearly equivalent to the latitude of the area [90,91]. The solar azimuth is the horizontal angle between the vertical plane normal to the surface and the vertical plane in which the center of the solar disc is contained, oriented in the north–south direction [91]. For this purpose, the azimuth values of 90°, 0°, +90°, 180° correspond to the positions east, south, west, and north of the panels, respectively [85,92]. Thus, the panels are oriented to the north in the southern hemisphere and the south in the northern hemisphere [93].

Other parameters that can likely affect the performance of photovoltaic modules are (i) the albedo, which is the amount of radiation reflected from the ground surface across the solar spectrum and (ii) the vertical shadow angle, sometimes referred to as the vertical profile angle, which is the direction in degrees of rotation of the center of the solar disc [91]. To these parameters, Oudrane et al. [94] and Nfaoui and El-Hami [95] added the hourly angle, which is a function of the daily spinning of the earth with respect to its axis, and the declination, which is the angle between the "center of the earth-sun" vector and the equatorial surface of the earth. Yilmaz et al. [96] considered in addition to these parameters the zenith angle which is the angle between the sun's direction and the vertical of the location.

In addition, the elevation height and the occupation of the surface where the PV array is installed can have an impact. These factors have been highlighted by Chemisana and Lamnatou [97], Ogaili and Sailor [98], Alshayeb and Chang [99], and Osma-Pinto and Ordóñez-Plata [100]. They evaluated the electrical energy generated by a photovoltaic array on rooftops using different elevations and different ground level supports. According to Alshayeb and Chang [99], the presence of vegetation at the bottom of the panels can be advantageous, resulting in an increase of 0.25 to 0.4% in the efficiency of the solar panels when the panels are installed at the height of 50 to 75 cm from the roof [100]. According to Chemisana and Lamnatou [97], vegetation below the panels leads to a decrease in ambient temperature that can cause an increase of 1.29–3.33% in the maximum power output of the PV array. Furthermore, Ogaili and Sailor [98] showed that the presence of vegetation could cause an increase in the energy output of 0.8% to 1.2% compared to a white or black colored substrate, respectively, when the panels were elevated at 18 cm from the roof.

5. Impact of Agrivoltaic Systems on Crops

5.1. Importance of Solar Radiation on the Process of Photosynthesis

Sunlight is the key factor in photosynthesis. Photosynthesis consists of the production of oxygen and glucose that crops can use for growth and development [101,102] as a result of the reaction between water and carbon dioxide absorbed through the stomata, which are small holes in the lower epidermis, and controlled by sunlight [103]. Equation (3) is a summary of the photosynthetic reaction.

$$6H_2O + 6CO_2 \overset{Solar\ energy}{\rightarrow} C_6H_{12}O_6 + 6O_2 \quad (3)$$

$$\Delta_rG^{o'} = +2870\ kJ/mol, \Delta_rG^{o} = +2875\ kJ/mol = \Delta_rG^{O''} \quad (4)$$

Photosynthesis can be broken down into two stages. The first step, called the light reaction, consists of the absorption of sunlight by the chlorophyll pigments [104], resulting in the production of electrons and protons, which are responsible for the production of adenosine triphosphate (ATP) and nicotinamide adenine dinucleotide phosphate (NADPH) at the thylakoid membrane [103]. The second step is the dark reaction in which NADPH and ATP generated in the light reaction is used to produce carbohydrate from CO_2 through the Calvin–Benson cycle in the chloroplast stroma [104–106]. Figure 11 gives an overview of the importance of light in the process of photosynthesis.

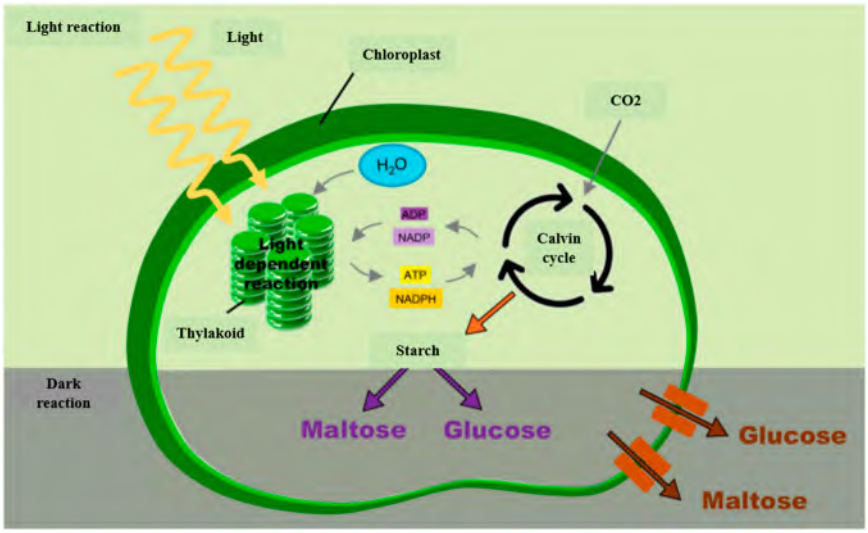

Figure 11. The overall process of photosynthesis at the chloroplast level [107].

Chlorophylls are the primary pigments in crop cells that absorb sunlight in the blue (450 nm) and red (650 nm) wavelengths and give the crop its green color. However, there are other pigments in crop cells, namely carotenoids, which absorb blue light and give the leaves their yellow color. Furthermore, the excitation of ions in the process of photosynthesis is driven by the absorption of specific wavelengths of light in the visible range [103], as shown in Figure 12.

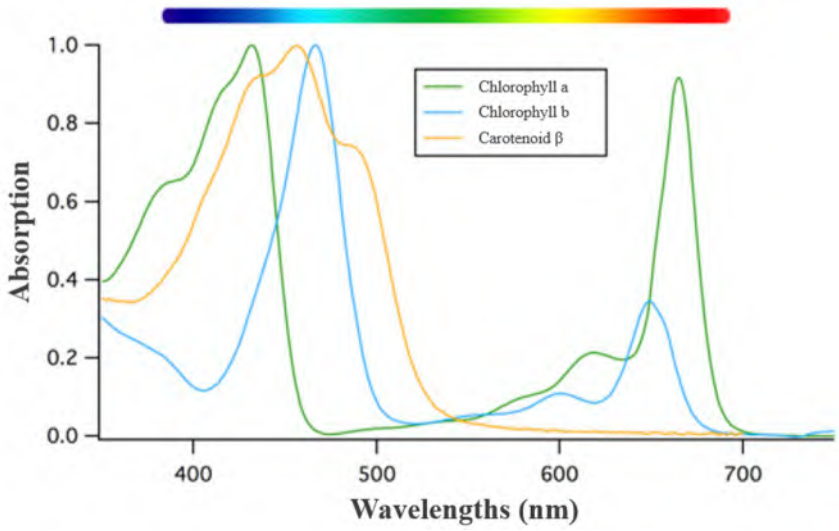

Figure 12. Basic absorption spectra of crops' main chlorophyll and carotenoid pigments [103].

Indeed, wavelengths from 430 to 500 nm are effective in chloroplast development and photosynthetic function [106,108]. In addition to promoting photosynthetic activity, wavelengths from 640 to 670 nm are necessary for leaf growth and crop biomass production [106,109]. Furthermore, according to Wang and Folta [110], the wavelengths 500–600 nm are of great importance in chlorophyll content, photosynthetic function, and consequently crop growth.

This part of the solar radiation of wavelength 400–700 nm is called photosynthetically active radiation and represents the part of solar radiation mainly used for photosynthesis [111,112]. However, the total proportion of solar energy in the photosynthetically active band represents only 48.7% of the average solar spectrum measured at the Earth's surface. At the same time, the chlorophyll pigment is considered as an imperfect radiation absorber

in the 400–700 nm band because it weakly absorbs solar radiation in the green band. Therefore, it is estimated that 90% of the radiation is photosynthetically absorbed by vegetation, and 10% is reflected [113]. According to Amthor [114], the solar radiation intercepted at the Earth's surface depends on the area's location, the presence or absence of clouds in the sky, and the sun's elevation. In addition, the fraction of incident solar radiation intercepted by crops is a function of leaf area and orientation. Furthermore, the total photosynthetically active radiation absorbed by chlorophyll pigments for a crop that has reached whole leaf area development is estimated at 92%.

5.2. Factors That Can Affect Crop Growth in Agrivoltaic Systems

Agrivoltaic systems are systems in which crops are grown, considering factors that may affect crop growth, including the level of shade, climatic factors, and water consumption [115].

Access to the limited amount of sunlight needed for the photosynthetic process is the main challenge for crop productivity under PV panels [24,116], as sunlight is the key factor playing a significant role in crop growth and development [117].

Touil et al. [118] reported that PV panels can cause a reduction of over 40% in the amount of solar radiation received by crops. A coverage rate of 50% or more can also hinder crop growth. For example, a panel-induced shading level of 50% led to a decrease in crop height and stalk diameter, and a decrease in net leaf photosynthesis rate, leaf specific weight, dry matter accumulation on leaves and stalks, and grain number of maize. To this end, the optimal level of shading to ensure energy requirements for photosynthesis consists of a level of photosynthetic photon flux density capable of both saturating CO_2 assimilation and favoring the stabilization of shading conditions and reducing photoinhibition [24].

Nevertheless, the shading induced by the photovoltaic field can be beneficial by reducing the amount of water lost through evaporation and therefore increasing water use efficiency [119]. To this end, these devices are favorable in drought-prone areas during hot periods, as they reduce crop water demands due to reduced evapotranspiration [38,53,54,120]. According to Yue et al. [121], agrivoltaic systems can increase soil moisture by 14.7% for fixed installations and 11.1% for mobile installations. Moreover, based on a study conducted by Adeh et al. [52], panels in agrivoltaic systems allow for more efficient water use (estimated at 328%) by maintaining higher soil moisture levels compared to soil moisture in a full-sun growing area. Barron-Gafford et al. [54] showed that the positive effect of agrivoltaic systems on water conservation is exacerbated by applying water to the crops based on a two-day irrigation frequency that maintains 15% higher soil moisture compared to the soil under full sun. However, although soil moisture remained higher under the panels, it was reduced by 10% based on a daily application of the crop's water requirements. Furthermore, studies conducted in dryland environments on the impact of agrivoltaic systems on specific crops showed that water use efficiency under the panels was estimated at 157%, 65%, and 12% for chili, tomato, and lettuce, respectively, for a 4 m panel elevation [50,118]. Furthermore, a simulation study by Elamri et al. [40] showed a reduction of less than 20% in the water requirement of lettuce as a result of the effect of panel shading.

The shading caused by the panels and the increase in soil moisture affects the microclimate of the area cultivated under the panels. Adeh et al. [52] established that the elevation of the PV panels by 1.2 to 2 m causes a considerable change in air temperature, relative humidity, and wind speed on the surfaces near the PV panels. In a study conducted in the USA on tomato cultivation, it was observed that the air temperature varied between 21.5 °C and 22.3 °C in the subplots cultivated in the open air, whereas it decreased to 19.8 °C under the panels (for an elevation of 2.2 m and a tilt angle of 18°). The rows had the highest average relative humidity at 79.38%, followed by sub-plots cultivated in the open air at 74.63%, and sub-plots located under the panels had an estimated humidity of 73.54%. The soil temperature was estimated to be 20 °C, 24.7 °C, and 25.6 °C under the PV panels, between the panel rows and the control, respectively. In addition, the wind

speed was lower (0.65 m/s) between the rows of panels, whereas it was 0.89 m/s in the open field [119]. According to Noor and Reeza [122], the microclimate under the panels varies differently depending on the area's climate and the land's topography. Their study in the tropics showed that the air temperature was the same in the open field and the higher and middle areas under the panels. However, it was higher in the areas of lower topography under the PV panels. Regarding relative humidity, these studies showed that relative humidity was higher under the PV panels, estimated at 65%, compared to 63.7% between the rows of PV panels and 53.5% in full sun.

The panels reduced the average soil temperature of 5.2 °C in summer with a minimum of 3.5 °C and a maximum of 7.6 °C, and an increase of 1.7 in winter in the UK [21,121]. Abu-Hamdeh [123] showed that the soil temperature under the panels recorded a decrease of 3.1 °C in arid zones and 1.1 in equatorial and temperate zones. Moreso, the soil temperature can vary depending on the installation technology. For example, the ground temperature under fixed panels was found to be lower than under mobile panels since the radiation intercepted by the panels is higher for mobile technologies [51,121]. Weinstock and Appelbaum [124] showed that agrivoltaic systems can lead to a reduction in soil temperature of 4 °C for fixed and 1.5 °C for mobile installations.

5.3. Impact of Solar Panels on Crops

The success of production in agrivoltaic systems is highly dependent on the choice of crops to be grown. Crops grown under PV panels are often subject to different climatic conditions than those grown in full sun because of the shading created by the solar panels. Furthermore, crops of different varieties of the same species may respond differently under the same conditions [29]. For this purpose, the impact of agrivoltaic systems on crops is summarized in Table 2, considering different crops and locations.

Table 2. Impact of photovoltaic panels on different crops in different localities.

Crops	Study Area	Height and/or Spacing or Shading Rate	Impact on Culture	Sources
Durum wheat	Montpelier, France	Height of 4 m Spacing 1.64 m (distance between the lower side of two consecutive panels) Tilt of 25°	• 11–29% reduction in dry matter • 8 to 11% reduction in yield	[24]
Lettuce and cucumber	Montpelier, France	Height of 4 m Tilt of 25°	• Reduction of evapotranspiration by 62% and 70% for lettuce and 73% to 81% for cucumber • Crop cover was significantly higher in the shaded treatments (150% between days 124 and 144)	[50]
Lettuce	Montpelier, France	Height of 4 m Two spacings: 1.6 m in full density and 3.2 m between rows in half density Tilt of 25°	• Crop axis under PV panels was 7.4 cm with 2.0 g dry matter per axis compared to 6.6 cm and 2.5 g per axis in full sun • Significantly reduced number of leaves in the shade • Increased leaf area	[49]
Lettuce	Kansas, USA state	Height of 4 m Two spacings: 6.4 m in half density and 3.2 m between rows in full density	• 42% reduction in yields for the 3.2 m spacing and 19% for the 6.4 m spacing in summer • No impact on yield for the 6.4 m spacing in spring but 21% reduction for the 3.2 m spacing	[38]

Table 2. *Cont.*

Crops	Study Area	Height and/or Spacing or Shading Rate	Impact on Culture	Sources
Chili and tomato	Tucson, USA	Height of 3.3 m above the soil surface at their lowest point Spacing of 1 m Tilt of 32°	• For Capsicum annuum var. glabriusculum, production is three times higher under the panels • For C. annuum var. annuum, there is no impact • For S. lycopersicum var. cerasiforme, production is two times higher under the panels	[54]
Maize	Chiba Prefecture, Japan	Height of 2.7 m Two row spacings: 0.71 m for high-density and 1.67 m for low-density Tilt of 30°	• Yields of 3.54 kg/m^2, 3.35 kg/m^2 and 3.23 kg/m^2 at a distance of 1.67 m in full sun and at a distance of 0.71 m, respectively	[55]
Grape	Ongjin-Gun, Republic of Korea	Height of 2 m Tilt of 15° Shading level of 30 of the total roof area	• Germination period, number of flowers and grape growth are identical in all treatments	[56]
Basil and spinach	Italy	-	• Reduction in marketable biomass yield by 15% and 26% for basil and spinach, respectively	[28]
Sesame, mung bean, kidney bean, corn and soybean	Jeollanam-do, South Korea	Height of 5.42 m Shading rates of 32%, 25.6% and 21.3%	• Yield reductions for all crops except maize at 21.3% shade • At 21.3%, yields increased by 6% for maize and decreased by 7%, 13%, 21% and 26% for sesame, soybean, mung bean and kidney bean, respectively • At 25.6%, yield reduction of 14% for sesame and 35–44% for beans • At 32%, yield reduction of 53% for sesame and 30–44% for other crops	[48]
Oilseed rape, onion, faba bean and forage maize in rotation with potato melon, carrot, onion and dry pea in rotation with tomato	Sevilla, Spain	Height of 5 m Spacing of 9.5 m between suppoted structure Tilt of 27°	• Reduction in crop yields under shade following a correlation of studies already carried out on the effect of shade on the area (reduction of 10%, 7%, 17%, 6%, 20%, 23%, 15% and 5% for carrot, maize, melon, onion, rape, potato, dry pea and tomato, respectively)	[58]
Celery	Southwest Germany	Row distance: 9.5 m (2.8 times module row width)Height (free space in the direction of the work/top edge): 5.5 m/8 m	• Crop height was 30.6% and 14% higher under panels in 2018 and 2017, respectively • Dry matter yield of above-ground biomass was 48% and 31.9% higher under panels • Bulb yield decreased by 18.9% in 2017 and increased by 11.8% in 2018	[59]

Table 2. *Cont.*

Crops	Study Area	Height and/or Spacing or Shading Rate	Impact on Culture	Sources
Red beet, winter wheat, potato and red clover	Southwest Germany	Height of 5 mSpacing of 6.3 mTilt of 20°	• Increase in crop height for all crops • Between 2017 and 2018: −19 to +3% for winter wheat, −20 to +11% for potato and −8 to −5% for red clover and	[125]
Rice, onion, garlic, rye, soybean, bean, maize, forage crop	South Korea	Height of 3.3 mSpacing of 1.5 mShading rate of 30%	• For rice, stem height was 3.8 cm higher under the panels and yields decreased by 18.7% in 2018 and 8.9% in 2019 • For soybeans and beans, yields decreased by 68.7% and 73.3%, respectively • For garlic and onions, yields decreased by 18.7% and 14.6%, respectively • For fodder crops, the height was 7.4 m higher under the panels, nevertheless the yield decreased by 3.1 t/ha	[126]
Rice, potato, sesame, and soybean	South Korea	Height between 4 m and 4.5 m	• No impact on growth except for sesame (lower stem length, number of branches and 1000 seed weight) • Yield reduction of 3% for potato, 19% for sesame, 18–20% for soybean and 13–30% for rice	[42]
Soybean	Monticelli d'Ongina, Italy	Height of 4 to 4.5 mSpacing between rows of trackers of panels of 12 mfour treatments: 27%, 16%, 9% and 18% shading	• Crop height of 98.25 cm at 27%, 90.81 cm at 18%; 86.95 cm at 16% and 85.04 cm at 9% shade under panels and 87.8 cm in full sun • Number of pods reduced by 19.4% at 27% shade and 18.2% at 18% shade compared to treatments with 16% or less shade • Grain yield reduced by 8%, 4.6% and 11.8% for 27%, 9% and 18% shade respectively compared to full sun versus 4.4% increase for 16% shade	[127]

6. Influence of Agrivoltaics Systems on PV Module Performance

Few studies have focused the impact of agrivoltaic systems on the performance of solar panels. This is because crops are most affected by these types of installations. However, Table 3 gives an overview of some of the advantages and disadvantages of these installations on solar panels highlighted by some authors.

Table 3. Impacts of agrivoltaic systems on the performance of solar PV panels.

Advantages/Disadvantages	Description	Source
Advantages on PV panel	Increase energy production due to increased area through the LER	[39,117]
	Decrease in temperature of solar panels could be achieved by using agricultural moisture, evaporation from agricultural activities, and transpiration from crops which results in the increase in electricity generation	[128]
	PV panels in agrivoltaic systems can generate between 3.05% and 3.2% more energy compared to PV installations without cultivated crops	[129]
	Decrease in ambient temperature can cause an increase of 1.29–3.33% in the maximum power output of the PV array	[97]
	The presence of surface green due to vegetation at the bottom of the panels can results in an increase of 0.25 to 0.4% in the efficiency of the solar panels	[99]
Disadvantages on PV panel	Agrivoltaic can reduce the efficiency of electricity generation or agriculture when taken separately	[39]
	Decrease in the electricity produced with the reduction in the density of solar PV panels	[38,48,55]

7. Models Already Developed in the Agrivoltaic Field

One of the first models developed to optimize agrivoltaics was carried out in Montpelier by [24]. This is a model for intercepting the radiation available on the panels (developed on R software) and simulating the crop's development (generic crop model STICS). The light interception model calculates the daily radiation at any point on the ground using a ray-tracing algorithm. The crop simulation model was used to predict the behavior of crops under the panels. For the light simulation, ray tracing algorithm was used to make the simulation. The daily direct and diffuse radiation quantity striking any point of the ground below the array consisted of the output.

The authors of [38] utilized the STICS model, which comprises four primary modules. These modules include the crop growth module, soil interaction module, crop management module, and microclimate module. The crop model determines the effects of climate and soil moisture content on the immediate microclimate surrounding the crops. Indeed, they set up a solar PV system model and a crop model to optimize the performance of the agrivoltaic system. In their PV model, they formulated an optimization problem whose objective was to maximize the incident solar irradiance on the PV, while considering the additional land cost due to minimizing inter-row shading. They proposed to reduce panel density or use semi-transparent panels to reduce the effects of shading. In order to optimize the geometry of an agrivoltaic system, the crop, solar irradiance, mounting height, environmental climate, and tilt angle are crucial. The module production model was developed on PVsyst.

The use of the STICS model is advantageous because it allows the assessment of the impact of the configuration of a given agrivoltaic installation on crop growth. Therefore, real data from field experiments are required to use the model.

Amaducci et al. [120] had developed a software platform on Scilab by coupling the radiation and shading model to the generic crop growth simulator (GECROS). The GECROS crop model predicts crop biomass and yields as a function of climatic factors such as radiation, temperature, wind speed, and partial vapor pressure, as well as the amount of water and nitrogen available in the soil. Regarding the shading radiation model, it consisted of calculating direct and diffuse radiation at ground level with a time step ts = 0.5 h and a spatial resolution of 0.12 m by developing a procedure to calculate whether a portion of soil that is shaded or that receives direct radiation. This study was conducted using a tracking system.

Malu et al. [130] carried out agrivoltaic system modeling to study the electrical performance of agrivoltaic systems when combining grape and energy production in the Nashik

District of Maharashtra State in India using the National Renewable Energy Lab's System Advisory Model (SAM) version 2014.1.14, which uses weather data, location of the study area, PV array size, DC/AC ratio, azimuth angle, required axis type, and tilt angle. Inputs data consist of the weather data, the ratio of DC to AC power, the azimuth angle, the tilt angle, the type of axis required, the size of the system array, and the tilt angle. However, the study focused more on energy production.

Elamri et al. [40] investigated the variations of water in soil and the productivity of crops under PV panels. For this purpose, they used a model called "AVirrig" adapted based on the existing "Optirrig" model. Optirrig was built to generate and optimize irrigation scenarios that operate at a daily time step. The inputs used in this model are rainfall, radiation, air temperature, reference evapotranspiration, soil water reserves, leaf area index, dry matter, and crop yield. "AVirrig", which also includes the "AVrain" model that describes the redistribution of rainfall by solar panels depending on the method of panel installation, consists of a reservoir model that assumes the presence of three water reserves in the soil. This is a specific adaptation of "Optirrig" for AV installations that take into account the fluctuation of the shadow created by the PV modules. In opposition to Malu et al. [130], this study focused more on agricultural production.

Similar to Amaducci et al. [120], Potenza et al. [127], performed modeling to optimize the growth of crops under panels in Italy by coupling the GECROS crop growth model with a set of algorithms to estimate and specialized shading, radiation, and crop-related parameters. The system simulates the entire crop growth cycle, carbohydrate distribution, and grain yield of crops under the panels. Crop height, leaf chlorophyll content, leaf area index, and specific leaf area were measured throughout the experiment. Radiation mapping, calculated on the cells with a resolution of 0.12 m $\times$ 0.12 m and a time step of 30 min, was used to determine the shadow depth. GECROS is advantageous because it allows the prediction of biomass and yield based on the knowledge of climatic parameters. Thus, a knowledge of the variation of climatic parameters under the panels allows to determine the adequate configuration of an agrivoltaic system.

Trommsdorff et al. [43] investigated the electrical efficiency of PV systems applied to crops and the behavior and productivity of crops under panels in Germany's largest agrivoltaic research facility. The study was conducted according to the variation of solar radiation available to the PV panels and the crops. All light simulations for the PV modules were performed with Radiance, which is a back ray tracer for optical calculations in virtual environments that takes into account both direct and diffuse fractions of the irradiance, allowing the simulation of ground reflections to analyze the electrical gains on the back side of the PV panels. In addition, they used ZENIT software tool, which considers, among other things, temperature coefficients, specific efficiency curves, maximum power points, and inverter power limitations to evaluate the overall electrical efficiency. Virtual sensors measured the radiation under the panels. Simulations were performed for different orientations of the APV field between South and South–West (0°, 15°, 30°, 45°) and different distances between rows of panels. Moreso, the photosynthetically active radiation under the panels was converted into biomass yield.

Kim et al. [48] focused on the electricity production of agrivoltaic systems and the increase in revenue when implementing such a system. Thus, they implemented a polynomial regression to develop a model for estimating the system's electricity production using machine learning. The model considered eight (8) parameters, including solar radiation, daily minimum and maximum temperature, daily rainfall, humidity, wind speed, shading ratio, and type of solar panel. However, the shading data used in the study was calculated as panel area over the system area. Therefore, the model does not provide an indication of the optimal configuration in terms of spacing, elevation, and inclination for the crop to be grown.

Pulido-Mancebo et al. [131] have developed a model for optimizing agricultural production under the panels to convert photovoltaic power crops into agrivoltaic systems. It consists of a mathematical model that simulates the solar incidence in a network of

representative points on the ground, depending on the geometry and design of the PV crop to be converted to agrivoltaics. The study focused on photovoltaic installations with rectangular collector planes inclined towards the south and one side of the rectangle (wider) oriented in an east–west direction and parallel to the ground and with the shorter side oriented in a north–south direction. The model is based on the representation of the sun's position with respect to the geometry of the collector array (latitude of the location, solar declination, day angle, and solar time) as well as the geometry of the PV system itself (a rectangle represents the system). The model geometrically determines the shading at any point on the ground by determining the direct and diffuse radiation on the horizontal ground without obstacles. The inputs were the declination, the latitude, solar time, and daily angle. This model is advantageous because it allows a quick overview of the radiation in the ground in agrivoltaic systems.

Nevertheless, these models do not directly give a specific elevation, spacing, and inclination for a given crop and given locality. These models are used to determine whether or not a selected configuration is suitable for a given crop and need to be optimize. All these modeling studies have been set up to study and verify the performance of a specific installation to see the impact of this installation on the yield of the crop being grown in this system. Moreover, Pulido-Mancebo et al. [131] have developed that simulates the solar incidence in a network of representative points on the ground; nevertheless, it does not directly give the optimal spacing between rows of panels and between panels and the elevation to choose for a given crop.

Therefore, considering the limited number of decision support studies that have been conducted to determine the ideal configuration, i.e., elevation, panel row spacing, and panel spacing and tilt for any given crop, this review article has been developed to clearly explain agrivoltaics. We believe that this review can be used as a guide to set up a model that will take into account geometric, geographical, climatic, crop, and PV panel factors which will have as outputs the optimal spacing between panels, elevation, and tilt that will result in maximizing the crop yield and power of the PV system in agrivoltaic systems.

8. Conclusions

The agrivoltaic system was first used in 1980. However, only a few studies were carried out in this field during this period. It is only since 2011 that many have started to work in this field. To this end, several studies have emerged in this field in recent years. These studies have mainly focused on implementing a given configuration of photovoltaic solar panels to reduce the effects of shading on crops. Several panel elevations and spacings were tested on several crops in different areas. However, these proposed arrangements were specific to the site and crop being tested. Thus, no study has been carried out to establish a model that allows for optimal panel elevation and spacing for a given area and crop. It is within this framework that this review was carried out. It gives a clear explanation of the agrivoltaic systems in full sunlight, the principle of operation of the panels, and the photosystem, both of which depend on solar radiation, as well as the factors that can affect their operation. It also shows the key factors that should be considered in an optimization model. This review examined the strengths and weaknesses of each type of installation to better select the system to be used and to optimize both the yield of the crops to be planted under the panels and the yield of the solar panels installed. For this purpose, the choice of an optimal elevation height, spacing, and tilt of the solar panels will reduce the impact of shading and increase crop yields, but also increase the power output of the solar photovoltaic panels, which is a twofold benefit. According to us, setting up a model that can be used for any area to find an optimal panel arrangement in the locality being studied would be an innovative solution that will be of high interest, especially in areas where the agrivoltaic system has never been tested. Furthermore, in the future, other studies may be conducted in the field of agrivoltaics, namely the evaluation of the environmental impact of the use of the panel structure which is becoming more imposing in elevated systems. Moreover, further research could also explore the economic implications of using

agrivoltaics for pumping water to support crop production and generating electricity for sale by small-scale farmers in rural areas where electricity access is limited.

Author Contributions: Conceptualization, A.S., Y.M.S. and A.K.T.; methodology, A.S., Y.M.S. and L.D.; writing—original draft preparation, A.S.; writing—review and editing, A.S., Y.M.S., A.K.T. and L.D. All authors have read and agreed to the published version of the manuscript.

Funding: The author Sarr Aminata is a recipient of a scholarship funded by the Regional scholarship and Innovation Fund/Partnership for Skills in Applied Sciences, Engineering and Technology (Rsif/PASET).

Acknowledgments: Our deepest thanks to the Regional Scholarship and Innovation Fund/Partnership for Skills in Applied Sciences, Engineering and Technology (Rsif/PASET) for supporting us throughout this study.

Conflicts of Interest: The authors declare that they have no conflict of interest.

Nomenclature

β	Slope
γ	Azimuth
α_s	Coordinates of solar altitude
γ_s	Solar azimuth
AC	Alternating current
A_i	Uncultivated agricultural area
A_n	Cultivated agricultural area
ATP	Adenosine triphosphate
CdTe	Cadmium telluride
DC	Direct current
DSSCs	Dye-sensitized solar cells
E	East
GECROS	Genotype-by-Environment interaction on CROp growth Simulator
h_1	Installation height greater than 2.1 m
h_2	Installation height less than 2.1 m
LER	Land Equivalence Ratio
N	North
NADPH	Nicotinamide adenine dinucleotide phosphate
PV	Photovoltaic
S	South
SAM	System Advisory Model
STICS	Simulateur mulTIdisciplinaire pour les Cultures Standard, or multidisciplinary simulator for standard crops
W	West
x	cultivated crop
y	electricity

Abstract

Solar energy is increasingly used to produce electricity in Europe, but the environmental impact of constructing and running solar parks (SP) is not yet well studied. Solar park construction requires partial vegetation removal and soil leveling. Additionally, solar panels may alter soil microclimate and functioning. In our study of three French Mediterranean solar parks, we analyzed:(1) effects of solar park construction on soil quality by comparing solar park soils with those of semi-natural land cover types (pinewood and shrubland) and abandoned croplands (former vineyards); and (2) the effect of solar panels on soil microclimate, CO_2 effluxes, and vegetation. We measured 21 soil properties of physical, chemical, and microbiological soil quality in one solar park and its surroundings to calculate integrated indicators of soil quality. We surveyed soil temperature and moisture, CO_2 effluxes, and vegetation below and outside solar panels of three solar parks. Soil aggregate stability was reduced by SP construction resulting in a degradation of soil physical quality. Soil chemical quality and a general indicator of soil quality were lower in anthropogenic (SP and abandoned vineyards) than in semi-natural (pinewood and shrubland) land cover types. However, differences between abandoned vineyards representing the preconstruction land cover type and solar parks were not significant. Solar panels reduced the soil temperature by 10% and soil CO_2 effluxes by 50% but did not affect early successional plant communities. Long-term monitoring is needed to evaluate the effects of solar panels on vegetation.

land cover, microclimate, plant communities, renewable energy, soil functions, soil respiration

1 | INTRODUCTION

The use of solar energy to produce electricity is increasingly common in Europe and requires large areas in order to be cost-effective (Murphy et al., 2015; Ong et al., 2013). Solar park construction involves clearing and grading the soil surface, burying of electric cables, vegetation removal, and soil compaction increasing runoff and erosion. Grading, compaction, and erosion change the physical and chemical properties of the soil and thus reduce its quality. Since solar park construction destroys the vegetation and affects the soil, a careful analysis of the environmental impact of solar parks is needed (Armstrong et al., 2016; Hernandez et al., 2015). Although soil quality is an important indicator of ecosystem functioning, the effect of solar park construction on soil quality has not yet been reported elsewhere. After the installation of solar panels, the vegetation is regularly mown or grazed limiting vegetation height to prevent shading of panels. The solar panels also change the microclimate such as temperature, humidity, and solar radiation (Armstrong et al., 2016; Tanner

et al., 2020). Such changes in microclimate may affect soil processes and plant communities under panels, in particular, in the European Mediterranean with high solar irradiation compared to temperate regions.

Soil quality is "...the capacity of a specific kind of soil to function, within natural or managed ecosystem boundaries, to sustain plant and animal productivity, maintain or enhance water and air quality and support human health and habitation" (Karlen et al., 1997). Three soil quality indicator groups are commonly used: physical, chemical, and biological soil properties (Bünemann et al., 2018; Costantini et al., 2016; Maurya et al., 2020). Physical properties, such as bulk density and texture, influence water holding capacity and plant communities by modulating root growth (Lampurlanés & Cantero-Martínez, 2003; Scarpare et al., 2019). Chemical properties, such as inorganic N, total C, and pH, control plant nutrition and microbiological activity. Biological indicators include the activity of decomposers such as invertebrates or microorganisms. These organisms control organic matter decomposition and nutrient cycling (Maurya et al., 2020).

Velasquez et al. (2007) developed a single general indicator of soil quality (GISQ) that integrates a set of physical, chemical, and biological soil properties. Such soil properties are chosen and measured to evaluate multifaceted aspects of soil functions and further combined to calculate sub-indicators of physical quality, chemical fertility, and biological functioning. The GISQ combines the subindicators to provide a global assessment of soil quality based on soil ecosystem services and facilitates the comparison of soils between different sites/habitats. In a comparative study on four land use types, (Raiesi & Salek-Gilani, 2020) showed, using an adapted GISQ, that soil quality was 1.5-times lower in anthropogenic than in natural soils. Joimel et al. (2016) observed a decrease in soil physico-chemical quality along an anthropization gradient from forest to urban soils, whereas Joimel et al. (2017) did not find any difference in biological quality of these soils. The construction of solar parks on natural and semi-natural land use types (e.g. forest, shrubland, and abandoned vineyards) may reduce soil quality and affect ecosystem functions such as infiltration and storage of water, fertility and plant reestablishment, soil organic matter, and nutrient cycling (Khare & Goyal, 2013; Romero-Díaz et al., 2017; Rutgers et al., 2009; Scarpare et al., 2019; Yin et al., 2020).

Plant communities and soil functioning may also be affected by changes in microclimate under solar panels. Solar panels reduce solar radiation, air humidity, and soil temperatures, but in winter, soil temperatures are generally higher under panels (Armstrong et al., 2016). Adeh et al. (2018) reported highest soil moisture and local heterogeneity of soil water conditions under solar panels. Such changes in microclimate may alter plant community composition and soil respiration that can be measured as CO_2 release. Mediterranean plant communities are dominated by heliophilous plants (Bagella & Caria, 2012). The reduction of solar radiation under solar panels may thus result in a plant community shift toward shade-tolerant species. Seed germination of Mediterranean species may be limited by light reduction (Gresta et al., 2010), and the mortality of heliophilous plants increases in competition to shade-tolerant species. (de Dato et al., 2010; Novara et al., 2012). The change in air and soil microclimate under panels reduced the soil respiration under temperate oceanic climate (Armstrong et al., 2016). Under Mediterranean climate with higher annual temperatures and summer drought, changes in microclimate under solar panels may be higher resulting in a strong disturbance of seasonal soil respiration dynamics (González-Ubierna & Lai, 2019). Plant communities contribute to soil CO_2 release by respiration of roots and rhizosphere microorganisms (Raich & Tufekciogul, 2000) but also by changes in soil structure (Yang et al., 2009; Zou et al., 2005). Furthermore, plants are the principal carbon source of decomposer microorganisms (Wall et al., 2012). Thus, solar panels may also change soil conditions indirectly by a shift in plant community composition since plants are very sensitive to change in microclimate.

The aims of our study were to assess: (1) the effect of solar park construction on soil quality in comparing solar parks with semi-natural land cover types (pinewood and shrubland) and abandoned vineyards; and (2) the effects of solar panels on soil microclimate, CO_2 effluxes, and vegetation under Mediterranean climate. We expected that: (1) solar park construction reduces physical, chemical, and biological soil quality; (2) solar panels change soil microclimate and plant community composition; and (3) solar panels change soil respiration according to the season.

2 | MATERIAL AND METHODS

2.1 | Study sites

Two studies were conducted in three solar parks (SP) located in Southern France (La Calade, Pouzols-Minervois and Roquefort des Corbières, Figure 1a.) with a distance of 10 to 30 km from one another (Table 1). These SP were constructed in 2011, 2014, and 2016, respectively, covered between 8.5 and 16 ha and used ground-fixed photovoltaic (PV) systems carrying the solar panels at a fixed inclination. The solar panels are aligned to form rows (height of 0.6 m min and 2 m max) exposed to the south, with a gap of 4 m between rows. The study region is characterized by typical Mediterranean climate with summer drought and mild, wet winters. The SP are mainly bordered by pinewood (*Pinus halepensis*), shrublands, and vineyards. The soils of the SPs are characterized by carbonatic pedofeatures (i.e., fine calcareous silty clay soil).

2.2 | Sampling designs

2.2.1 | Study 1: Effect of solar park construction

To study the effects of solar park construction on soil quality, four sampling plots (50 × 2 m) separated by 150 m were randomly chosen within the SP at Roquefort des Corbières (inter-rows between solar panels). In the surroundings of the SP, we randomly selected four sampling plots (100 m^2) for each of the three dominant habitat types in the study region: pinewood, shrubland, and abandoned vineyards (Figure 1b).

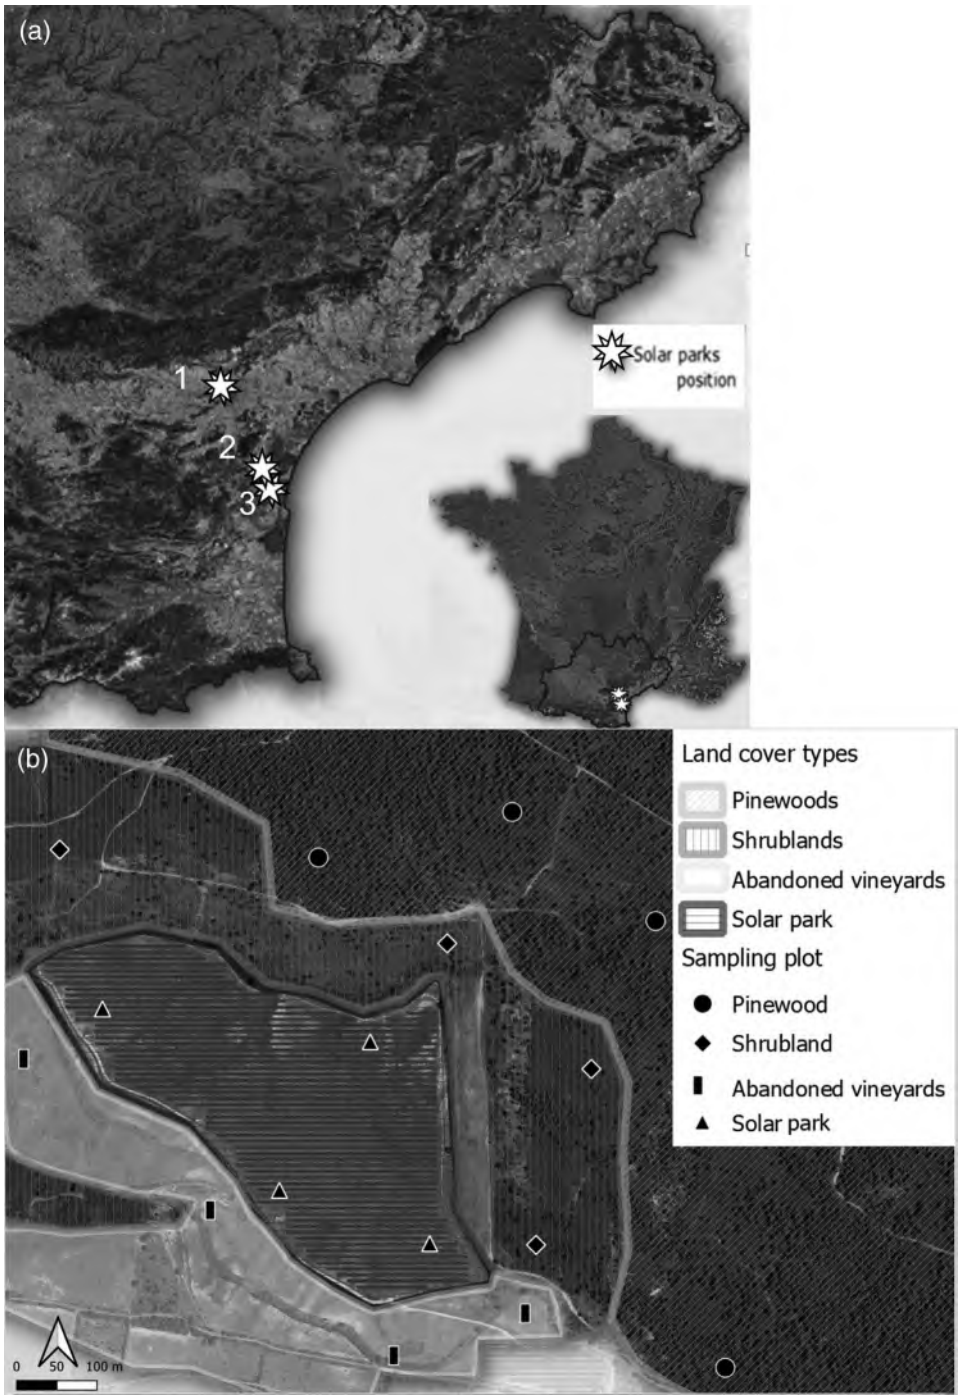

FIGURE 1 (a) Position of the three solar parks with 1: Pouzols-Minervois, 2: Roquefort-des-Corbières, and 3: La Calade (a), (b) the Roquefort-des-Corbières solar park in detail with surrounding land use types and sampling points

These three land cover types are also representative of regional land use (forestry, ancient pastures, and viticulture), and the studied SP was constructed on an abandoned vineyard. The plots were at least 200 m apart from each other and not more than 400 m from the SP. The pinewood is essentially composed of *P. halepensis and Quercus coccifera*. The shrublands are dominated by *Quercus coccifera*, *Pistacia lentiscus*, *Rosmarinus officinalis*, *Myrtus communis*, *Genista scorpius*, *Brachypodium retusum*, and *Cistus monspelliensis*. The vineyards had been abandoned for 5 years before solar park construction and were dominated by grapevine, *Anisantha rubens*, *Dittrichia viscosa*, and *Lysimachia arvensis*. In March 2016, 10 soil samples were randomly collected (10 cm depth) within each plot, mixed to one composite sample per plot. Composite samples were sieved (mesh size: 2 mm) prior to analyses. An aliquot of samples was air-dried (1 week, 30°C). For each sample, another aliquot was stored at 4°C for microbial analyses.

2.2.2 | Study 2: Effect of solar panels

To study the effect of solar panels on soil respiration, temperature, and moisture and on plant communities, we randomly selected within each of the three SP four sampling plots (50 × 2 m) below the solar

TABLE 1 Environmental and technical characteristics of solar parks

	La Calade	Pouzols-Minervois	Roquefort des Corbières
Altitude (m)	77	100	62
Slope (%)	5	5	5
Temperature (annual mean, °C)	15.5	13.6	15.5.
Precipitation (annual mean, mm)	557	648	557
Sunshine duration (annual mean, hr)	2465	2119	2324
Soil texture	Loamy soil	Loamy soil	Loamy soil
Land cover before construction	Shrubland	Abandoned Vineyards and shrublandsQ	Abandoned Vineyards
Commissioning of the SP	2011	2014	2016
Maximum power (Kwc)	5102	4950	11,152
Solar panel soil localisation	Ground-fixed		
Solar panel cell technologies	Crystalline		
A solar panel power (Wc)	180	250	260
Number of solar panels	26,856	19,800	46,473
Area of the SP (ha)	8.5	10.7	16

panels, both separated by at least 100 m, and four adjacent sampling plots (50 × 2 m) in the inter-rows between the solar panel.

2.3 | Measurements of soil physico-chemical and microbiological quality

2.3.1 | Soil physical properties

Water content (g kg ^{1}) was determined after drying samples (24 h, 105°C). Water holding capacity (WHC) was analyzed according to Saetre (1998) but using a modified protocol. Ten grams of dried soil were weighted in a PVC cylinder and saturated with water. WHC was defined as the water content remaining in the soil after 12 h (4°C). The different soil fractions (i.e., sand, silt, clay) were determined using the Robinson's pipette method (Olmstead et al., 1930) after organic matter removal by oxidation with H_2O_2 (30%, 48 h). Bulk density (BD) was determined by measuring dried soil mass sampled in a Siegrist's cylinder. According to Huang et al. (2004), a value of 2.65 g cm^{-3} was assumed for real soil density (RD). Soil porosity was calculated using the following equation.

$$\text{Soil porosity} = 100 \times \frac{\text{RD} - \text{BD}}{\text{RD}} \quad (1)$$

Mean weight diameter (MWD) of soil aggregates was measured according to Kemper & Rosenau (1986).

2.3.2 | Soil chemical properties

The soil pH was measured in distilled water and KCL (1 M) (Aubert, 1978). Total carbon (TC) and Nitrogen (TN) content were determined by combustion in an elemental analyzer CN FlashEA 1112 (ThermoFisher) (NF ISO 10694, NFISO 13878). Calcium carbonate ($CaCO_3$) content was measured using a Bernard calcimeter (Müller & Gastner, 1971) and the percentage of C in $CaCO_3$ (C—$CaCO_3$) was determined as C—$CaCO_3$ = 11.991/100 × $CaCO_3$. Inorganic nitrogen (NH_4^+ and NO_3^-) was extracted in KCL solution (1 M) and analyzed calorimetrically using the nitroprusside-salicylate and nitrosalicylic acid method according to Mulvaney (1996) and Keeney & Nelson (1983), respectively.

2.3.3 | Soil microbiological properties

Microbial biomass (MB) was measured using substrate-induced respiration (SIR) rates (Anderson & Domsch, 1978). Basal respiration was determined without adding glucose to calculate the metabolic quotient qCO_2 (the ratio of basal respiration to microbial biomass), which is a sensitive ecophysiological indicator of soil stress (Anderson, 2003). Three enzyme activities (i.e., fluorescein diacetate hydrolase, phosphatase and tyrosinase) involved in carbon and phosphorous cycles were assessed (n = 3 per sample) to determine the catabolic potential of microbial communities. Fluorescein diacetate hydrolase (FDase, U g^{-1} dry weight) was measured according to Green et al. (2006), phosphatase (U g^{-1} dry weight) according to Tabatabai and Bremner (1969) and the activity of tyrosinase (μmol min^{-1} g^{-1} dry weight) according to Saiya-Cork et al. (2002).

2.4 | Measurements of solar panel effects on soil moisture, temperature, and in situ respiration

Soil respiration, temperature, and moisture were recorded in March and June 2017 in each sampling plot of the study on solar panel

1099145x, 2021, 18, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ldr.4101 by University Of Arizona Library, Wiley Online Library on [02/07/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

effects. In situ CO_2 release (g CO_2 m^{-1} hr^{-1}) from soils, plant roots, soil organisms, and chemical oxidation of C compounds was measured after removal of aboveground vegetation, using a portable gas analyzer (IRGA, EGM-4, PP-system). The device was connected to a closed soil respiration chamber (SRC-1, PP systems, Massachusetts). To prevent leakage of CO_2 when placing the chamber on the soil, a PVC tube (10 cm × 11 cm) was buried 1 cm deep into the soil prior to measurements. Soil temperature was recorded in a depth of 7 cm using the soil temperature probe (STP-1, PP-system) connected to the respirometer. Soil moisture was recorded on four points at 7 cm depth using a portable time-domain reflectometry (TDR) device (Delta-T Devices, ML2 Theta Probes).

2.5 | Measurements of solar panel effects on vegetation

In the sampling plots of the study on solar panel effects, vegetation surveys were carried out in 2016 and 2017. Three rectangular subplots of 10 m^2 (2 m × 5 m) were placed at the ends and the centre of each plot. Percentage cover of all occurring vascular plant species was estimated as the vertical projection of aboveground plant organs. A ratio of shadow-tolerant (sciaphilous) to hemi-heliophilous and heliophilous plant species (Julve, 2020) was calculated.

2.6 | Statistical analyses

We calculated a general indicator of soil quality (GISQ) according to Velaquez et al. (2007). Information on 21 variables of physical, chemical, and microbiological soil properties was used to create three subindicators related to main soil functions: (1) physical properties that determine the infiltration and storage of water, (2) chemical properties that affect fertility and plant reestablishment in solar parks, and (3) microbiological properties that drive soil organic matter decomposition and nutrient cycling. For each group of variables (physical, chemical, and microbiological), a principal component analysis (PCA) with data scaled to unit of variance was run using "FactoMineR" (Husson et al., 2008) and "Factoextra" (Kassambara & Mundt, 2020) packages. The Kaiser-Meyer-Olkin measure (>0.50) and Bartlett's test of sphericity (0.05) were used to test the sampling adequacy of variables included in the PCA. Variables with communality values <0.05 were removed, and main components were identified using the latent root criterion (eigenvalues >1.0). A synthetic index of quality for each group of variables at a plot *i* (Iq_i) was calculated as the sum of *n* variables (*vi*) multiplied by their respective weight (*wi*) in the determination of axes 1 and 2 of the PCA [Equation (2)].

$$Iq_i = \sum_{i=1}^{n} w_i v_i \quad (2)$$

The values of Iq_i were then reduced to a common range (0.1 to 1.0) using a homothetic transformation to obtain the sub-indicators of physical, chemical, and microbiological soil quality [hereafter pSQ, cSQ, and mSQ, respectively, Equation (3)]. In this equation, a is the maximal and b the minimal *Iq* value for the plot *i*.

$$p,c\,\text{or}\,mSQ = 0.1 + \frac{Iq_i - b}{a - b} \times 0.9 \quad (3)$$

Finally, a PCA was run with the three sub-indicators. The GISQ was obtained by summing the products of the respective contributions of variables to factors 1 and 2 by the % inertia explained by factors, respectively. Finally, the sum of these products gave the following formula for the GISQ [Equation (4)]:

$$\text{GISQ} = 0.29\,\text{pSIq} + 0.28\,\text{cSIq} + 0.33\,\text{mSIq} \quad (4)$$

All data were analyzed using R software (3.6.1, R Core Team, 2013). Effects of land cover type on soil physical, chemical, and microbiological properties, sub-indicators of soil quality, and GISQ were assessed using one way-analysis of variance (ANOVA). In the case of a significant land cover type effect, a Tukey HSD post hoc test was used to analyze differences between specific land cover types. To analyze the effect of solar panels on soil temperature, water content, CO_2 effluxes, and vegetation, linear mixed-effect models (LMMs) (R package "lme4") were applied including month and treatment (below vs outside panels) as fixed factors and solar park identity as a random factor. Assumptions of ANOVA were checked by Shapiro–Wilks test for normality and by Levene test for homoscedasticity. When necessary, data were transformed using the "bestNormalize" package (Peterson, 2021) to meet these assumptions. Effects of solar panels on plant communities were visualized by nonmetric multidimensional scaling (nMDS) based on the Bray–Curtis dissimilarity. Differences in plant community composition were tested using permutational multivariate analysis (PERMANOVA) in R package "vegan" (Oksanen et al., 2007). A subsequent pairwise post hoc test was conducted to analyze differences between factor levels. False discovery rate was used to correct for multiple comparisons.

3 | RESULTS

3.1 | Effects of solar park construction on soil properties

Seven of the eight tested physical soil properties were significantly different between land cover types (Table 2). Among these seven properties, only two showed a significant difference between the two semi-natural (pinewood and shrubland) land cover types and the SP. Soil water content was 5.5% lower in the SP ($p < 0.01$) than in shrubland. The mean weight diameter of aggregates was twice as high in abandoned vineyards as in SP and three times higher in pinewood and shrubland than in SP ($p < 0.001$). Organic carbon was about 2.5 times higher in semi-natural than in anthropogenic land cover types ($p < 0.001$). Sand and silt content, soil porosity, and bulk density were

Note: Mean values with SEs in parentheses. Different letters indicate significant differences between land cover types (significant *p*-values in bold)
Abbreviations: BD, bulk density; BR, basal respiration; FDAse, fluorescein diacetate hydrolase; MB, microbial biomass; MWD, mean weight diameter; OC, organic carbon; qCO_2, metabolic quotient; TC, total carbon; TN, total nitrogen; WC, water content; WHC, water holding capacity

significantly different between abandoned vineyards and pinewood (Table 2). Silt content and soil porosity were 1.4- and 1.3-times lower in abandoned vineyards than in pinewood, respectively. Sand content and BD were about 1.5-times higher in abandoned vineyards than in pinewood. Pinewood and shrubland showed similar physical properties without significant differences.

For most soil chemical properties, SP showed significant differences to pinewood and shrubland but not to abandoned vineyards (Table 2). Total carbon contents were 1.44-times higher in semi-natural land cover types than in anthropogenic land cover types ($p < 0.01$). Organic carbon contents were about 2.76-times higher in semi-natural land cover types than in anthropogenic land cover types ($p < 0.01$). Total nitrogen (TN) content showed the same pattern. TN was twice as high in pinewood and shrubland as in the SP and abandoned vineyards ($p < 0.001$). The water pH ranged between 8.02 and 8.11 and showed a small but significant difference between shrubland and abandoned vineyards.

Two microbiological properties were significantly different between land cover types (Table 2). Land cover type had a significant influence on basal respiration ($p < 0.03$) being two times lower in the SP and abandoned vineyards than in forest and shrubland. The FDAse activity was two times higher in shrubland and pinewood than in the SP and abandoned vineyards. Microbial biomass was twice as low (marginally significant) in SP and abandoned vineyards as in the semi-natural land cover types.

3.2 | Effects of solar park construction on soil quality

The first two axes of the PCA run on physical properties explained 80.56% of the total variance (see A.1.A in Appendix S1). The semi-natural land cover types are separated from the anthropogenic soils along the first axis. Silt, water content, water holding capacity, and mean weight diameter of aggregates had the highest score on the first PCA axis, while soil porosity was strongly correlated with the second axis (see A.1.A, Appendix S1). The highest physical quality index of 0.92 was measured in pinewood and shrubland being two times higher than in abandoned vineyards ($p < 0.001$). The pSQ (Figure 2a) was two times and four- times lower in SP than in the abandoned vineyards and semi-natural land cover types, respectively ($p < 0.01$).

The first two axes of the PCA used to calculate the sub-indicator of soil chemical quality (cSQ) explained 80.98% of the total variance (see A.1.B, Appendix S1). The semi-natural land cover types are

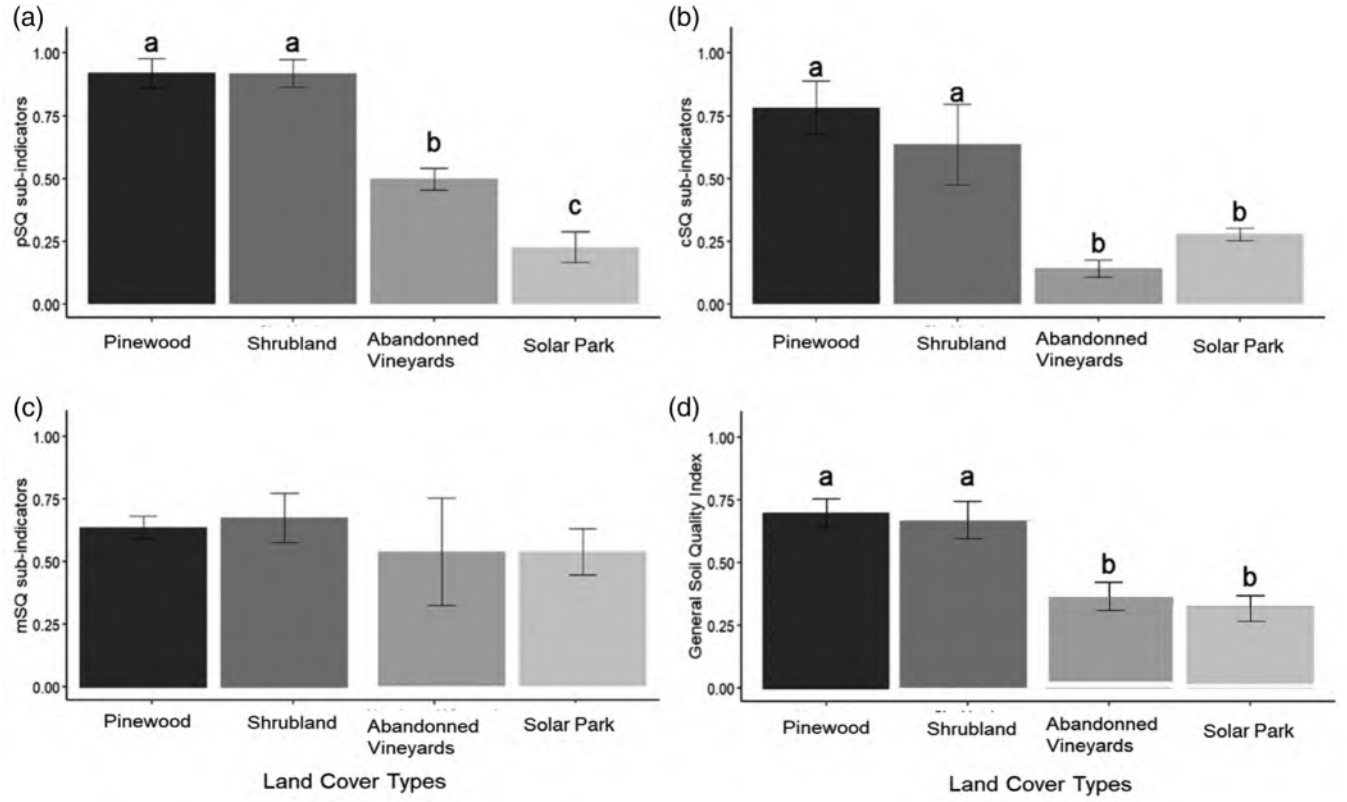

FIGURE 2 Sub-indicators of soil physical (a), chemical (b), and microbiological (c) quality and general soil quality indicator (d) for different types of land cover. Error bars are means ± SE. Different letters indicate significant differences ($p < 0.05$)

separated from the anthropogenic soils along the first axis. Total carbon, organic carbon, TN, and ammonium were most correlated with the first axis and nitrate with the second axis (see A.1.B, Appendix S1). With a value of 0.18, the cSQ was four times lower in the SP and abandoned vineyards than in shrubland and pinewood ($p < 0.001$, Figure 2b).

The first two axes of the PCA used to calculate the sub-indicator of soil microbiological quality explained 80.28% of the total variance (see A.1.C, Appendix S1). Basal respiration, microbial biomass, FDAse, and phosphatase were highly correlated with the first PCA axis, while the qCO_2 was correlated with the second one (see A.1.C, Appendix S1). The mSQ was not significantly different between land cover types ($p = 0.74$) (Figure 2c).

The General Indicator of Soil Quality was four-times lower in the SP and abandoned vineyards than in the pinewood and shrubland ($p < 0.001$).

3.3 | Effects of solar panels on soil temperature, water content and in situ CO_2 effluxes

Soil temperature and water content were significantly different between months ($p < 0.05$; Figure 3a,b). Solar panels significantly decreased soil temperature in March and June (Figure 3a) but did not affect soil water content ($p = 0.79$). Soil CO_2 effluxes did not change between months but were twice as high outside solar panels than below solar panels ($p < 0.001$).

3.4 | Effects of solar panels on plant communities

Neither the species richness nor the total cover of plant community was significantly affected by the solar panels (Table 3). A marginally significant difference was detected for the ratio 'Sciaphile: Heliophile plants,' being higher below than outside solar panels. The NMDS and PEMANOVA did not reveal any significant solar panel effect on plant community composition ($p = 0.3461$, Figure 4). However, community composition was significantly different between the solar parks ($p < 0.001$). No significant difference was detected between observation years (data not shown).

4 | DISCUSSION

Solar park (SP) construction reduced physical and chemical soil quality compared with semi-natural land cover types (forest and shrubland) but not biological soil quality. A change in soil temperature and CO_2 effluxes also demonstrated a negative solar panel effect on soil microclimate and functioning. However, in early stages of plant succession following solar park construction, plant community composition below and outside solar panels was not significantly different.

4.1 | Effects of solar park construction on soil quality

Soil quality assessments require the measurement of a wide range of physical, chemical, and biological properties involving a high complexity of potential analyses (Maurya et al., 2020). In this study, we assessed soil quality using a multiproxy approach including 21 soil properties. The reduction of the number of variables using PCA to group these properties allows an integrated evaluation of soil quality based on their main functions, such as infiltration and storage of water, soil fertility, plant reestablishment and soil organic matter and nutrient cycling. We found that two of three integrated sub-indicators and the general indicator of soil quality were lower in SP than in the semi natural land cover types.

Among the physical soil properties, the aggregate MWD was 1.5-times lower in the SP than in the semi-natural land cover types (Table 2). A low MWD may result in a low aggregate stability. Similarly, Kabir et al. (2017) showed that the MWD decreases in anthropogenic soils associated with a degraded vegetation. In our study, soil leveling and vegetation removal prior to SP construction may have decreased soil organic matter (SOM) content reducing MWD. By binding colloids and stabilizing soil structure, SOM plays a key role in soil physical properties and nutrient cycling (Six et al., 2004). Telak & Bogunovic (2020) showed a decrease in SOM and MWD in a vineyard of Croatia after intensive and frequent tillage. Such mechanical disturbance for many years may have affected soil structure of the vineyard on which the studied SP (Roquefort des Corbières) was constructed. Accordingly, overall physical soil quality of SP was lower than that of abandoned vineyards, which was in turn lower than that of semi-natural land cover types. The physical soil quality index (Figure 2a) revealed that the construction of a SP increased the degradation of the physical soil quality of habitats already degraded by land management (abandoned vineyards). In particular, the stability of the soil, key factor of soil functioning, was lower in SP than in abandoned vineyards. Moreover, a lower SOM affects microbial activity and production of mucus resulting in a decrease of aggregate MWD and thus a soil more sensitive to erosion (Blavet et al., 2009; Le Bissonnais et al., 2018). The soil leveling and vegetation removal during SP

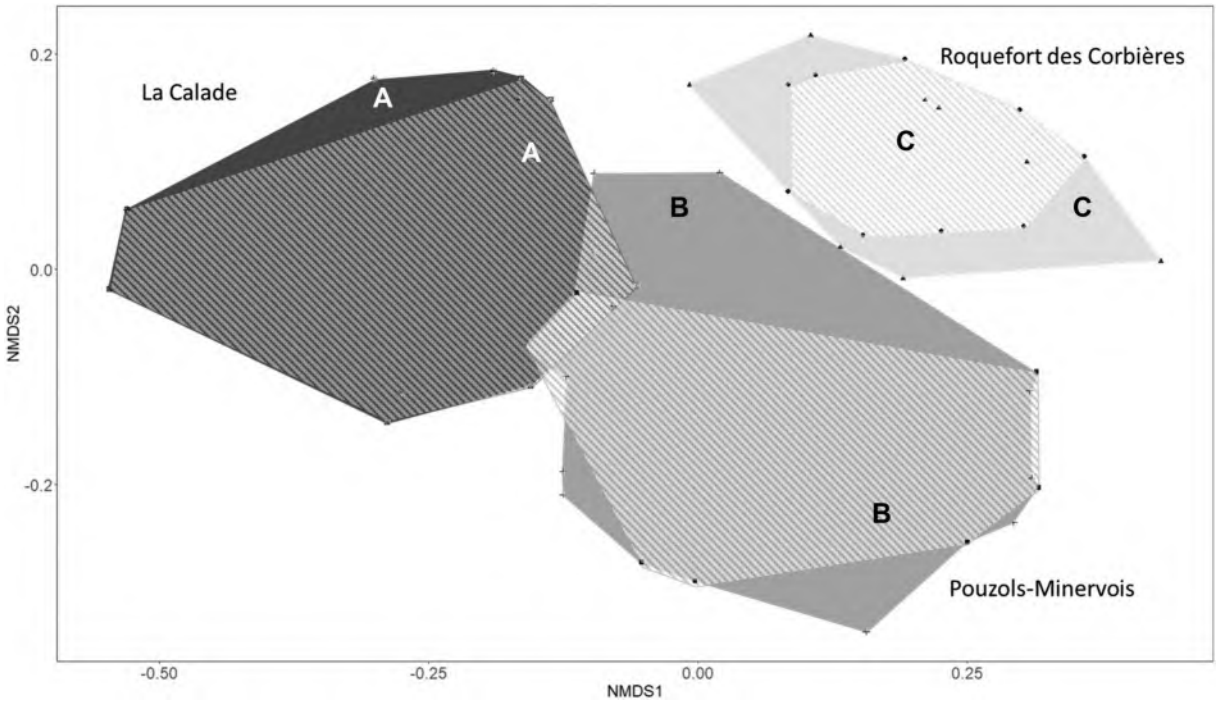

FIGURE 4 Nonmetric multidimensional scaling (NMDS) plot with polygons indicating the plant species composition of the three solar parks under (hatched polygon) and outside (solid polygon) solar panels, NMDS stress: 0.084. Different letters indicate significant differences after pairwise post hoc test ($p < 0.05$)

construction may have increased surface runoff and soil erosion (Rabaia et al., 2021).

In contrast to our expectations, the SP construction did neither increase soil bulk density nor decrease porosity compared to the abandoned vineyards (Table 2). In our study, soil bulk density was found to be lower in abandoned vineyards than in semi-natural land cover types. The past land management of vineyards may have degraded these properties before SP construction limiting effects of construction work. It is well known that the use of agricultural machinery considerably increases the soil bulk density (Dunjó et al., 2003). Under similar Mediterranean climate and land use history in Spain, the bulk density was 30% higher in vineyards than in pinewood (Dunjó et al., 2003). Such changes in soil physical properties can reduce the infiltration and storage of water. To improve the process of water infiltration and the capacity of water storage, a decompaction of the soil surface may be useful in particular if soils were already compacted by previous land management. Such decompaction also facilitates the germination and establishment of plant species (Bassett et al., 2005). The resulting improved revegetation may limit erosion and protect functions supported by soil physical quality (Beatty et al., 2017).

Soil chemical properties, such as total and organic carbon and TN are directly linked to soil fertility and plant growth (Liu et al., 2014). In our study, these properties showed lower values in anthropogenic soils than in semi-natural land cover types (Table 2). Joimel et al. (2016) obtained similar results along a gradient from natural to anthropogenic habitats in which total carbon and nitrogen decreased significantly from forests to vineyards. Soil disturbance such as soil tillage in vineyards or construction activities increases mineralization of organic matter reducing organic C and N (Brantley & Young, 2010). Accordingly, Choi et al. (2020) found a significantly lower C and N content in SP than in grassland soil. In our study, SP construction did not reduce neither C and N content nor soil chemical quality compared to degraded vineyard soil (Table 2). Consequently, the construction of SP did not further degrade the soil chemical properties. The low index of chemical quality (Figure 2b) is thus most likely related to the past vineyard management. Low C and N content suggest that nutrient cycling was lower in vineyards and SP soils and that several SP soil functions (carbon sequestration, soil structure, biological processes) were hampered compared to semi-natural soils. Appropriate site selection may limit such a loss of key soil functions by SP construction (Choi et al., 2020).

Soil microorganisms (i.e. bacteria and fungi) contribute actively to soil nutrient cycling (Schimel & Schaeffer, 2012). Thus, their genetic and physiologic characteristics are important indicators of ecosystem functioning such as nutrient cycling (Ranjard et al., 2011). Microbiological soil properties showed differences between land cover types for fluorescein diacetate hydrolase (FDAse) activity and basal respiration. FDAse is an appropriate proxy to evaluate soil microbial activities because the ubiquitous esterase enzymes (e.g., lipase, protease) are involved in the hydrolysis of FDA (Schnürer & Rosswall, 1982). In our study, the FDAse was two times lower in anthropogenic soils (Table 2) suggesting a reduction of microbiological activity and nutrient cycling. Soil basal respiration showed the same pattern confirming

1099145x, 2021, 18, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ldr.4101 by University Of Arizona Library, Wiley Online Library on [02/07/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

a degradation of soil functions compared to semi-natural soils (Sparling, 1997). Under a similar Mediterranean climate in Italy, basal respiration was three to four-times lower in vineyards than in coniferous forests, mixed forests, and shrublands (Marzaioli et al. (2010). The decrease in soil respiration may be related to the lower organic carbon and nitrogen content or the decrease in microbial biomass (Fernandes et al., 2005). Previous vineyard management, in particular, soil tillage, may have severely decreased microbial biomass resulting in low microbial activity. Five years of abandonment was probably not sufficient to entirely reestablish microbial communities (Quintana et al., 2021). Despite the reduction of microbial properties in abandoned vineyards and solar park soils, the microbiological soil quality index (mSiQ) was not significantly different between land cover types (Figure 2c). Other microbiological properties (BM and phosphatase) mainly contributing to the first PCA axis were hardly affected by land cover type and thus overruled significant response variables in mSiQ calculation.

As a consequence of lower physical and chemical sub-indicators, the general indicator of soil quality was about three times lower in SP compared to semi-natural land cover types (Figure 2d). The key processes involved in degradation of soil quality were soil tillage, partial topsoil removal increasing erosion (Quinton et al., 2010), and organic matter mineralization. Reduced organic matter content and increase of soil compaction decrease water holding capacity (Mujdeci et al., 2017) and soil stability (Simansky et al., 2013). Soil restoration by revegetation may improve soil physical and microbiological qualities of solar parks (Hernandez et al., 2019). Revegetation may increase the stability of aggregates by increasing root biomass and the production of binding agents (Erktan et al., 2016). The root exudates can also stimulate microbial biomass and activity and thus improve nutrient cycling (Eisenhauer et al., 2010; Feng et al., 2019).

4.2 | Effects of solar panels on soil microclimate, vegetation, and in-situ CO_2 effluxes

Climatic conditions influence both soil microbial activities (Shao et al., 2018) and plant communities (García-Fayos & Bochet, 2009). In our study, solar panels reduced the soil temperature in spring and in summer by about 5°C (Figure 3a). Similarly, Armstrong et al. (2016) found a soil temperature reduction of 2°C under solar panels during the summer (UK). The lower temperature under solar panels was the direct effect of shading although night temperatures may be higher (Tanner et al., 2020). Solar panels also intercept precipitation, and Tanner et al. (2020) found a significant reduction in soil humidity under solar panels in the Mojave Desert. However, we did not find any significant soil humidity difference under solar panels and outside (Figure 3b). The result may be explained by a lower evapotranspiration limiting humidity losses during drought periods as suggested by Tanner et al. (2020).

Mediterranean vegetation is dominated by heliophilous plants (Bagella & Caria, 2012). So we expected that light reduction by solar panels strongly affects plant communities. However, we did not find a significant effect of solar panels on plant community composition and structure (Figure 4). The effect of solar panels on the ratio of shadow-tolerant to heliophilous species was only marginally significant and no influence on plant species richness was detected (Table 3). Other studies showed, however, a reduction in plant cover and species richness under solar panels resulting from lower germination and higher mortality (Armstrong et al., 2016). Due to light limitation, heliophilous plants are expected to be less competitive under solar panels (Chen et al., 2004). However, protection against strong solar radiation and drought during Mediterranean summer may have compensated for reduction of light and precipitation in our study. Accordingly, Tanner et al. (2020) observed that in a desert plant richness was marginally greater under their solar panels than in the control. In our study, the absence of a solar panel effect on the vegetation (Figure 4, Table 3) may also be explained by the low age of our solar parks limiting differential effects on the vegetation. In early successional stages, the vegetation is dominated by ubiquitous annual species germinating and developing under a great variety of environmental conditions. Responses to the specific microclimate under solar panels may be slow in Mediterranean vegetation types (Coiffait-Gombault et al., 2012; Kinzig et al., 1999). Long-term monitoring is required to finally evaluate the influence of solar panels on plant communities.

A lower soil respiration is an indicator of lower litter decomposition and nutrient cycling suggesting that these ecosystem functions may be reduced under solar panels (Incerti et al., 2011). In our study, soil respiration was highly affected by solar panels (Figure 3c). Half of the CO_2 fluxes from soils are produced by heterotrophic organisms (Bond-Lamberty et al., 2004). Heterotrophic respiration, but also plant respiration, is driven by environmental factors, mainly temperature and moisture, explaining the strong influence of solar panels (Francioni et al., 2020; Moinet et al., 2019). Accordingly, Armstrong et al. (2016) found a reduction of soil CO_2 effluxes under solar panels in May and June. We already detected a reduced CO_2 efflux from March onward suggesting that the warm Mediterranean spring results in earlier temperature differences between soils under and outside solar panels compared to temperate oceanic climate. This early decrease in temperature under solar panels compared to controls outside solar panels may have reduced microbial activity and thus heterotrophic respiration. The reduction of CO_2 effluxes under solar panels may also be the result of light reduction reducing plant growth and root respiration.

5 | CONCLUSIONS

Physical, chemical, and general soil quality indexes were lower in a solar park than in semi-natural land cover types. Clearing and grading the soil surface during solar park construction resulted in a strong degradation of soil physical quality, especially of soil structure, but did neither disturb soil chemical quality nor global quality compared to abandoned vineyards. These results suggest that solar parks should be preferably constructed on anthropogenic soils or that construction must be accompanied by environmental compensation measures

1099145x, 2021, 18, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ldr.4101 by University Of Arizona Library, Wiley Online Library on [02/07/2025]. and/or ecological restoration. At our Mediterranean study sites, solar panels reduced soil temperature from spring onward. Neither light nor spring temperature reduction under solar panels altered plant communities in early stages of plant succession but reduced CO_2 effluxes. Our study demonstrated that solar park construction and solar panels changed soil quality and microclimate to a magnitude known to affect key soil functions. Long-term monitoring including different seasons is required to evaluate the final response of soil properties and vegetation to solar panels.

Subject: Biglow Canyon RFA4 Response to Certificate Holder Response to Public Comment - Eakin/OWGL
Attachments: BIGL RFA4_Comment Letter to Oregon Wheat Growers_02132026.pdf

Dear Mr. Eakin,

Thank you for your comments regarding the Proposed Order on Request for Amendment 4 of the Biglow Canyon Wind Farm Site Certificate. As required by Oregon Administrative Rule 345-027-0367(8)(a), please find attached Portland General Electric's and the project developer, BrightNight's, written responses to your comments. Yesterday you should have received an email from Christopher Clark, the Oregon Department of Energy (the Department) Senior Siting Analyst for this amendment. The email contains the Department's Responses to comments and, should you choose to, directions for how to reply to our comment responses. Please refer to that email for guidance.

Thank you.

Re: Biglow Canyon Wind Farm Request for Amendment 4 – Response to Comments on Proposed Order (BCWAMD4Doc24-20)

Dear Mr. Eakin,

Portland General Electric (PGE) and the project developer BrightNight (BN) appreciate the comments from the Oregon Wheat Growers League (OWGL) regarding the Proposed Order on Request for Amendment 4 (RFA 4) of the Biglow Canyon Wind Farm (BCWF) Site Certificate. PGE recognizes the importance of dryland wheat production to Sherman County and values OWGL's perspective on agricultural viability and community impacts.

OAR 345-027-0367(8) requires PGE to respond to all comments that are made with "sufficient specificity," as that term is defined in OAR 345-027-0367(7)(a). We note that OWGL's comments may not necessarily meet that standard but are valuable to inform the process, and we offer the following in response to your concerns. The responses below are organized by the interpretation of your comments received and are further identified with the same issue identification number provided in Table 1: List of Issues and Commenters in the Oregon Department of Energy's Response to Comments document dated February 12, 2026.

1. Direct Agricultural Impacts (LU-16)

OWGL expressed concern regarding statements in the Proposed Order suggesting that lost agricultural production revenue by the landowner/farmer may be replaced by lease payments, noting that landowners and farmers are not always the same entity. PGE and BN acknowledge that land ownership and agricultural operators are not always the same entity, and that impacts may differ between landowners and tenant operators. BN worked closely with the landowner and the tenant farmer to address the early conclusion of the existing lease. The parties reached a mutually agreed-upon termination arrangement. The compensation reflects a negotiated resolution between the private parties and considers the remaining lease term, anticipated agricultural use, and other relevant factors. The agreed-upon amount was designed to provide substantial consideration in excess of several years of farming revenue, which would mitigate any farm losses while still allowing the farmer to conduct farming operations and earn additional revenue elsewhere.

The agricultural economic analysis presented in BCWF RFA 4 Attachment K-2 of Exhibit K and referenced the Proposed Order evaluates direct, indirect, and induced impacts from removing

land from agricultural production. Impacts to the agricultural economy are assessed in terms of employment, labor income, and economic output using the IMPLAN economic modeling package The Community Investment Plan (CIP) then ensures that the rural local economic benefits will offset potential adverse impacts the development of BCWF RFA 4 may have on Sherman County's agricultural economy. Mitigation under the Energy Facility Siting Council (EFSC) Land Use Standard and the CIP address local agricultural community and economic impacts at a county and community level, rather than compensating individual producers for lost production. That type of impact is handled by private agreement, as mentioned above.

2. Indirect and Induced Impacts (LU-10)

OWGL raised concerns regarding indirect impacts associated with loss of funding from wheat assessments that support research, market development, and grower services. Based on the estimated average annual reduction in wheat production and an assessment fee of $0.05 per bushel, Biglow Solar may result in an annual reduction of $2,241 in wheat assessment revenues.

The Economic Impact Analysis in the record (Attachment K-2, Agricultural and Fiscal Impact Analysis) evaluates indirect and induced impacts to the local agricultural economy using an established input-output modeling framework. The analysis is conducted for Sherman County and specifically assesses impacts to the local agricultural economy. The analysis captures changes in agricultural production and associated multiplier effects for the grain sector in Sherman County, and informed the mitigation funding amount provided through the Community Investment Fund.

The analysis is based on the estimated direct economic output (sale) value that would be foregone as a result of removing land from production for the life of the project. IMPLAN models the impact of this reduction to the local economy in terms of indirect and induced impacts. Indirect impacts capture the associated reduction in expenditures on goods and services related to the production process. Modeled relationships are linear and based on spending. Because the relationships are linear, the analysis captures the impacts of any reduction in spending in Sherman County that may occur as a result of forgone wheat assessment revenues.

The CIP was developed through outreach with agricultural organizations and producers, including representatives of the Oregon Wheat Commission and regional grain cooperatives. The CIP is designed to offset indirect and induced agricultural impacts at a sector-wide level and includes investments supporting long-term agricultural resilience, soil health, workforce development, and wildfire risk reduction.

Accordingly, while wheat assessment revenues were not evaluated as a discrete category, the indirect impacts to the local agricultural economy in Sherman County associated with changes in production were estimated and mitigated through the sector-based approach reflected in the record (Attachment K-2, Agricultural and Fiscal Impact Analysis). As discussed below, we propose revisions to the final CIP to address OWGL's concern regarding selecting mitigation projects and ensuring input from wheat growers.

3. Agricultural Mitigation and Community Investment Plan (LU-9, LU-11, LU-12, LU-13, LU-14, LU-15)

PGE and BN address each of OWGL's points on the CIP in turn:

- Administration: PGE and BN support revising the final CIP to include a representative from the OWGL on the Selection Committee. PGE requests that ODOE acknowledge this request and recommend to EFSC that the CIP be revised in Section 4.2.1 to identify the addition of one representative from the OWGL.

- Farm production: The record reflects outreach efforts to date and use of the best available county-level and state-level data and analysis tool to ensure that the economic modeling adequately accounted for indirect and induced impacts to the agricultural economy. PGE and BN maintain that the evidence provided in the record, and the stakeholders consulted, adequately inform the market conditions for Sherman County wheat growers. If other potential indirect impacts are observed, anyone may apply to the CIP as a project proponent for funding, including OWGL.

- Agrivoltaics: The proposed pre-screened agrivoltaics research project in the CIP focuses on collecting data to inform new techniques and advances for dryland wheat farming, specifically Project 1: Dryland Wheat Agrivoltaics Research in Sherman County (Project 1). We too think OWGL's input would be valuable in the development of this project and anticipate that a project proponent for this funding would seek the input from OWGL when developing the project proposal to ensure that the research directly benefited the Sherman County wheat economy. PGE requests that ODOE acknowledge this request and recommend to EFSC that the final CIP be revised at Section 5 to require the project proponent (for Project 1) to consult OWGL when developing the project proposal to include in the CIP funding application.

- Weed Control: We agree with OWGL that weed control is not a separate mitigation effort, but a mandatory and integral part of project construction and operation. See Section 4 below.

- Fire: We agree with OWGL that fire risk minimization and mitigation is not a separate mitigation effort, but a mandatory and integral part of project construction and operation. See Section 5 below.

4. Weed Control

Weed control is a requirement for the life of the facility, from construction through operation and decommissioning. The Proposed Order requires maintenance of vegetative cover beneath and between solar panels, implementation of weed management measures, and monitoring to ensure ongoing compatibility with agricultural uses through the Comprehensive Solar Revegetation and Soil Management Plan. The following Site Certificate conditions require defined practices and compliance demonstrations, providing sufficient specificity to protect soil productivity and watershed function over the life of the Facility: PRE-SP-01 (finalization of the plan referenced above), CON-SP-02 (adherence to the plan during construction), and OPR-SP-06 (adherence to the plan during operation of the facility).

5. Wildfire Risk Mitigation

We recognize wildfire risk is of the utmost concern to the community and have worked with ODOE to develop robust revegetation and wildfire mitigation plans that are separate and distinct from agricultural mitigation. The Proposed Order requires development and approval of wildfire

mitigation and emergency response measures prior to construction, including coordination with local fire agencies. These requirements are sufficiently specific to guide on-site implementation and coordinated response and are enforceable through ongoing compliance obligations. These concerns are addressed through Site Certificate conditions PRE-WF-01 / PRO-WMP-01 (Wildfire Mitigation Planning) and OPR-WF-01 (Operational Wildfire Mitigation), as well as incident reporting and corrective action requirements under GEN-OE-05 through GEN-OE-07.

In closing, thank you for your comments and we hope we have addressed OWGL's concerns. We are happy to engage directly if additional conversations are helpful; our contact information is above. PGE and BN look forward to continued coordination with OWGL on Biglow Solar.

Sincerely,

Lenna Cope

Re: Biglow Canyon Wind Farm Request for Amendment 4 – Response to Comments on Proposed Order (BCWAMD4Doc25-03-P4)

Dear Mr. Hilderbrand,

Portland General Electric (PGE) and the project developer BrightNight (BN) appreciate your oral comments regarding the Oregon Department of Energy's Proposed Order on the Request for Amendment 4 of the Biglow Canyon Wind Farm Site Certificate.

PGE and BN appreciate your perspective as a farmer in Sherman County and recognize the challenges facing many family farms today. We also value the insight you shared regarding your own experience with other renewable energy projects in the area. In your comments, you noted that thoughtfully planned renewable energy projects can help secure a more diversified and resilient future for Sherman County, and that, in some cases, solar can save farms. We agree that renewable energy development can coexist with ongoing agricultural use while contributing to the economic diversification and long-term resilience of Sherman County, and we value your support. PGE and BN share your goal of ensuring that renewable energy development proceeds responsibly and with strong natural resource protections in place.

We appreciate your comments and look forward to continued coordination as the project moves forward.

Sincerely,

Lenna Cope

Re: Biglow Canyon Wind Farm Request for Amendment 4 – Response to Comments on Proposed Order (BCWAMD4Doc24-14)

Dear Mr. Hilderbrand,

Portland General Electric (PGE) and the project developer BrightNight (BN) appreciate your written comments regarding the Oregon Department of Energy's Proposed Order on the Request for Amendment 4 of the Biglow Canyon Wind Farm Site Certificate.

PGE and BN appreciate your perspective as a fourth-generation farmer in Sherman County and recognize the challenges facing many family farms today. We value your insight into how projects like Biglow can provide a stable, predictable source of income through lease payments and community mitigation benefits that are not tied to crop yields or market conditions. PGE and BN agree that renewable energy development can coexist with ongoing agricultural use, while contributing to the economic diversification and long-term resilience of Sherman County. PGE and BN share your goal of ensuring that renewable energy development proceeds responsibly and with strong natural resource protections in place.

We appreciate your comments and look forward to continued coordination as the project moves forward.

Sincerely,

Lenna Cope

Re: Biglow Canyon Wind Farm Request for Amendment 4 – Proposed Order Response to Comment (BCWAMD4Doc24-15)

Dear Mr. Weis,

Portland General Electric (PGE) and the project developer BrightNight (BN) appreciate your comments regarding the Proposed Order on Request for Amendment 4 (RFA 4) of the Biglow Canyon Wind Farm (BCWF or Facility) Site Certificate. PGE and BN recognize the importance of managing vegetation and fire risk for the Facility and look forward to continued collaboration and coordination with Sherman County Weed District. The response below is identified with the same issue identification number provided in Table 1: List of Issues and Commenters, in the Oregon Department of Energy's Response to Comments document dated February 12, 2026.

Vegetation Management (SP-04)

The Proposed Order provides a comprehensive vegetation and fire risk management structure for all phases of project development. The Oregon Department of Energy (ODOE), recognizing neighbor concerns, recommended conditions of approval that go above and beyond other existing site certificates. PGE and BN provided comments to ODOE on the plans and conditions contained in the Proposed Order to ensure that there was a common understanding of the requirements and that the plans and conditions contained best practices, informed by local stakeholders. Of particular importance is the Comprehensive Solar Revegetation and Soil Management Plan that outlines actions taken in preparing the site prior to construction, throughout construction, and during operation of Biglow Solar that support native vegetation for watershed health, control erosion, and prevent the introduction or spread of noxious weeds.

You expressed concern in your comment letter with the proposed vegetation heights of 1 to 3 inches during the dry season, as represented in Section III.N.1 of the Proposed Order, because several bunchgrass species proposed for planting could be negatively impacted by maintaining vegetation at such a low height. You proposed that, in your professional opinion, allowing a grass height of 4 to 8 inches during the dry season would better support continued establishment, promote a stronger root system, and result in healthier long-term growth.

PGE and BN appreciate your professional input on this matter as the supervisor of the Sherman County Weed District. PGE is requesting that ODOE take your professional recommendation into consideration and revise the Proposed Order and implementing plans accordingly to require management of grass height at 4 to 8 inches during dry season.

We look forward to coordinating with you to ensure vegetation is managed properly at the Biglow Solar facility. We are committed to listening to community concerns and to operating this facility in a way that reflects our shared interest in protecting people, property, and the landscape we all value.

Please reach out if you have questions or would like to discuss further. As previously discussed, there will be continued engagement of the community and neighbors as this project moves forward.

Sincerely,

Lenna Cope

Re: Biglow Canyon Wind Farm Request for Amendment 4 – Response to Comments on Proposed Order (BCWAMD4Doc24-21; BCWAMD4DOC25-03-P8)

Dear Ms. Whitman,

Portland General Electric (PGE) and the project developer BrightNight (BN) appreciate the oral and written comments from the Sherman County Soil and Water Conservation District (SWCD) regarding the Proposed Order on the Request for Amendment 4 (RFA 4) of the Biglow Canyon Wind Farm (BCWF or Facility) Site Certificate. OAR 345-027-0367(8) requires PGE to respond to all comments that are made with "sufficient specificity," as that term is defined in OAR 345-027-0367(7)(a). We note that your comments may not necessarily meet that standard but are valuable to inform the process, and we offer the following responses. The responses below are organized by the interpretation of your comments received and are further identified with the same issue identification number provided in Table 1: List of Issues and Commenters in the Oregon Department of Energy's (ODOE) Response to Comments document dated February 12, 2026.

PGE and BN agree with SWCD that proactive planning, accountability, and long-term protection for Sherman County soil, water, and other natural resources is very important. We also recognize the importance of a strong working relationship; we apologize if we did not adequately engage you throughout the process despite our attempts to speak with you by phone or in person. We may have misunderstood your desired engagement when you indicated during our phone call on June 18, 2025, that you did not support Biglow Solar and would not discuss ideas regarding agricultural mitigation unless, or until, the project was approved. SWCD plays an important role within the agricultural community, and we hope to develop this strong working relationship with you to foster watershed health for the benefit of Sherman County. PGE and BN are committed to working with SWCD as the plans are finalized prior to construction.

1. Soil Resources, Erosion and Vegetation Management (SP-08, SP-11, SP-12)

PGE and BN recognize the challenges of siting a solar facility on agricultural lands with high erosion hazard due to runoff on steep slopes and high winds, and we also recognize the long history of ongoing support that the SWCD has provided to the community to address issues related to erosion and weed control. We believe the soil protection, vegetation management, and mitigation measures outlined in the Proposed Order protect against adverse impacts to the local natural resources that SWCD works to protect.

SWCD expressed concern regarding soil disturbance, compaction, erosion, and the loss of irreplaceable topsoil as well as potential compaction and erosion from traffic and maintenance

activities. In response, the Comprehensive Solar Revegetation and Soil Management Plan includes specific requirements for topsoil protection and long-term soil stability, including segregation and replacement of topsoil during construction, pre- and post-construction soil compaction testing, and mechanical decompaction where necessary prior to revegetation. These measures are intended to minimize impacts on soil productivity and reduce the potential for long-term loss of topsoil, particularly in agricultural areas.

These concerns are addressed under the Energy Facility Siting Council (EFSC) Soil Protection Standard, which requires that construction and operation of the Facility be conducted to avoid or minimize adverse impacts on soil resources. Compliance with the Biglow Comprehensive Solar Revegetation and Soil Management Plan serves as the primary regulatory mechanism for ODOE, as recommended in the Proposed Order, to ensure coordinated implementation of soil protection, erosion control, and vegetation management measures under EFSC standards.

BCWF RFA4 Proposed Order Attachment D includes a draft of the Comprehensive Solar Revegetation and Soil Management Plan. The plan requires, among other things, the following actions to mitigate potential impacts to soil resources:

- Use of best management practices (BMPs) during construction to minimize erosion, control dust, and prevent the introduction or spread of noxious weeds and invasive plants. (Attachment D: Section 3.0, Appendices D and F)
- Pre-construction compliance, including coordination with the County and ODOE; soil compaction testing; installation of stormwater, erosion, and sediment controls as required by the 1200-C construction stormwater permit; and conducting noxious weed surveys and maintaining weed control activities until just prior to construction (Table 3 in Section 4.0 of Attachment D).
- Construction compliance activities designed to limit soil disturbance and compaction, manage dust, and prevent the introduction or spread of noxious weeds. Soil stabilization and reclamation activities will occur during and following construction, and disturbed areas will be revegetated using approved seed mixes appropriate for the local soils and climate (Table 4 in Section 5.0 of Attachment D).
- Specified access routes for construction and operational activities, to reduce the potential for soil compaction and erosion during ongoing maintenance activities. Operational requirements addressing these concerns are included in OPR-SP-01 through OPR-SP-03.
- Long term vegetation and weed management, including monitoring throughout the life of the facility to identify and treat problem areas using appropriate methods before they have a chance to spread (Attachment D: Appendices C and G).

Site Certificate condition PRE-SP-01 mandates finalization of this plan prior to construction; conditions CON-SP-02 and OPR-SP-06 require adherence to the final plan during construction and operations of the facility, respectively.

With implementation of these measures, potential impacts on soil resources will be avoided or minimized to the extent practicable and mitigated consistent with EFSC's Soil Protection Standard.

2. Water Resources and Stormwater Management (SP-11)

SWCD raised concerns regarding altered drainage patterns, concentrated runoff, sediment delivery, and downstream water quality impacts. Stormwater and runoff control are addressed through the approved draft Comprehensive Revegetation and Soil Management Plan, including PRE-SP-01 and associated construction and operational soil protection conditions, which require identification of drainage patterns, implementation of BMPs, and ongoing monitoring to minimize sediment transport to ditches, streams, and waterways.

3. Agricultural Compatibility and Weed Management (SP-08, SP-12)

SWCD identified concerns related to the conversion of agricultural land, loss of vegetative cover, and long-term stewardship. The EFSC Land Use Standard requires that Biglow Solar be compatible with existing land uses and that impacts to agricultural lands be minimized and mitigated. As discussed above, the Proposed Order requires maintenance of vegetative cover beneath and between solar panels, implementation of weed management measures, and monitoring to ensure ongoing compatibility with agricultural uses. Site Certificate conditions (PRE-SP-01, CON-SP-02, OPR-SP-06) require defined practices and compliance demonstrations, providing sufficient specificity to protect soil productivity and watershed function over the life of the Facility.

4. Public Safety, Wildfire Risk, and Hazardous Materials (SP-07)

SWCD noted Sherman County's elevated wildfire risk and expressed concern regarding firefighter safety and potential impacts on soils and waterways from damaged project components. The EFSC Soil Protection, Public Services, and Wildfire Prevention and Risk Management standards collectively require that facilities be designed and operated to protect public health and safety.

Consistent with these standards, the Proposed Order requires development and approval of wildfire mitigation and emergency response measures prior to construction, including coordination with the local fire district. These concerns are addressed through Site Certificate conditions PRE-WF-01 / PRO-WMP-01 (Wildfire Mitigation Planning) and OPR-WF-01 (Operational Wildfire Mitigation), as well as incident reporting and corrective action requirements under GEN-OE-05 through GEN-OE-07.

With respect to project design, Biglow Solar plans to deploy crystalline photovoltaic (PV) modules which are glass encapsulated. The glass encapsulation limits the potential dispersal of internal materials, reducing the risk of toxin release beyond toxic hazards of standard structure fire smoke. The proposed battery energy storage system (BESS) uses advanced fire safety and containment systems designed to detect, isolate, and neutralize potential thermal events before they can spread. These systems are built with multiple layers of protection, including thermal sensors, automatic shutdown systems, and dedicated containment compartments to prevent propagation. The units are UL 9540A tested, which means they've been stress-tested under extreme conditions to meet national safety standards. The BESS system design uses a central BESS yard where all batteries will be housed and containerized batteries, each with monitoring and alarming capabilities to support preventative measures during operation.

The BESS yard will also be graveled and designed to maintain non-combustible clear zones, eliminating available fuel and limiting fire spread potential. In the event of battery failure, the containerized design, internal separation, and emergency response protocols are intended to localize impacts within individual units and prevent migration of materials beyond the immediate

footprint. Any damaged components would be promptly secured, removed, and disposed of in accordance with applicable hazardous materials regulations, thereby minimizing the potential for impacts to underlying soils or adjacent waterways.

These requirements guide on-site implementation, coordinated emergency response, and are enforceable through ongoing compliance obligations under the Site Certificate.

5. Compliance, Monitoring, and Enforcement (SP-06, SP-08)

SWCD emphasized the importance of accountability and enforceable commitments. Facilities approved by EFSC are subject to enforceable Site Certificate conditions, routine compliance reporting, inspections, and corrective action requirements. The Proposed Order contains numerous mandatory conditions, including the following conditions that implement the standards discussed above and ensure that commitments related to erosion control, weed management, fire prevention, and natural resource protection are enforceable for the life of the project.

- Organizational Expertise:
  - PRO-OE-01 (Final Operations and Maintenance (O&M) Plan)
  - OPR-OE-01 (Requirement to adhere to O&M plan)

- Wildfire Mitigation
  - PRO-WF-01 (Final Operational Wildfire Mitigation Plan)
  - OPR-WF-01 (Requirement to adhere to Operational Wildfire Mitigation Plan)

- Soil Protection and Vegetation Management
  - PRE-SP-01 (Final Comprehensive Solar Revegetation and Soil Management Plan)
  - OPR-SP-06 (Monitor and maintain vegetation and erosion controls according to above plan)

6. Pre-Construction Planning and Timing

SWCD requested assurance that construction would not proceed before adequate natural resource protection plans are in place. Biglow Solar will not begin construction until approved plans are in place. Under the Proposed Order's recommended pre-construction condition PRE-SP-01, ground-disturbing activities are prohibited until required plans are finalized, reviewed, and approved, ensuring sufficient specificity, accountability, and protection of natural resources before construction begins.

In closing, PGE and BN share SWCD's goal of ensuring that renewable energy development proceeds responsibly and with strong natural resource protections in place. Consistent with our commitment to develop a strong working relationship with SWCD to foster watershed health to benefit Sherman County, PGE will continue coordinating with SWCD as protection plans are developed finalized prior to construction and implemented during project execution. We appreciate SWCD's comments and welcome any additional questions or comments SWCD may have regarding these responses. PGE and BN look forward to continued coordination with SWCD as detailed planning and implementation proceed.

Dear Larry,

Thank you for your comments regarding the Proposed Order on Request for Amendment 4 of the Biglow Canyon Wind Farm Site Certificate. As required by Oregon Administrative Rule 345-027-0367(8)(a), please find attached Portland General Electric's and the project developer, BrightNight's, written responses to your comments. Yesterday you should have received an email from Christopher Clark, the Oregon Department of Energy (the Department) Senior Siting Analyst for this amendment. The email contains the Department's Responses to comments and, should you choose to, directions for how to reply to our comment responses. Please refer to that email for guidance.

Thank you,
Kenny

Re: Confidential Submittal for the Request for Amendment (RFA) 4 to the Site Certificate for the Biglow Canyon Wind Farm

Dear Mr. Clark

Portland General Electric Company (PGE or Certificate Holder) requests that the Oregon Department of Energy keep the enclosed information confidential to the extent permitted by law. The enclosed information includes a copy of the PowerPoint that presented during the November 2025 meeting with the Confederated Tribes of Warm Springs Reservation of Oregon, which includes map of the recorded archaeological sites.

As required, the following paragraph is included:

We request that the Oregon Department of Energy treat these records as confidential and exempt from disclosure to the extent permitted by law, and that the records be kept separate from the public record of the Biglow Canyon Wind Farm Request for Amendment 4 to the Site Certificate, with the further understanding that the records will not be disclosed unless required by law. In the event of a public records request for the information, we request that the Applicant be notified.

Thank you for your consideration of our request.

Sincerely,

Lenna Cope

Re: Biglow Canyon Wind Farm Request for Amendment 4 – Response to Comments on Proposed Order (BCWAMD4Doc24-09)

Dear Mr. Squiemphen, III,

Portland General Electric (PGE) and project developer BrightNight (BN) appreciate receipt of your comment letter on behalf of the Confederated Tribes of Warm Springs Reservation of Oregon (CTWSRO), dated January 15, 2026, regarding the Oregon Department of Energy's (ODOE) Proposed Order on Request for Amendment 4 (RFA 4) of the Biglow Canyon Wind Farm Site Certificate.

PGE and BN acknowledge that the proposed solar components under RFA 4 are located within the ceded lands of CTWSRO and an area of ongoing cultural, historical, and archaeological importance. We appreciate CTWSRO's continued participation in government-to-government consultation with the State of Oregon.

PGE is committed to cultural resource protection, implemented to be consistent with the Amended Site Certificate and the Energy Facility Siting Council's (Council) Historic, Cultural, and Archaeological Resources standard (OAR 345-022-0090). Archaeological monitoring, inadvertent discovery procedures, and continued Tribal consultation are being applied to ensure appropriate protection of cultural resources during ground-disturbing activities, consistent with approved plans and Site Certificate assumptions.

In your letter you stated:

> […] *recent communications from the applicant and its consultants suggest a narrowing of cultural resource compliance measures that does not appear to align with the recommendations documented in the survey or with the substance of consultation discussions. Specifically, the applicant has characterized archaeological monitoring as limited in scope and duration, focused on a single location, rather than implementing monitoring for all ground-disturbing activities occurring within proximity to recorded cultural resources as recommended.*

As explained later in this letter, ODOE did not recommend monitoring during all ground-disturbing activities as a condition of the Site Certificate, and PGE agrees with that finding. However, we would like to clarify that archaeological monitoring, if required, would not be focused on a single location; it would be focused for all ground-disturbing actions within 20-meters of eligible and unevaluated sites, as defined by the GeoVisions report and the State

Historic Preservation Office's (SHPO) concurrence. The project has been designed to avoid all such sites with a 20-meter buffer; thus, monitoring of the 20-meter buffers is not expected to be necessary. If project design changes, or in the event of inadvertent discoveries during construction, then monitoring would be implemented and impacts would be evaluated.

In your letter you also state:

> […] *the survey concludes that the current construction plan would result in an adverse effect to archaeological resources. CTWSRO is concerned that this determination, and the associated recommendation for monitoring, inadvertent discovery response, and Tribal involvement, are not being fully reflected in how the applicant is proposing to implement cultural resource protection measure as the Project moves toward construction.*

Based on the results of the GeoVisions report, which "recommends the client avoid all sites and isolates in the process of construction and operation for the project," PGE and BrightNight modified the proposed design to include avoidance of all sites determined eligible or unevaluated, including a 20-meter buffer. Based on the avoidance measures and the concurrence from SHPO on eligibility, it was our understanding that the project would be avoiding all possible adverse effects pending any inadvertent discoveries during construction. If the concern is that it is the recommendation of the CTWSRO to monitor all project activities regardless of the results of the GeoVisions report or the associated SHPO concurrence, PGE and BrightNight welcome continued consultation to identify specific or expanded areas of concern within the current design.

On July 10, 2025, SHPO concurred with GeoVisions' eligibility recommendations and further clarified that the recommended 20-meter avoidance buffer applies to National Register of Historic Places (NRHP)-eligible and unevaluated, but not ineligible, resources. The current project design avoids all NRHP-eligible and unevaluated resources by at least 20 meters, based on the results of the GeoVisions report and SHPO concurrence. One NRHP-ineligible resource is being impacted as allowed for by SHPO's response and draft Proposed Order. This design, including the avoidance measures and lack of impacts to all identified eligible or unevaluated archaeology sites, is the same as that shared with you during our November 2025 meeting at your offices (see attached **confidential** PowerPoint presentation for reference). Following the presentation, which included GeoVisions staff, it was our understanding that since no concerns were raised with the proposed avoidance measures, there was no discussion or assumption of monitoring during construction.

This approach is consistent with ODOE's siting standard for Historic, Cultural, and Archaeological Resources (OAR 345-022-0090(1)(a)–(c)) and established practice for evaluating significant impacts. Under OAR 345-022-0090(1)(a), impact determinations focus on NRHP-eligible and unevaluated resources. With respect to Siting Standard B (OAR 345-022-0090(1)(b)), which applies to archaeological resources on private land, ODOE considers impacts to NRHP-ineligible resources to be mitigated through documentation and recordation completed during pre-construction surveys.

Consistent with this framework, PGE and BrightNight are prioritizing development of the final RFA 4 design to avoid archaeological resources identified by GeoVisions as NRHP-eligible or unevaluated by a minimum of 20 meters. However, PGE notes that while GeoVisions' recommendations for avoidance of NRHP-ineligible resources and for archaeological monitoring during all ground-disturbing activities, including within 20 meters of those resources, may be in line with conditions imposed for the existing wind facility, those conditions are inconsistent with

the SHPO concurrence.

The Proposed Order further recommends replacing prior wind-facility cultural resource conditions with new, project-specific conditions applicable to the solar components, including conditions requiring avoidance of identified significant resources and updated cultural resources monitoring and inadvertent discovery procedures. As described in the Proposed Order (Section III.J, Historic, Cultural, and Archaeological Resources), the cultural resource conditions imposed for the existing wind facility (Conditions 69 through 73) were developed for a different facility type and relied on a broader, less resource-specific compliance framework. ODOE explains that those legacy conditions are not fully consistent with the level of specificity now required for the solar components proposed under RFA 4 or with current agency approaches to cultural resource avoidance, monitoring, and inadvertent discovery.

Accordingly, ODOE recommended replacing the legacy conditions with new, solar-specific Historic, Cultural, and Archaeological Site Certificate conditions, including GEN-HC-02 and GEN-HC-03 (resource-specific avoidance requirements), PRE-HC-01 (updated Inadvertent Discovery Plan), CON-HC-01 (construction-phase compliance), and OPR-HC-01 (operational compliance). These conditions identify individual resources, establish defined avoidance buffers, and require updated monitoring and inadvertent discovery procedures. The recommended changes are intended to align the Site Certificate with current standards and practices, not to reduce cultural resource protections.

PGE understands that GeoVisions prepared the cultural resources survey report to support consultation and regulatory review, and the survey's conclusions do not necessarily reflect the views or positions of the CTWSRO Tribal Historic Preservation Office (THPO). PGE does not have record of a request from CTWSRO THPO, through informal coordination or at our November 2025 meeting at CTWSRO's offices or formal government-to-government consultations, for protective measures beyond those reflected in the Proposed Order and draft Amended Site Certificate. If the CTWSRO THPO believes that certain resources should be managed differently or that additional protection measures should be required, PGE supports continued government-to-government consultation between CTWSRO THPO and ODOE, as determinations regarding applicable standards, conditions, and mitigation requirements fall within the Council's and ODOE's purview.

PGE agrees with CTWSRO that cultural resource protection measures should not be reduced through project-level interpretation or contractor scoping decisions. However, based on the results of the GeoVisions report, the design was modified to avoid all impacts to identified archaeology sites, including a 20-meter buffer. Construction planning and contractor requirements will be structured to ensure consistency with Site Certificate obligations and approved plans, and continued consultation with CTWSRO THPO will remain an essential component of that process as construction planning advances.

PGE appreciates CTWSRO's engagement in this proceeding and its efforts to ensure that the consultation record is accurately reflected. Due to the avoidance measures implemented within the modified design, it is our understanding, based on the GeoVisions report, that the proposed solar components will not have any impact on any NHRP-eligible or unevaluated sites, eligibility as concurred with by the Oregon SHPO. In the event of inadvertent discoveries during construction, the project will pause, and the appropriate consultations will occur in order to evaluate potential effects and next steps, as determined by the Inadvertent Discovery Plan.

Please do not hesitate to contact us if further discussion would be helpful.

Sincerely,

Kenny Gunn

Biglow Solar + Storage Project Overview

OVERVIEW
PGE and BrightNight have partnered to bring a solar and storage project to the existing Biglow Canyon Windfarm in Sherman County, Oregon.

CAPACITY
385-Megawatts in two phases. Today, we're discussing phase 1 (125 MW PV and 125 MW BESS).

FOOTPRINT
Overall study area is 3,980 acres. Actual project footprint for Phase 1 is ~750 acres (Phase 1 study area 1,409 acres).

INTERCONNECTION
Utilizing the existing Biglow Canyon Substation. Ideal optimization of existing infrastructure to reduce project impact.

PERMITTING
Currently moving through the Oregon EFSC process.

Tax Revenue
At least $40,000,000 in tax revenue generated over the life of phase 1 of the project.

Schedule Overview

2024

April-Sept

- Surveys Complete (cultural resources, habitat, raptor, wetlands, botanical)
- Meetings with community leaders
- Initial tribal outreach

2025

April

- Application for Amendment to existing EFSC Site Certificate deemed published and complete by ODOE

July

- Preliminary layout
- Technology selection
- Agricultural mitigation meetings

August

- Sponsorship of the Sherman County Fair
- Open house, Aug. 19

November

- Anticipate completing EFSC application submission

December

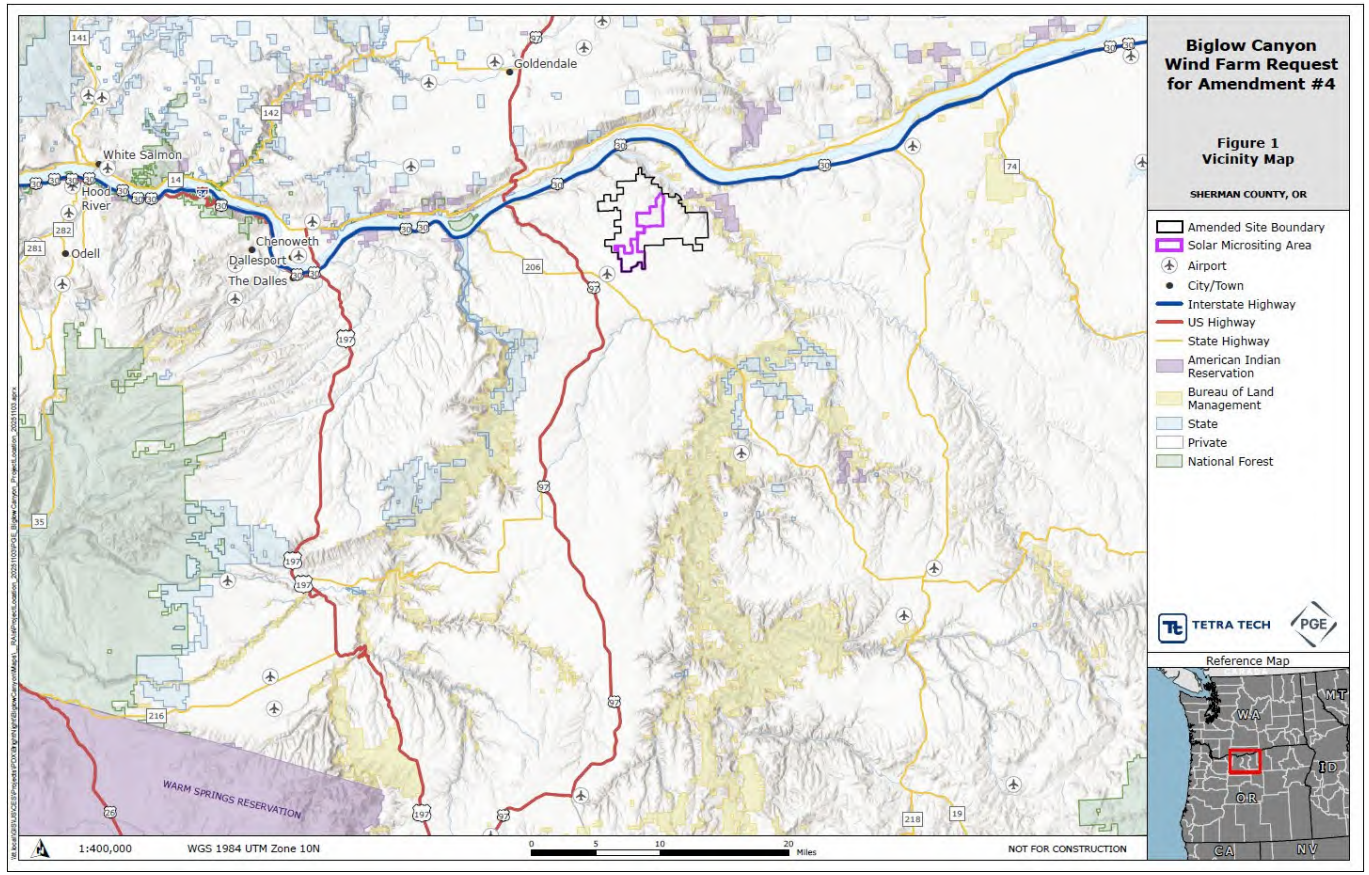
- EFSC issues "draft proposed order," tentative hearing date set

2026

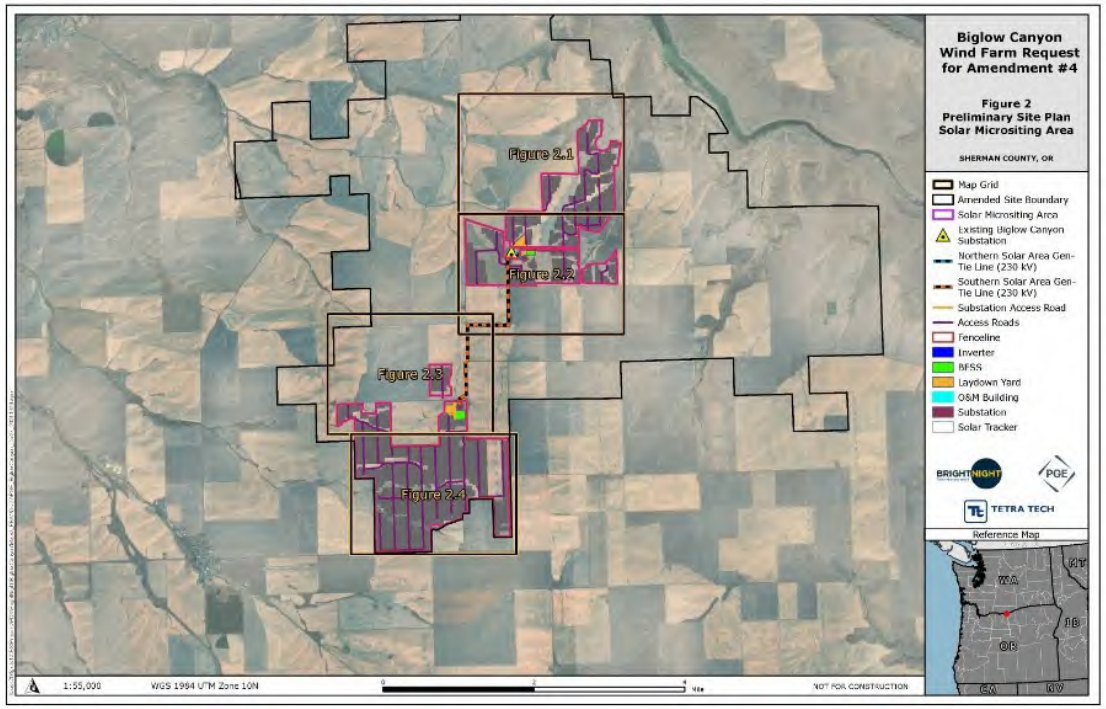
March

- Council review and determination

Q2



- Construction of phase 1



2027

Q2

- Anticipated construction of phase 2

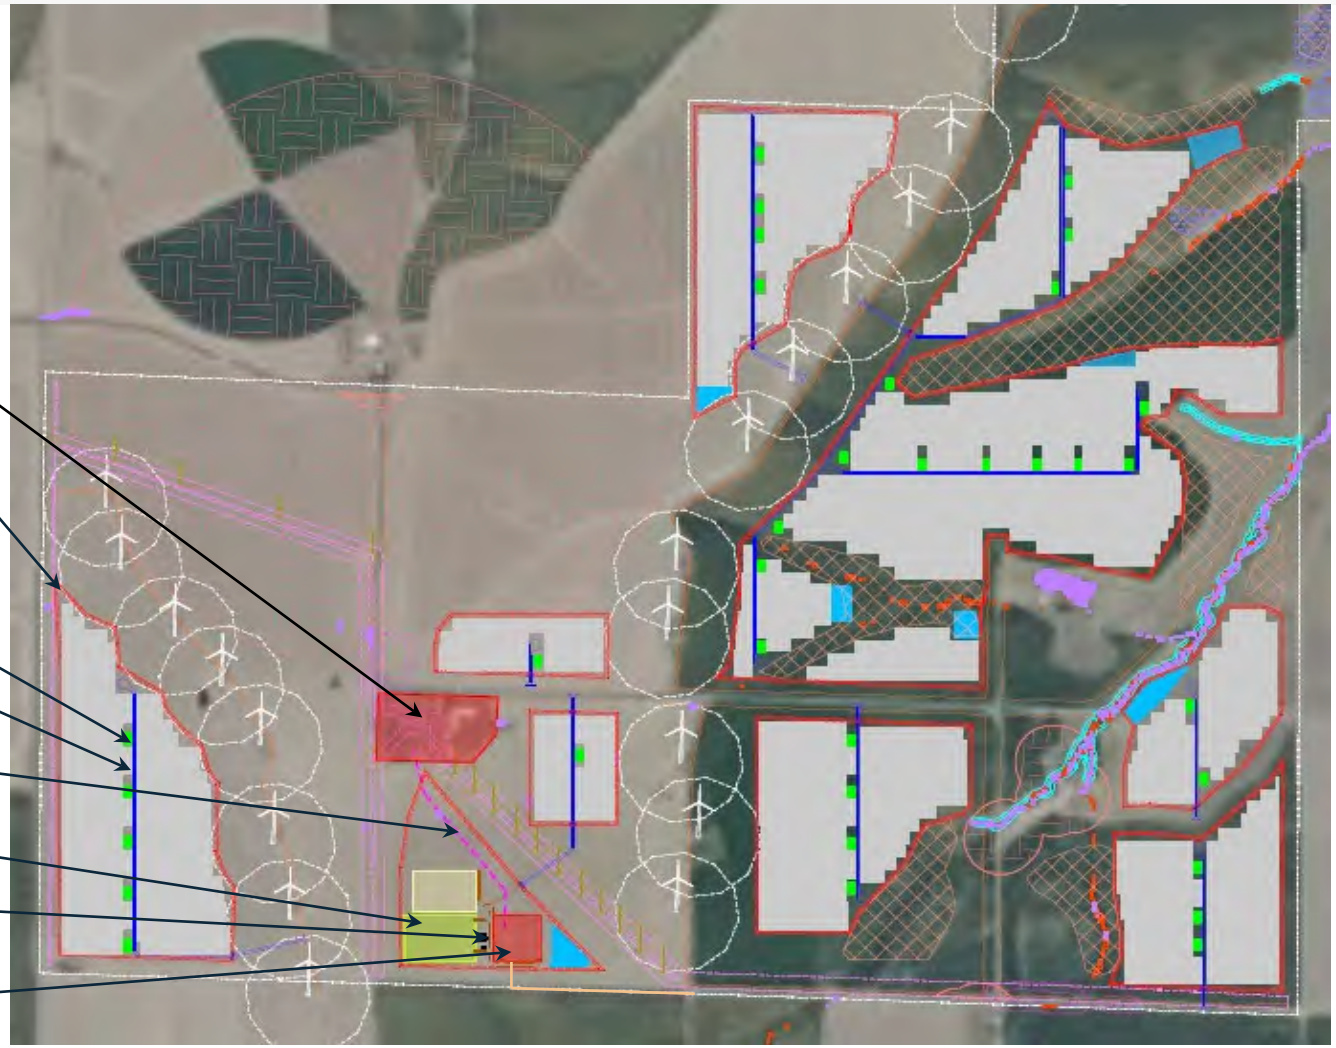
RFA Site Boundary and Micrositing Corridor

Phase I Preliminary Site Layout

Existing Biglow Canyon Substation

New solar array fence line

New inverters



New interior roads 16’

New onsite gen-tie

New BESS

New O&M building

New project substation w/ 24’ entry road and 20’ internal roads

Environmental Diligence cont'd

- Special Status Species Surveys and Habitat Categorization (Tetra Tech)
  - No listed plant or animal species observed
  - Land use predominately dry land wheat (Category 6 habitat)
  - Minimal impacts to Category 2 and 3 habitats mitigated at an offsite HMA
  - Preconstruction surveys will be implemented
- Wetland Delineation (Tetra Tech)
  - 3 wetlands (1 jurisdictional), 4 waterways (1 jurisdictional)
  - ODSL approved delineation results on 8/12/2025
  - Project will be micro-sited to avoid all impacts to wetlands and waters

Subject: RESPONSE to ODOE and PGE
Attachments: Response to ODOE PGE due 2272026.pdf

Follow Up Flag: Follow up
Flag Status: Completed

Chris, I sent three documents up to the portal, including this one. Can you make sure I did it right? Hope you had a good vacation! Kathy

We will be satisfied with the 4-6" weed height under the solar panels and around the fencing if ODOE promises to add it to the site certificate and add teeth to the site certificate. Our main concern is still fire.

The fact remains that there is enough room on the Biglow transmission lines for solar because the wind towers have not been maintained. Biglow Wind Farm Phase 3 continues to have major issues, and 50 towers are still not operating. It has been four years since the blade drop, and PGE estimates another three years before all the towers in Phase One are repaired and operational. We do not trust their operational expertise.

PGE/BrightNight included 50 pages on agrivoltaics in their rebuttal. This is another concern. Where is the common sense? We have no water. We are basically a desert. A windy desert.

Merriam-Webster: The meaning of **DESERT** is arid land with usually sparse vegetation; especially: such land having a very warm climate and receiving less than 25 centimeters (10 inches) of sporadic rainfall annually.

Our rainfall averages 7-10 inches a year. Does OSU really believe another five inches will mysteriously appear under the solar panels when they implement agrivoltaics?

The CIP plan in Amendment E includes plans to study agrivoltaics, with a cost estimate of $100,000-$300,000. (Annually?!) This is a waste of money. I doubt PGE will have enough funds and water to keep the panels clean and working optimally. This money could be better spent on real mitigation: fire mitigation.

The five-person board is cherry-picked by a lead county commissioner (Joe Dabulskis, not a lawyer) who wants the income from solar and is the Chair of CREA (a direct conflict of interest IMHO), an association that lobbies for green energy in Salem. OSU will be paid, and the rest of the committee are all pro-solar, ie. stand to profit and make money off solar. This is not a fair fight or an unbiased board.

I object to PGE's claim that it has addressed the wildfire issue. They have not addressed it with specificity to this project, but rather in general in the entire state of Oregon.

Solar has a much larger footprint and a much higher fire risk. Why aren't PGE and BrightNight developing a more robust fire plan? We are at the end of the Columbia Gorge (a venturi). The winds are stronger in northern Sherman County (hence a wind farm), and we are a dry tinderbox (desert).

The management at PGE has not recognized our concerns or been proactive. They have given us lip service, and won't even agree to the 4-6" for fire, much less a hold harmless clause. They have not operated in good faith at the Biglow Wind Farm. Even if there isn't enough "specificity" to address many of the comments from *multiple agencies*, this has to be addressed before we have another 80,000-acre fire like 2018.

The Certificate Holder requests that these terms be replaced with "low-growing, fire-resistant vegetation," or that the documents otherwise clarify that these buffer areas are intended to be maintained with low-growing, fire-resistant vegetation rather than fully devoid of vegetation.

This shows the *magical thinking* behind this amendment in the wildfire section. There is no fire-resistant vegetation. Nothing stays green out here year-round. A fire travels a half mile in ten minutes or less in our conditions.

Ten feet is a joke. Fifty feet is barely enough to turn a fire truck around (Fire Chief Bert Norris), according to our fire marshals, *who are all volunteers and change frequently.* Chief Burbank is a great guy who has been here about three years and he is not on board with this. BrightNight has talked with the fire chiefs, but that doesn't mean the fire chiefs are okay with the fire plan. We and hundreds of other farmers have been fighting fire here for over 40 years. We are the experts. The certificate holder held one meeting did a presentation with the North Sherman Fire Department. The meeting was not well-publicized or attended. Further dialogue and input from volunteer firefighters is needed.

5. Maintaining vegetation at a 1- to 3-inch height would substantially increase vegetation management costs without providing commensurate fire-risk reduction benefits.

Actually, 1"- 3" is the only height that would provide commensurate fire-risk reduction. But we will be happy with 4" - 6"! Too much erosion? Too hard to maintain? Only because this is a dangerous place for a solar project. Gravel? Sheep? The compelling and well-voiced concerns of our county's Conservation Department were dismissed for not enough specificity.

Well, this should be enough specificity to warrant extreme concern. But the game is rigged, and the criteria have already been determined despite common sense and facts. ODOE needs to reexamine its criteria for inclusion in challenging the site certificate. Their requirements are too rigorous, and we all feel dismissed without being heard.

The Certificate Holder requests the following changes to the first bulleted item in Section

3.4.2 PV System:
• Routine module inspections and annual infrared/aerial thermal imaging with anomalies detected via SCADA generating corrective work orders within 48 hours according to the final Operations and Maintenance Plan.

No - routine is not defined… every day, multiple times a day during fire season! And 48 hours is too long for corrective work orders during fire season. PGE is laden with bureaucracy *instead of common sense.*

Section 4.2 Specifications for Fire Protection Equipment:

The Certificate Holder requests to remove Drip Can: 5 gallon capacity from the list of fire suppression equipment required to be carried in maintenance vehicles and stored on-site at the O&M building. O&M staff are not expected to have experience using this type of equipment and will not be conducting activities requiring the use of drip cans.

This is precisely my worry. In a nutshell. PGE has never trained its people in firefighting and appears to have no intention of doing so. Instead, they are relying on volunteer firemen – us, the farmers and citizens of Sherman County. We are the experts in this drama, and our concerns are falling on deaf ears.

Comprehensive Solar Revegetation and Soil Management Plan
Biglow Canyon Wind Farm F-8
Vegetation Management Objectives for Permanent Disturbance Areas
During the operation of the Solar Components, vegetation under the solar panels will be managed to minimize fire risk and erosion by maintaining low-growing vegetation.
Prohibition on Use of Domestic Sheep and Goats for Vegetation Management
The Certificate Holder may not keep or use domestic sheep, goats, or other livestock at the Facility for vegetation control or other purposes without written approval from ODOE. Any request to use domestic sheep, goats, or other livestock at the Facility must be accompanied by a description of practices and controls that will be implemented to prevent zoonotic disease transmission to wild sheep populations. ODOE may impose additional requirements to prevent zoonotic disease transmission based on consultation with ODFW. This prohibition does not apply to landowners grazing livestock outside the Solar Components in accordance with their leases.

Success Criteria for Permanent Disturbance Areas
The Certificate Holder will establish uniform (i.e., evenly distributed, without large bare areas) perennial, non-invasive vegetation that provides 70 percent or more cover on all exposed areas within the Solar Components in compliance with the soil protection standard (Oregon Administrative Rule [OAR] 345-022-0022); National Pollutant Discharge Elimination System 1200-C permit requirements; and Sherman County requirements.

Integrated Vegetation Management Measures

To support reclamation success and reduce wildfire risk throughout all phases (i.e., both construction and operations) of the Solar Components, vegetation management will be implemented consistent with the draft Construction Wildfire Mitigation Plan and anticipated Operations Wildfire Management Plan. In the interim, while those plans are being finalized, this section establishes the minimum vegetation management and fire prevention requirements that will apply during the construction and operation of the Solar Components. Vegetation will be managed in accordance with the applicable provisions of the 2025 Oregon Fire Code, Section 1205.5.1

(Oregon State Fire Marshall 2025):

"A clear brush free area of 10 feet shall be required around the perimeter of the ground-mounted photovoltaic arrays or as determined by the fire code official. A maintained vegetative surface or noncombustible base, approved by the fire code official, shall be installed and maintained under the photovoltaic arrays and associated electrical equipment installations."

These measures are intended to minimize ignition potential, maintain defensible space, support consistent vegetation control, and outline inspection practices that will contribute to long-term fire resiliency. At a minimum, the following criteria will be met:

a. Vegetation Height and Clearance
b. Vegetation within and adjacent to the Solar Components will be maintained at a height of less than 12 inches, with a minimum vertical clearance of 12 inches from all electrical and mechanical equipment.

High wind, low humidity, and high fuels are nearly unstoppable conditions for a fire. I *do not* believe that the plan has done a good job of addressing this danger. Ten feet? Ten feet might work in the Willamette Valley, but not in our location in eastern Oregon. Fire lines around the project, and much lower fuel loads within the project, are not sufficient for our winds.

Ten inches? Twelve inches? That is too high a fuel load. There are very few volunteers in our county stupid enough to go into a solar farm to fight a fire. PGE/BrightNight needs to train and pay its employees to fight fire. They need to have them on site during the fire season 24/7. The Avangrid project in Gilliam County has learned this the hard way, with five fires in its facility in one fire season!

Background
Oregon adopted legislation in 1993 and updated it in 1995 and 2001 to protect farm and forest practices from adjacent conflicting issues. The program is called Oregon's Right to Farm laws. It protects farmers from claims over smell, dust, noise, and other trespass or nuisances associated with farming.

Oregon Department of Agriculture Literature
https://www.oregon.gov/oda/shared/Documents/Publications/NaturalResources/RightToFarm.pdf

ORS 30.930 to 30.947, Farming and Forest Practices
ORS 30.936 and 30.937, Immunity from private action based on farming practices

For EFSC certificates, the project Owners must sign and record a covenant acknowledging these laws.

These laws need to be updated for fire before the Biglow Project and other solar facilities in Sherman County are constructed.

Falling pieces
Request for Amendment 4 for Biglow Canyon Wind Farm
Page 23 Long Term Facility Maintenance Plan
4.2.1 Long-term Facility Maintenance Plan

"Over the course of more than 15 years of operation at the Existing Facility, the Certificate Holder has encountered technical challenges that have offered valuable insights into both technical and procedural vulnerabilities and informed continuous improvement efforts. The Certificate Holder has implemented targeted improvements specific to the Existing Facility, including changes to internal management structure and personnel, a change in the turbine O&M provider with a newly negotiated contract to mitigate future technical challenges and better align with site-specific performance goals, and improved monitoring of contractor performance. Improved preventative maintenance, robust monitoring, and corrective action planning will result from these ongoing changes.

The specific types of technical challenges with the Existing Facility would be unlikely to occur with the Solar Components due to the difference in technology. Lessons learned from more than a decade of wind facility operations at BCWF are being directly integrated into the planning and management of the proposed Solar Components. Past challenges have informed the adoption of more robust preventative maintenance and corrective action protocols, improvements to vendor contracts to ensure the contracts use asset management and equipment health as the measure for vendor performance, stronger consequences for poor performance, and improved quality control and assurance oversight of vendors.

This response is inadequate.

Replace the words "falling pieces" with "FIRE".

If PGE can't run a safe wind farm, how can they be trusted to maintain a safe solar facility? We are still in the middle of nowhere, with no housing for personnel. The workers drive in every day, and the remote monitoring at this site has never been reliable enough to eliminate on-site personnel. *How in the world are these concerns "UNLIKELY TO OCCUR" just because solar is a different technology?*

"…the issues do demonstrate a deficiency in the adequacy of the existing site certificate conditions in ensuring systematic oversight of vendor performance, preventive maintenance, and safe, reliable construction and operation.

The Department has recommended the Council adopt additional conditions of approval to improve oversight and ensure the safe operation of the proposed solar components, including recommended Organizational Expertise Conditions 1 and 2 which require the finalization of the Draft O&M Framework Plan included as Attachment C to the Proposed Order. The Department may consider additional changes to these conditions or plan should the commenter suggest any in their reply.

There is no doubt in my mind that PGE can maintain a solar facility. The problem is: WILL THEY? They have not maintained the wind. We have a vote of NO CONFIDENCE.

OAR 345-022-0010
Organizational Expertise Applicable and complies. The Council has previously found that the Certificate Holder has the ability to construct, operate, and retire the BCWF. As part of RFA4 the Certificate Holder has described the violations or citations issued and demonstrated how those violations or citations were addressed to the satisfaction of the issuing agencies. RFA 4 does not alter the Certificate Holder's ability to comply with the Site Certificate Conditions. See Section 5.3 above for accompanying analysis.

All you have to do is look around the wind towers. The soil was not restored to its original condition. Alkali is on top, and the wheat is sparse.

OAR 345-022-0022
Soil Protection
Applicable and complies. Permanent and temporary disturbance will occur as a result of the components proposed in RFA 4 including the solar modules, BESS, and proposed substation. RFA 4 does not alter the Certificate Holder's ability to comply with the Site Certificate conditions. See Exhibit I in Attachment 4 for accompanying analysis and Section 4.4.3 for anticipated temporary and permanent disturbance impacts.

Canyon Wind Farm in RFA 4. These changes include amending the BCWF description to incorporate the Solar Micrositing Area/RFA 4 Site Boundary, increasing the peak generating capacity for solar energy generation, increasing the area of solar photovoltaic energy generation, adding battery energy storage, and modifying the construction start and completion dates. Additionally, the BCWF description was modified to remove related or supporting facilities that were authorized by Amendment

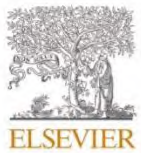
2 but were not built by the construction start and completion timelines in the Second Amended Site Certificate, and therefore are no longer authorized to be constructed.
• Addition of new conditions to address wildfire prevention, and to specify requirements for other resources as they pertain directly to the addition of Solar Components and RFA 4 Site Boundary.

Wildfire prevention has not been addressed with specificity.

We need the completed fire plan in place before the build, not after. All my other concerns still stand, but FIRE is #1.

My concerns about climate normal were dismissed because NOAA is a government agency with expertise. I was not questioning NOAA's expertise – I am questioning the way their numbers are being used. Issue SP-05

You claim I have no proof of my 50-year soil claim, yet neither do they. Issue WF-01: Concerns about burn probability data used in fire risk analysis. Issue WF-02: Concerns about the use of climate normals for fire risk analysis. In Exhibit V, Issue WF-03: Concerns about fuel models used for fire risk analysis.



No one is taking our local knowledge or issues into consideration. **We have no paid fire department. Buying us fire trucks will not help unless someone drives them.** We used our tractors and disks to create firebreaks. We carry water on our pickups. PGE employees are not going to carry anything – not drip cans or other firefighting tools.

A few photos from the 64 pages of agrivoltaics in the *Midwest* submitted from PGE/BrightNight in their BIGL RFA4 comment letter to us. This has no bearing or validity here in Sherman County, Oregon. I would love to see what the wind will do to vertical solar panels, and it would be great to have enough water for the crops under them.

To me, this shows the disconnect we have between truth and fiction. ODOE uses specificity and OARs to approve projects. They need to inject common sense into the equation.

FSEC actually listened when we presented our concerns, and my hope is that ODOE follows through with their promise of increased monitoring of PGE's Biglow solar. This project is being rushed, whether you concur or not. Issue GS-01

ABSTRACT

The increasing pressure on land resources for food and energy production along with efforts to maintain natural systems necessitates the development of compatible land uses that maximize the co-benefits of multiple ecosystem services. One such land sharing opportunity is the restoration and management of native grassland vegetation beneath ground-mounted solar energy facilities, which can both protect biodiversity and restore related ecosystem services. In this paper, we applied the InVEST modeling framework to investigate the potential response of four ecosystem services (carbon storage, pollinator supply, sediment retention, and water retention) to native grassland habitat restoration at 30 solar facilities across the Midwest United States. Compared to pre-solar agricultural land uses, solar-native grassland habitat produced a 3-fold increase in pollinator supply and a 65% increase in carbon storage potential. We also observed increases in sediment and water retention of over 95% and 19%, respectively. We applied these results to project the potential benefits of adoption of native grassland management practices in current and future solar energy buildout scenarios. Our study demonstrates how multifunctional land uses in agriculture-dominated landscapes may improve the provision of a variety of ecosystem services and improve the landscape compatibility of renewable energy and food production.

1. Introduction

Solar photovoltaic (PV) energy technologies have exponentially increased across the globe over the past decade (Kabir et al., 2018; Irsyad et al., 2019). Currently, there are over 33 gigawatts (GW) of ground-based large-scale (>1 MW) solar PV energy production in the U. S. (EIA, 2019a), representing about 1.5% of total U.S. electricity generation in 2018 (EIA, 2019b). The proliferation of large-scale solar energy developments is expected to continue across the U.S. over the next decade. For example, the U.S. Department of Energy's National Renewable Energy Laboratory, through its Standard Scenarios Report, Hernandez et al., 2014), and approximately 7500 km^2 of total land will be needed to meet 2030 projected solar energy production (Hartmann et al., 2016), roughly the combined size of the states of Delaware and Rhode Island.

Given their large land requirements, questions about the sustainability of solar energy developments have emerged in terms of their compatibility with other land uses such as agriculture (Moore-O'Leary et al., 2017; Hernandez et al., 2019). Ground-based solar energy developments are increasing in agricultural landscapes, due in large part to the siting of utility-scale solar energy developments on former agricultural fields (Adelaja et al., 2010; Adeh et al., 2019). Croplands are

Another method of optimizing elevated agrivoltaic systems is to use an optimal tilt angle and orientation to increase the yield of the solar panels and the crops grown under them (Figure 7). Various tilts and orientations have been tested for different locations for fixed installations. According to Trommsdorff et al. [44], solar tracking modules allow for more flexible light management under the panels. The process of tracking PV systems involves installing a mechanical system that can adjust the orientation and tilt of the modules at different times of the day, with the goal of optimizing energy production. Two categories of solar tracking systems are used: single-axis trackers and dual-axis trackers. In the first configuration, the PV module array tracks the sun horizontally according to its angle of incidence (altitude) or vertically according to its orbit (azimuth). The second configuration combines the two, producing a more significant amount of energy. These mobile systems optimize crop yields through greater light availability during critical growth periods. In addition, the flexibility of the tilt angle provides constructive protection against hail or extreme radiation by adjusting their orientation as required.

(a) (b)

Figure 7. (a) Single-axis solar tracker module [44] and (b) dual-axis solar tracker module [60].

One of the main constraints of installing aerial agrivoltaic systems is the high investment and maintenance cost. The wide spacing of the panels can create favorable conditions for crop growth and development, but it leads to a reduction in energy density due to the reduced number of panels installed on the plot. Also, the spacing between rows of panels can increase the investment cost in areas with high land costs and limited land availability [29]. However, these systems face shading constraints [33], so these installations are favorable for viticulture. Moreover, dual-axis systems with large arrays of PV modules can

BIGL RFA4_Comment Letter to Kathy and Kevin McCullough_02132026 (1).pdf
Open with Preview

exposure to sunlight. The main crops used in this type of agrivoltaic system are grapes, small fruit trees, and delicate vegetables. In contrast, inter-row PV systems are systems in which agricultural production is usually carried out in the space between the rows of

panels. The distance between two consecutive rows of the panels can be considerable in this type of installation to facilitate the passage of large agricultural machinery. The most common crops in inter-row solar systems are grasses, hardy vegetables, and higher-value horticultural crops [29]. The different configurations are established to compare their impact on the level of shading created by the panels and their consequences on crop yields to determine the optimal density for an agrivoltaic installation [44]. Another way to increase the efficiency of a PV system is to install double-sided PV panels [45]. Figure 2 summaries the different configurations.

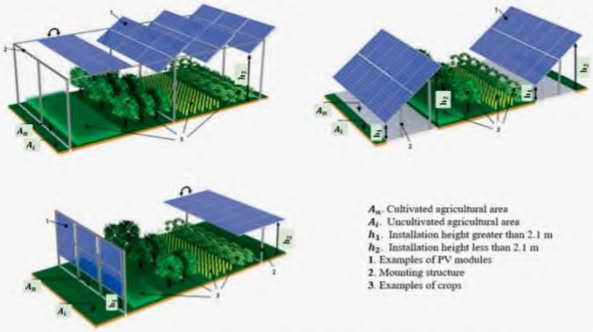

Figure 2. Overview of different configurations of agrivoltaic installations [44].

Several configurations and technologies have been developed and tested to optimize production in agrivoltaic systems. Therefore, the installation must meet the requirements of both the crop and the photovoltaic panels, which can be achieved by using optimal panel spacing and installation height that also allows the passage of agricultural machinery and appropriate panel technology [44]. Macknick et al. [46] have identified three types of approaches for the implementation of agrivoltaic systems: (i) the energy production approach, which focuses on optimizing the solar energy produced (thus minimizing changes in standard solar development practices), while cultivating between and/or under the panels, (ii) the agricultural production approach which focuses on optimizing biomass production (minimizing changes in existing vegetation management activities), while taking energy production into account, and (iii) the integrated agricultural and energy production approach (incorporating vegetation and energy priorities into system design).

These approaches are based on implementing one of the two installation techniques:

create shading under the panels, while other parts of the ground surface receive maximum sunlight [44].

3.2.2. Vertically Mounted Agrivoltaic Systems

The mounting of solar panels vertically to the ground is also a method of optimizing agrivoltaic systems (Figure 8). It consists of an installation technique in which the modules are oriented in the east–west direction, which has proved to be more efficient for permanent crops, or in the north–south direction, where energy production is a priority [61]. These systems require a significant distance between consecutive rows of vertical supports. For example, [62] studied vertical arrays using a 10 m spacing between the rows. A report by [26] showed that the yield of oats and potatoes decreased by 50% when the distance between rows was decreased in length from 20 to 5 m. In addition, [26] reported that 10% of the land near the panels does not have to be cultivated and can be used as ecological zones. Bifacial panels are widely used in these systems.

Figure 8. Vertical agrivoltaic installation with bifacial modules in Sued [62].

Monterey County declares state of emergency over Moss Landing lithium battery plant fire

Monterey County supervisors on Tuesday declared a state of emergency in response to last week's major fire at the Vistra lithium battery plant in Moss Landing.

The emergency declaration came during a special meeting where officials gave updates on the fire and ongoing response. While the fire has burned itself out, there are still a lot of questions from local leaders and neighbors about what's next.

"This was the beginning," said Josh Contreras as he showed photos he took of the incident from his houseboat.

The images show a fireball on the horizon, not even a mile away.

"I walked up the docks, and then I took more photos," he said. "Because you could see the flames, probably almost as tall as the towers that stand here."

The fire at the Moss Landing Vistra Power Plant, located about 90 miles south of San Francisco, broke out last Thursday afternoon, escalating in the early evening to the point where the incident triggered evacuations for about 1,200 Monterey County residents in the area and shut down a section of Highway 1 in both directions.

Moss Landing Power Plant fire / Credit: KION

Concerned over the potentially toxic runoff if fire crews turned hoses on the burning lithium batteries, officials instead are allowing the to burn itself out.

Officials said the fire was largely out as of late Friday morning during a press conference, but it flared up significantly for a few hours that afternoon before dying down again. Officials were eventually able to lift the evacuation orders by early Friday evening. The stretch of Highway 1 near the plant remained closed until Sunday.

Now that the fire is out, he is one of the many people living in the area what lies in the future for the facility.

"If they do battery packs, they should keep it in more deserted areas," Contreras said.

"This technology is ahead of the government's ability to regulate it," Monterey County Supervisor Glenn Church said during the emergency meeting Tuesday. "And the industry's ability to control it."

The massive fire at one of the world's largest lithium battery storage plants in Northern California has shaken a local community worried about possible long-term impacts and brought scrutiny to the emerging industry's safety practices.

The fire at a power plant and battery facility operated by Vistra Energy in the Monterey County community of Moss Landing began Thursday afternoon, forcing evacuations and the closure of coastal Highway 1. A Monterey County official on Friday called it the largest fire ever of its kind.

The Moss Landing Power Plant, about 95 miles south of San Francisco, is owned and operated by Vistra subsidiary Dynegy and also houses two independent battery storage plants. The plant that is burning is owned by Vistra Energy while a second battery storage facility on the same site is owned by Pacific Gas and Electric, which said the incident was not a PG&E event.

There have been no injuries reported in the fire, which is being allowed to burn itself out as is standard procedure for such fires, according to the Monterey County Emergency Operations Center. However, the smoke from the fire has forced other residents not under evacuation orders to close their windows and remain indoors.

Monterey County Supervisor Glenn Church called the incident a "Three Mile Island event" for the industry, referencing the 1979 partial meltdown at a Pennsylvania nuclear power plant, the worst nuclear accident in U.S. history. The battery energy storage systems industry, known by the acronym BESS, develops systems to store energy from electric, solar, electric, wind, and other energy systems.

"I think that this is, uh, can best be described as a worst-case scenario of a disaster that's happened here. Nobody really predicted anything on this line," said Church. "This is really a lot more than just a fire, it's a wake-up call for this industry. And if we're going to be moving ahead with sustainable energy we need to have safe battery systems in place."

On Tuesday, the American Clean Power Association disputed Church's Three Mile Island comparison, calling it "misleading and dangerous." ACP also noted that the risk and impact associated with the potential meltdown of a nuclear reactor and release of radioactive materials is far greater than the risk of a worst-case failure at a battery storage facility.

Massive battery projects involving hundreds of megawatts are becoming more common in the U.S. and across the globe. California law requires investor-owned utilities to store energy and the state is expected to need 50 gigawatts of battery storage to meet its 2045 goal of getting all of its power from carbon-free sources from the current 7 gigawatts today, according to Reuters.

In a statement to CBS News Bay Area, ACP spokesperson Phil Sgro said,

"We are aware of the ongoing incident at Moss Landing and are gathering additional information from our partners and stakeholders on the ground. While fire-related incidents at battery energy storage sites are rare, and investigations into historical incidents have not found health risks to neighbors or the surrounding community, we are not able to comment on the unique circumstances of this particular incident as the response is still ongoing.

"The energy storage industry works closely with fire officials and emergency responders to ensure the safety of its neighbors and appropriately respond to any safety incident. The industry is committed to meeting and exceeding the latest and most rigorous safety standards for energy storage facilities, and coordinates with local fire departments, first responders, and regulatory bodies to ensure storage projects account for the safety needs of every community.

"Safety is the first and foremost priority of the industry and, after the incident is resolved and there is a thorough investigation, the industry will ensure the lessons learned are applied to prevent future incidents and inform safety standards and best practices."

Church said he has fielded numerous questions from his constituents on why it happened, how it happened, and how to prevent a similar accident in the future. Church added it is the fourth fire at the site, a former Pacific Gas and Electric facility, since 2019 and said he and other county officials were previously assured it would not happen again. He called for increased safety protocols for the industry at federal, state, local, and private levels.

The battery plant fire on the shore of Monterey Bay is also situated next to environmentally sensitive areas such as Elkhorn Slough, designated a "wetland slough of international importance."

Church said while he understands the need for the battery industry, he said the transition to sustainable energy "cannot, will not come before the safety of families and environment."

"This never should have happened," said a visibly shaken Church. "And so, there is obviously some gaps going on here of information, there's some gaps going forth here on safety, there's gaps going here that are going to take some time to understand, but they gotta be - there's gotta be lessons that we learn from this."

Church said it was the largest fire ever of its kind and also called for an independent investigation into the incident.

"If renewable energy is going to be a future, it really needs to rest with safe energy," said Church. "And I'm not going to rest and leave this until I know we have a safe environment and a safe operation in the Moss Landing area."

Monterey County officials declared a local state of emergency over the fire on Tuesday.

Texas-based Vistra Energy senior director of community affairs Brad Watson also spoke at the press conference, saying the company considers itself part of the community and has taken the incident very seriously. Watson apologized to all those affected by the current situation.

"We are hurting today because we know primarily it's impacted and disrupted the people who live around our site, our neighbors, our friends, and businesses, and for that, we are sincerely sorry," said Watson.

Watson said it will listen to the community residents on how the company can consider ways to provide assistance. The company was contracting with an air quality monitoring company to keep residents informed of any possible health impacts from the fire's smoke and coordinate its findings with the U.S. Environmental Protection Agency.

The cause of the fire has not yet been determined.

According to ACP, fire-related incidents at BESS sites are incredibly rare, with 20 incidents in the last 10 years at U.S. operating energy storage facilities even as energy storage deployments have grown by more than 25,000% since 2018.

Re: Biglow Canyon Wind Farm Request for Amendment 4 – Response to Comments on Proposed Order

Dear Mr. and Mrs. McCullough,

Portland General Electric (PGE) and project developer BrightNight (BN) appreciate your comments regarding the Oregon Department of Energy's Proposed Order on Request for Amendment 4 (RFA 4) of the Biglow Canyon Wind Farm (BCWF) Site Certificate. Oregon Administrative Rule (OAR) 345-027-0367(8) requires PGE to respond to all comments that are made with "sufficient specificity," as that term is defined in OAR 345-027-0367(7)(a).

We note that your comments contained in the 13 written comment letters and oral testimony provided at the public hearing may not necessarily meet that standard but are valuable to inform the process. PGE and BN reviewed your comments carefully and offer the following responses, organized into five categories of issues that we hope accurately respond to your concerns. The responses below are organized by the interpretation of your comments received and are further identified with the same issue identification number provided in Table 1: List of Issues and Commenters in the Oregon Department of Energy's (ODOE) Response to Comments document dated February 12, 2026.

1. Organizational Expertise (OE-01)

PGE recognizes that one of your primary concerns regarding RFA 4 relates to maintenance issues at the existing BCWF. PGE acknowledges the operational incidents documented at the BCWF and has implemented targeted improvements specific to the BCWF, including changes to internal management structure and personnel; a change in the turbine operations and maintenance provider with a newly negotiated contract to mitigate future technical challenges and better align with site-specific performance goals; and improved monitoring of contractor performance. Improved preventative maintenance, robust monitoring, and corrective action planning will be the result of these changes, which are still ongoing.

As we talked about with you previously, and addressed during our public testimony at the hearing, lessons learned from past challenges have resulted in more robust preventative maintenance and corrective action protocols, stronger vendor performance accountability, clearer performance standards tied to equipment health, and improved quality assurance and quality control oversight. These lessons have informed the design, operational planning, and compliance framework for the proposed solar and battery energy storage systems under RFA 4 (Solar Components or Biglow Solar).

Most notably, the Proposed Order introduces a new requirement for a Comprehensive Operations and Maintenance Plan (O&M Plan) for the Solar Components (*see* Proposed Order

Attachment C; and draft amended Site Certificate conditions OPR-OM-01 through OPR-OM-03). This O&M Plan is intended to serve as the governing operational document for the Solar Components and must be finalized and approved by ODOE prior to commencement of operations.

Under draft amended condition OPR-OM-01, PGE must submit a final O&M Plan consistent with the framework outlined in Attachment C and Table 5 of the Proposed Order. The O&M Plan consolidates and carries forward commitments from multiple operational plans introduced under RFA 4, including:

- The Operational Wildfire Mitigation Plan;
- The Comprehensive Solar Revegetation and Soil Management Plan; and
- Hazardous materials management and emergency response plan requirements.

The O&M Plan establishes preventive maintenance procedures, monitoring protocols, documentation standards, emergency preparedness measures, and regulatory compliance procedures that will govern the facility throughout its operational life. It also requires submission to ODOE of contact information, qualifications, and defined roles for primary vendors, contractors, and management personnel responsible for operations.

In addition, draft amended condition OPR-OM-02 requires annual reporting to ODOE that includes detailed information regarding facility status, power production reliability and efficiency, monitoring results, compliance activities, and any facility modifications. While annual reporting has existed previously, the scope and specificity of the required documentation under RFA 4 are expanded and more detailed.

Draft amended condition OPR-OM-03 strengthens incident reporting requirements by requiring timely notification to ODOE, written documentation within defined timelines, and tracking of corrective actions. Significant events require root cause analysis and documentation of corrective measures. ODOE retains inspection and enforcement authority and may require additional corrective actions, if warranted. Retirement and restoration surety requirements (RET-01 through RET-03) remain in place to ensure financial resources are available for remediation or decommissioning, if necessary.

The O&M Plan Framework (Attachment C and Table 5 of the Proposed Order) establishes enforceable requirements in the following areas:

a. Preventive Maintenance and Asset Monitoring (Section 3.4)
    - Routine, scheduled inspections and condition-based maintenance consistent with manufacturer specifications and industry standards;
    - Supervisory control and data acquisition (or SCADA)–based monitoring of solar arrays, substations, and battery energy storage system (BESS) components; and
    - Documentation and tracking of maintenance activities in auditable logs.

b. Regulatory Compliance and Site Certificate Conditions (Section 3.5; OPR-OE-01)
    - Integration of all applicable Site Certificate conditions into day-to-day operational procedures;
    - Clear assignment of roles and responsibilities, including required submission of

contact information and qualifications for key personnel and contractors; and

- Requirement that material plan changes be submitted to ODOE for review and approval.

c. Emergency Preparedness and Incident Response (Section 3.6; PRO-OE-01; OPR-OE-01)

- A site-specific Emergency Response Plan prior to operations;
- Fire detection, alarms, and shutdown capabilities integrated with monitoring systems;
- Mandatory incident reporting to ODOE "as soon as reasonably possible," followed by written documentation within defined timelines; and
- Required root cause analysis and documented corrective action tracking for significant events.

d. Monitoring, Reporting, and Public Accountability (OPR-OM-02 and OPR-OM-03)

- Mandatory annual reporting to ODOE detailing facility status, reliability and efficiency metrics, compliance activities, and any facility modifications;
- Expanded scope and specificity of reporting compared to the legacy wind facility;
- Defined reporting timelines and written documentation requirements; and
- ODOE inspection authority and enforcement authority, including the ability to require corrective actions, additional inspections, or modifications if warranted.

e. Long-Term Operational Continuity and Transition Planning (Section 4.0)

- Defined roles during the initial Build-Transfer Agreement period;
- Clear transition of full O&M responsibility to PGE after Year 5; and
- Ongoing regulatory responsibility always remains with PGE as Certificate Holder.

These requirements are enforceable through the amended Site Certificate. Noncompliance may result in inspection findings, corrective action requirements, or enforcement action by ODOE. In addition, retirement and restoration surety requirements (RET-01 through RET-03) remain in place to ensure financial resources are available if remediation or decommissioning becomes necessary.

Your comments under the Energy Facility Siting Council (EFSC or Council) Organizational Expertise Standard express concerns regarding whether the facility will be adequately maintained and whether there will be accountability for operational issues. The Proposed Order and the implementing plans and conditions directly address those concerns through mandatory reporting, defined timelines, corrective action tracking, inspection authority, and enforceable Site Certificate conditions. We hope this response helps address your concerns regarding organizational expertise and PGE's ongoing accountability and compliance.

2. Wildfire Prevention and Risk Mitigation (issue numbers identified in subsections)

PGE and BN recognize that another one of your primary concerns regarding RFA 4 is wildfire prevention and risk mitigation. Living and farming next to new energy infrastructure raises

important questions, especially about safety and wildfire risk. Wildfire mitigation plays a critical role in how Biglow Solar is designed, constructed, and operated. The Proposed Order contains integrated requirements, both in conditions and in plans, to ensure that wildfire risks are managed to acceptable levels.

a. *Construction Phase Wildfire Mitigation (PS-01, PS-02, SP-01, SP-04)*

The Draft Construction Wildfire Mitigation Plan (WMP; Attachment G of the Proposed Order) includes the following actions and information to mitigate wildfire risk during construction:

- Onsite training that covers best practices to prevent fire ignition; type, location, and proper use of fire protection equipment; location of water sources and proper usage; and specific procedures and actions applicable during fire season and red-flag warnings (Attachment G, Section 3.1).
- Facility design features intended to reduce fire risk, with a section dedicated to BESS fire protection that describes BESS components, all applicable standards and codes that must be followed, and other facility components installed to ensure proper testing, handling, and back-up protection (Attachment G, Section 4.1.4).
- Specifications for fire protection equipment to ensure firefighter safety (Attachment G, Section 4.2).
- Vehicle use Best Management Practices to minimize fire risk from vehicle travel, equipment use, and fueling activities (Attachment G, Section 4.4).
- Fire weather monitoring and restrictions during fire season (Attachment G, Section 4.5).
- Vegetation management (Attachment G, Section 4.6), aligned with the draft Comprehensive Solar Revegetation and Soil Management Plan (Attachment D of the Proposed Order), to ensure consistent vegetation management that prevents erosion, supports native vegetation for watershed health, reduces wildfire fuels, and prevents the introduction or spread of noxious weeds. This includes vegetation height restrictions, especially around electrical equipment; non-combustible buffers around buildings, roads and the site perimeter; and weed monitoring and removal in coordination with the Sherman County Weed Board and Oregon Department of Agriculture.

PGE and BN acknowledge ODOE's recommendation in the Proposed Order to maintain vegetation at a reduced height of 1 to 3 inches during the dry season (June–October). PGE and BN also note the comment submitted by the Sherman County Weed District (BCWAMD424-15), which advises that maintaining vegetation at 1 to 3 inches may not be feasible if erosion control is a priority and instead recommends a grass height of 4 to 8 inches during the dry season for the proposed bunchgrass species. We recognize the Weed District's local expertise regarding soil stability and vegetation performance and appreciate the perspective provided.

The vegetation height standards identified in the draft Comprehensive Vegetation and Soil Management Plan and draft Construction Wildfire Mitigation Plan (WMP) provide for vegetation to be maintained below 10 to 12 inches year-round. These standards were developed based on practical vegetation management considerations intended to support long-term wildfire risk reduction while maintaining vegetation health and site stability. Maintaining vegetation at 1 to 3

inches during the dry season presents several practical and ecological considerations:

GE and BN acknowledge ODOE's recommendation in the Proposed Order to maintain vegetation at a reduced height of 1 to 3 inches during the dry season (June–October) and request that the vegetation height requirements be limited to a height of 10 to 12 inches year-round. Based on practical vegetation management considerations, this approach best supports wildfire risk reduction for the following reasons:

- Repeated low mowing to such reduced heights would be detrimental to perennial grasses included in the approved seed mix, as repeated damage to bunchgrass crowns would likely result in plant mortality within a few growing seasons.
- Extremely low mowing would favor the establishment of annual grasses, thereby increasing fine fuels rather than reducing fire risk.
- Low mowing would significantly reduce or eliminate wildlife habitat, particularly for ground-nesting birds and beneficial insects.
- Mowing at such low heights at the beginning of the dry season increases the risk of fire ignition due to sparks generated when mowing equipment contacts rocks or hard surfaces.
- Maintaining vegetation at a 1- to 3-inch height would substantially increase vegetation management costs without providing commensurate fire-risk reduction benefits.

The draft Construction WMP will be finalized prior to construction as required by draft amended condition PRE-WF-01, and contractors and employees must adhere to the plan pursuant to CON-WF-01.

a. Operational Phase Wildfire Mitigation (WF-12)

Wildfire mitigation does not end at construction. PGE is developing a site-specific Operational WMP, which will provide any site-specific information outlined in ODOE's Operational WMP template that is not already addressed in PGE's 2026-2028 Corporate WMP which was filed with the Oregon Public Utility Commission on December 31, 2025. The Operational WMP will include the same components as described for the Construction WMP above; however, the construction-specific actions will be replaced with site-specific operations and maintenance actions.

The site-specific Operational WMP under development for the Biglow Solar facility will be submitted to ODOE for review and approval prior to beginning operation of the solar facility, as required by PRO-WF-01; onsite contractors and employees will adhere to this plan as required by OPR-WF-01, as well as incident reporting and corrective action requirements under GEN-OE-05 through GEN-OE-07. Importantly, wildfire prevention and response measures are also integrated into the enforceable O&M Plan required under draft amended conditions OPR-OM-01 through OPR-OM-03. The O&M Plan:

- Incorporates operational wildfire mitigation requirements into day-to-day procedures;
- Requires ongoing vegetation management to reduce fuel loads and maintain defensible space;
- Integrates fire detection, alarm systems, and shutdown capabilities with 24/7 monitoring systems;

- Establishes incident reporting, documentation, and corrective action requirements if a fire-related event occurs; and
- Subjects wildfire-related operations to mandatory annual reporting, inspection, and enforcement oversight by ODOE.

Through this integrated framework, wildfire mitigation is not a stand-alone document, but an ongoing operational obligation embedded within the broader compliance and accountability structure governing the facility.

b. Setbacks and Vegetation Management Buffers (WF-07, WF-08)

PGE and BN recognize that vegetation management is integral to wildfire mitigation and serves as a primary risk-reduction measure during both construction and operations. The recommended setbacks and vegetation management buffers reflected in ODOE's Proposed Order were carefully developed to integrate industry best practices, applicable regulations, and relevant operational experience. These setbacks and buffers are incorporated into the associated draft plans and site design and will be carried out through implementation.

- Vegetation will be managed in accordance with the applicable provisions of the Oregon Fire Code:
  - Non-combustible buffer (10 feet) shall be required around either side of the perimeter fence.
  - A maintained vegetative surface or non-combustible base shall be installed and maintained under the photovoltaic arrays and associated electrical equipment.
- Vegetation standards apply (in addition to the above):
  - Within the solar arrays – vegetation maintained at a height of less than 12 inches, with a minimum vertical clearance of 12 inches from all electrical and mechanical equipment.
  - Along access roads – 10-foot low-growing, fire-resistant vegetation buffer on either side.
  - The BESS yard is designed with non-combustible materials (e.g., metal, etc.). No vegetation is allowed inside the BESS yard, and all surfaces are gravel or pavement.
  - The areas surrounding the O&M, BESS, and substations and within defensible space areas will implement a 20-foot non-vegetated perimeter buffer maintained as graveled or earthen surface.

c. Coordination with Local Fire Authorities (PS-01, PS-02)

PGE and BN have conducted extensive outreach in the community and with local emergency responders. On August 12, 2025, BN presented at a North Sherman County Rural Fire Protection District Board meeting, where proposed project details were shared alongside an overview of planned fire prevention and wildfire mitigation measures (presentation as given at the meeting is provided as Attachment A to this comment letter). In addition to this presentation, the project team has been coordinating closely with Sherman County Emergency Services and the North Sherman County Rural Fire Protection District, and has met multiple times, both in person and

over the phone, with Fire Chief Burbank to review site-specific fire mitigation measures, including:

- Adequate perimeter access for firefighting equipment;
- Placement of three on-site water tanks, including one located at the BESS yard; and
- Support for firefighter training and equipment through the Proposed Community Investment Fund (Proposed Order, Attachment E).

Feedback provided by Chief Burbank on the Construction Wildfire Mitigation Plan indicates that the plan is sufficient to address and mitigate wildfire risk during construction.

d. Fire Risk Analysis (WF-01, WF-02, WF-03)

Your comments raised several questions concerning the wildfire risk analysis included in the record. The first was related to burn probability data, the second was use of climate normals, and the third was in regard to fuel models.

With respect to climate normals, the data used to describe climate normals in BCWF RFA 4 Exhibit V are published by the National Oceanic and Atmospheric Administration, a widely accepted and respected source of climate data. These data indicate seasonal average temperatures which, when combined with precipitation and wind speed data, can be used to paint a full picture of wildfire risk at a given site. Wildfire mitigation actions described in the Construction WMP and the Certificate Holder's system-wide Operational WMP take into account high summer temperatures, low precipitation, and other factors (including extreme weather events) that affect the risk of wildfire ignition and spread.

With respect to burn probability and fuel models, BCWF RFA 4 Exhibit V Section 2.1.2 describes the fuel models used to analyze risk of wildfire within the Biglow Solar Micrositing Area. Including Fuel Models 102 (low load, dry climate grass) and 242 (burnable wheat fields), which describe 93 percent of the Solar Micrositing Area, in the risk analysis establishes a more conservative model than the existing conditions and overestimates the fuel load due to current fallow practices on fields at the Biglow Solar site, including chemical fallow, as you noted in your comment. Thus, the analysis results indicating a high burn probability may be greater than the actual risk at the Biglow site. The data and models used for the Biglow Solar burn probability analysis were developed by Oregon State University, the Oregon Department of Forestry, the Washington Department of Natural Resources, the U.S. Forest Service, the U.S. Bureau of Land Management, and Pyrologix, a company that supports wildfire mitigation. This collaborative effort described in "PNW Quantitative Wildfire Risk Assessment Methods" McEvoy, Dunn, and Rickert 2023[1]). is considered sufficient for developing accurate burn probability analyses.

e. Battery Energy Storage System Fire Safety Design and Risk Minimization (WF-05)

We appreciate your detailed recommendations regarding BESS design criteria to minimize fire risk. Public safety and wildfire risk reduction are central considerations in the design of the Biglow Solar facility, including the BESS.

Consistent with the EFSC Wildfire Prevention and Risk Mitigation, Public Services, and Soil Protection standards, the Proposed Order requires that facility components be designed,

[1] McEvoy, A., C. Dunn, and I. Rickert. 2023. PNW Quantitative Wildfire Risk Assessment Methods. Unpublished Manuscript. Available online at the website https://oe.oregonexplorer.info/externalcontent/wildfire/PNW_QWRA_2023Methods.pdf.

constructed, and operated to protect public health, safety, soils, and nearby agricultural lands.

We note that the design of all Solar Components and the proposed BESS incorporates multiple layers of engineered fire prevention and containment protections, including:

- BESS enclosures are manufactured to meet applicable building, electrical, and fire code standards, including resistance to environmental stressors. The centralized BESS yard layout further reduces exposure to potential turbine debris compared to dispersed configurations and site design maintains appropriate setbacks from turbines (520 feet).
- Each BESS unit includes thermal sensors, continuous monitoring, alarm systems, and automatic shutdown capabilities. These systems are designed to detect overheating or abnormal operating conditions early and initiate protective measures. The system is UL 9540A tested, meaning it has undergone rigorous fire propagation testing under nationally recognized safety standards.
- BESS will be housed in enclosed, containerized units located within a centralized BESS yard. Each unit includes internal separation and dedicated monitoring systems designed to detect abnormal conditions and isolate potential thermal events before propagation. The containerized configuration localizes any potential incident within an individual unit.

The wildfire mitigation measures outlined in the Construction and Operational WMPs, as well as the vegetation management measures outlined in the Comprehensive Solar Revegetation and Soil Management Plan and the enforceable O&M Plan requirements, and the engineered safety features incorporated into the BESS design, are intended to protect nearby homes, agricultural lands, and natural areas in Sherman County, where dry vegetation, high summer temperatures, and windy conditions increase fire risk.

In Proposed Order Section III.N.2, ODOE recommends that EFSC find that these plans sufficiently characterize wildfire risk within the analysis area using current data from reputable sources and that the facility components will be designed, constructed, and operated in compliance with wildfire mitigation plans.

Your comments related to fire risk, while relevant under the EFSC Wildfire Prevention and Risk Mitigation Standard, the EFSC Land Use Standard, and the EFSC Public Services Standard, are addressed by the Proposed Order and its recommended plans and conditions. We hope these responses help alleviate your concerns related to wildfire risk because it has been the subject of much discussion, input, and scrutiny throughout the EFSC review process.

3. Land Use

PGE recognizes your concern regarding the conversion of agricultural lands to renewable energy development.

a. *Loss of Agricultural Land*

With respect to the first concern, we hope the findings from the Agricultural and Fiscal Impact Analysis (AIA) included as BCWF RFA4 Attachment K-2 and the Community Investment Plan (Proposed Order, Attachment E), help alleviate these concerns. The AIA quantifies direct, indirect, and induced impacts from removing land from agricultural production, and then the CIP proposes mitigation measures to offset impacts. The AIA demonstrates that land removed from agricultural production by Biglow Solar represents 0.6 percent and 1 percent of the average annual acres of winter wheat harvested in Sherman County and Oregon, respectively. The CIP

incorporates many ideas provided by the community, including yours, that direct mitigation dollars to help fund important projects that benefit the local agricultural economy and offset impacts.

In addition, because issues relating to agricultural land supply, tenant farming, and agricultural impacts were raised in the record by your family, PGE and BN acknowledge that land ownership and agricultural operations are not always the same, and that project impacts may differ between landowners and tenant operators. BN worked closely with both the landowner and the tenant farmer to address the early conclusion of the existing lease. The parties reached a mutually agreed-upon lease termination arrangement.

The negotiated compensation reflects a private resolution between the parties and considered the remaining lease term, anticipated agricultural use, and other relevant factors. The agreed-upon amount was intended to provide substantial consideration in excess of several years of projected farming revenue, mitigating potential losses while allowing the farmer to continue agricultural operations elsewhere.

b. Wildfire Risk to Agricultural Neighbors (LU-07)

We feel it necessary to document for the record that PGE and BN have agreed to honor your request to impose a half-mile setback from your property line, which goes above and beyond any setback standard in code. This request was honored in response to concerns about wildfire mitigation, along with visibility of the facility from your property. As committed previously, this Micrositing Corridor setback will be included in the Biglow Solar final design and is memorialized by the First Amendment to Option and Land Lease with John Scharf.

Further, as discussed during the public hearing, liability matters are not within the jurisdiction of EFSC; and therefore, comments regarding liability do not address a Council Standard.

Your comments related to land use, while relevant under the EFSC Land Use Standard, are already addressed by the Proposed Order and its recommended plans and conditions, or by the private agreements already reached by your family.

4. Fish and Wildlife Habitat (FW-01)

Your comment letter submitted January 1, 2026, expresses concern that some wildlife species were not addressed in BCWF RFA 4 Exhibit P. The analysis in Exhibit P focuses on impacts to wildlife habitat, and the analysis in Exhibit Q focuses on threatened and endangered species as required by the following OARs governing issuance of site certificates by the Council.

OAR 345-022-0060 requires that in order for the Council to issue a site certificate, "the Council must find that the design, construction and operation of the facility, taking into account mitigation, are consistent with the general fish and wildlife habitat mitigation goals and standards of OAR 635-415-0025 (Implementation of Department Habitat Mitigation Recommendations) (1) through (6) in effect as of February 24, 2017." OAR 345-022-0070 requires that in order for the Council to issue a site certificate, they must find (after consultation with the Oregon Department of Agriculture and/or Oregon Fish and Wildlife Commission) that the design, construction, and operation of the proposed facility, taking into account mitigation, are not likely to cause a significant reduction in the likelihood of survival or recovery of state-listed threatened or endangered species. The analysis in Exhibit Q determined that no state listed or candidate species are expected to be affected by the Biglow Solar Components.

The Biglow Solar Components have been designed to avoid many habitat impacts. The Draft Habitat Mitigation Plan included in Proposed Order (Attachment F) addresses the potential temporary and permanent impacts to wildlife habitat from the Biglow Solar Components that cannot be avoided and establishes a habitat mitigation area (HMA) adjacent to the Carty Generating Facility in Morrow County. PGE discussed the location of the HMA with the Oregon Department of Fish and Wildlife and received assurance that the mitigation goals for in-kind and in-proximity habitat can be met.

Your comments, while relevant under the EFSC Fish and Wildlife Habitat and Threatened and Endangered Species standards, are already addressed by the Proposed Order and its recommended plans and conditions.

5. Vegetation Management and Soil Protection (SP-01)

Your comment letter submitted on January 29, 2026, expresses concern about soil and vegetation quality at the end of the solar facility's life. Tetra Tech, on behalf of PGE and BN, conducted a literature review of the effects of solar energy facility development on vegetation and soils, focusing on impacts experienced in arid grassland and shrubland-type environments compared to preexisting agricultural land use. The resulting memo and copies of the reviewed publications are included as an attachment to this letter (Attachment B) and outline benefits such as microhabitats around solar panels with lower air temperatures and evapotranspiration rates, higher soil water content, and additional surface roughness that slows wind speeds and protects against erosion. Planting native vegetation with deeper roots around the panels protects soil from erosion and allows nutrients to be cycled into the soils to greater depths. This improves soil structure, soil organic matter content, nutrient levels, and subsequently, the ability of the soil to sequester carbon. Any negative effects from the solar panels, as outlined in the memo, would be addressed through mitigation actions outlined in the Comprehensive Solar Revegetation and Soil Management Plan.

Your comments, while relevant under the EFSC Soil Protection Standard, are already addressed by the Proposed Order and its recommended plans and conditions. It is our position that none of your comments under the EFSC Soil Protection Standard rise to the level of requiring modifications to the Proposed Order.

6. Good-Faith Participation and Record of Outreach

PGE and BN have made extensive, sustained efforts over multiple years to engage with you directly, respond to questions, and provide access to project information and technical resources. Separate and apart from the RFA 4 amendment process, the Operations Manager of the existing BCWF facility has also maintained communication with you regarding operational and maintenance concerns, ensuring that your feedback was heard and addressed where appropriate.

Since fall of 2024, BN has dedicated significant time and resources to supporting a constructive relationship with you. These efforts have included repeated meetings, phone calls, written correspondence, and the availability of subject matter experts to address your specific concerns, including fire-safety engineers, agricultural mitigation specialists, and project design personnel. We also provided written follow-up and technical materials when you were unable to attend scheduled discussions. We recognize that meaningful engagement and thoughtful project refinement do not occur overnight; accommodations require study, engineering review, coordination with landowners, and regulatory alignment. Nevertheless, we have consistently

worked to respond to your concerns in a deliberate and substantive manner.

In addition to studies required by EFSC rules, BN voluntarily elected to prepare detailed visual simulations from your residence and from specific viewpoints you identified as being of greatest interest to you. These simulations were not required under the EFSC rules or any applicable Site Certificate condition. BN undertook this additional effort solely to provide you with site-specific, location-based information regarding potential visual impacts and to ensure that your concerns could be evaluated using accurate, project-specific renderings rather than generalized assumptions. This work reflects our commitment to transparency and good-faith engagement beyond what is required by the regulatory process.

We are committed to continuing to work with you and your family constructively. Given the accommodations implemented and the enhanced regulatory requirements included in the Proposed Order, we believe the record demonstrates that substantial and meaningful efforts have been made to address the concerns raised.

Please reach out if you have questions or would like to discuss further. We are committed to continuous engagement of the community and neighbors as this project moves forward.

Sincerely,

Dan Wilson

Project Description

Biglow Solar + Storage Project Overview

OVERVIEW
PGE and BrightNight have partnered to bring a solar and storage project to the existing Biglow Canyon Windfarm in Sherman County, Oregon.

CAPACITY
385-Megawatts in two phases. Today, we're discussing phase 1 (125 MW PV and 125 MW BESS).

FOOTPRINT
Study area is 3,980 acres. Actual project footprint is ~676 acres.

INTERCONNECTION
Utilizing the existing Biglow Canyon Substation. Ideal optimization of existing infrastructure to reduce project impact.

PERMITTING
Currently moving through the Oregon EFSC process.

Tax Revenue
At least $40,000,000 in tax revenue generated over the life of the project.

Schedule Overview

2024

April-Sept

Survey Complete (cultural resources, habitat, raptor, wetlands, botanical)

Meetings with community leaders

Initial tribal outreach

2025

April

Application for Amendment for existing EFSC Site Certificated deemed published and complete by ODOE

July

Preliminary layout

Technology selection

Agricultural mitigation meetings

August

Sponsorship of the Sherman County Fair

Open house, Aug. 19

September

Anticipate completing EFSC application submission

November

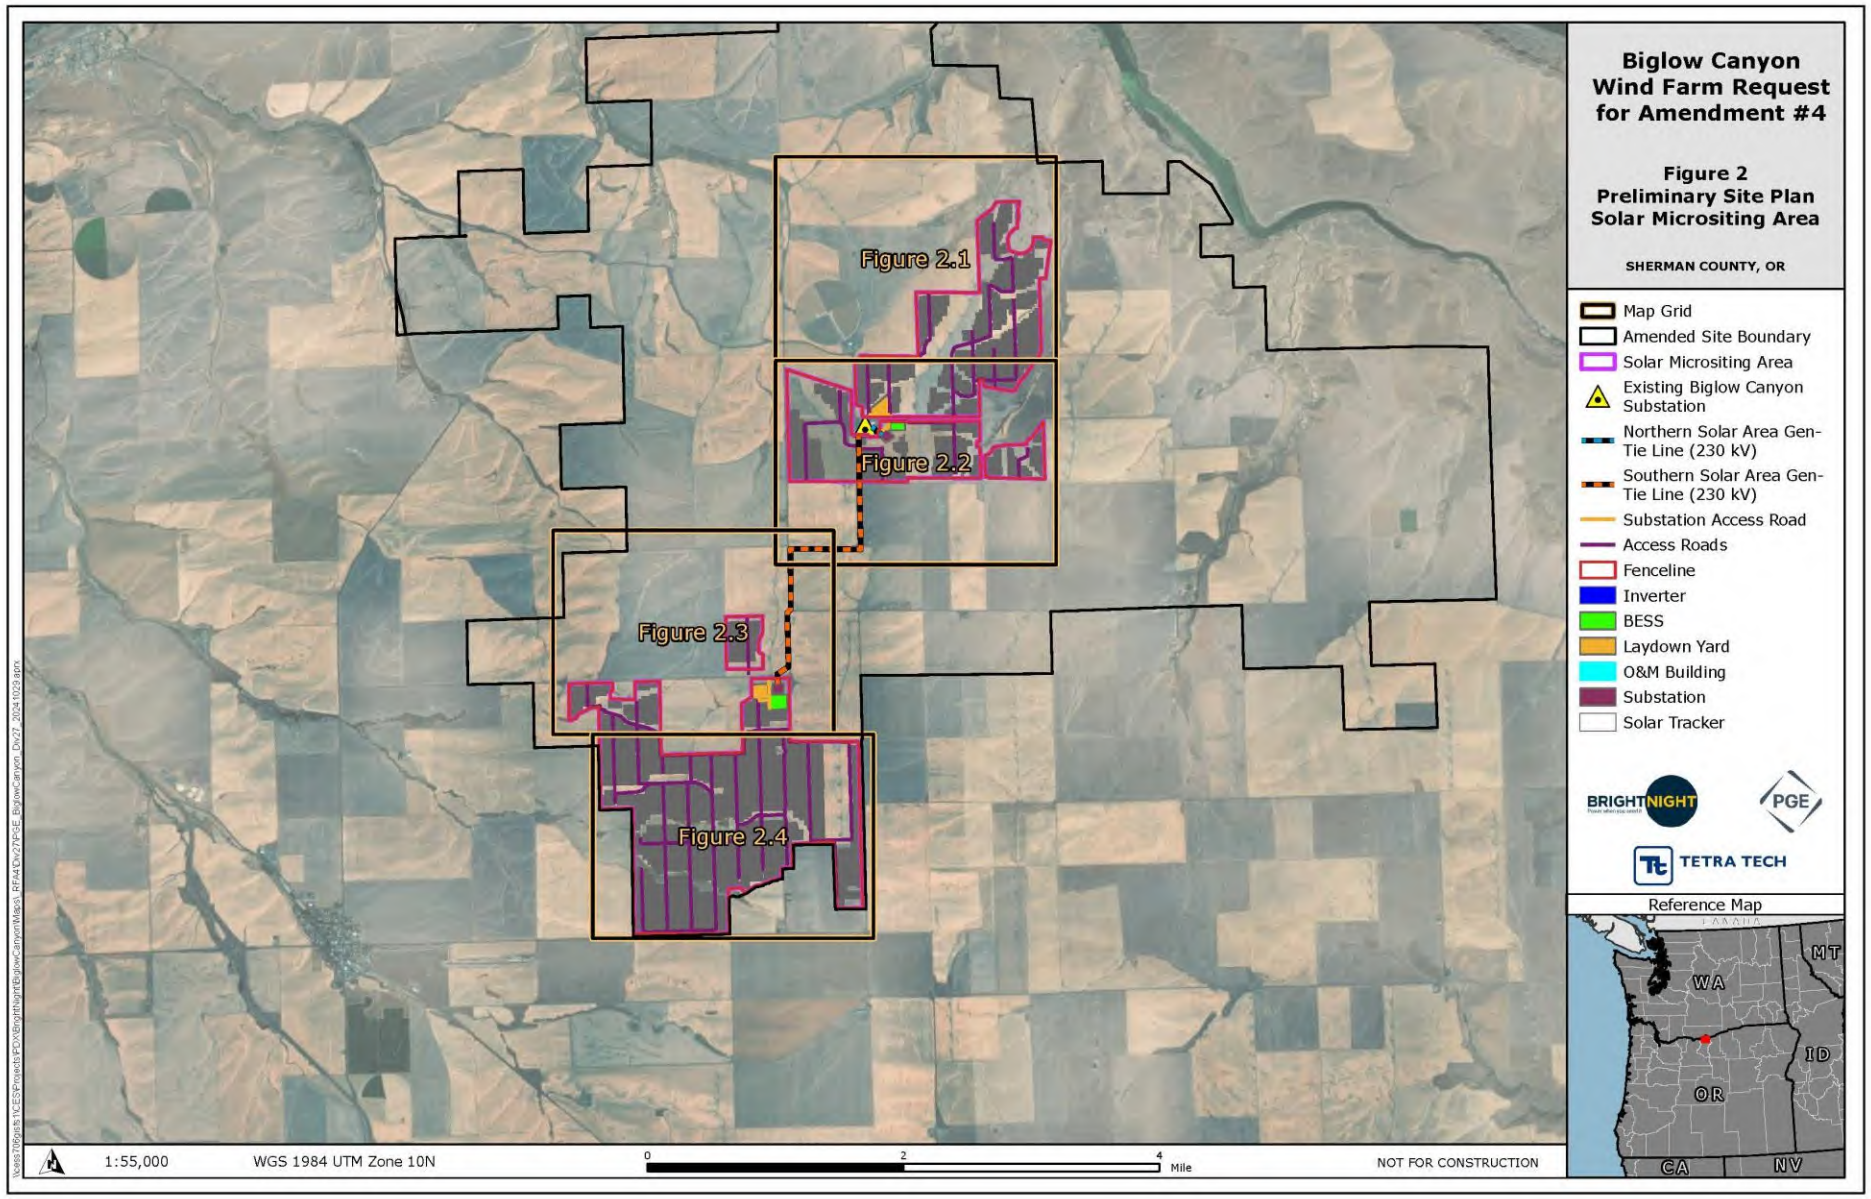
EFSC issues "draft proposed order," tentative hearing date set

2026

January

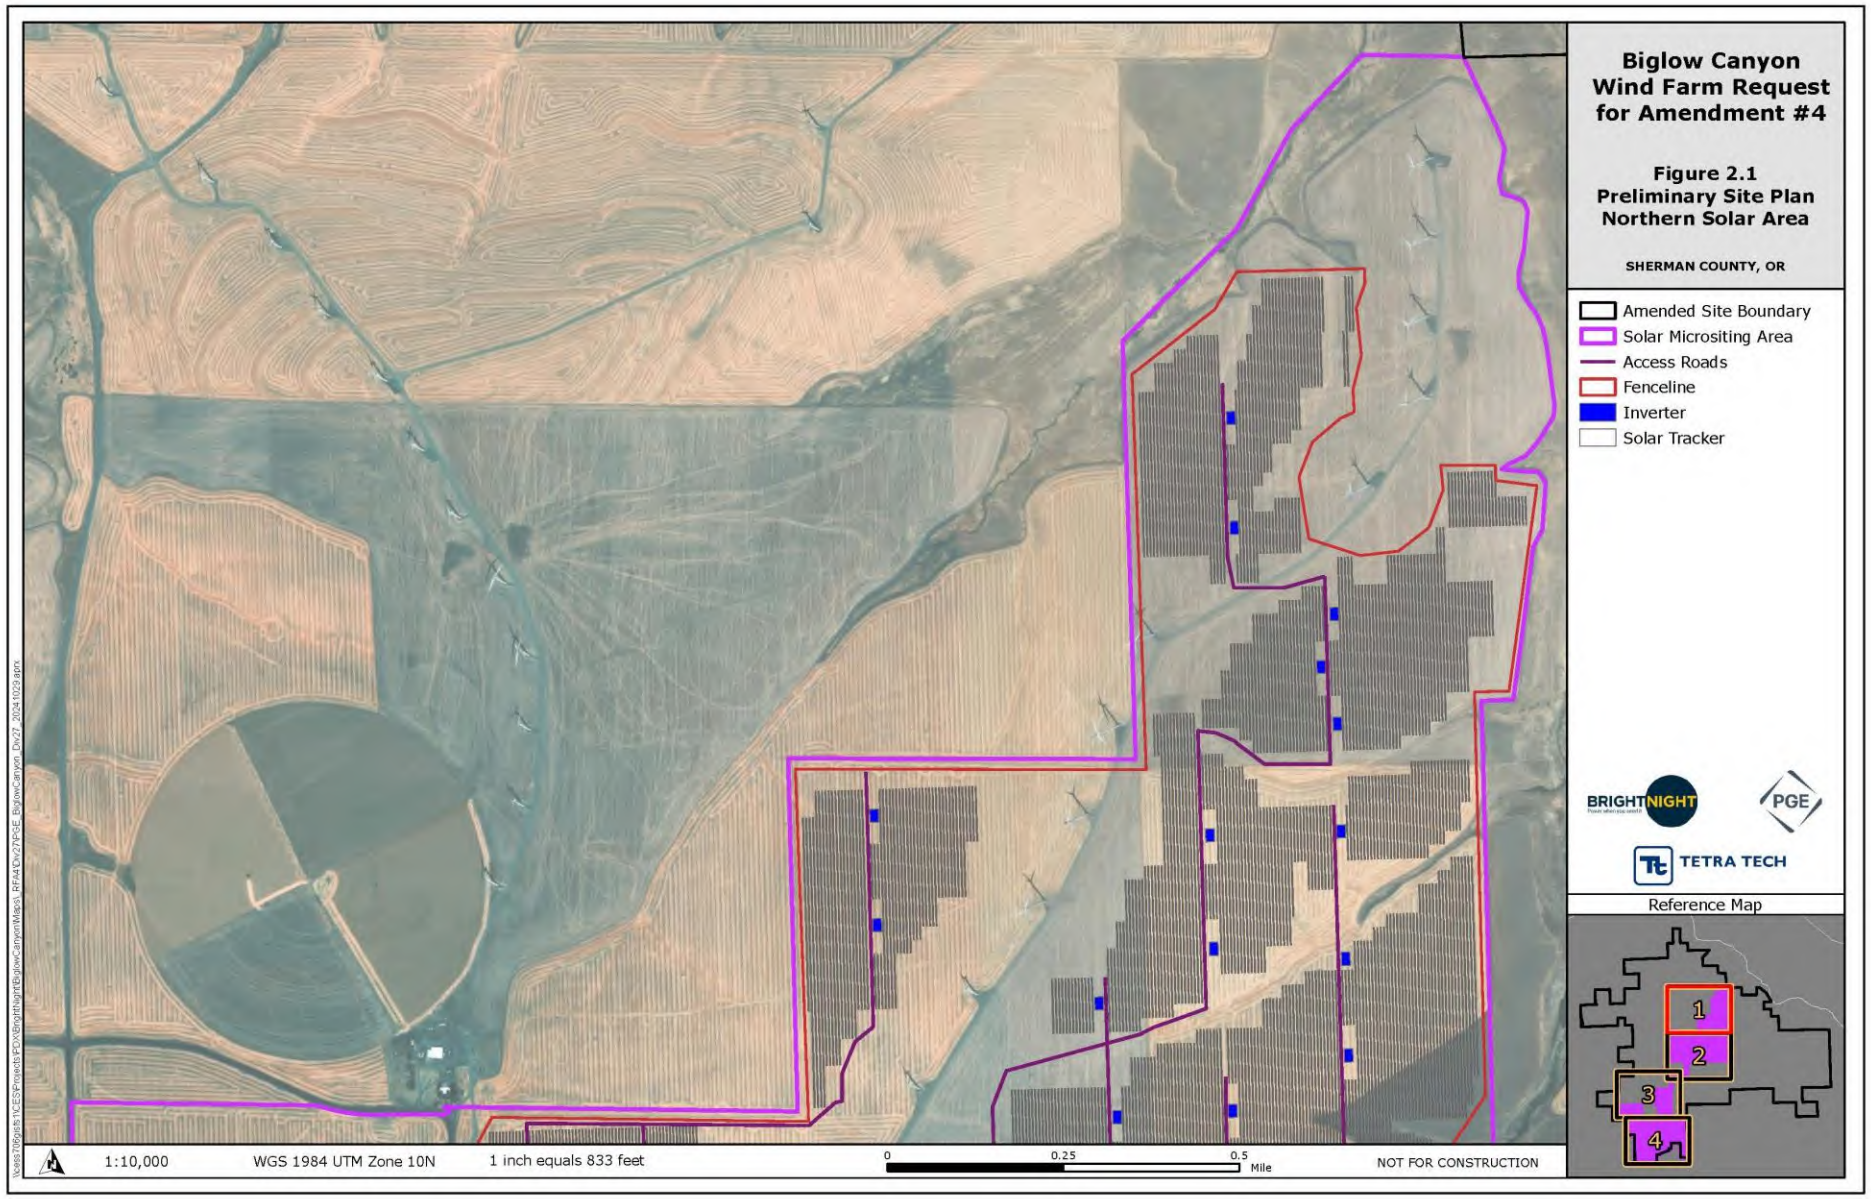
Council review and determination

Q2



Construction of phase 1

2027



Q4

Anticipated construction of phase 2

Fire Prevention

BrightNight plans to use the "Tesla Megapack" battery system at the Biglow Solar and Storage Project. This industry-leading equipment features exceptional safety and prevention technology:

Noise

The Megapack is self-contained and operational noise levels are designed to minimize noise pollution. The Greenwater project will abide by all local noise ordinances.

Emissions

In the unlikely event of a fire, emissions are extremely limited. Any emissions would originate from the plastic enclosures, not the batteries. Concentrations are so small there would would be no negative impact to air quality in the surrounding area

Proactive Fire Control

Megapack is designed to prevent battery fires and be resilient if they occur. Fires are extremely rare. Testing has shown that if one occurs, Megapack safety systems can control and contain a fire within the unit.

Containment

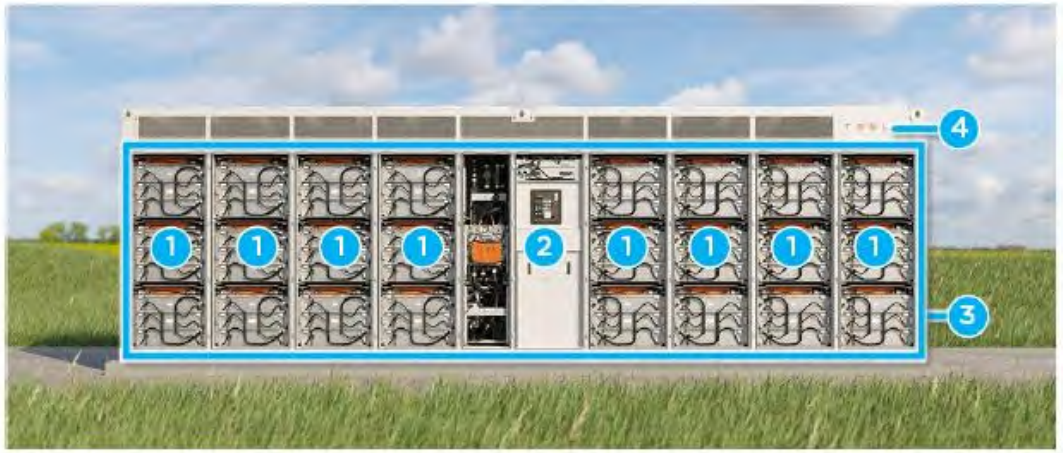
Each Megapack unit is self-contained. This important safety feature helps prevent potential soil or water contamination and prevents the spread of an unlikely fire event.

Water Runoff

Megapacks are designed to make it difficult for water to come in contact with the enclosed battery cells.

Lithium Batteries

Tesla Megapack Fire Protection Systems



BESS projects are safe for the environment. Self contained systems with no emissions during normal operation.

24/7 Monitoring. Megapack installations are remotely monitored by Tesla 24/7, allowing for early detection, diagnosis and troubleshooting of system errors while providing live support to first responders when needed.

Proactive Fire Control. Megapack is designed to prevent battery fires and be resilient if they occur. Fires are extremely rare. Testing shows that if one occurs, Megapack safety systems can control and contain a fire within the unit. Typically contained to a single module with no visible flames on the exterior.

Recyclable at End of Life. At the end of the system's lifetime BrighNight will safely remove the battery enclosures and recycle the majority of components.

1. Battery modules with active and passive fuses – externally serviceable
2. Touch-safe Customer Interface Bay
3. Non-walk-in IP66 enclosure and deflagration mitigation
4. Thermal roof with overpressure vents

UL Listed Equipment. Equipment is fully test and listed by the UL testing company for the products in your house.

Fire Event Gas Byproducts. Gases resulting from a Megapack fire are similar to those of a typical structure fire: hydrogen, carbon dioxide, carbon monoxide and methane. Expected fire size is less than a house or vehicle fire.

Fire Event Water Runoff. Megapack units are designed to make it difficult for water to come in contact with the enclosed battery cells. Fire water runoff testing has shown no harmful levels of contaminants. (Note: Tesla's Emergency Response Guide recommends no direct water application to a Megapack fire.)

Attachment B: Memo – Effects of Solar Energy Development on Vegetation and Soils

TETRA TECH

Memo

To:	Kathleen Campanella
Cc:	Maribeth Sawchuk
From:	Anjali Manoj, GIT (Tetra Tech); Kiana Ziola (Tetra Tech)
Date:	July 2, 2025
Subject:	Effects of Solar Energy Facilities Development on Vegetation and Soils

Several research publications were reviewed to determine the impacts of the development of solar energy facilities to the vegetation and soils at these sites. A specific emphasis was given to impacts experienced in arid grassland and shrubland type environments and the impacts were primarily compared to a pre-existing agricultural land use context as these are the typical scenarios applicable to the most solar energy facilities in Washington and Oregon.

Per Natural Resource Conservation Service published data about soil health in the Inland Northwest, in areas dominated by agriculture, especially monoculture crops like wheat, the soils typically have low organic matter, are depleted of nutrients, and have reduced water retention capacity due to the deteriorated soil structure (NRCS 2025). Repeated tillage combined with the shallow rooting depth of crops like wheat when compared to native plants often results in highly compacted layers at the tillage depth and interruptions to natural nutrient cycling processes. These are results Tetra Tech has consistently seen during soil monitoring at various renewable energy sites across eastern Washington and Oregon. The dominant monoculture crops in these regions also implies reduced vegetation diversity as compared to the native grassland and shrubland ecosystems that historically stood in the place of these agricultural lands. Therefore, multifunctional land uses such as the conversion to solar energy facilities have the potential to improve the provision of a variety of ecosystem services (Walston et al, 2021). This is especially true when the solar energy infrastructure in these facilities is interspersed with native vegetation between the photovoltaic (PV) arrays.

In the case of when pre-existing agricultural lands are converted to solar energy facilities with native grassland and shrubland vegetation interspersed, most research indicate that vegetation and soils improve on numerous metrics primarily due to the effect of the PV panels. PV panels favor the creation of heterogeneous microhabitats with lower air temperatures, lower evapotranspiration rates, and higher soil water content as a result of shading. Additionally, the PV panels create surface roughness that slow down wind speed and therefore add protection to vulnerable soils from wind erosion. These conditions can be beneficial to native plants that are seeded to establish in between the PV panels as they provide a better scenario for plant growth, especially in the initial stages of the vegetation efforts (Liu et al, 2019). When native vegetation establishes, the roots penetrate deeper into the soil as compared to crops like wheat. This serves to protect the soils better from erosion by wind and water and allows nutrients to be cycled in the soils to greater depths. Native grasslands and shrublands also feature increased litter that is protected from wind erosion. This further helps in improving soil structure, soil organic matter content, nutrient levels, and subsequently, the ability of the soil to sequester carbon (Liu et al, 2019; Lambert et al, 2021). The increased biodiversity through the re-establishment of native grassland and shrubland vegetation provides some landscape level benefits as well including improved pollinator supply which can benefit agriculture in the surrounding areas (Walston et al, 2019).

Research also points to how the development of solar energy facilities can have some disadvantages. For vegetation seeking to establish under or within the shade radius of the PV panels, the PV panels will intercept sunlight and impact the amount of solar radiation available to plants for photosynthesis in these areas (Sarr et al, 2023). As a result, vegetation communities may struggle to take hold and establish around the panels. The consequence of this is that the

growth of dominant plant species may be inhibited while subdominant species and weeds may take over (Gómez-Catasús et al, 2024). Another likely negative effect of the PV panels noted by some research is the alteration of the local distribution of precipitation. During precipitation, the areas under the panel receive lesser water inputs while areas along the edges of the panels may receive much high-water inputs from the runoff of the PV panels. This effect is only in the period immediately post precipitation and eventually stabilizes between all areas around the panels as the excess water received in the runoff areas of the panels is made up for by the decreased water loss from evaporation experienced under the panels from shading (Gómez-Catasús et al, 2024). Another concern from the development of solar energy facilities is compaction of soils, especially during construction. This is a well-known potential impact in anticipation of which several best management practices, monitoring programs, and adaptive management measures are designed and implemented under the guidance of appropriate authorities ahead of beginning any construction activities of these facilities. Ultimately, the potential disadvantages posed by the development of solar facilities can be mitigated and prevented by a large extent. The ability of the development of solar energy facilities to ameliorate vegetation and soil conditions is dependent on the successful implementation of revegetation efforts post the development of solar energy facilities combined with effective soil protection and reclamation measures.

While the points noted above are primarily investigating the case of agricultural fields that are converted to solar energy facilities with native grasslands and/shrublands interspersed, they are similarly applicable to the case of agricultural fields that are converted to solar energy facilities with agriculture interspersed (Walston et al, 2021). Apart from the shading effect of panels reducing the available area for crop production, there are no significant detriments noted to the crops or the soil from solar energy facilities (Sarr et al, 2023). It is important to note however that the benefits to vegetation and soils noted above will be seen to a much smaller degree due to the nature of crop plants as opposed to native vegetation (Walston et al, 2021).

Overall, research indicates that the development of solar energy facilities serves a net benefit effect to vegetation, soils, and in turn, the ecosystem in the long term by providing an opportunity for the rehabilitation of soils and vegetation that have been affected by agriculture-related interruptions to natural nutrient cycling. When the energy facilities are eventually decommissioned, the improved vegetation communities and soil quality can be a great benefit to continue the establishment of the native grasslands and shrublands or to return the land to agriculture in the future, should the need arise.

ABSTRACT

The increasing pressure on land resources for food and energy production along with efforts to maintain natural systems necessitates the development of compatible land uses that maximize the co-benefits of multiple ecosystem services. One such land sharing opportunity is the restoration and management of native grassland vegetation beneath ground-mounted solar energy facilities, which can both protect biodiversity and restore related ecosystem services. In this paper, we applied the InVEST modeling framework to investigate the potential response of four ecosystem services (carbon storage, pollinator supply, sediment retention, and water retention) to native grassland habitat restoration at 30 solar facilities across the Midwest United States. Compared to pre-solar agricultural land uses, solar-native grassland habitat produced a 3-fold increase in pollinator supply and a 65% increase in carbon storage potential. We also observed increases in sediment and water retention of over 95% and 19%, respectively. We applied these results to project the potential benefits of adoption of native grassland management practices in current and future solar energy buildout scenarios. Our study demonstrates how multifunctional land uses in agriculture-dominated landscapes may improve the provision of a variety of ecosystem services and improve the landscape compatibility of renewable energy and food production.

1. Introduction

Solar photovoltaic (PV) energy technologies have exponentially increased across the globe over the past decade (Kabir et al., 2018; Irsyad et al., 2019). Currently, there are over 33 gigawatts (GW) of ground-based large-scale (>1 MW) solar PV energy production in the U.S. (EIA, 2019a), representing about 1.5% of total U.S. electricity generation in 2018 (EIA, 2019b). The proliferation of large-scale solar energy developments is expected to continue across the U.S. over the next decade. For example, the U.S. Department of Energy's National Renewable Energy Laboratory, through its Standard Scenarios Report, estimates around 200 GW of installed electric capacity among ground-mounted solar facilities by 2040 under its Mid-Case scenario, and more than 500 GW of ground-mounted solar facilities by 2040 under its Low-PV Cost scenario (Cole et al., 2019). Like other forms of energy development, land use represents a major challenge for future solar energy deployment. Ground-based solar energy developments require between 2.5 and 3.5 ha per megawatt (MW) (Ong et al., 2013; Hernandez et al., 2014), and approximately 7500 km^2 of total land will be needed to meet 2030 projected solar energy production (Hartmann et al., 2016), roughly the combined size of the states of Delaware and Rhode Island.

Given their large land requirements, questions about the sustainability of solar energy developments have emerged in terms of their compatibility with other land uses such as agriculture (Moore-O'Leary et al., 2017; Hernandez et al., 2019). Ground-based solar energy developments are increasing in agricultural landscapes, due in large part to the siting of utility-scale solar energy developments on former agricultural fields (Adelaja et al., 2010; Adeh et al., 2019). Croplands are generally flat, open, and relatively undeveloped, making them ideal locations for solar energy development (Adeh et al., 2019). This pattern of conversion from agriculture to solar energy development can represent a land use tradeoff between food production and renewable energy production (e.g., Krishnan and Pearce, 2018). As the pressure intensifies on land resources for energy and food production, greater emphasis has been placed on solutions that maximize mutual benefits of multiple

ecosystem services. Recent approaches have suggested the integration of solar energy with food production, biodiversity conservation, and other ecosystem services (i.e., the energy-food-ecology nexus; Moore-O'Leary et al., 2017; Hernandez et al., 2019). For example, the co-location of solar energy and agriculture, often termed as "agrivoltaic systems", could improve the land-use potential of solar sites for energy and food production (Ravi et al., 2016; Dinesh and Pearce, 2016; Hoffacker et al., 2017; Barron-Gafford et al., 2019). In one study, Barron-Gafford et al. (2019) found that shading by solar PV arrays benefitted the production of crops such as Chiltepin peppers (*Capsicum annuum var. glabriusculum*), jalapenos (*C. annuum* var. *annuum*), and tomatoes (*Solanum lycopersicum var. cerasiforme*) by increasing yields and reducing water requirements while also creating cooler microclimate conditions that improved solar energy production.

Other research surrounding the energy-food-ecology nexus of solar energy has focused on the restoration of native grassland vegetation at ground-mounted solar facilities ("solar-native vegetation") to improve biodiversity and other ecosystem services such as pollination of adjacent croplands (Moore-O'Leary et al., 2017; Walston et al., 2018; Hernandez et al., 2019). In the United States, this approach has focused on vegetation management efforts at solar facilities aimed at establishing native grassland vegetation, such as milkweed (*Asclepias* spp.), native forbs and wildflowers, and other pollinator-friendly vegetation, either among the solar PV arrays or elsewhere within the solar facility footprint area, that attract and support native insect pollinators and other beneficial insect predators by providing food resources, refugia, and nesting habitat. Highlighting the potential significance of this approach, recent research found that over 3500 km^2 of agricultural land near existing solar energy facilities in the U.S. may benefit from increased pollination services through the establishment of solar-native vegetation (Walston et al., 2018).

Conventional ground management approaches at solar facilities often involve the establishment and management of low-growing turfgrass (Walston et al., 2018). While turfgrass provides some ecosystem service value for biodiversity and soil and water control, shifting to native grassland management practices at these locations has the potential to improve the ecosystem services potential of solar energy facilities. Compared to conventional turfgrass approaches, native grassland vegetation may improve ecosystem services related to biodiversity, carbon storage, water conservation, soil retention, and pollination of nearby croplands. Favorable microclimate conditions created by solar PV arrays, such as lower temperatures and greater soil moisture, can improve the performance of native grasses, which increases aboveground biomass and related carbon sequestration (Armstrong et al., 2016; Adeh et al., 2018). In addition, native grasses and forbs typically have deeper root systems than row crop agriculture and turfgrass (Schenk and Jackson, 2002), with root depths of some native grassland species exceeding 2–5 m (Packard and Mutel, 1997). Deeper root systems create the potential for improved soil stabilization and reduced water runoff (Hernandez-Santana et al., 2013). To date, however, these solar-native vegetation ecosystem service benefits have not been adequately quantified or evaluated in a common framework that allows for an understanding of a suite of ecosystem services. Thus, to build upon the previous efforts to understand the ecosystem service benefits of solar-native vegetation, this paper focuses on modeling the potential supply of ecosystem services resulting from different vegetation management approaches at solar energy facilities. Specifically, we were interested in addressing the following question: *What are the multiple ecosystem service benefits of solar-native vegetation compared to pre-existing land uses and other types of vegetation management practices at solar facilities*? To address this question, we conducted a geospatial land use change assessment for solar energy facilities in the Midwest and we developed spatially-explicit models at a regional scale aimed at quantifying differences in the following ecosystem services associated with solar-vegetation management options: pollinator supply, carbon storage, soil retention, and water yield. We then project these results to examine ecosystem service implications of future solar energy development within the region.

2. Methods

2.1. Study area

We examined ecosystem services associated with vegetation management practices at solar energy facilities within the Midwestern region of the United States (Fig. 1). This region is approximately 1.1 million km^2 in size and includes the states of Illinois, Indiana, Iowa, Michigan, Minnesota, Missouri, and Wisconsin. The predominant land use in this region is agriculture (37% of the study area), followed by forest (33%) and grasslands and other herbaceous land cover types (17%). The climate is humid temperate, with an average annual precipitation of 725 to 1100 mm (USDA, 2019). Average annual minimum and maximum temperatures in the region are −9 degrees Celsius (°C) and 29 °C, respectively (USDA, 2019).

Euro-American settlement and associated agricultural intensification has resulted in the decline of the region's grasslands, a diverse vegetation system that was much more dominant and widespread throughout the region prior to the mid-1800s. For example, over 99% of the tallgrass prairie in Illinois, Indiana, Iowa, Minnesota, and Missouri have been lost primarily due to agricultural expansion (Samson and Knopf, 1994). As such, many of the current terrestrial ecological restoration objectives within the region focus on restoration of native grassland and prairie systems. For solar sites in the Midwest, increasing emphasis has been placed on native grassland restoration among the PV arrays (Clean Energy States Alliance, 2020), which is a more compatible habitat type for solar energy development than other habitat types such as forests or wetlands.

2.2. Identification of solar energy facilities and data preparation

We identified the location of large-scale ground-based solar energy facilities (>1 MW) from the U.S. Energy Information Administration (EIA) for the year 2018 (EIA, 2019). The EIA reports generator-level specific information on electricity production facilities, including latitude and longitude information for facility locations and nameplate electricity capacity (MW). We queried the EIA database to only those sectors that were utility or industrial ground-based facilities (sectors 1 and 2). By doing so, we omitted large commercial rooftop facilities from our study. We then used a Geographic Information System (GIS; ArcGIS version 10.6.1) to map the approximate point location of each facility using the latitude and longitude coordinates reported by the EIA. We overlaid these points with the latest online World Imagery basemap within ArcGIS (ESRI, 2019) and digitized the footprint boundaries of all solar sites observable in the imagery. Solar facility polygons were drawn to include the PV panel area plus other areas observable within the fenced area of the facility (e.g., disturbed soil, laydown areas, operations facilities). Most of the World Imagery available for the region was obtained in 2018. We then calculated the size (ha) of each digitized solar facility's footprint polygon. For these facilities, we correlated facility electric capacity (MW) and footprint size (ha) and we used this relationship to estimate the footprint size for solar facilities that were not observed or incomplete in the satellite imagery. The 2018 list of all solar energy facilities in the Midwest, along with corresponding footprint sizes, is provided in Supplement 1.

We conducted a land use change assessment to determine what percentage of solar facilities in the Midwest were developed on former agricultural fields or other land use-land cover (LULC) types. We performed this assessment only for those solar facility footprints that could be delineated in a GIS. Because large-scale solar energy development largely did not appear in the Midwest until 2012, we used 2010 LANDFIRE Existing Vegetation Types (http://www.landfire.gov/evt.php) as the pre-solar land use dataset and determined the composition

of 2010 land use types intersecting the solar facility footprints as the measure of LULC change (see Supplement 1).

2.3. Scenarios

To determine the ecosystem services among vegetation management activities at mapped solar energy facilities, we designed three land use scenarios for the solar energy facility footprints: an agriculture scenario (the baseline "pre-solar development" land use) and two solar energy development scenarios – a solar-turfgrass scenario and a solar-native grassland scenario (Fig. 2). Because we assumed the majority of solar facilities in the region were previously under corn-soybean agricultural production (Supplement 1), we replaced all land uses in the solar footprint polygons with agriculture to represent the pre-solar land use. We considered this scenario to be the baseline scenario for comparison. The second scenario we evaluated was a solar-turfgrass vegetation scenario in which we assumed the sodding of cool-season turfgrass within the solar facility. This scenario also involves regular vegetation maintenance at the solar facility such as active mowing and herbicide applications to minimize or prohibit the growth of vegetation (<0.3 m high) within the solar facility footprint. Turfgrass is a common vegetation management practice at solar facilities and this scenario was considered to be the business as usual ("BAU") scenario for operating solar facilities. The third scenario we evaluated was a solar-native grassland scenario in which we assumed the intentional establishment of native prairie grasses and forbs in the solar facility footprint that provide forage and nesting habitat for native insect pollinators. Compared to the turfgrass scenario, the solar-native grassland scenario involves management activities that allow the vegetation to flower and reach heights up to 1 m within the solar PV arrays (the maximum height typically allowed at solar PV arrays to avoid shading of the panels). Because native grasses and forbs typically have deeper root systems than turfgrass (Schenk and Jackson, 2002), we assumed greater above- and below-ground vegetation biomass under the solar-native grassland scenario compared to the solar-turfgrass scenario.

2.4. Modeling framework

We used a multiple service model called Integrated Valuation of Environmental Services and Tradeoffs (InVEST, version 3.6; Sharp et al., 2018) to evaluate ecosystem services under each of the three land use scenarios at the Midwest solar energy facilities. The InVEST suite of tools has been developed to assist decision makers in comparing the impacts of different land use scenarios on the provision of ecosystem services. To our knowledge, this is the first application of InVEST to examine ecosystem service response to solar energy land uses. We used the following four existing InVEST models: Pollinator Model (for pollinator habitat quality), Carbon Storage Model, Sediment Delivery Ratio (SDR) Model (for soil retention), and Water Yield Model (for water retention). A detailed description of our modeling methods and parameters can be found in Supplement 2. Each of these InVEST models incorporate spatial datasets on land use-land cover (LULC) and some of them use elevation,

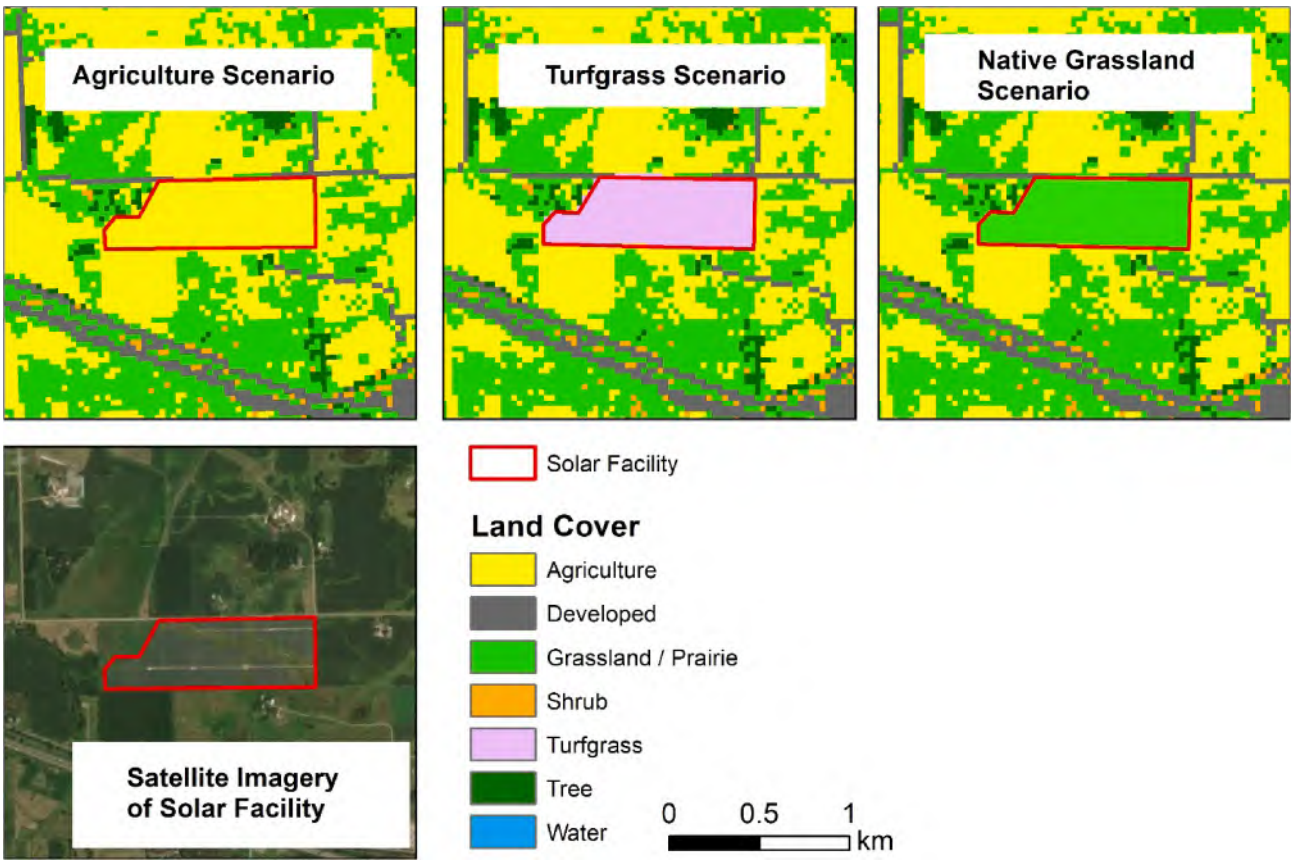

Fig. 2. Vegetation scenarios evaluated in this study. The agriculture scenario represents the pre-solar land use.

rainfall, and soil and vegetation properties, along with tabular biophysical parameters, to conduct spatially-explicit assessments of ecosystem services. The spatial datasets used in the models are also described in Supplement 2.

For this LULC dataset, we used a 30 m raster dataset of vegetated land cover from the 2014 LandFire Program (Existing Vegetation Types; http://www.landfire.gov/evt.php). We initially summarized the LULC map across the entire Midwest region into seven broad LULC classifications based on vegetation life form: developed, agriculture, barren or sparsely vegetated, grassland, shrubland, forested, and water and wetlands. We then updated the LULC map to create an eighth LULC classification representing solar energy facility developments using the footprint polygons delineated from satellite imagery. We selected a total of 30 solar facility footprint polygons, with a minimum of 3 footprints in each state, to update the LULC raster dataset (Fig. 1). This LULC update was performed by overlaying the facility footprint polygons on the initial LULC map and reclassifying the underlying pixels of the LULC map to a unique solar-specific LULC code.

All of the InVEST models also require tabular biophysical parameters to relate land cover types from the LULC map to the individual ecosystem service processes. We reviewed the existing literature to identify studies utilizing these InVEST models in the United States to parameterize each model. Surrogate vegetation and LULC types were used to identify the biophysical parameters to include in each scenario (Table 1).

We used the surrogate LULC types to review existing literature from previous InVEST modeling studies in the United States and summarize the biophysical parameters for each model (Table 2). We ran each model using upper- and lower-bound parameter values based on the 25% and 75% quartile range of values reported in the literature. We used this range to estimate the uncertainty in models and we used the midpoint (average) values in comparing ecosystem services across scenarios. For

Table 1
Land use-land cover (LULC) surrogates for the three land use scenarios modeled in this study.

Scenario	Surrogate LULC types
Agriculture (baseline pre-solar land use)	Row crop agriculture LULC types (e.g., corn-soybeans).
Solar-turfgrass	Residential, suburban, and turfgrass LULC types.
Solar-native grassland	Native grassland and prairie LULC types.

all ecosystem service estimates, we focused on the change in the service delivery for the solar-native grassland scenario compared with the solar-turfgrass scenario and the baseline agriculture scenario. For each scenario, we assumed the surrogate vegetation (Table 1) was consistently and uniformly distributed across all solar facilities. We were not able to use InVEST to model the effect of solar panels on these ecosystem services so we assumed this effect to be constant across all three land use scenarios.

The InVEST Carbon Storage Model is a carbon stock estimation model that is explicitly connected to land cover type. This model calculates total carbon storage (Mg C/ha) for each land cover type based on the aggregation of four carbon pools: aboveground carbon density, belowground carbon density, soil organic carbon density, and dead organic matter carbon density (Sharp et al., 2018). We used this model to examine differences in total carbon storage associated with each scenario.

The InVEST Pollinator Model was designed to model and map patterns of pollinator habitat quality and potential pollination service values across landscapes (Sharp et al., 2018). This model utilizes information on floral resource availability (associated with each LULC type), along with tabular inputs on nesting and foraging parameters for individual pollinator species or species groups, to estimate the supply,

Table 2
Biophysical parameters used in the InVEST Models. The range represents the upper- and lower-bound parameter values used in the models

	Carbon storage model[a]	Pollinator model[b]		Sediment (SDR) model[c]	Water yield model[d]	
Scenario	Total carbon storage (Mg C/ha)	Ground nest availability	Floral resource availability	USLE C-factor	Root restricting layer (mm)	Kc
Agriculture	68.0–88.6	0.137–0.213	0.270–0.400	0.30–0.43	775–925	0.55–0.60
Solar-turfgrass	87.0–104.4	0.310–0.530	0.460–0.580	0.03–0.08	775–925	0.65–0.75

abundance, and service value of insect pollinators across the landscape. In this study, we used the pollinator supply InVEST output to assess the ability of each scenario vegetation type to support insect pollinators. As described by the InVEST model (Sharp et al., 2018), pollinator supply is a unitless index (between 0 and 1) indicating where pollinators originate on the landscape. For the purpose of comparing the different vegetation scenarios, we used native bumblebees (Family Apidae) and native sweat bees (Family Halictidae) as the modeled guilds (Supplement 2).

The InVEST Sediment Delivery Ratio (SDR) Model estimates the overland movement of sediment based on topography, climate, soil, and land cover properties. The SDR model is a spatially-explicit model working at the spatial resolution of the input digital elevation model raster (Sharp et al., 2018). For each pixel, the model computes the amount of annual soil loss from that pixel based on a revised Universal Soil Loss Equation (USLE). It then calculates the SDR, which is the proportion of soil loss that reaches the catchment. Finally, the model uses the USLE and SDR to calculate erosion as total catchment sediment export (tons/ha). Inputs for the SDR model include raster maps for LULC, elevation, rainfall, and soil erodibility, along with tabular biophysical attributes related to sediment retention based on land cover type (Supplement 2). We used this model to estimate the amount of surface soil erosion associated with each vegetation scenario. Because sediment erosion represents a negative impact on the landscape, we considered erosion to be the inverse of a positive ecosystem service – soil retention, or the ability of a modeled vegetation type to retain soil.

The InVEST Water Yield Model calculates the net water yield at pixel-based and watershed scales based on the difference between precipitation and actual evapotranspiration. Actual evapotranspiration is a function of reference evapotranspiration, root restricting layer depth, plant available water content, and land cover type (Sharp et al., 2018). Following the methods described by Bai et al. (2019), we used the Water Yield model as an interim step in quantifying water retention: the ability of the modeled land cover type to intercept water from runoff. Water retention is calculated by subtracting runoff from water yield as follows:

$$WR_{ij} = WY_{ij} - Runoff_{ij}$$

where WR_i is the annual water retention (mm/yr) for pixel i on LULC type j, WY_{ij} is the annual water yield (mm/yr) for pixel i on LULC type j (calculated from InVEST), and $Runoff_{ij}$ is the annual surface runoff (mm/yr) for pixel i on LULC type j. Runoff is a product of annual precipitation and a runoff coefficient for each LULC type based on slope and soil type (Supplement 2). Because most solar energy developments are constructed on low slopes (<10%; Hartmann et al., 2016) and most agricultural areas in the region are loamy soils (Hollinger, 1995), we calculated LULC-specific erosion coefficients based on assumed slope of <10% and loamy soil properties.

2.5. Synthesis

We compared the output from the four InVEST models among the three vegetation scenarios. These comparisons were made on a unit-area basis for the 30 modeled solar energy developments and projected to the current amount of large-scale solar energy development in the Midwest region. We also explored the future potential for these ecosystem services by projecting these results to a future solar energy development scenario. Based on solar energy targets identified from state legislation and energy websites (e.g., Illinois Future Energy Jobs Act [S.B. 2814, 2016]; SEIA, 2019; MISO, 2019), we estimated the total foreseeable potential large-scale solar energy development within the Midwest region in the next 10–15 years (2030–2034). Using a solar land use-MW relationship calculated from delineated existing solar footprints in the region (Supplement 1), we estimated the future aggregate solar footprint size and projected our InVEST model results to this scenario.

3. Results

3.1. Solar energy development

We identified 276 large-scale solar facilities in the Midwest region that were operating in 2018, representing a total nameplate electricity capacity of 1183.8 MW (Supplement 1). The state of Minnesota contained most of the region's solar energy development both in terms of the number of facilities and total electricity capacity (Fig. 1; Table 3). Approximately 59% of the solar facilities and over 62% of the region's solar electricity capacity occurred in Minnesota. The state of Iowa contained the fewest number of solar facilities (n = 5) and the lowest amount of large-scale solar electricity generation (9.2 MW).

We identified and mapped the facility footprints of 192 solar facilities from the ESRI World Imagery. The remaining 84 solar facilities were either incomplete or not yet constructed at the time the satellite imagery was collected. We determined a land use-MW relationship of 3.0 ha per MW for all 192 delineated solar facilities (Supplement 1) and applied this relationship to estimate the footprint sizes for the remaining 84 solar facilities. Using the GIS-derived and estimated solar footprint sizes, we determined the total current footprint size among all solar facilities in the Midwest to be approximately 3416 ha (34.2 km^2).

Table 3
Summary of current (2018) large-scale solar energy development in the Midwest region.[a]

State	Current number of solar facilities	Current total nameplate capacity (MW)	Total current estimated footprint size (ha)[b]
Illinois	6	38.5	86.7
Indiana	60	214.3	574.2
Iowa	5	9.2	15.9
Michigan	13	98.3	250.1
Minnesota	163	741.5	2252.7
Missouri	17	61.1	173.2
Wisconsin	14	20.9	63.2
Regional total	276	1183.8	3416.0

[a] Sources: Data for 2018 solar facility development obtained from EIA (2019).
[b] Estimated total footprint size was based on solar footprint polygons digitized in GIS (for those facilities that could be mapped and located with satellite imagery) a land use relationship of 3.0 ha per MW of nameplate capacity for those facilities that could not be located within satellite imagery (Supplement 1).

Page 1358 of 1567

We determined the pre-solar construction land uses by identifying and quantifying the amount of 2010 LULC types within the 192 delineated solar facility footprints. By far, the dominant pre-construction LULC type converted to solar energy was row crop agriculture, comprising 70% of the 2010 LULC types within the solar footprint polygons (Supplement 1). This represents a conversion of approximately 2391 ha (23.9 km^2) of row crop agriculture to current ground-based solar energy development. Other forms of LULC conversion included developed areas (15.0%, 512.4 ha), pasture and hay fields (5.4%, 184.5 ha), and forest and riparian areas (4.5%, 153.7 ha).

3.2. InVEST model results

Ecosystem service model results for the 30 Midwest solar facilities, averaged by state, are presented in Table 4 (see Supplement 2 for more detailed results). Differences in modeled ecosystem service results among scenarios were primarily related to LULC changes. We used the variability in reported biophysical parameter values (Table 2) to calculate the range (and midpoint average) of ecosystem service results under each scenario. We found the patterns of ecosystem service provision among scenarios were consistent for the entire Midwest (Fig. 3). For example, the solar-native grassland scenario retained more water than the solar-turfgrass scenario, which retained more water than the agriculture scenario (solar-native grassland > solar-turfgrass > agriculture). We therefore present remaining results using the regional averages of modeled ecosystem services.

Carbon Storage. On average for the entire Midwest region, the solar-native grassland scenario had a potential carbon storage capacity of 129.3 Mg C/ha, which was 65% and 35% greater than the agriculture and solar-turfgrass scenarios, respectively (Table 4; Fig. 3).

Pollinator Supply. On average, the solar-native grassland scenario improved pollinator supply by 3-fold and 30% compared to the agriculture and solar-turfgrass scenarios, respectively (Table 4; Fig. 3).

Sediment Export. On average, sediment export under the solar-native grassland scenario was 0.007 tons/ha/year, which was a reduction of over 95% and 77% compared to the agriculture and solar-turfgrass scenarios, respectively (Table 4; Fig. 3).

Water Retention. On average, water retention under the solar-native grassland scenario was 885.0 mm/yr, which was 19% and 9.5% greater than the agriculture and solar-turfgrass scenarios, respectively (Table 4; Fig. 3).

Table 4
State and Midwest regional average ecosystem service results.

State	Agriculture scenario	Turfgrass scenario	Native grassland scenario
Carbon storage (Mg C*ha^{-1})			
All States	78.3	95.7	129.3
Pollinator supply (unitless index)			
Illinois	0.032	0.071	0.094
Indiana	0.032	0.072	0.094
Iowa	0.032	0.074	0.093
Michigan	0.032	0.076	0.095
Minnesota	0.033	0.074	0.098
Missouri	0.034	0.076	0.101
Wisconsin	0.034	0.079	0.100
Regional average	0.033	0.074	0.096
Sediment export (tons*ha^{-1}*yr^{-1})			
Illinois	7.084	0.536	0.131

Missouri	748.9	820.5	907.3
Wisconsin	762.2	824.7	904.1
Regional average	744.3	808.0	885.0

3.3. Projections to current and future energy scenarios

Using the Midwest regional averages for all calculations, the solar-native grassland scenario for all existing solar facilities (3416 ha) had the potential above- and below-ground carbon storage capacity of 267,473 Mg C, which was 174,216 Mg and 114,778 Mg greater than the agriculture and solar-turfgrass scenarios, respectively (Table 5). The solar-native grassland scenario conserved over 1000 tons more sediment from erosion than the agriculture scenario and 79 tons more sediment than the solar-turfgrass scenario. For existing solar energy developments, the solar-native grassland scenario retained over 4,800,000 m^3 and 2,600,000 m^3 more water than the agriculture and solar-turfgrass scenarios, respectively (Table 5). Because InVEST calculates pollinator supply as a unitless index value, we did not make future projections for pollinator habitat quality.

Based on solar energy targets identified from state legislation and energy websites (e.g., Illinois Future Energy Jobs Act [S.B. 2814, 2016]; SEIA, 2019; MISO, 2019), we conservatively estimated the amount of large-scale solar energy development for a future 2030–2034 time period to be approximately 10,000 MW (10 GW). This represents about 5% of the national 2030 goal for ground-mounted solar set forth by the U.S. Department of Energy (U.S. Department of Energy, 2012). Several Midwestern states such as Minnesota, Illinois, Indiana, and Wisconsin already have a queue of expected solar projects that would collectively reach this level of development in the next 5 years. Based on our calculated regional solar land use estimate of 3.0 ha per MW (Supplement 1), we estimated this future regional solar development footprint to occupy approximately 30,000 ha (300 km^2). If all solar facilities incorporated native grassland vegetation management strategies under this future energy scenario, the total above- and below-ground carbon storage potential of these facilities could exceed 3,800,000 Mg C, which would represent 1,500,000 Mg C and 1000,000 Mg C greater storage potential than agriculture and solar-turfgrass scenarios, respectively (Table 5). Under this future energy scenario, region-wide adoption of solar-native grassland management strategies has the potential to conserve over 9000 tons of sediment loss from erosion annually and retain over 40,000,000 m^3 of water from runoff annually (Table 5).

4. Discussion

Ecosystem services of vegetation management options at solar energy facilities are an emerging field of study. Our study demonstrates how multifunctional land uses in agricultural-dominated landscapes have the potential to improve the provision of a variety of ecosystem services. Numerous studies have demonstrated the effectiveness of native grassland restoration in agricultural landscapes in conserving insect pollinators and restoring important ecosystem services (e.g., Hernandez-Santana et al., 2013; Blaauw and Isaacs, 2014; Schulte et al., 2017). While field studies at solar facilities are currently under way to measure the ecosystem services of different vegetation management options, it will take several years for these field data to become available. To obtain initial estimates, we focused on examining the potential ecosystem services in a spatially-explicit manner using secondary data sources and scaled our model results to regional estimates. Our models included input parameters from previous studies in the U.S. that evaluated ecosystem service tradeoffs among various land uses, including

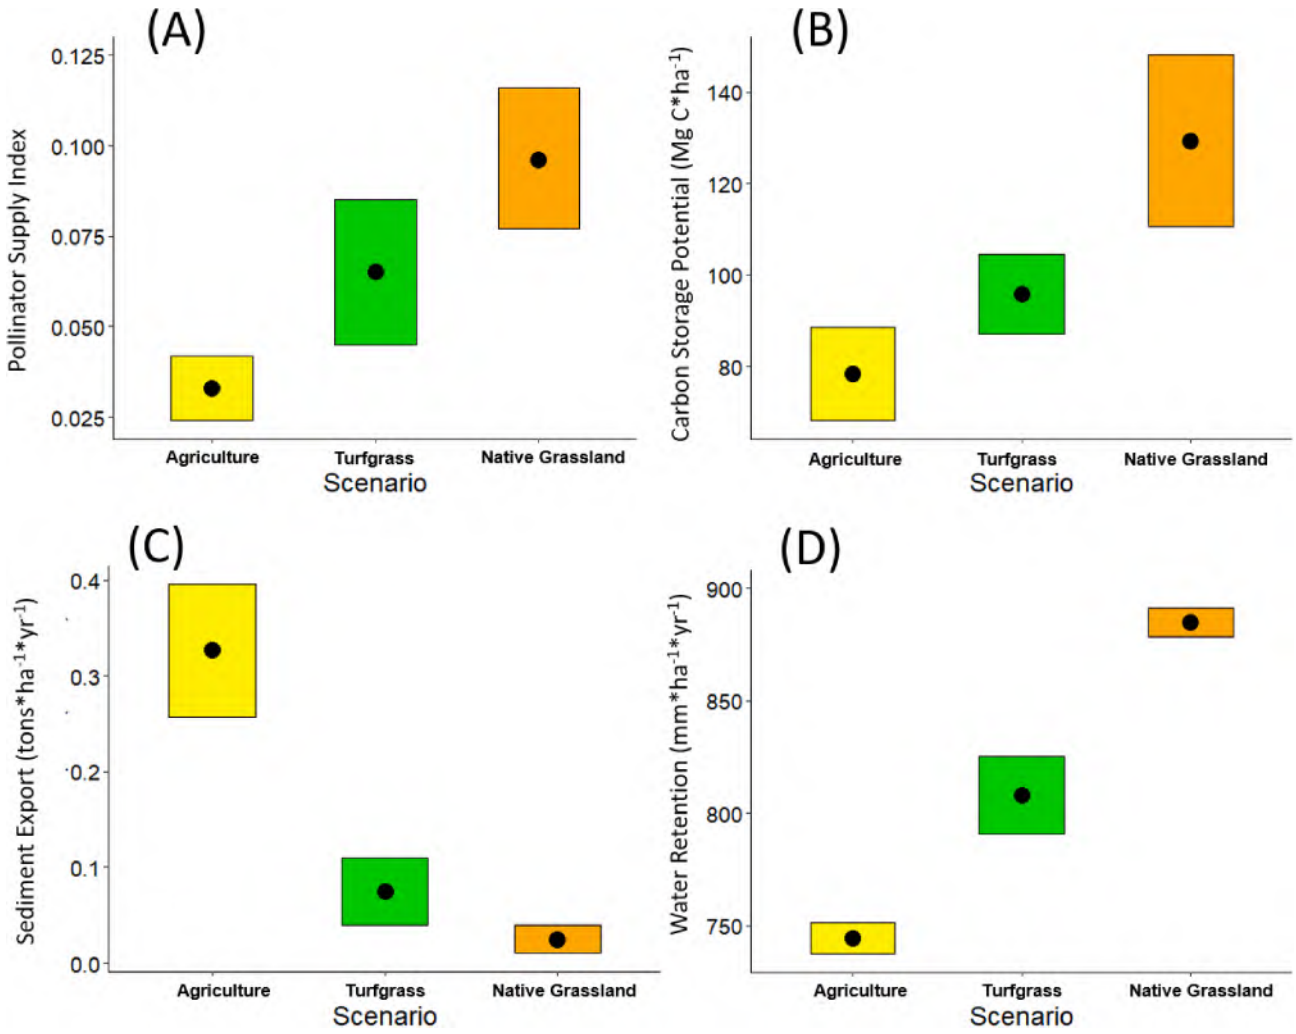

Fig. 3. Average ecosystem service values for the thirty Midwest solar facilities modeled with InVEST: (A) pollinator supply, (B) carbon storage, (C) sediment export, and (D) water retention. Tiles represent the upper- and lower-bound estimates based on the 25% and 75% quartiles. Points represent the midpoint average values.

Table 5
Ecosystem services projected to the entire current and future solar energy development footprints in the Midwestern U.S.

Solar development time peirod[a]	Agriculture scenario	Turfgrass scenario	Pollinator scenario
Carbon storage (Mg C)			
Current	267,473	326,911	441,689
Future	2,349,000	2,871,000	3,879,000
Sediment export (tons*yr^{-1})			
Current	1117.0	102.5	23.9
Future	9810.0	900.0	210.0
Water retention (m^3*yr^{-1})			
Current	25,425,300	27,601,300	30,231,600
Future	223,290,000	242,400,000	265,500,000

[a] Current time period refers to existing solar energy facilities in the Midwest as of 2018 (1.2 total GW), with a total estimated footprint size of 3416 ha (34.2 km^2) (EIA, 2019). Future time period refers to a future solar energy development scenario (10 GW), with an estimated footprint size of 30,000 ha (300 km^2).

our land use surrogates (agriculture, native grassland and prairie, and turfgrass/suburban land use types). This approach allowed us to examine the potential tradeoffs in vegetation management land uses at solar energy facilities.

There is ample research supporting the InVEST ecosystem service model parameters and output related to our surrogate land cover types (see Table 2 and Supplemental 2). For example, in a study of land use impacts on ecosystem services in Minnesota, Johnson et al. (2012) examined tradeoffs in total carbon storage using estimates of 108 Mg C * ha^{-1}, 100 Mg C * ha^{-1}, and 67.7 Mg C * ha^{-1} for native grassland, developed, and agricultural land use types, respectively. In Wisconsin, Meehan et al. (2013) used the InVEST pollinator model with biophysical parameters similar to ours to associate pollinator habitat with LULC types. They found that switching from annual row crop agriculture (corn) to perennial grasses in Wisconsin would increase pollinator abundance by an average of 11%. In Iowa, Schulte et al. (2017) discovered that prairie strips in corn-soybean dominated agricultural settings reduced total water runoff from catchments by 37%, resulting in the retention of 20 times more soil as compared to an agricultural baseline scenario.

As expected, our models suggest that solar-native grassland improves habitat for local insect pollinators. Overall, we detected a 3-fold increase in pollinator supply under the solar-native grassland scenario compared to the pre-solar development land use scenario (agriculture) and a 30% increase in pollinator supply compared to the solar-turfgrass scenario. The implementation of pollinator-friendly vegetation at current and future solar energy facilities has the potential to benefit biodiversity by providing habitat for insect pollinators and other wildlife (e.g., birds; Clean Energy States Alliance, 2020). In addition, increased abundance and diversity of native pollinators associated with solar-native grassland could improve the services these organisms provide for pollination of

nearby agriculture. A number of studies have found direct correlations between pollinator habitat enhancements in agricultural settings and improved agricultural production associated with beneficial increases in pollinator services (Blaauw and Isaacs, 2014; Pywell et al., 2015; Venturini et al., 2017). In the Midwest, dominant crops such as soybeans may benefit from the presence of native pollinators. For example, pollinator habitat enhancement around soybean fields in Ohio increased native pollinator visitation to soybean flowers and increased soybean yields by up to 23% (Cunningham-Minnick et al., 2019). There are nearly 400 km^2 of soybean fields within 1.5 km of existing solar facilities across the seven Midwest states in this study (Walston et al., 2018), highlighting the potential agricultural pollinator service implications of solar-native grassland.

Compared to baseline agricultural land uses, our models suggest that solar-native grassland has the potential to increase the total carbon storage capacity of all current and future solar energy sites in the Midwest by over 170,000 Mg C and 1,500,000 Mg C, respectively. Putting these estimates into context, compared to the agricultural baseline scenario, the potential total future solar-native grassland carbon storage benefit is equivalent to offsetting the CO_2 emissions from over 5000 GWh of electricity generated from coal-fired power plants (World Nuclear Association, 2011). There are also future implications of solar-native grassland for sediment and water retention. The future solar-native grassland scenario has the potential to reduce over 9000 tons of sediment loss as a result of surface erosion annually and retain over 40,000,000 m^3 of surface water runoff annually from future solar sites. These increases in ecosystem services are equivalent to offsetting the amount of erosion and runoff of over 1000 ha (10 km^2) of row crop agriculture in the Midwest annually (NRCS, 2010).

It is important to clarify that the full ecosystem service benefits modeled in our study may not be immediately observed after the establishment of solar-native grassland. Rather, ecosystem services may gradually increase over time as the native grassland community matures. For example, soil organic carbon accumulates at former row-crop agricultural fields that have been restored to native prairie grasses at a rate of approximately 0.68 Mg C*ha^{-1}*yr^{-1} (McLauchlan et al., 2006). At this rate, an average 10 MW solar facility (30 ha) situated on land formerly used for agriculture that has been planted with native grassland vegetation will accumulate over 200 Mg of soil organic carbon after 10 years of operation. Over the timeframe of a solar energy facility lease period (which may be 20–30 years), therefore, we expect the site's ecosystem service potential to increase and more closely resemble modeled outcomes. Nevertheless, some ecosystem service benefits of solar-native grassland may be more quickly realized. For example, in as little as 3 years post-seeding, newly established native grasslands in Iowa are capable of reducing erosion and runoff in agricultural landscapes (Hernandez-Santana et al., 2013). In another study in Michigan, the establishment of native wildflowers in agricultural systems doubled the abundance of native bees and increased their visitation to nearby blueberry crops by 25% in less than 3 years after wildflower planting (Blaauw and Isaacs, 2014).

Our study focused on comparing the potential ecosystem services of different land management scenarios at solar energy facilities. We recognize some practical considerations in our study that warrant further investigation. First, the InVEST models we used have unique assumptions that relate land use classifications to ecosystem services (Sharp et al., 2018). Therefore, our modeling results were limited by the accuracy of the 30 m land use raster dataset we used and the general ecosystem service relationships that have been developed for those land use classifications. Second, our models did not incorporate sensitivity analyses or field-based validation efforts with primary data collected at solar facilities. Instead, we focused on examining a range of possible ecosystem service outcomes based on secondary sources of data from previous InVEST studies that examined surrogate land use types. This approach allowed us to understand the uncertainty in model results and we used average values to compare scenarios. Validation of our models consisted of comparisons to other InVEST studies that evaluated our land use surrogates. As discussed above, the relative differences in our model results were consistent with these previous studies. Third, we were not able to measure how solar panels may influence the modeled ecosystem services so we assumed the influence of solar panels to be constant. However, the presence of solar panels may influence ecosystem processes. For example, soil evapotranspiration processes may decline by 10–30% under solar panels compared to open sites (Marrou et al., 2013). For these reasons, greater emphasis should be placed on interpreting the relative implications of our results rather than the actual ecosystem service value calculations. Additional work is needed to collect the primary data on ecosystem services at solar energy facilities, collect data on the temporal patterns of these ecosystem services in relation to habitat establishment, and examine the effects of solar panels on processes such as runoff, erosion, and carbon storage.

5. Conclusions

The establishment of native grassland vegetation at solar energy facilities is a strategic land use practice to improve the landscape compatibility of solar energy development (Walston et al., 2018; Hernandez et al., 2019). Recent attention on this strategy from the solar industry, natural resource agencies, conservation organizations, and state governments underscores the amount of multidisciplinary coordination involved in implementing solar-native grassland (EPRI, 2019; Clean Energy States Alliance, 2020). In regions where native grasslands have been lost to other human activities such as agriculture, native grassland restoration at solar energy facilities represents a win-win solution for energy and the environment through the improved ecosystem services provided by the native habitat that may encourage future solar energy adoption. While several states have passed legislation and scorecards to guide the implementation of solar-native vegetation habitat standards, decisions regarding establishment of solar-native grassland also consider the costs of particular seed mixes and costs of seedling establishment, vegetation height restrictions, and long-term maintenance needs (Clean Energy States Alliance, 2020).

This paper is the first to compare the potential ecosystem services related to vegetation management practices at solar energy facilities. Since none of the calculated ecosystem service benefits of solar-native grassland accrue solely to the solar industry or any other group of stakeholders, the calculated values may be better considered as benefits for society-as-a-whole. These findings may be used to build cooperative relationships between the solar industry and surrounding communities to better integrate solar energy into agricultural landscapes. We focused on the potential non-monetary aspects of these ecosystem services in this study. Additional work is needed to collect the primary data that would support economic evaluations to inform solar-native grassland business decisions for the solar industry and quantify the economic benefits of services provided to nearby farmers, landowners, and other stakeholders.

Abstract

The arid sandy areas have great potential for producing solar power, and a large number of solar photovoltaic (PV) power (SPP) stations have been set-up in these regions across the world. Construction of SPP at large scale certainly changes the land surface with consequences on the local ecosystem. However, few studies have focused on these impacts. This study explored the influence of SPP on vegetation by modifying microhabitats. The soil water content (SWC), evaporation, photosynthetically active radiation (PAR), soil and air temperature (AT), vegetation coverage, biomass, and species richness were measured under different positions of the SPP and outside. The results showed that SWC in the station was much higher than that observed outside the SPP, and the evaporation in the SPP was lower than outside ($P < .05$). The PAR below the PV panel line zone is much lower than the interval (IT) zone. The surface coverage, biomass, and species richness were significantly higher in the SPP than outside the IT zone and outside the SPP ($P < .05$). The AT under the panel was 1.67 times lower than above during the plant growing season. The microhabitat index has a high correlation with biomass, coverage, and species richness. PV panels could impact microhabitat in arid sandy areas and accelerate vegetation recovery progress and quality. The SPP construction would not only supply clean energy but also bring unintended ecological benefits in the future.

microhabitats, photovoltaic panels, sandy ecosystem, soil water content, vegetation recovery

1 | INTRODUCTION

Fossil fuels, such as coal, oil, and natural gas, dominate worldwide electricity generation, as well as transportation, heating, and industrial energy demands since the 20th century. This dependence on fossil fuels deepens the impact of global warming and boosts climate change risks. Compared with fossil fuels and other energy sources, such as nuclear power, renewable energy sources, such as solar and wind power, provide viable options for energy supply because of their abundant provision and wide availability on earth (Barthelmie et al., 2014; Miller, Gans, & Kleidon, 2011; MacDonald et al., 2016). Related to multiple climate benefits and sustainable development, renewable energy sources have been widely embraced as a primary solution to the current challenges of global energy demand, climate change, and environmental and societal sustainability (Dincer, 2000; Panwar, Kaushik, & Kothari, 2011). Solar energy is considered as one of the

Yu Liu and Rui-Qi Zhang contributed equally to this work and are co-first authors.

most promising alternatives due to its characteristics: inexhaustible, carbon-emission free, and nongenerating liquid or solid waste products (Ito et al., 2003; Tsoutsos, Frantzeskaki, & Gekas, 2005; Ahmed, Al Amin, Hasanuzzaman, & Saidur, 2013; Solangi, Islam, Saidur, Rahim, & Fayaz, 2011). By using solar photovoltaic (PV) panels, solar energy could be translated to electricity and grid connected though PV power stations (Singh, 2013; Sahu, 2016). The solar energy market has got extensive attention from worldwide governments (Creutzig, 2017). Updated to 2017, the total global PV installed capacity already reached 404.5 GW, nearly 225-times higher than the capacity in 2000 (1.8 GW). In 2017, China had installed 53.3% of the world's solar capacity, with an increase of 52.8 GW to its capacity in 2016 (Europe Solar Power, 2018). The United States was the world's second largest PV market and increased 10.6 GW compared with its capacity in 2017. In the same year, Japan holds 12.2% of the global share, whereas Germany took up to 10.6% (Europe Solar Power, 2018). Thus, the PV industry has become a fast-growing industry that has gradually developed a huge market worldwide.

The PV installed capacity of Africa and the Middle East region has also developed very strongly due to their high solar radiation potential. The regional radiation potential values are the most significant data for locating solar power stations (Janke et al., 2010; Sánchez-Lozano, Teruel-Solano, Soto-Elvira, & García-Cascales, 2013; Jahangiri, Ghaderi, Haghani, & Nematollahi, 2016). Other semiarid and arid areas of the world, such as Nevada (USA), Baja California (Mexico), Atacama (Chile), Southern Spain (Organization for Economic Cooperation and Development—Europe), Empty Quarter (Arabian Peninsula), Gobi (China and Russia), Rajasthan (India), Sahara (North Africa), Kalahari (South Africa), and Great Victoria, Gibson, and Tanami (Australia), have a great potential for installing large-scale PV power stations due to the combined conditions of a large amount of available land and areas with high air optical quality (Ito et al., 2003; Muneer, Asif, & Kubie, 2003).

In the latest years, the Chinese Government has prompted plenty of efforts to maintain and develop the solar industry. The solar recourses are unevenly distributed throughout China, which decreases from northwest to southeast. The provinces located in the northwestern part, such as Xizang, Qinghai, Gansu, Xinjiang, and Ningxia concentrate most of the solar energy and thus are considered as the future energy base of China (Wu et al., 2014). Due to the low density of solar energy in nature, and the current transfer efficiency of the solar PV power (SPP; Ito et al., 2003), the solar PV stations need a large land area to install PV panels. Compared with the densely populated and land-scary east part of China, the northwest region of the Country is highly suited to install solar electric stations when considering both land use efficiency and solar energy distribution. Nonetheless, most parts of these regions are plateauing and desert, such as the Gobi and the steppes, which have the most sensitive ecological vulnerability in the whole state (Du, Zuo, Li, Wang, & Xue, 2019). SPP construction would cause significant soil surface disturbances that increase the risk of land degradation of the fragile arid ecosystem.

Some studies have evaluated the environmental impacts of the SPPs during their life cycle, including metrics about the energy payback time and greenhouse gases emissions (Northrup & Wittemyer, 2013). Emissions reduction and health benefits brought by the SPP's establishment are not open to question (Hosenuzzaman et al., 2015). Visual impacts, air pollution, and natural resource depletion associated with the installation of PV panels were also evaluated (Tsoutsos, Frantzeskaki, & Gekas, 2005). Some researchers have mentioned that SPP could impact and modify landscape during their construction through activities, such as earth movement and by equipment and facilities transportation (Tsoutsos, Frantzeskaki, & Gekas, 2005, Hernandez, Hoffacker, & Field, 2015). Besides, Wu et al. (2014) reported that large-scale concentrated solar power plants in Northwest China had huge and positive influences on the ecological environment, especially in alleviating soil erosion. The ecological impacts of PV panels are often assumed to be negligible, and thus, few studies in the literature investigate the influence of SPP's establishment on the local sandy ecosystem. Besides, many of these effects are hypothesized with little peer-reviewed evidence (Northrup & Wittemyer, 2013). Li et al. (2018) used a climate model with dynamic vegetation to estimate the unintended climate consequences led by large-scale installations of wind and solar farms. These studies indicated that the effects of large-scale solar farms are consistently conducted with significant locally, and further studies are required to assess the impacts of smaller solar farms installed at specific locations (Li et al., 2018). Nevertheless, the environmental and ecological impacts of PV panels are still unresolved questions. The previously available studies about PV panels have not dealt in detail with the impacts on ecological effects in the arid sandy ecosystem.

The study aim is to highlight both the ecological effects and the vegetation changes brought by SPP installed in an arid and sandy landscape of Western China. The SPP located in Yinchuan City was chosen for this study because it is located on the border of the Mu Us Desert. This is a transitional region and is highly sensitive to human activities, such as land use changes (Cao, Yu, Georgescu, Han, & Wu, 2015), and natural factors (Liang et al., 2016). The main contribution of this study is the quantification of the effects of the PV panel establishment on the soil water content (SWC), evaporation, soil and air temperature (AT), surface coverage, biomass, and species richness. The results of this study will enable to ascertain the ecological significance of solar PV station in arid and sandy regions.

2 | MATERIALS AND METHODS

2.1 | Study sites

This study was carried out in the SPP (38°31′57″N, 106°36′47″E; 1,222 m a.s.l.) constructed near Yinchuan City, at Xingqing District (Figure 1a). This area is located in the southwest border of the Mu Us Desert, in the Ningxia Hui Autonomous Region, China. The study area is part of the wind erosion zone, and it has a moderate temperate continental monsoon climate. The average annual precipitation is ~200 mm, and the annual evaporation is ~2,250 mm. The mean annual temperature is 8.4°C. The annual hours of sunshine are 3,075.5 hr, and the mean annual frost-free period is ~160 days. The most

maximum wind frequency is the west wind. The annual daily maximum wind speed (>5 m s^{-1}) days were 167 days in the region. The region's annual solar radiation value could reach 5,600 MJ m^{-2}. The soil type is light sierozem. Natural vegetation is scarce without the presence of forest. Dominant plant species in this area are mainly psammophytic shrubs and herbaceous plants, including *Halogeton arachnoideus*, *Artemisia scoparia*, *Artemisia ordosica*, and *Artemisia sphaerocephala*. All the experiments were conducted in the Baofeng SPP station, which was constructed in 2016. This station occupies an area of about 15.33 km^2 and has an installed capacity of 640 MW.

2.2 | Field experiments

The PV power station was constructed by a vast installation unit, which is 7-m long in the east–west direction, 6.8-m width in the south–north direction, and 2.15-m height above the ground. The PV panels in the installation unit were controlled by an automatic optical tracking system (single axis), which can rotate in the east–west direction. The schematic diagram of the installation unit is shown in Figure 2c–e. We defined three kinds of districts in this study. In one installation unit, the area district vertically below the PV panel line (axis horizontality) in south–north direction was defined as the below line (BL) zone, and the area district between two PV panel lines was defined as the interval (IT) zone. The area district 30 m nearby solar power station was defined as the outside (OS) zone. We randomly selected five installation units in the SPP to stand for the BL zone (5 points) and the IT zone (5 points), and the other 5 points around the SPP stands for the OS zone. All 15 points are shown in Figure 1b. The vegetation in and around SPP is natural growing without any type of grazing (Figure 2a,b). Microhabitat indicators such as soil moisture, soil temperature (ST), evaporation, and photosynthetically active radiation (PAR) were measured in each zone. The AT above and below the PV panel was monitored by temperature sensors throughout the year. An intensive field study was conducted to examine the aboveground biomass, vegetation coverage, and plant species in the three zones. All soil and plant samples were collected from July 23 to 27, 2018.

2.3 | Sampling and measurements

A dual-range digital thermometer (OS542, OMEGA, USA) was used to measure the ST at every point. ST was measured three times every

1099145x, 2019, 18, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ldr.3408 by University Of Arizona Library, Wiley Online Library on [01/07/2025]. FIGURE 2 (a, b) The vegetation conditions inside and outside the photovoltaic (PV) power station. (c) Example of outside (OS) station zone. (d) The front view (in south–north direction) of an installation unit; (e) the top view of an installation unit. (f) The size of one PV panel. The area district vertically below the PV panel line (axis horizontality) in south–north direction was defined as the below line (BL) zone (orange strip), and the area district between two PV panel lines was defined as the interval (IT) zone (green strip). The area district 30 m nearby solar power station was defined as the outside (OS) zone [Colour figure can be viewed at wileyonlinelibrary.com]

2 hr from 10:00 a.m. to 6:00 p.m. at each point (same location). The position to measure ST is randomly selected at each point about 5-cm height above the ground. The ST of each zone is the average value of 5 points in 6 hr. PAR was also measured three times every 2 hr from 10:00 a.m. to 6:00 p.m. at each point (same location). PAR was measured randomly by a canopy effective radiation recorder (ECA-GG01, Beijing ECOA Company, China) under the vegetation canopy (10 cm above the ground) in the three zones. The average value in 6 hr of 5 points for each zone stands for the PAR of the three zones.

The AT above (10 cm above the panel) and under (100 cm above the ground) the PV panels were monitored with a temperature sensor (S-THB-M002, HOBO, USA) from August 2017 to July 2018. The sensor reads the AT every 5 min. After outliers rejection, we group the AT value in 24 hr day^{-1} and use the daily mean temperature to calculate monthly mean AT. Temperature variation is observed in July 2018. Temperature variation is the difference value of AT above panel and under the panel in 24 hr (the average AT value in 24 hr of July 2018).

Three culture dishes (internal diameter of 150 mm) were utilized as evaporation pan to measure the evaporation of two consecutive days at each point: July 24 and 25. The position of dishes is randomly selected at each point. The culture dishes were filled with water and weighed twice: just before installing and then 24 hr later. The evaporation capacity (*EC*; mm) was calculated as follows:

$$EC = (W_1 - W_2)\rho_w / S_b, \quad (1)$$

where W_2 (g) is the weight of the dish with the remaining water after 24 hr, W_1 (g) is the weight of the dish with the water when it was settled, ρ_w is 1 g cm^{-3}, and S_b is the base area of the standard small evaporation pan (r = 10 cm).

The gravimetric SWC (%) of the 0- to 100-cm soil depth range was measured every 10-cm soil layer by a 4-cm diameter and 20-cm height soil auger at each point. Soil samples were collected in a 1.0m × 1.0m quadrat at each point. A total of 150 soil samples were taken in the three zones. The soil samples were stored in aluminum specimen boxes and weighed immediately after collection (using an electronic balance) and then weighed again after the samples were dried at 105°C for 24 hr. The SWC of each soil layer was calculated as follows:

$$SWC_i = (m_{i1} - m_{i2})/m_2\, 100\%, \quad (2)$$

1099145x, 2019, 18, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ldr.3408 by University Of Arizona Library, Wiley Online Library on [01/07/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

where m_1 (g) is the soil sample weight after collection, and m_2 (g) is the weight of the dried soil samples. i is the number of the soil layer, i = 1, 2, 3, ..., 10.

Mean SWC of 0–100 cm (%) was calculated below:

$$SWC = (SWC_1 + SWC_2 + SWC_3 + \ldots + SWC_{10})/10. \quad (3)$$

Plant coverage and species richness were estimated by using five quadrats of 1.0m × 1.0 m. The position of quadrats was randomly selected in each point. All the aboveground plant parts were collected and dried at 75°C for 72 hr in each quadrat, and then the dry mass in each quadrat was weighed. The average value of the dry mass represents the biomass of vegetation in the three zones. The number of species and vegetation coverage was estimated at each quadrat, and the species richness and vegetation coverage of each zone were calculated as the mean value of species number and vegetation coverage obtained in the five quadrats.

2.4 | Data preprocessing and statistical analyses

All data preprocessing was performed using Excel 2013 worksheet software (Microsoft Office Suite, USA). The one-way analysis of variance, Pearson correlation analysis, and the tests of significance were conducted by using SPSS 22.0 software (IBM, Montauk, NY, USA). Significant differences were determined at a significance level of .05. The figures were plotted by using SIGMAPLOT 12.5 software (Systat Software Inc., San Jose, CA, USA), and the table was produced with Excel 2016.

3 | RESULTS

3.1 | Effects of solar PV panels on surface microhabitats

The results showed clear differences in the SWC, evaporation, soil temperature (ST), and PAR between the BL, IT, and OS zones. One the one hand, the spatial pattern of SWC in 0- to 100-cm depth of the three zones was all decreased with increasing soil depth (Figure 3a). However, SWC in the OS zone was always lower than the values in the BL and IT zones considering within 100-cm soil layer. ST has the highest value (33.4°C) in the OS zone, whereas the BL zone had the lowest (30.2°C). The ST of the IT and OS zones is about 3°C higher than the BL zone (Figure 3c). The evaporation and PAR of the three zones were depicted in Figure 3b,d. The evaporation in the OS zone was significantly higher than in the other two zones in the SPP (P < .05), which was two times higher than the BL zone and 1.5 times higher than the IT zone, whereas inside SPP, the evaporation of the IT

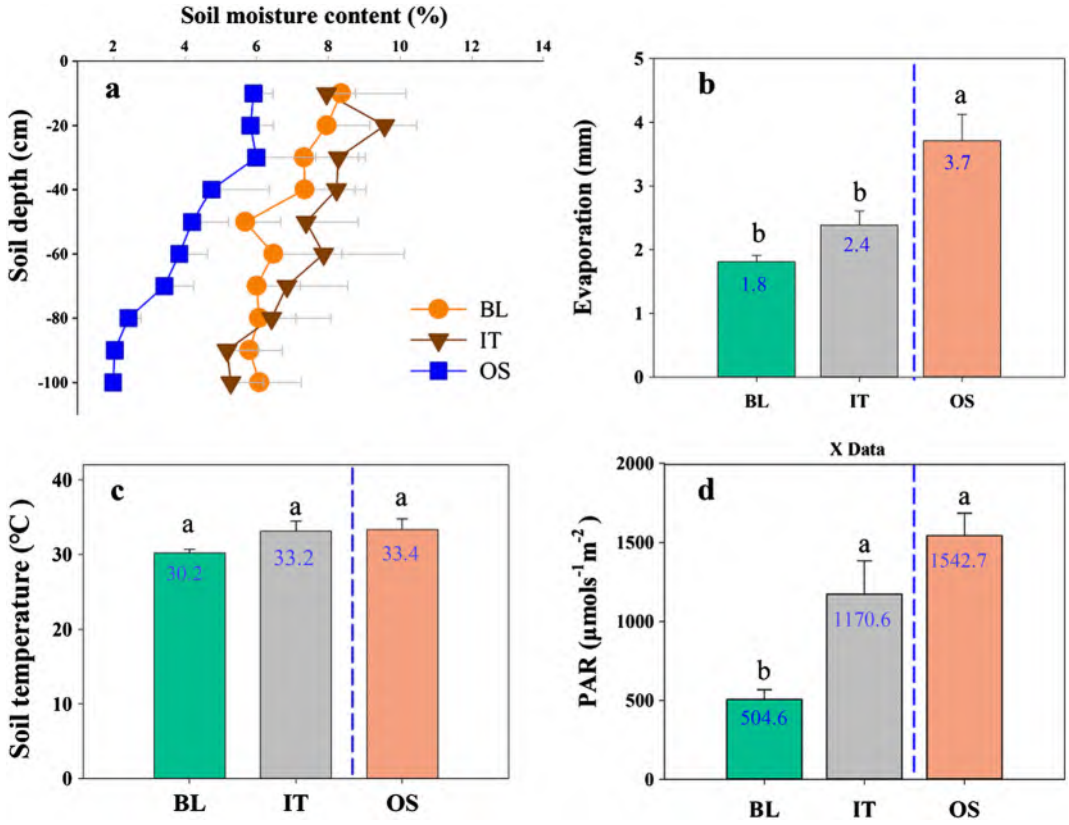

FIGURE 3 Soil moisture (0–100 cm in depth), soil temperature, evaporation, and photosynthetically active radiation (PAR) in the area district vertically below the photovoltaic panel line (axis horizontality) in south–north direction (BL), area district between two photovoltaic panel lines (IT), and area district 30 m nearby solar power station (OS) zones. Means with different letters are significantly different (P < .05) between the three zones. The error bars indicate standard errors [Colour figure can be viewed at wileyonlinelibrary.com]

1099145x, 2019, 18, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ldr.3408 by University Of Arizona Library, Wiley Online Library on [01/07/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

zone was 33% higher than the evaporation in the BL zone. Concerning PAR, the highest to lowest PAR values of the three zones was OS > IT > BL. The PAR of the BL zone was significantly lower than the other two zones ($P < .05$): 56.9% and 67.4% lower than in the IT and OS zones, respectively. Besides, the PAR in the OS zone is higher than the IT zone, but between them, there was no significant difference ($P > .05$).

The monthly average AT above the PV panel mirrored the trend of the AT under the panels: In both cases, AT started rising in February and reached the peak values in July (Figure 4a). Between September and November, the AT above and under the PV panel showed little difference. However, during the remaining 9 months, the monthly average AT of above panel was higher than under the panel. During the plant growing season (from April to August), above the panel's average AT of growing season was 36.21°C, whereas under the panel, the average temperature was only of 21.78°C. AT above the panel was ~1.67 times higher than that under the panel during the growing seasons. This AT above and under the PV panel also changed within a day (Figure 3b). We pick July 2018 to observe the daily AT difference between above and under the PV panel. From 12:00 p.m. to 6:00 p.m., AT was strongly reduced by PV panels. During these 6 hr, the temperature variation was above the mean AT variation estimated for the 24-hr period (19.27°C) and reached the biggest temperature variation time period within 1 day.

3.2 | Effects of solar PV panels on vegetation recovery

The biomass and surface coverage in the BL and IT zones were higher than the values in the OS zone (Figure 5a,b). The biomass of the BL and IT zones was 30 and 15.4-times higher than that in the OS zone, whereas the surface coverage was 6.8 and 6.2 times higher than in the OS zone, respectively ($P < .05$). Inside the solar station, the BL and IT zones did not have significant differences in the coverage ($P > .05$), whereas the biomass in the BL zone was nearly 2-times higher than in the IT zone ($P < .05$). The species richness of the three zones showed clear differences between the areas inside and outside the SPP (Figure 5c). The IT zone presented the highest species richness (5.5), the BL zone showed intermediate values (4.5), and the OS zone had the lowest values (2.6). There was no significant difference between the two zones inside the SPP; however, both the BL and IT zones had significant differences ($P < .05$) compared with the OS zone in species richness.

3.3 | The correlation between microclimate and vegetation

The results of correlation analysis for the ecological and vegetation indices are set out in Table 1. The correlation between biomass and ST, evaporation, and SWC was significant ($P < .05$). Besides, biomass between PAR was highly significant ($P < .01$), and its coefficient of correlation was more than −.76. Coverage also had a highly significant correlation with evaporation, PAR, and SWC ($P < .01$). Species richness had a significant correlation with SWC ($P < .05$) and a highly significant correlation with PAR ($P < .01$), and its coefficient of correlation reached −.81. We also concluded that evaporation was negatively correlated with coverage and biomass; SWC was positively correlated with coverage, biomass, and species richness, whereas PAR was negatively correlated with coverage, biomass, and species richness; and ST was also negatively correlated with biomass.

4 | DISCUSSION

Large-scale SPP has been mainly installed in the areas that have minimal competition for land surface against natural and other human land uses, such as deserts like the Gobi, and steppes (Hernandez, Hoffacker, Murphy-Mariscal, Wu, & Allen, 2015). These regions are sensitive to environmental changes where wind erosion might be intensified and sandstorm probability could be increased due to land use changes. Multiple environment impacts may change a lot during

Species richness							1.00

Note. Microhabitat indices include soil temperature (ST), evaporation, photosynthetically active radiation (PAR), and mean soil water content of 0- to 100-cm soil layer (SWC). Vegetation indices include coverage, biomass, and species richness.

*Correlation is significant at 0.05 level.

**Correlation is significant at 0.01 level.

the SPP's life cycle, especially during the beginning stage. Our study indicates that the existence of SPP would influence the local environmental and ecological status quo. The panels created a heterogeneous radiation habitat and covered ground owing to the fluctuant shading, thus leading a changing energy cycle (Cossu et al., 2014). The changing of the energy cycle led to the variation of the environmental factors. Previous studies have shown that PV panels of large-scale solar farms in the Sahara directly reduced the surface albedo, creating positive albedo–precipitation–vegetation feedback, which triggered an increasing temperature and precipitation (Li et al., 2018). On a smaller scale, this study has shown that the presence of PV panels changed the microhabitat factors in different ways. PV panels convert solar radiation into electricity (Lewis et al., 2006), according to the law of conservation of energy, and the land surface under the power station would receive less radiation than the uncover land (Zhou et al., 2012). Besides, the vegetation coverage in the SPP is much higher than the outside, which further reduced the solar radiation reaching the surface. Hence, the PAR in the station was significantly lower than the PAR outside the station, especially in the BL zone.

ST changed in a quite different way due to the influence of the PV panels, and the ST of the BL zone is still 3°C lower than the IT and OS zones, which was still influenced by the PV panel (Figure 2c). The AT under the panels differed from the AT above the PV panels. AT under the panels was suitable for plants during their growing season. From April to August, the average temperature of the panel was only 21.78°C. A likely explanation is that the radiative balance was modified by the panel shelter, the panels directly decrease solar energy transfer of heat energy through electricity converting and shading

1099145x, 2019, 18, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ldr.3408 by University Of Arizona Library, Wiley Online Library on [01/07/2025]. effect, which provided an open structure with sufficient air circulation (Marrou, Dufour, & Wery, 2013). Plants in arid sandy areas always facing heat stress conditions and in most cases leaves are dried during the growing season. High temperatures could cause serious physiological injuries to plants, such as scorching of leaves and stems, leaf abscission, and senescence (Wahid, Gelani, Ashraf, & Foolad, 2007). Moreover, high temperatures could affect the shoot net assimilation rates that reduce the plant growth, which consequently leads to a decrease in the total dry weight of the plant (Bita & Gerats, 2013). The results of this study showed that PV panels could effectively reduce the temperature during both the growing season and the hottest time of the day, which could to some extent let plants alleviate heat stress and prevent plant productivity decrease.

The water condition was also influenced by the PV panels. The SWC in the SPP was higher than in the area out of it, whereas evaporation just showed the opposite trend. SWC is only recharged by rainfall in the study region. However, the PV panel has changed this process in two aspects. For one thing, the panels directly intercepted part of the precipitation, which could vertically fall into the BL zone without panels. Besides, rainfall could be temporally stored in the panels, and then due to its inclination, the rainfall would redistribute to the soil surface (Armstrong, Waldron, Whitaker, & Ostle, 2014). Thus, SWC in the IT zone was slightly higher than in the BL zone (Figure 2a). The shading effect of the panels explained the significantly lower evaporation that was observed in the SPP (Figure 2b). These results agreed with the study of Marrou, Guilioni, Dufour, Dupraz, and Wery (2013) who found that the shadow of the panels could save up to 14–29% of evapotranspired water in vegetable crops. Furthermore, the shading effects can increase the sensible heat flux of the ground layer, encouraging a decrease of the latent heat flux and soil heat flux, thus limiting evaporation (Coutts, Daly, Beringer, & Tapper, 2013). All these effects caused the observed heterogeneity of SWC distribution. SPPs are usually located in areas that lack water and accompanied by high potential evaporation. Through Pearson correlation analysis, it was shown that there was a high correlation between vegetation coverage, SWC, and evaporation ($P < 0.01$), and its coefficient of correlation was more than 0.72 and −0.79, respectively. Plants that grow in arid areas are highly affected by both temperature (Beedlow, Lee, Tingey, Waschmann, & Burdick, 2013) and water availability (Zhou, Zhang, Ji, Downing, & Serpe, 2011). When vegetation is facing prolonged drought stress, SWC would strongly control the spatiotemporal patterns of biomass (Kammann, Linsel, Gößling, & Koyro, 2011). In water-limited areas, water is the foundation of vegetation planting (Kammann, Linsel, Gößling, & Koyro, 2011). Besides, good water conditions have positive effects on juvenile crop stages, which is vital to vegetation establishment (Marrou, Dufour, & Wery, 2013). The mean vegetation fractional coverage in middle Asia, where Northwestern China is included, ranges from 3% to 33% (Zhang et al., 2016). In our study, we found that the vegetation coverage of the OS zone was 13.4%, just among the average level of coverage. However, the vegetation coverage in the SPP was about 85% lower than that of the BL zone (93.5%), which is a value much higher than the average level of vegetation coverage at a regional scale. At the same time, the biomass and species richness were significantly higher in the SPP than in the area outside. The construction of SPP destroyed the low coverage of natural vegetation; however, after 2 years (2016–2018) of recovery, significant differences in vegetation characteristics had already shown. The vegetation in the SPP had shown a better recovery in terms of quality and speed, which got highly correlation with microhabitat indices SWC and evaporation. This study has indicated that SPP can provide a better water condition for plant growth in arid sandy ecosystems. Under the context of global warming and water resource shortage, the effects of panels could maintain a relatively higher SWC in the soil and lower evaporation, leaving more water for plant growth, and thus facilitate the destroyed vegetation recovery or improve the vegetation coverage in sandy areas. These benefits provide a consistent advantage in the near future.

Prior studies focused on dryland and desert ecosystems have noted the importance of vegetation coverage and biomass to provide important ecological services such as soil protection and animal feeding (Jiang, Liu, Zhang, Zhang, & Wang, 2019). The soil erosion process is influenced by natural and human factors, and thus, it has a close-fitting connection with climate conditions, such as precipitation and temperature, ground cover (e.g., vegetation cover), and land uses (Li et al., 2017; Wei et al., 2017). The ultimate means to combat desertification and protect soil from wind erosion is vegetation construction (Su et al., 2007). Vegetation cover has a lower and upper threshold for controlling wind erosion. A plant coverage lower than 10% has little ability to reduce wind velocity at the soil surface, whereas the effect of vegetation on reducing wind erosion has basically reached the maximum when plant cover is ~40% or above (Jiang, Liu, Zhang, Zhang, & Wang, 2019). This study has indicated that PV panels favored the development of a microhabitat with lower evaporation and higher SWC, moderate temperature, and PAR, which enabled vegetation development with high coverage, biomass, and biodiversity in SPP. The average vegetation coverage in the SPP was 90.5%, which could effectively destroy the wind–sand flow structure. Meanwhile, the PV panels covered more land, modifying the land surface properties, in particular, increasing the surface roughness, which could slow down wind speed. In these two aspects, wind erosion could be efficiently reduced and controlled. Moreover, the higher biomass in the station could let more litter get into the soil, which provides nutrition and improves the soil structure (Jia, Huang, Miao, Lu, Li, Liu, Shen, He, & Wu, 2018; Jia, Liu, He, Miao, Huang, Zheng, Han, & Wu, 2018) that enhances the soil water holding capacity. Meanwhile, the observed better soil water conditions could provide a better scenario for the plant growth, higher biomass production, and total coverage. These changes created positive vegetation–water feedback associated with the other influence brought by SPP. Altogether, these results reflected that the establishment of SPP enhances the resistance capacity of an area against wind erosion and has positive ecological effects under adverse climatic conditions. SPP's installation in arid sandy areas could provide not only electricity energy but also huge ecological benefits brought by a good vegetation condition, which could help other researchers and policy-makers to pay more attention to the ecological benefits besides the economic profits. Our study was just a primary

1099145x, 2019, 18, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ldr.3408 by University Of Arizona Library, Wiley Online Library on [01/07/2025]. research of the PV panel's ecological effects, and further studies will be needed in more sites to gather large datasets that can support sound conclusions.

5 | CONCLUSIONS

SPP in arid areas could perpetuate the efficient use of regional solar recourses and bring both economic and ecological benefits. SPP installation had a big influence on the surface microhabitat in the arid sandy ecosystem of Western China. Higher SWC and lower evaporation constitute better water conditions, which were the key factors of improving the ecological environment in the sandy areas. Moreover, the PV panels could relieve heat stress by adjusting the air and ground temperature during the plants' growing season. This hydrological process and the modified temperature conditions supported the plant growth and thus accelerated vegetation recovery. After 2 years (2016–2018) of recovery, vegetation coverage in the station reached a very high value (90.5%), which could provide effective protection to soil against wind erosion. Furthermore, biomass and species diversity increased owing to the combined influences of the PV panels. Therefore, PV panels made the surface microhabitats different to some extent, and positive vegetation–microhabitat feedback thus could promote the ecological restoration in the arid sandy region.

Abstract

Solar photovoltaic (PV) has become the second renewable energy source, giving rise to potential conflicts with biodiversity conservation. However, the information available about the impacts and mitigation measures of solar PV energy is scarce and scattered, and a rigorous and comprehensive review on the topic is lacking. Here, we review the state of knowledge on its impacts and mitigation measures and identify main knowledge gaps. For that, we reviewed more than 2000 articles, out of which only 180 assessed the impacts of solar PV ($N = 138$) and/or propose mitigation measures (65). Even though Asia and Europe head the list of regions with the highest PV installed capacity (59% and 22%, respectively), a large portion of the existing knowledge is drawn from North American environmental contexts (48% of the studies), specifically from deserts (41%). Impacts were addressed on plants (26%), arthropods (14%), birds (10%), microorganisms (10%), reptiles (7%), mammals (4%), and bats (1%), but also on abiotic factors (e.g., humidity and temperature; 20%) and ecosystem services (3%). Most studies addressed the impact of PV on habitat alteration at landscape (33%) and microhabitat scale (20%), and on microclimate at microhabitat scale (17%), but other topics have been scarcely addressed (e.g., impact on microclimate at landscape scale or the potential of agrivoltaic systems). Lastly, 53% of the studies employed a single PV facility, and preconstruction situations were rarely reported (8%). There is a strong environmental context bias in the current understanding of PV impacts, which might not be extrapolable to other environmental situations like farmlands, where most of the solar PV capacity is being installed. Moreover, standardized and robust sampling designs are lacking to address cumulative, long-term, and long-scale impacts and produce comparable findings across contexts. Given the lack of empirical evidence and the irrepressible development of PV energy, it is advisable to apply an iterative monitoring and adaptive process

ecological impacts, renewable energies, solar panel, utility-scale solar energy, wildlife

1 | INTRODUCTION

Renewable energy is expanding rapidly, reaching an installed global energy capacity of around 3400 GW in 2022 (EI, 2023). These trends are expected to accelerate in the coming years, as an increase of about 1400 GW is forecasted by 2027 (IEA, 2023). The main driving force of this development has been the need to meet the increase in energy demand of a growing human population while meeting the goals set by the Paris Agreement to reduce carbon emissions and mitigate the impacts of climate change (IPCC, 2023; UNFCCC, 2015). Solar photovoltaic (PV) has recently experienced the most notable increase among all renewable energies (Figure 1) (Ritchie et al., 2023) and is projected to surpass natural gas and coal by 2026 and 2027, respectively, becoming the largest energy source (EI, 2023). Nowadays, Asia has the largest installed capacity of PV in the world (618.8 GW in 2022), followed by Europe (227.3), North America (128.9), South America (32.7), Oceania (27.4), and Africa (11.6) (Figure 1), with China (392.4 GW), United States (111.5), and Japan (78.8) being the top three countries (EI, 2023; Ritchie et al., 2023).

PV production costs have decreased rapidly, emerging as one of the most cost-effective technologies for generating electricity worldwide and one of the most promising potentials for mitigating climate change (IPCC, 2022). The establishment of large-scale PV projects comes with a wide range of environmental consequences, including pollution, erosion, and the occupation of land, which stands out as a prominent concern due to the impacts it triggers on biodiversity (Hernandez, Easter, et al., 2014). The viability of PV projects depends on multiple factors (economic, social, technical, and environmental; Wang et al., 2009), and current site planning is often guided by cost–benefit analysis, prioritizing cheap lands close to the transmission network, in detriment of environmental and landscape attributes in some cases, such as seminatural and agricultural habitats in Japan and Korea (Kim et al., 2021). Indeed, a large portion of PV facilities has been installed in agricultural lands, followed by natural and seminatural habitats (Kim et al., 2021; Kruitwagen et al., 2021; Ortiz et al., 2022)—especially arid lands and grasslands—and a clear overlap exists with important conservation areas (Kiesecker et al., 2019; Pérez-García et al., 2022), with the largest conflict occurring in Eastern Asia, Western Europe, and North America (Rehbein et al., 2020). This fact, together with the forecasted increase on PV (EI, 2023), raises concerns about potential conflicts between PV development and biodiversity conservation goals. The current challenge is that the assessment of environmental impacts and the implementation of measures to minimize them keep up with the fast rate of solar PV development for a sustainable energy transition that integrates biodiversity conservation.

The information available about the impacts and mitigation measures of PV energy is scarce and scattered, and some of the potential impacts described are based on hypotheses with little evidence support or on extrapolation from other human infrastructures (Lafitte et al., 2022). Although previous studies have attempted to compile the available information, most have a strong focus on specific contexts (e.g., deserts in the United States; Cypher et al., 2021; Hernandez, Easter, et al., 2014; Lovich & Ennen, 2011) and/or impacts (e.g., collision with PV panels; Kosciuch et al., 2020; Smallwood, 2022; Walston et al., 2016) and thus, a rigorous and comprehensive overall review is lacking. The aim of this study is to review the state of knowledge about impacts and mitigation measures of PV energy on wildlife and ecosystems and to identify the methodological limitations and knowledge gaps where future research efforts should be invested. For that, we reviewed research articles published in peer-reviewed scientific journals, identifying the geographic location, study contexts, ecosystem components, and impacts covered to get a thorough view on the knowledge and claims about PV impacts. Moreover, we assessed whether the number of research studies by world regions has been proportional to the expansion of PV energy to detect where PV development has surpassed the pace of research progress, posing a greater risk to the preservation of biodiversity. The results of this work will help to gain insight into the impacts of PV energy, as well as to guide future research efforts prioritizing knowledge gaps.

2 | METHODS

Following the practical guide for systematic searching and study screening for literature reviews suggested by Foo et al. (2021), we conducted a rapid evidence assessment

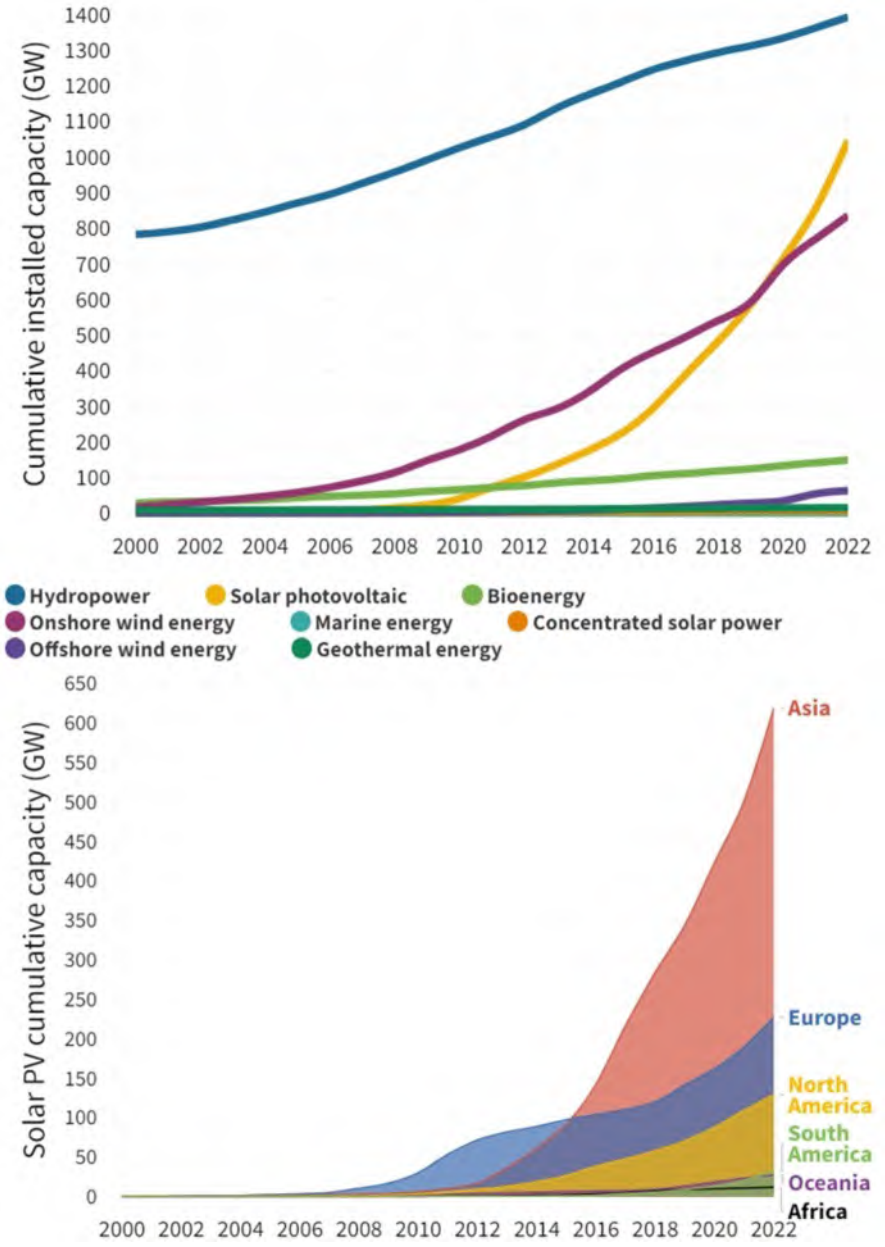

FIGURE 1 Installed global renewable energy capacity by technology from 2000 to 2022 (top) and solar photovoltaic (PV) cumulative capacity from 2000 to 2022 per continent (bottom). *Source*: EI (2023) and Ritchie et al. (2023).

(REA) in September 2023 using all databases in ISI Web of Science (WOS). This REA followed the following steps:

- Search of research articles based on explicit evidence search criteria (see below);
- Systematically collecting data;
- Synthesizing the data.

This was supplemented by searching reference lists and citations of included studies and relevant reviews. Our search was limited to title, abstract, and keywords, and included the following terms: ("photovoltaic energ*" OR "photovoltaic panel*" OR "solar array*" OR "solar development" OR "solar energ*" OR "solar facilit*" OR "solar farm*" OR "solar installation*" OR "solar panel*" OR "solar park*" OR "solar plant*" OR "solar power" OR "utility-scale solar") AND ("*diversity" OR "ecosystem*" OR "*habitat*" OR "wild*"). From the search terms and resulting number of articles in WOS, we excluded records that did not directly address the impacts of PV energy. Although the review was focused on PV energy, we also kept those studies addressing the impacts of concentrating solar energy (CSP) when impacts could be relevant or comparable to PV energy. We only kept those articles based on

1755263x, 2024, 4, Downloaded from https://conbio.onlinelibrary.wiley.com/doi/10.1111/conl.13025, Wiley Online Library on [01/07/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

empirical data and removed perspective and policy pieces. The remaining articles were assessed for relevant information and characterized according to broad category classes (Table 1).

First, we divided the articles into the main topics addressed in this review: impact on biodiversity, mitigation of biodiversity impacts, or both. In studies evaluating mitigation measures, we specified the level within the mitigation hierarchy (i.e., avoidance, minimization or compensation of impacts), and we briefly described the mitigation measured applied. To evaluate the environmental contexts underlying current knowledge on impact and mitigation measures of PV energy, we noted the studied topic as well as the geographic location (continent and country), climate (according to Köppen climate classification system), study context (e.g., habitat) covered by each study, and the targeted ecosystem components (biotic or abiotic factors and ecosystem services). Lastly, to assess the methodological limitations of current research, we noted the scale of the studies (whether they covered one or more PV facilities), the study design employed (before-after-control-impact [BACI]; control-impact [CI]; impact [I]; before-after [BA]; Table 1). Further explanation of the compiled information can be found in Table 1.

3 | RESULTS AND DISCUSSION

3.1 | Mismatch between PV deployment and impact research

We found 180 articles assessing the impacts of PV energy on biodiversity (N = 138) and/or proposing mitigation measures (65) (Table S1). These references can be consulted at the "Observatory of Scientific Literature Related to Photovoltaic Solar Energy and Biodiversity", published and updated by the Steppe-Forward Chair. The number of studies has increased significantly from 2015 onwards, with a notable increase from 2022 in Asian and European countries (Figure 2).

Most of the research has been carried out in North America (N = 75; 48.1% of the studies)—with the United States (73, 46.8%) being the main contributor—followed by Europe (34, 21.8%), Asia (26, 16.7%), Africa (6, 3.8%), South America (3, 1.9%), Antarctica, and Oceania (1, 0.6%; Figures 2 and 3). Therefore, even though Asia and Europe head the list of regions with the highest PV installed capacity (59.1% and 21.7%, respectively), a large proportion of the existing knowledge is drawn from North American contexts, which only hold the 12.3% of PV energy installed worldwide (Figures 2 and 3).

Of the empirical studies with specific information on the covered habitats (N = 92), 38 (41.3%) were carried out

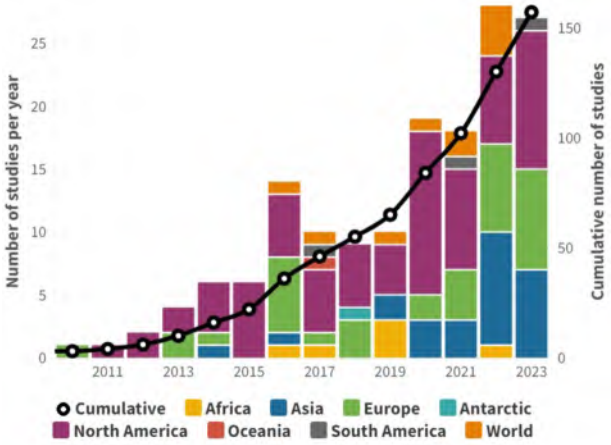

FIGURE 2 Number of studies reviewed assessing the impacts of photovoltaic (PV) energy or measures to minimize them from 2010 to September 2023 per region. Studies carried out under lab conditions (1) and reviews on specific impacts without a geographic focus (23) were removed, totaling 156 articles. "World" refers to studies carried out at global scale.

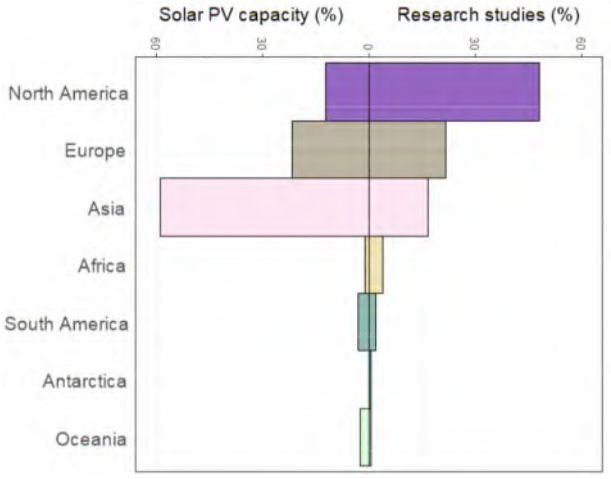

FIGURE 3 Proportion of research studies assessing the impacts of photovoltaic (PV) energy or measures to minimize them (right) and of cumulative installed capacity (left) per region. The percentage of studies is calculated from a total of 156, after removing those carried out under lab conditions (1) and reviews on specific impacts without a geographic focus (23).

in desert ecosystems, 20 in agroecosystems (21.7%; vineyards, abandoned or active fields, and pasturelands), 17 in grasslands (18.5%), and eight in urban environments (8.7%; quarries and waste dumps). Forest, shrubland, and tundra habitats were represented by no more than five studies (<5.5%), and nine studies (9.8%) were experimental tests. A high proportion of studies focused on abiotic factors (e.g., microclimate and soil properties; N = 27 out of 132 empirical studies, 20.4%) and to a lesser extent on ecosystem services (N = 4, 3.0%), whereas most studies

Summary of results		

Note: Wherever applicable, the categories defined for each parameter are specified, as well as a brief explanation. We highlight with an asterisk the fields that were duplicated in case a study addressed more than one topic, ecosystem component, or study context. Lastly, we indicate between brackets the number of studies under each category, considering only the articles incorporated in this study.

Abbreviation: PV, photovoltaic.

[a]The "lake-effect" hypothesis suggests that waterbirds and aquatic insects mistake solar arrays for water bodies, colliding with the infrastructure as they attempt to land. This could either result in direct mortality or leave individuals injured or stranded. See the main text for more information.

addressed biotic components ($N = 80$, 60.6%). Plants were the most studied group ($N = 35$, 26.5%), followed by arthropods ($N = 19$, 14.4%), birds and microorganisms ($N = 13$, 9.8%), reptiles ($N = 9$, 6.8%), mammals ($N = 5$, 3.8%), and bats ($N = 2$, 1.5%). When we cross-reference this information, we observe that the knowledge about the different ecosystem components is not evenly based in all habitats or study contexts. For instance, most information for reptiles comes from deserts, but information for mammals in this ecosystem is lacking as well as for arthropods in grasslands (Figure 4). Similarly, little information is available on bats, and knowledge on aquatic arthropods is mainly drawn from experimental assays.

Most studies addressed the impact of PV energy on habitat loss or alteration at both landscape ($N = 43$, 32.6% of the 132 empirical studies) and microhabitat scales ($N = 27$, 20.4%), and on microclimate at microhabitat scale ($N = 23$, 17.4%) (Figure 5). Furthermore, a high proportion of studies addressed land-use planning, aiming to identify compatible areas for PV development and biodiversity conservation ($N = 25$, 18.9%). As the number of studies per topic decreases, the context bias in current knowledge becomes more evident. For example, most studies addressing the impact of PV energy on collision rates and microclimate at landscape scale have mainly been carried out in deserts and arid climates, and little knowledge exists about the potential of agrivoltaic systems (Figure 5). Moreover, the lake effect hypothesis has been tested mainly under experimental conditions. Regarding methodological aspects, a total of 56 studies (53.3% out of 105 empirical studies with this methodological information) were focused on a single PV facility or experimental array, and 49 studies (46.7%) were based on more than one. Only two (1.9%) studies used a BACI design and seven (6.7%) used a BA design.

3.2 | Impacts of PV energy

The available information to date on the potential impacts of PV energy on biodiversity is summarized in Figure 6. As highlighted in Figure 5, some of these impacts have been addressed in specific environmental contexts and climates (e.g., heat island effect) and should therefore be treated with caution.

3.3 | Impacts on microclimate and soil properties

There is a lack of research on the microclimate impacts of PV energy, and current knowledge is mainly based on

1755263x, 2024, 4, Downloaded from https://conbio.onlinelibrary.wiley.com/doi/10.1111/conl.13025, Wiley Online Library on [01/07/2025]. FIGURE 4 Study contexts (left-hand side) and ecosystem components (abiotic, biotic, and ecosystem services; right-hand side) covered in the research literature on the impacts of photovoltaic (PV) energy or measures to minimize them. Colored bands indicate relationships between them. Some investigations cover more than one ecosystem component or study context.

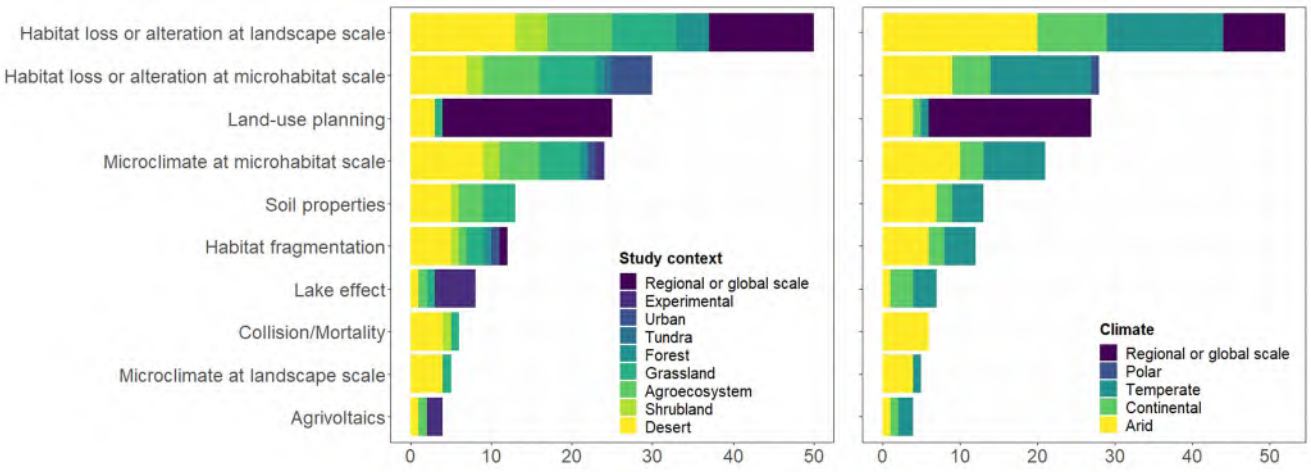

FIGURE 5 Topics addressed in the literature according to study contexts (left) and climates (right).

arid climates (Figure 5). In this climate contexts, PV facilities can alter the energy balance of short- and long-wave radiation by the introduction of darker and less reflective surfaces, which reduce albedo and increase the absorbed solar insolation (Barron-Gafford et al., 2016). Besides, vegetation removal reduces heat dissipation through transpiration and enhances heat gain and storage in soils, energy that will be later re-radiated in the form of heat (Barron-Gafford et al., 2016). Consequently, nighttime temperatures within PV facilities rise 3–4°C compared to surrounding (dryland) ecosystems, thereby inducing a "Heat Island" effect (Barron-Gafford et al., 2016). At a finer

1755263x, 2024, 4, Downloaded from https://conbio.onlinelibrary.wiley.com/doi/10.1111/conl.13025, Wiley Online Library on [01/07/2025]. FIGURE 6 Impacts of photovoltaic (PV) energy at landscape (left) and microhabitat (right) scale. At landscape scale, PV facilities produce habitat loss and fragmentation, and alter the microclimate by inducing a heat island effect at nighttime, at least in arid and temperate climates (see Figure 5). At microhabitat scale, PV panels alter the physical and chemical properties of soils and create novel shade, runoff, and radiation exposure gradients, altering microclimate and ultimately microsite habitat conditions. Given that temperature, water, and light are three key determinants for plant growth, novel conditions trigger a cascade of processes that impact on the plant community, but it can also result on habitat alteration for myriad of taxa (microorganisms, pollinators, birds, bats, and mammals). Lastly, mortality of volant wildlife through collision with PV panels or associated power lines is one of the most recorded PV impacts.

scale, PV panels intercept sunlight, reducing photosynthetically active radiation and creating novel shade conditions underneath (Tanner, Moore-O'Leary, et al., 2020; Wu et al., 2022), thereby decreasing air, surface, and soil temperature and variation as compared to the interval (IT) zone (i.e., area between panel arrays) and control sites during warm seasons (Armstrong et al., 2016; Lambert et al., 2021; Liu et al., 2019; Suuronen et al., 2017; Tsafack et al., 2022). However, this pattern is reversed during nighttime and in cold seasons, partly due to the inhibition of dew formation (Marrou, Guilioni, et al., 2013) and/or to the heat re-radiated from the soil and trapped under PV arrays (Barron-Gafford et al., 2016). Panels also alter the local distribution of precipitation, reducing water inputs below the panels but increasing them in the edge via storm runoff of PV panels. Even though humidity and soil moisture might be higher in runoff areas immediately after rainfall (Moscatelli et al., 2022; Tanner, Moore-O'Leary, et al., 2020), the shielding effect of PV panels reduces water loss by evaporation (Liu et al., 2019, 2022) and evapotranspiration (Marrou, Dufour, et al., 2013), ultimately increasing soil moisture (Suuronen et al., 2017) or smoothing the differences with the IT, runoff, and control sites (Choi et al., 2020). Other factors such as air circulation and turbulence, soil properties, and PV systems (e.g., tracking vs. fixed panels) might shift these microclimate patterns (Moscatelli et al., 2022; Suuronen et al., 2017; Yuan et al., 2022; Yue et al., 2021). More studies are needed to confirm whether these effects can be extrapolated to other environmental contexts and climates.

PV construction can also alter the physical and chemical soil properties, but these effects are highly dependent on land-use history, vegetation management, and control sites used in the comparison. Physical soil quality is degraded after PV installation since it reduces soil aggregate stability, a key factor of soil functioning (Lambert et al., 2021). Chemical soil quality also seems to be degraded in PV facilities (decreased in organic carbon, total carbon, and total nitrogen) as compared to seminatural habitats, but it is similar to that observed in other anthropogenic soils (e.g., abandoned vineyards) (Choi et al., 2020; Lambert et al., 2021). However, other studies have reported higher nitrogen and carbon values in IT soils than under PV panels or arable control sites (Moscatelli et al., 2022) and higher

1755263x, 2024, 4, Downloaded from https://conbio.onlinelibrary.wiley.com/doi/10.1111/conl.13025, Wiley Online Library on [01/07/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

electrical conductivity, phosphorus, potassium, soil organic matter, and fast-acting potassium in vegetated PV parks compared to bare land controls (Bai et al., 2022; Yuan et al., 2022). Similarly, another study observed that phosphorus, potassium, nitrate nitrogen, and soil pH increased 6 years after PV installation (Liu et al., 2022). Further research is needed to understand the mechanisms underlying these changes on soil properties.

3.4 | Habitat fragmentation, loss, or alteration

Habitat destruction and/or alteration occur at both broad scale (i.e., landscape) and fine scale (i.e., microhabitat). The physical onsite footprint and spacing of PV has been estimated at 1 ha for a 0.12–0.83 MW/ha (Grippo et al., 2015; Hernandez, Hoffacker, et al., 2014; Wu et al., 2014). At landscape scale, habitat loss due to PV construction has been described to be a threat for several taxonomic groups such as reptiles (Averill-Murray et al., 2013), arthropods (McCoshum & Geber, 2020), bats (Szabadi et al., 2023), and birds (Haga et al., 2020). In terrestrial animals, it can also impact broad-scale ecological processes such as daily, seasonal, and migratory movements through the creation of connectivity barriers (i.e., non-permeable perimetral fencing) (Averill-Leskova et al., 2022; Murray et al., 2013; Sawyer et al., 2022). At finer scale, PV panels per se represent a harsh environment, which can be colonized by a highly diverse microbial community composed of drought-, heat-, and radiation-adapted species (Moura et al., 2021; Tanner et al., 2018; Tanner, Molina-Menor, et al., 2020). Moreover, PV panels create novel shade and moisture gradients (see above), ultimately altering microsite habitat conditions with both winner and loser species resulting from the new PV ecosystem. The diversity and activity of soil fungi and prokaryotes seem to be higher in PV parks, especially in runoff areas, than in bare ground and arable controls (Bai et al., 2022; Moscatelli et al., 2022), and soil extracellular enzyme activity, an indicator of microbial function capacity, might increase after installation (Liu et al., 2022). However, soil archaea community structure and diversity does not differ between PV soils and adjacent deserts (Yuan et al., 2022). Future research should deepen on the impact of PV construction across the microclimate-soil-microorganism system due to its role in biological processes and ecosystem functioning (Bai et al., 2022).

PV panels can also impact on the plant community, although the responses might vary between habitats, seasons, and species, let alone vegetation management strategies (Tanner et al., 2021; Tanner, Moore-O'Leary, et al., 2020). In hydric stressful climates, PV panels could soften the harsh environmental conditions and alleviate heat stress, thereby increasing seed bank survival and aboveground plant productivity and diversity (Liu et al., 2019; Tanner, Moore-O'Leary, et al., 2020). However, the opposite effect might be found in communities that benefit from rainfall and sun exposure, reaching the lowest rates of photosynthesis and plant biomass under PV panels and their maximum productivity and diversity values at the runoff or IT zones (Bai et al., 2022; Moscatelli et al., 2022; Tanner et al., 2021). Overall, plant community composition might change by inhibiting the growth of dominant species and leaving room for subdominant ones (Bai et al., 2022; Uldrijan et al., 2022). Moving up the trophic chain, we find that arthropod pollinators use IT and under-panel habitats interchangeably, even though abundance and diversity tend to be lower under PV panels (Graham et al., 2021). Other authors have found that induced changes on the plant community and microclimate, together with targeted management measures (see *Mitigation hierarchy* below), might convert PV installations on invertebrate refuges (Jeal, Perold, Seymour, et al., 2019; Suuronen et al., 2017).

Overall, both habitat destruction (landscape) and the alteration of the abiotic conditions (microhabitat) result in habitat modification, loss and/or fragmentation for myriad of species (McClung et al., 2019). These changes combined with displacement due to visual or noise disturbances, might trigger behavioral responses (i.e., perception and habitat-use; Chock et al., 2021), ultimately resulting in population-level impacts across many taxa (Smallwood, 2022). A lower bat activity (Szabadi et al., 2023; Tinsley et al., 2023) and bird diversity and/or density has been found within PV parks (DeVault et al., 2014; Jeal, Perold, Ralston-Paton, et al., 2019; Visser et al., 2019), but no differences have been observed on bird reproductive success (Kitazawa et al., 2019). Conversely, PV panels might provide perches and thermal refuges that would be otherwise limited in specific contexts (e.g., deserts), or they could even offer foraging, roosting, sheltering, and nesting habitats (DeVault et al., 2014; Gerringer et al., 2022; Nordberg et al., 2021; Visser et al., 2019). Further research is needed to understand the consequences of habitat alteration following PV installation on wildlife habitat-use patterns and populations.

3.5 | Wildlife mortality

Direct mortality of flying wildlife (bats, birds, and aquatic insects) through collision with PV panels and other infrastructures (i.e., power lines and perimetral fences) is one of the most addressed impacts of PV energy, but most information comes from unpublished reports that employ non-standardized methodologies (Smallwood, 2022). Bird mortality rates at PV projects have been estimated between

1755263x, 2024, 4, Downloaded from https://conbio.onlinelibrary.wiley.com/doi/10.1111/conl.13025, Wiley Online Library on [01/07/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

2.49 and 10.7 fatalities/MW/year (Kosciuch et al., 2020; Visser et al., 2019; Walston et al., 2016). A recent work provides more accurate estimates by adjusting the results of previous reports performed from 1982 to 2018 for the effect of body size on carcass detectability, obtaining a mortality rate of 11.61 (95% CI = 8.37–17.56) bird fatalities/MW/year and 0.06 (95% CI = 0.01–0.1) bats/MW/year at 11 PV projects (Smallwood, 2022), considering only collision with PV panels and ignoring other sources of mortality (i.e., power lines and perimetral fences). Future studies should account for other sources of bias on carcass counts, such as carcass disappearance due to decomposition or removal by scavengers, in order to obtain more accurate quantifications of mortality (see for example Gómez-Catasús et al., 2021). Moreover, mortality estimates alone do not say much about their ecological and conservation significance, which depends on their larger-scale, population-level consequences, which are influenced by population descriptors (i.e., size and trends) and life-history traits (e.g., pace of life and reproductive strategy). A recent study found that of 23 priority species colliding at wind and solar facilities, 11 (48%) were vulnerable to population-level effects (Katzner et al., 2020), especially non-local, nocturnal migrant species.

Information on the factors influencing collision risk and fatality estimates is scarce. In relation to species-specific factors, songbirds (Passeriformes), pigeons, and doves (Columbiformes) seem to suffer the highest mortality rates (Kosciuch et al., 2020; Smallwood, 2022). These species groups are generally abundant in the studied regions, and they share several traits (e.g., ground dwelling and inhabit anthropogenic landscapes). Migratory and aquatic birds also suffer high collision rates, although their contribution to mortality rates seem to vary with the occurrence of water bodies, wintering grounds and migration routes in the surroundings, suggesting that their collision risk is context-dependent (Walston et al., 2016; Kosciuch et al., 2020). Moreover, collision rates vary with phenology, being more frequent in fall and winter, coinciding with the higher abundance of birds following the breeding season and with migratory movements to the wintering grounds (Kosciuch et al., 2020). We found no studies evaluating the effect of site descriptor factors on fatality rates, and only one study addressed PV park attributes, showing a negative effect of PV capacity (Kosciuch et al., 2020).

The mechanisms underlying collision events are poorly understood. The most discussed hypothesis is that aquatic insects might mistake solar panels as natural water bodies (i.e. "lake effect" hypothesis) due to polarization of light reflected, which they used to locate water bodies for egg-laying (Horváth et al., 2010), turning into ecological traps (Horváth et al., 2009, 2010). More recently, it has been observed that solar panels can polarize not only visible light (390–700 nm), but also ultraviolet light (<380 nm), which is also a cue used in habitat selection for some aquatic insects (Fraleigh et al., 2021). Although the "lake effect" hypothesis has been widely exposed as a potential mechanism underpinning also bird and bat collisions (PV panels might provide analogous reflections of echolocation calls than water bodies; Greif & Siemers, 2010; Russo et al., 2012), there is little evidence proving this causal factor. Other potential explanation widely discussed is that insectivorous wildlife might be attracted to PV panels due to the higher abundance of insect prey (Diehl et al., 2016; Horváth et al., 2010), being stranded, injured, or killed at solar panels (Smith & Dwyer, 2016), but we have found no evidence for this hypothesis either. Further research is needed to test these hypotheses and to understand how these organisms perceive solar energy infrastructures.

3.6 | Mitigation hierarchy: From prevention to compensation

The implementation of PV facilities must follow the mitigation hierarchy procedure to avoid, reduce, and ultimately offset its negative impacts on wildlife. First, proactive land-use planning is essential, considering ecological and conservation attributes in deciding project locations that secure wildlife habitat preservation as well as the maintenance of other important land-uses such as agricultural land (Hermoso et al., 2023). Land sparing (i.e., the promotion of PV sprawl in urban areas or degraded lands) has been proposed as an alternative to mitigate habitat loss and soil degradation in natural and semi-natural habitats (DeVault et al., 2014; Hernandez et al., 2015; Kim et al., 2021; Lambert et al., 2021) rather than PV construction in remote areas, which requires additional transmission infrastructure with further impacts on biodiversity (Biasotto & Kindel, 2018).

In a second step, PV projects should contemplate minimization measures for those impacts that are unavoidable. The concept of *conservoltaic* consists on the combination of PV energy production and biodiversity conservation (Nordberg & Schwarzkopf, 2023). For instance, lessening vegetation disturbance during construction or the application of habitat restoration practices might help to combat desertification (Xia et al., 2022), alleviate soil degradation (Ormeño et al., 2016), or minimize habitat loss (Armstrong, Kulikowski, et al., 2021; Cypher et al., 2021; Gerringer et al., 2022), and targeted vegetation management during operation can create habitat islands for wildlife (Blaydes et al., 2021, 2022; Guiller et al., 2017). The installation of permeable security fencing or the translocation of sensitive species outside the project's footprint are other potential mitigation measures (Agha et al., 2020; Brand et al.,

1755263x, 2024, 4, Downloaded from https://conbio.onlinelibrary.wiley.com/doi/10.1111/conl.13025, Wiley Online Library on [01/07/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

2016; Cypher et al., 2021). Another emerged land sharing strategy is the co-location of PV energy with agricultural practices, such as crop cultivation or animal husbandry (so-called "*agrivoltaic systems*"), which promises to maximize food and energy production while minimizing the impacts on ecosystems (e.g., water use efficiency and erosion prevention; Barron-Gafford et al., 2019; Hernandez et al., 2019; Vaverková et al., 2022), even increasing PV panel efficiency through dust accumulation and cooling (Hernandez et al., 2019; Nordberg et al., 2021). However, the potential of this land sharing strategy to mitigate impacts on biodiversity and to be considered within the mitigation hierarchy deserves more attention. Overall, if properly managed, PV farms have the potential to promote important ecosystem services (e.g., carbon storage and biological pest control; Armstrong, Brown, et al., 2021; Barron-Gafford et al., 2019; Randle-Boggis et al., 2020; Semeraro et al., 2018; Walston et al., 2018, 2021, 2022) and even to enhance or restore previous ecosystem goods and services in degraded lands (Hernandez et al., 2019). However, further research is needed to empirically test these potential synergies and to verify whether they are generalizable or not to all climatic-environmental contexts (Figure 5).

Mortality due to collision (both with power lines and PV panels) is another impact to mitigate in PV facilities. First, the widely known power line collision mitigation measures should be implemented (Bernardino et al., 2018). On the other hand, PV panel collision mitigation has been studied in aquatic invertebrates, suggesting that specific panel designs might be effective tools to disarm the panel-induced ecological trap (e.g., employment of a white, non-polarizing gridding; Black & Robertson, 2020; Horváth et al., 2010) and matte colors or anti-reflective coatings (Száz et al., 2016; Horváth et al., 2020; but see Blaho et al. [2014]). Further research is needed to find effective tools that mitigate collision impacts across taxa. Finally, offsite compensatory mitigation is employed as last resort to offset for unavoidable impacts, including land acquisition and the restoration of off-site habitats. We have not found any reference evaluating the effectiveness of these measures in PV facilities specific contexts, but it is recommended to use the available scientific knowledge on similar conservation strategies so that they can be conveniently designed and implemented, always supported by a monitoring of their effectiveness to achieve adaptive management.

3.7 | Conclusions and research gaps

Research on PV impacts on biodiversity have not increased proportionally to its development, with a significant knowledge deficit compared to other currently less widespread energies, such as wind energy (e.g., Marques et al., 2014; Nazir et al., 2020; Peste et al., 2015; Powlesland, 2009; Wang et al., 2015; Wang & Wang, 2015). Besides, there is a notable decoupling between PV development and progress of research on its impacts by region: although PV capacity is concentrated in Asia and Europe (ca. 59% and 22%, respectively), where the greatest conflicts with conservation areas occur (Rehbein et al., 2020), most of the knowledge on PV impacts comes from North American contexts (48%). This inevitably leads to a bias in the current knowledge about PV impacts (41% in deserts), which might not be extrapolated to other environments like farmland, where most of the PV capacity is sited (Kruitwagen et al., 2021). We detail below the *main conclusions drawn* and the *knowledge gaps* where research efforts should be invested so that biodiversity conservation can keep up with the accelerating development of this renewable energy:

- **Adaptive, collaborative strategies to avoid and compensate PV impacts.**
  The urgent call to combat the impacts of climate change makes the advance of PV energy inevitable. However, given the lack of empirical evidence found in this review for some PV impacts and mitigation measures (see Figure 5), the development of PV should be accompanied by adaptive planning and management, applying an iterative process where every new facility is accompanied by extensive monitoring, contributing for the acquisition of new knowledge that will be applied in future installations in close collaboration with stakeholders (Köppel et al., 2014). Further research is needed on: 1) wildlife use of PV facilities; 2) the impacts of specific configurations (e.g., landscape context); and 3) the effectiveness of management and mitigation/compensation schemes applied within and outside the PV facilities to maximize the benefits on biodiversity and ecosystem services. This knowledge is essential to identify optimal locations and land sharing opportunities of 'conservoltaic' systems (Nordberg & Schwarzkopf 2023). Lastly, the increasing efficiency of PV panels allows foreseeing an optimization of land surface occupied by facilities.
- **Need for diversification of environmental contexts and ecosystem components.**
  Most information available on the impacts of PV comes from desert ecosystems (41%), but there is a lack of research in grasslands and farmland. Moreover, only 80 studies reviewed have focused on specific species or groups of species, even in regions with good scientific knowledge of species ecology and threats like the EU where 76 species (mainly birds and reptiles; 48%

1755263x, 2024, 4, Downloaded from https://conbio.onlinelibrary.wiley.com/doi/10.1111/conl.13025, Wiley Online Library on [01/07/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

and 38%, respectively) included in the Birds and Habitat Directives are reported threatened by solar power development (European Environment Agency, 2023). Given that most PV impacts are context-dependent, future research efforts should be invested in those contexts and ecosystem components for which the greatest knowledge gaps have been found (e.g., microclimate impacts on agroecosystems, grasslands, or shrublands in continental climates or the effectiveness of agrivoltaics in arid and continental climates; Figure 5), diversifying environmental conditions and prioritizing those species that are more threatened by PV development.

- **Lack of standardized and robust sampling designs**. A large portion of the studies were carried out on a single PV project (53%), and preconstruction estimation of baseline situations was rarely reported (8%), with only two studies employing a strict BACI framework. There is a need to use comprehensive BACI designs that provide critical information on the direct responses of sensitive wildlife, including a large number of years and facilities (i.e., long-term and large-scale studies) as well as preconstruction and control-site data for interpreting postconstruction changes. Moreover, the employment of standardized protocols—especially for collision studies—would allow findings to be comparable across contexts, opening the way to more robust and generalizable conclusions (Conkling et al., 2021).
- **Lack of knowledge regarding the cumulative and synergistic ecological impacts.** Recent studies have proven that medium-sized PV plants result in higher loss of seminatural habitats than large-sized PV plants, probably due to more strict environmental impact assessment on mega-solar PV facilities, which might lead to the fragmentation of large projects (Kim et al., 2021). The scattered distribution of small facilities might result in a high cumulative environmental impact that would not be detected by independent assessments, supporting the need for cumulative and synergistic environmental impact assessments (Serrano et al., 2020).
- **Disentangling the mechanisms underlying wildlife collision with PV panels is mandatory to design effective mitigation measures.** There is an urgent need to identify the species (e.g., morphological and local abundance), site (e.g., landscape context), and PV facility (e.g., size) specific factors determining collision events to improve our understanding of this process and properly design mitigation measures. In addition, more research is needed to understand how species perceive PV facilities in relation to surrounding landscape elements and the mechanisms underpinning maladaptive behaviors such as the attraction to PV panels suffered by some taxonomic groups (Chock et al., 2021). Lastly, to properly disentangle these mechanisms, an accurate quantification of casualty estimates is mandatory, which should be corrected by all bias sources when counting carcasses, including imperfect detection and carcass disappearance due to decomposition or removal by scavengers, as well as the underlying potential factors influencing these bias sources (e.g., vegetation structure, carcass age, carcass size, and observer) (see Gómez-Catasús et al. [2021] for an example with power lines).

ACKNOWLEDGMENTS

We thank Gerald Puig for his help with the design of the graphical abstract summarizing the impacts of PV energy. We are also grateful to Núria Pou and Anna Farràs who were in charge of elaborating the "Observatory of Scientific Literature Related to Photovoltaic Solar Energy and Biodiversity". This research is a contribution to the Steppe-Forward Chair (UAM-CTFC-TotalEnergies). Julia Gómez-Catasús was funded by the Steppe-Forward chair (UAM-CTFC-TotalEnergies) and a Margarita Salas postdoctoral fellowship (CA4/RSUE/2022-00205) provided by the Spanish Ministry of Universities and Universidad Autónoma de Madrid (Spain).

CONFLICT OF INTEREST STATEMENT

The authors declare no conflicts of interest.

DATA AVAILABILITY STATEMENT

The dataset and all code for figures and analyses in this manuscript will be archived on a public repository such as Github.

Abstract: Agrivoltaic systems, which consist of the combination of energy production by means of photovoltaic systems and agricultural production in the same area, have emerged as a promising solution to the constraints related to the reduction in cultivated areas due to solar panels used in agricultural production systems. They also enable optimization of land use and reduction in conflicts over land access, in order to meet the increasing demand for agricultural products and energy resulting from rapid population growth. However, the selected installation configurations, such as elevation, spacing, tilt, and choice of panel technology used, can have a negative impact on agricultural and/or energy production. Thus, this paper addresses the need for a review that provides a clear explanation of agrivoltaics, including the factors that impact agricultural and energy production in agrivoltaic systems, types of panel configurations and technologies to optimize these systems, and a synthesis of modelling studies which have already been conducted in this area. Several studies have been carried out in this field to find the appropriate mounting height and spacing of the solar panels that optimize crop yields, as this later can be reduced by the shade created with the solar panels on the plants. It was reported that yields have been reduced by 62% to 3% for more than 80% of the tested crops. To this end, an optimization model can be developed to determine the optimal elevation, spacing, and tilt angle of the solar panels. This model would take into account factors that influence crop growth and yield, as well as factors that affect the performance of the photovoltaic system, with the goal of maximizing both crop yield and energy production.

1. Introduction

Of all natural resources, water, energy, and food are the most essential to sustain life on earth [1,2]. Water, energy, and food share common challenges of limited accessibility, increasing global demand, and sustainability constraints [3]. Moreover, these essential resources are expected to face a significant surge in demand due to rapid population growth, in order to meet the basic needs of the population [4]. Indeed, according to UN projections, the world's population will increase from 8.5 billion in 2030 to 9.7 billion in 2050 and reach about 10.4 billion in the 2080s [5]. Moreover, according to the FAO [6], agricultural production will have to be doubled to meet demand in developing countries, while these countries will have to face constraints related to increased competition for access to water and energy and the impacts of climate change. To this end, it has been predicted that production needs to be increased by 60% [7] or even doubled to meet the

population's needs in the face of population growth and changing diets [8]. The major constraints to agricultural development are related to access to water and energy for irrigation. Irrigation is the controlled delivery of water for agriculture through artificial systems to meet water needs not met by rainfall for crop growth and development [9]. Sophisticated and water-efficient irrigation techniques have significantly increased energy requirements. The energy cost required to operate these systems compromises the viability of many irrigation networks [10]. To this end, new perspectives have emerged, namely the use of renewable energy in irrigation systems as an alternative to pumping systems powered by fossil fuels [11,12], bearing in mind that the high cost of fuels and the lack of electricity, especially in rural areas, are factors that negatively affect the functioning of irrigation systems [13]. Solar PV panels are utilized due to their environmental benefits, cost-effectiveness, and ability to address issues of fossil fuel scarcity and unavailability in certain regions. The energy sector has seen significant and accelerated progress in terms of innovations observed with the use of renewable energy. A total of 20% of global energy consumption in the world comes from renewables, and about 30% of investment in renewables is in wind power and 60% in solar power [14].

Solar photovoltaic energy has emerged as an environmentally friendly and economically viable alternative with lower energy costs [9,13]. In addition, photovoltaic panels are among the leading renewable energy technologies in the world and have seen continuous decrease in costs over the years. It is predicted that 25% of the electricity needed in 2050 will come from solar PV, with a reduction of 4.9 Gt of CO_2 corresponding to a 21% decrease in emissions in the energy sector [15].

Nevertheless, using solar panels to pump water for irrigation can significantly reduce cultivated areas due to the space occupied by the solar panels [16]. One solution to this problem is, therefore, the adoption of agrivoltaic systems. These dual-use systems involve raising the PV panels to use the space under the panels for agricultural purposes [17]. Thus, this system reduces the issue of conflicts regarding land access [18,19]. Agrivoltaics can also significantly reduce the constraints on access to electricity for populations. According to Jamil et al. [20], agrivoltaic practices on only 1% of cultivated land can satisfy the energy demands of at least one-quarter of the population in Canada. However, solar panels installed in an area can impact microclimate, temperature, and solar radiation distribution, water, biodiversity, air quality, and ecosystem-energy balances [21,22]. Given the impact of solar panels on crops, several studies have investigated the optimal panel layout to maximize crop production in the presence of the panels. These studies have mainly focused on determining the height and spacing of the panels to create a suitable environment for crops under the panels. However, these arrangements were determined through studies that primarily focused on the irradiation received under the PV array and the resulting shading on the crops, with specific arrangements being tested [23–25]. Other studies have examined panel orientation through field experiments [26]. Kim et al. [27] worked on modeling the hybrid performance of an agrivoltaic system in South Korea. Their model focused on the variation of the amount of electricity generated and the crop yield obtained based on the incident radiation, as well as the impact of atmospheric conditions on the radiation. Three different shading ratios were tested to compare the levels of shading (21.3%, 25.6%, and 32%), with the shading ratio calculated as the panel area divided by the system area. A height of 5.42 m was used for all three tests and the shading rate was based on the density of the modules. However, there is still limited research and decision-making tools to determine the appropriate configuration for the crop being grown. Thus, modeling studies to determine the optimal height, spacing, and inclination of the panels to maximize growth and development for a given crop and the performance of the panels would help users to find the right configuration.

In order to achieve our purpose, this review focuses on a clear explanation of agrivoltaic systems and the functioning of its different components, as well as the factors that affect each of them. We believe that a large literature review will allow us to identify the most important parameters to consider for the design of the optimization model. The present paper will also summarize the studies carried out on the possible configurations of agrivoltaic systems, as well as the overall successes and failures of the arrangements and orientation.

2. Definition and Terminology

An agrivoltaic practice is a concept that originated in 1980 [23]. It is defined as a land-use concept that directly integrates solar energy production and agricultural activities, which are practiced under the photovoltaic field installation, both of which are highly dependent on sunlight [28]. Agrivoltaics has several names that vary according to region and application, such as "dual-use", "co-location", "agri-PV", "agri-solar", "solar sharing", "pollinator-friendly solar", etc. [29]. Indeed, it is a symbiotic relationship in which both activities interact directly and benefit from this co-location [30]. This practice leads to synergies by optimizing the potential offered by both production systems [31], especially in agroforestry systems [32].

Agrivoltaic practices can be carried out in different ways depending on the activities carried out by the population in a given area (Figure 1). Agrivoltaic applications represent the combination of energy production with (i) agricultural production in the field or (ii) agricultural production in greenhouses or livestock rearing, or (iii) provision of ecosystem services through vegetation management or (iv) different agricultural practices combined [29].

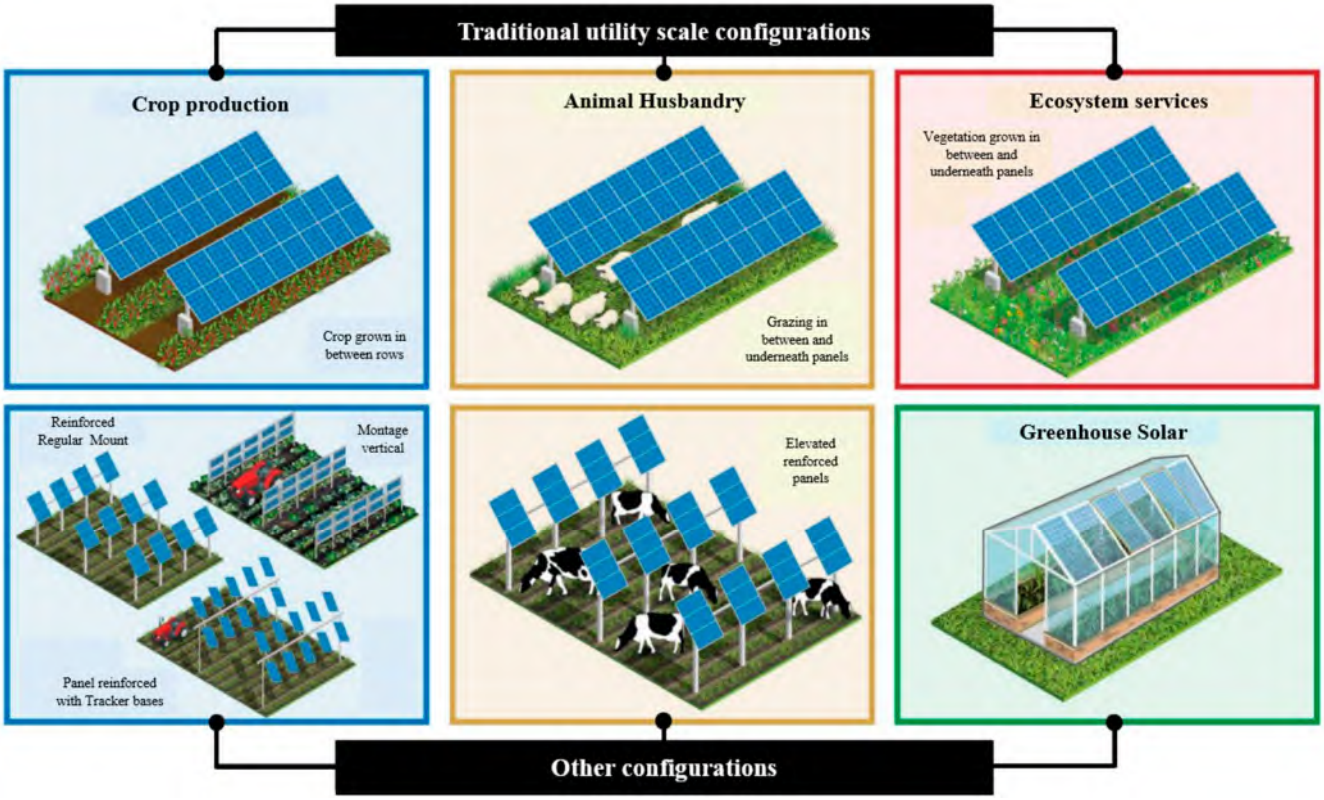

Figure 1. The different agrivoltaic systems [29].

Agrivoltaic technology has an important role in strengthening the water–energy–food relationship [33], given the increasing future need for energy and food production in the face of population demand [34]. Indeed, one of the constraints on the development of PV systems is the increased competition for land due to high population growth and rising food demand [35]. Although land resources are limited, the need for energy and food is increasing, leading to increased competition for land between the two sectors. In response to this growing competition, agrivoltaics was conceived to keep the two activities in balance [36]. Due to their dual use, agrivoltaics would mitigate competition for space and offers the possibility to install large PV systems, while keeping the land accessible for food production [37]. Thus, agrivoltaics system reduces land constraints concerning the placement of solar PV plants for electricity generation [38]. Moreover, this system has proven to be a particularly effective way to increase land use efficiency [32]. Land use efficiency is determined by the so-called parameter Land Equivalence Ratio (LER). The method of measuring land use in integrated agricultural and electricity production systems was originally derived from the intercropping method applied in the farming sector to increase land yield and total income [39]. The LER is a function of the area of the PV system and the total area needed to meet the agricultural and electricity production of the system [40]. Agrivoltaic systems can increase overall land productivity by 35–73%, thus they avoid using land solely for energy production at the expense of agricultural production [41]. According to Lee et al. [42] and Weselek et al. [31], agrivoltaics can increase land productivity by 60–70%, and for Dinesh and Pearce [38], it can increase the economic value of land by more than 30% by minimizing yield losses due to shading effects through appropriate crop selection. According to Trommsdorff et al. [43], land use efficiency varies depending on time and climate. In 2017, the Land Equivalence Ratio (LER) in Germany indicated an increase in land productivity from 56% to 70%, and this value reached 90% during the dry and hot summer of 2018. Abidin et al. [39] reported that applying agrivoltaics to less than 1% of the world's cultivated land could offset the global energy demand. Although agrivoltaics may reduce the efficiency of electricity generation or agriculture when viewed in isolation, studies have shown that the synergy between the two activities can lead to increased overall efficiency. For example, the combination of two hectares of land (1 ha of crops and 1 ha of solar panels each considered individually) corresponds to 100% of crops and 100% of solar energy. However, the use of agrivoltaics in two hectares of land corresponds to 160% cultivation and 160% energy (i.e., 80% of crop and 80% of energy in only 1 ha of land) [39].

As reported by Trommsdorff et al. [43], Formula 1 is used to calculate LER. However, Formula (2) can be used to take into account the high land loss due to the surface occupied by the mounting structure of the solar PV panels.

$$LER = \frac{Yeild_x(dual)}{Yeild_x(mono)} + \frac{Yeild_y(dual)}{Yeild_y(mono)} \quad (1)$$

$$LER = \frac{Yeild_x(dual)}{Yeild_x(mono)} + \frac{Yeild_y(dual)}{Yeild_y(mono)} - 8.3\% \quad (2)$$

x is the cultivated crop and y is the electricity.

3. Solar Panel Installation Techniques to Optimize Agrivoltaic Systems

3.1. Classification of the Different Agrivoltaic Installations

The module configurations in agrivoltaic systems can be categorized into elevated and inter-row systems. The modules are installed above the crop at more than 1.8 m in elevated systems. Growing crops under elevated solar panel installations typically leads to a decrease in the amount of solar radiation they receive, which can cause shading and reduced exposure to sunlight. The main crops used in this type of agrivoltaic system are grapes, small fruit trees, and delicate vegetables. In contrast, inter-row PV systems are systems in which agricultural production is usually carried out in the space between the rows of

panels. The distance between two consecutive rows of the panels can be considerable in this type of installation to facilitate the passage of large agricultural machinery. The most common crops in inter-row solar systems are grasses, hardy vegetables, and higher-value horticultural crops [29]. The different configurations are established to compare their impact on the level of shading created by the panels and their consequences on crop yields to determine the optimal density for an agrivoltaic installation [44]. Another way to increase the efficiency of a PV system is to install double-sided PV panels [45]. Figure 2 summaries the different configurations.

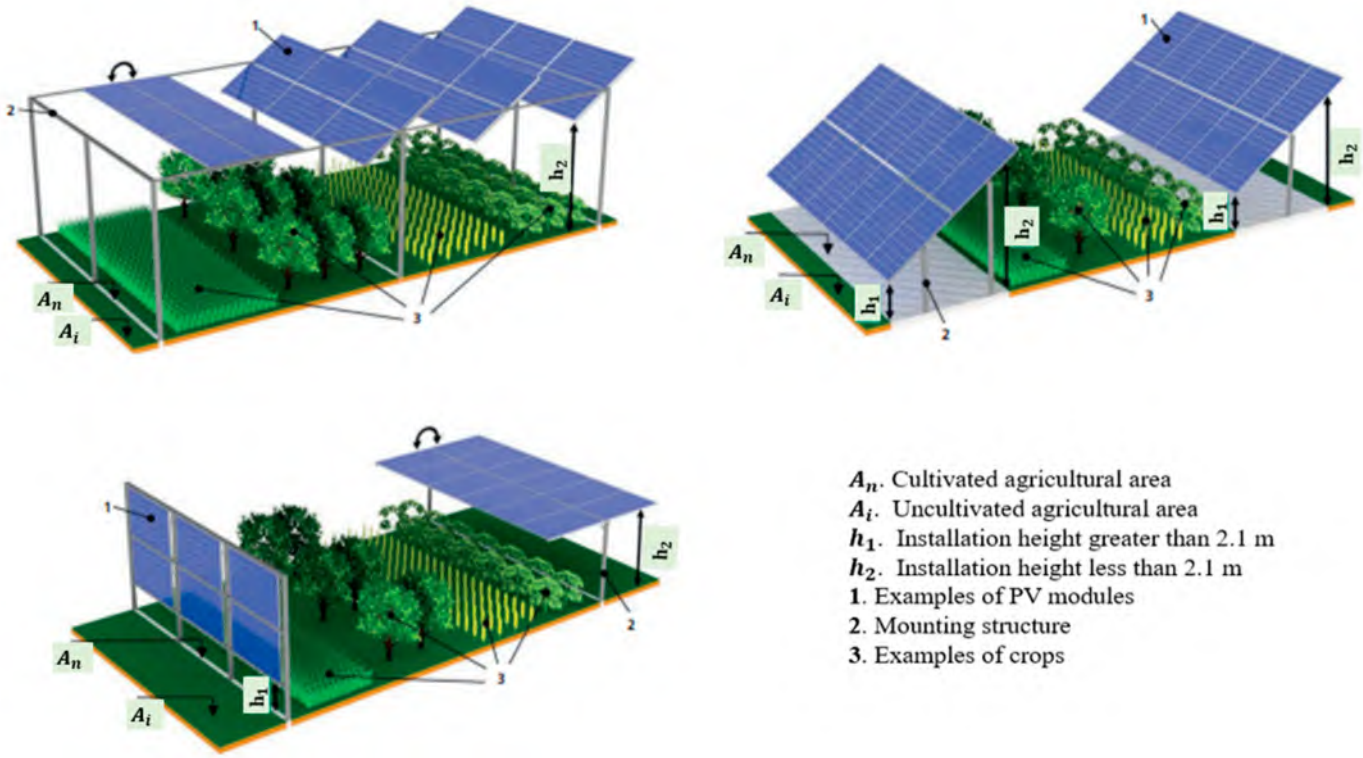

Figure 2. Overview of different configurations of agrivoltaic installations [44].

Several configurations and technologies have been developed and tested to optimize production in agrivoltaic systems. Therefore, the installation must meet the requirements of both the crop and the photovoltaic panels, which can be achieved by using optimal panel spacing and installation height that also allows the passage of agricultural machinery and appropriate panel technology [44]. Macknick et al. [46] have identified three types of approaches for the implementation of agrivoltaic systems: (i) the energy production approach, which focuses on optimizing the solar energy produced (thus minimizing changes in standard solar development practices), while cultivating between and/or under the panels, (ii) the agricultural production approach which focuses on optimizing biomass production (minimizing changes in existing vegetation management activities), while taking energy production into account, and (iii) the integrated agricultural and energy production approach (incorporating vegetation and energy priorities into system design).

These approaches are based on implementing one of the two installation techniques: open agrivoltaic systems, in which the PV module are installed at the ground level via support, and closed agrivoltaic systems, in which the modules are installed on greenhouses, thus serving as a cover [44]. However, only open agrivoltaic systems are considered in this paper. For this purpose, a general classification of the different agrivoltaic systems is proposed in Figure 3.

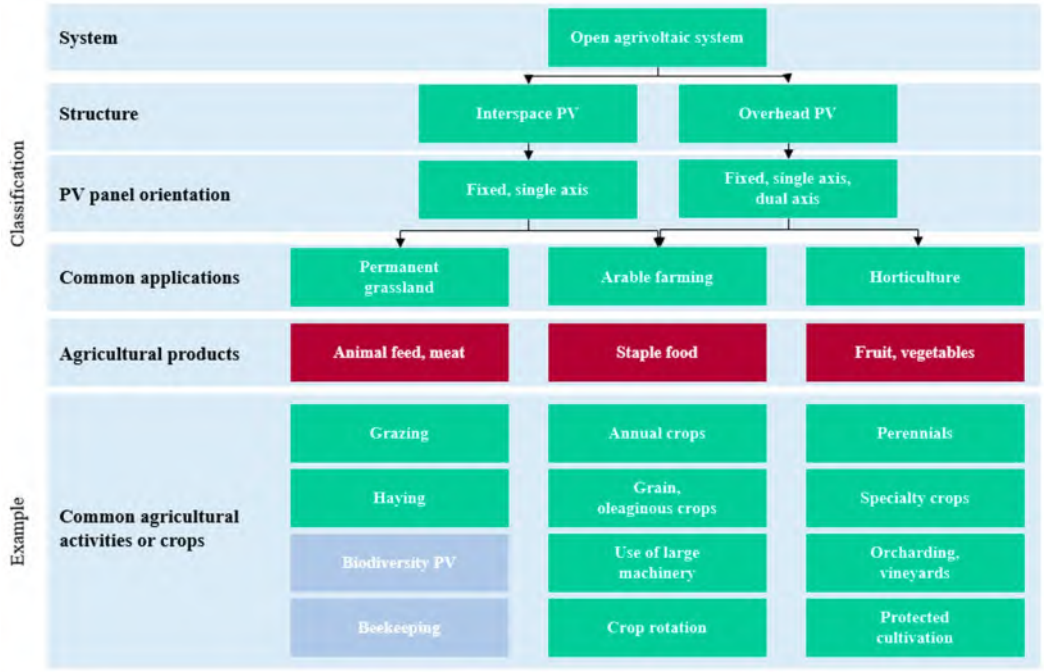

Figure 3. Summary of different agrivoltaic field systems [44,47].

3.2. Installation Techniques to Optimize the Agrivoltaic System

3.2.1. Mounting Height or Overhead of Agrivoltaic Systems Installation

The first agrivoltaic installation in the world was developed by Goetzberger and Zastrow at the Fraunhofer Institute (Germany) in 1980. It employed a height of 2 m and a spacing of 6 m between panel rows [23]. Since then, several studies have been carried out to determine the optimal elevation and spacing of solar photovoltaic modules to maximize energy and agricultural production. The ability of crops to grow and develop underneath PV modules raises structural issues in the case of aerial systems [44]. The height of the panels is an essential factor in the success of the various agrivoltaic practices. However, there are no recommendations for the panels' ideal height for an agrivoltaic installation. The height of the PV panels depends on several factors, including the geographical location of the site, the crop to be cultivated, the soil types, and financial resources. Thus, the height of the panels defines the crop to be grown on the site, the location of the crops in the systems (between the rows of panels or under the PV panels), and the equipment that can be used. Moreso, the solar panels installed in the agrivoltaic systems can have different configurations depending on the climate and soil to protect the structures from certain climatic hazards, namely high winds and freezing. For this purpose, a height of 1.8 m of the tubes supporting the PV panels is considered the minimum viable height for vegetable production under the panels. However, a tube height of 2.4 m is preferable for crops. This is because crops are grown between rows of panels at heights below 1.8 m, except for low-lying crops that appreciate shade. The elevation of the modules promotes a more even distribution of sunlight under the solar PV panels. In addition, these higher installations also allow the movement of equipment and people under the modules [29].

According to Trommsdorff et al. [44], overhead systems should be mounted at a minimum height of 2.1 m from the ground. In 2004, agrivoltaic systems started to be installed in Japan with installation heights of 3 m [31]. Dupraz et al. [24] used a 4 m elevation to assess the impact of this configuration on crop yields at Montpellier in 2010. This height was chosen to ensure access to large agricultural machinery on the site. In Germany, the impact of shading of the panels on crops was studied in 2016 by installing the PV panels at a distance of 5 m from the ground. In the USA, a 3.3 m high system was installed over the same period to assess the impact of agrivoltaic systems in arid environments [33]. Kim et al. [48] investigated the effect of agrivoltaic systems in South Korea using an

elevation of 5.2 m. Several studies were undertaken involving a range of configurations of agrivoltaic systems on different crops [28,38,49–59]. In addition, standard heights of solar panels can be used for sheep grazing whereas higher panel heights are required for cattle grazing [29]. Figure 4 gives two example of elevated agrivoltaic installation.

Figure 4. (**a**) Panels installed at the height of 4 m in Montpellier © Dupraz, (**b**) Panels installed at the height of 5 m in Germany © Fraunhofer ISE [33].

For traditional industrial-scale solar installations, minimal spacing is required between rows to avoid the shading of one onto another, but spacing between PV modules of a same row is not necessary. For an open agrivoltaic system, the spacing between rows on the one hand and the spacing between modules in the same row on the other hand must be carefully determined according to the type of crop. A wide panel spacing increases the capacity and uniformity of solar radiation penetration to the crop, thus reducing the impact of shading from the panels. Spacings tested ranged from 0.2 m [29] to 6.4 m [50]. A typical image concerning the spacing between modules is depicted on Figure 5. The spacing between rows of panels increases the efficiency of elevated agrivoltaic systems (Figure 6). In addition to enhancing the uniformity of solar radiation distribution to the crops, this configuration also increases the number of crop rows under the panels, facilitates the movement of large farm machinery, and increases the space available for farm workers. The spacing between rows in the aerial systems tested in the field ranged from 0.71 m [55] to 9.5 m [58].

Figure 5. Panels spacing for an experiment in the USA [29].

Figure 6. Spacing between rows of panels allowing movement of farm machinery under the PV panels © Fraunhofer ISE [44].

Another method of optimizing elevated agrivoltaic systems is to use an optimal tilt angle and orientation to increase the yield of the solar panels and the crops grown under them (Figure 7). Various tilts and orientations have been tested for different locations for fixed installations. According to Trommsdorff et al. [44], solar tracking modules allow for more flexible light management under the panels. The process of tracking PV systems involves installing a mechanical system that can adjust the orientation and tilt of the modules at different times of the day, with the goal of optimizing energy production. Two categories of solar tracking systems are used: single-axis trackers and dual-axis trackers. In the first configuration, the PV module array tracks the sun horizontally according to its angle of incidence (altitude) or vertically according to its orbit (azimuth). The second configuration combines the two, producing a more significant amount of energy. These mobile systems optimize crop yields through greater light availability during critical growth periods. In addition, the flexibility of the tilt angle provides constructive protection against hail or extreme radiation by adjusting their orientation as required.

(**a**) (**b**)

Figure 7. (**a**) Single-axis solar tracker module [44] and (**b**) dual-axis solar tracker module [60].

One of the main constraints of installing aerial agrivoltaic systems is the high investment and maintenance cost. The wide spacing of the panels can create favorable conditions for crop growth and development, but it leads to a reduction in energy density due to the reduced number of panels installed on the plot. Also, the spacing between rows of panels can increase the investment cost in areas with high land costs and limited land availability [29]. However, these systems face shading constraints [33], so these installations are favorable for viticulture. Moreover, dual-axis systems with large arrays of PV modules can

create shading under the panels, while other parts of the ground surface receive maximum sunlight [44].

3.2.2. Vertically Mounted Agrivoltaic Systems

The mounting of solar panels vertically to the ground is also a method of optimizing agrivoltaic systems (Figure 8). It consists of an installation technique in which the modules are oriented in the east–west direction, which has proved to be more efficient for permanent crops, or in the north–south direction, where energy production is a priority [61]. These systems require a significant distance between consecutive rows of vertical supports. For example, [62] studied vertical arrays using a 10 m spacing between the rows. A report by [26] showed that the yield of oats and potatoes decreased by 50% when the distance between rows was decreased in length from 20 to 5 m. In addition, [26] reported that 10% of the land near the panels does not have to be cultivated and can be used as ecological zones. Bifacial panels are widely used in these systems.

Figure 8. Vertical agrivoltaic installation with bifacial modules in Sued [62].

Vertical panels are favorable to crops as they allow a homogeneous distribution of sunlight, facilitate farm machinery movement, cleaning of solar panels, and access to crop rainwater. It is more economical, as it reduces the support cost, which is lower than that of aerial systems [39]. However, according to Katsikogiannis et al. [61], the constraint of its usage is the reduction in the electrical energy produced. Indeed, these systems allow for a 50% increase in LER and for a 33% reduction in electrical production compared to conventional single PV systems. According to Reagan and Kurtz [63], electrical production can be increased by 10–20% compared to traditional techniques by using a 2 m spacing between the supports, which results in a substantial reduction in crop yield [26].

Table 1 gives the strengths and weaknesses of the different installations.

Table 1. Summary of the strengths and weaknesses of the different installations.

Type of Installation	Strengths	Weakness
Inter-row systems	• Considerable space in this type of installation facilitates the passage of large agricultural machinery • Low investment cost	• Crop yield reduction due to uncultivated space

Table 1. *Cont.*

Type of Installation	Strengths	Weakness
Elevated systems with spacing between rows of panels	• Spacing between rows of panels and between panels enhance the uniformity of solar radiation • Can create crop protection in temperate zones • Crops under panels increase crop yields • Facilitates the movement of large farm machinery • Increases the space available for farm workers	• High investment and maintenance cost • Can create a shadow under the panels • Reduction in energy density due to the reduced number of panels installed
Tracking systems	• Greater light availability during critical growth periods • Constructive protection against hail or extreme radiation	• High investment and maintenance cost • Dual-axis systems with large arrays of PV modules can create irregular distribution of light to crops
Vertical mounting systems	• Homogeneous distribution of sunlight • Facilitate farm machinery movement • Cleaning of solar panels • Access to crop rainwater • Reduced cost of the installation structure • Increased electricity production for small distances between installation structures	• Reduction in agricultural production for small distances between installation structures (2 m) • Reduction in electricity production for large distances between the installation structures (20 m)

4. Factors Affecting the Operation of Photovoltaic Systems

Agrivoltaics relies mainly on the distribution of sunlight for photovoltaic energy production and photosynthesis. Therefore, the solar radiation spectrum is shared between the solar panels and the crops underneath [34]. Indeed, the principle of photovoltaics is the conversion of sunlight into direct current electricity. This production of electrical energy is the result of the absorption of photons from photovoltaic cells exposed to the sun, which in turn release free electrons to produce electrical energy [64–68]. Furthermore, the solar cell is the main component of the solar photovoltaic system [69].

Solar cells can be grouped into four generations based on the specific constituent elements and their periods. The first generation of PV cells is based on silicon wafer technology, including monocrystalline and polycrystalline cells [70]. The cells have an efficiency of between 18% and 20%, depending on the quality of the silicon used. However, according to Blakers et al. [71], the maximum efficiency reported for polycrystalline silicon cells could be as high as 26–27%. The theoretical maximum efficiency of monojunction silicon cells is around 30% and is called the Shockley–Queisser limit. The basic structure of these cells usually consists of a glass front and back cover, encapsulation layers, a solar cell matrix, and solder joints to electrically connect the individual cells [72]. Second-generation solar cells are thin-film cells that have a reduced maximum thickness of a few nanometers or tens of micrometers, compared to first-generation cells. This reduction in thickness helps to decrease the material usage and cost of silicon solar cells. These cells are made of two heterojunction layers squeezed between two contact layers. Efficiencies of 22.6% have been achieved with cadmium telluride (CdTe) thin films [73]. Third-generation cells consist of dye-sensitized solar cells (DSSCs), perovskite, and organic solar cells. DSSCs are limited by the synthesis of organic dyes and their chemical stability. For this reason, perovskite has been used as an alternative to DSSCs, and more than 21% efficiencies have been achieved in a very small area. The fourth-generation tandem solar cells are made of composite materials, consisting of polymers mixed with nanoparticles to have the properties of a single absorbing layer. The tandem solar cell is characterized by a top and bottom solar cell and an intermediate buffer layer. The upper GaAs cells absorb solar radiation, which is then transmitted to the Si of the lower cells [74]. The electrodes extract the generated charge carriers, and a photo-current flows through the thin buffer layer between the two solar cells [75]. The four generations mentioned are shown in Figure 9.

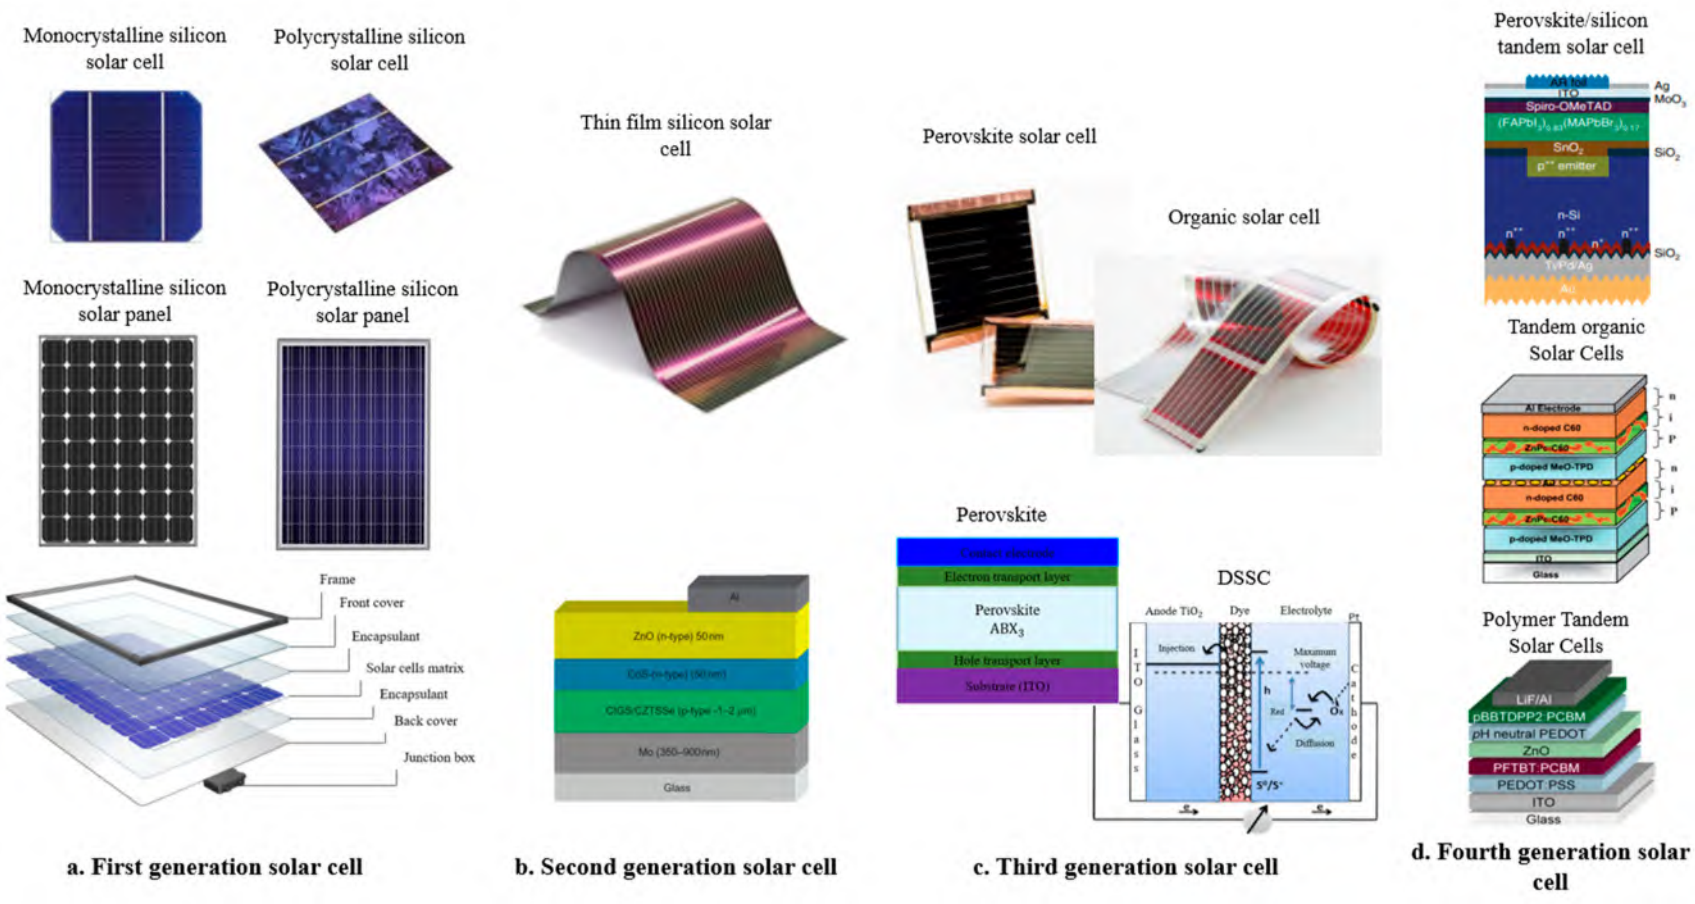

Figure 9. The four different generations of solar cells and their structures [74,76–80].

First-generation solar cells, namely monocrystalline and polycrystalline silicon-based cells, are the most commonly available in the commercial world [74]. According to Zhang et al. [76] and Rabanal-Arabach [77], 80–85% of the panels on the market belong to silicon technology.

In temperate regions with much sunshine, solar radiation is often too intense for some crops, especially in the summer. Shading screens are often installed in the systems to reduce the intensity of this radiation. These are semi-transparent solar panels [28,81,82]. Indeed, different opaque, transparent, and semi-transparent technologies are used in agrivoltaic systems and lead to different changes in sunlight availability throughout the day [29]. Bifacial panels are also widely used in agrivoltaic systems, as they use the light from the ground side (opposite side of the module) to generate electricity. Depending on the level of radiation on the back side, this can increase electricity production by up to 25% [44]. Agrivoltaic systems must be designed to grow appropriate vegetation depending on the available solar energy, soil, ambient climate, and other conditions. Therefore, the optimal conditions in agrivoltaic systems should be specific to the area where the system is implemented.

The PV module energy production mainly depends on the cells' temperature and the solar radiation. These parameters are related to the following factors: azimuth, tilt, latitude, solar declination, the slope, vertical shadow angle, hourly angle, zenith angle, elevation height, presence of vegetation at the bottom of the panels. The performance of a solar panel is determined by the amount of solar radiation it receives, whereas the temperature can create power losses (high temperature) or enhance the power (low temperature). The amount of solar radiation that the PV array receives changes depending on the geographical location, the sun's movement, the climatic conditions of the area, and the orientation of the panels [83]. Ideally, a photovoltaic installation should have the incident solar flux perpendicular to the array surface to maximize the panels' energy potential [84,85]. Thus, the optimal orientation must be determined due to the perpetual movements of the sun.

The orientation of the panels is determined through two parameters i.e., the azimuth and the tilt. The movement of the sun is a function of its elevation which depends on two parameters, namely the latitude and the solar declination. Furthermore, according to Jafarkazemi and Saadabadi [86], the azimuth angle of the surface, latitude, time of day, slope or tilt angle, day of the year, and incident radiation angle determine the amount of solar radiation received by the PV panels installed on a given area (Figure 10).

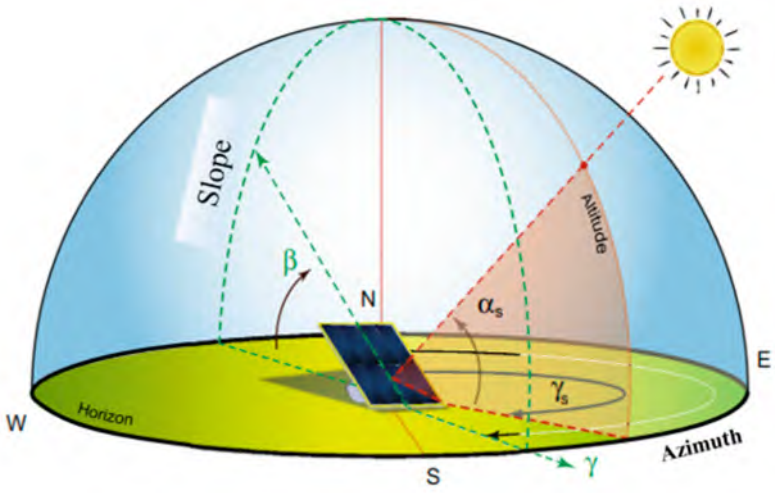

Figure 10. Factors affecting the performance of solar PV panels [87].

In particular, the electrical energy resulting from the transformation of the solar energy absorbed by the panels is strictly related to the slope (the tilt angle) and the azimuth angle [88]. The tilt angle (elevation angle) represents the angle formed by the horizontal

plane of the installation and the PV panels for a fixed structure [85,89]. A change in the tilt angle simultaneously leads to a change in the amount of radiation reaching the surface of the PV panels [89]. However, as a general rule, the tilt angle for a PV array installation is nearly equivalent to the latitude of the area [90,91]. The solar azimuth is the horizontal angle between the vertical plane normal to the surface and the vertical plane in which the center of the solar disc is contained, oriented in the north–south direction [91]. For this purpose, the azimuth values of 90°, 0°, +90°, 180° correspond to the positions east, south, west, and north of the panels, respectively [85,92]. Thus, the panels are oriented to the north in the southern hemisphere and the south in the northern hemisphere [93].

Other parameters that can likely affect the performance of photovoltaic modules are (i) the albedo, which is the amount of radiation reflected from the ground surface across the solar spectrum and (ii) the vertical shadow angle, sometimes referred to as the vertical profile angle, which is the direction in degrees of rotation of the center of the solar disc [91]. To these parameters, Oudrane et al. [94] and Nfaoui and El-Hami [95] added the hourly angle, which is a function of the daily spinning of the earth with respect to its axis, and the declination, which is the angle between the "center of the earth-sun" vector and the equatorial surface of the earth. Yilmaz et al. [96] considered in addition to these parameters the zenith angle which is the angle between the sun's direction and the vertical of the location.

In addition, the elevation height and the occupation of the surface where the PV array is installed can have an impact. These factors have been highlighted by Chemisana and Lamnatou [97], Ogaili and Sailor [98], Alshayeb and Chang [99], and Osma-Pinto and Ordóñez-Plata [100]. They evaluated the electrical energy generated by a photovoltaic array on rooftops using different elevations and different ground level supports. According to Alshayeb and Chang [99], the presence of vegetation at the bottom of the panels can be advantageous, resulting in an increase of 0.25 to 0.4% in the efficiency of the solar panels when the panels are installed at the height of 50 to 75 cm from the roof [100]. According to Chemisana and Lamnatou [97], vegetation below the panels leads to a decrease in ambient temperature that can cause an increase of 1.29–3.33% in the maximum power output of the PV array. Furthermore, Ogaili and Sailor [98] showed that the presence of vegetation could cause an increase in the energy output of 0.8% to 1.2% compared to a white or black colored substrate, respectively, when the panels were elevated at 18 cm from the roof.

5. Impact of Agrivoltaic Systems on Crops

5.1. Importance of Solar Radiation on the Process of Photosynthesis

Sunlight is the key factor in photosynthesis. Photosynthesis consists of the production of oxygen and glucose that crops can use for growth and development [101,102] as a result of the reaction between water and carbon dioxide absorbed through the stomata, which are small holes in the lower epidermis, and controlled by sunlight [103]. Equation (3) is a summary of the photosynthetic reaction.

$$6H_2O + 6CO_2 \overset{Solar\ energy}{\rightarrow} C_6H_{12}O_6 + 6O_2 \quad (3)$$

$$\Delta_rG^{o'} = +2870\ kJ/mol, \Delta_rG^{o} = +2875\ kJ/mol = \Delta_rG^{O''} \quad (4)$$

Photosynthesis can be broken down into two stages. The first step, called the light reaction, consists of the absorption of sunlight by the chlorophyll pigments [104], resulting in the production of electrons and protons, which are responsible for the production of adenosine triphosphate (ATP) and nicotinamide adenine dinucleotide phosphate (NADPH) at the thylakoid membrane [103]. The second step is the dark reaction in which NADPH and ATP generated in the light reaction is used to produce carbohydrate from CO_2 through the Calvin–Benson cycle in the chloroplast stroma [104–106]. Figure 11 gives an overview of the importance of light in the process of photosynthesis.

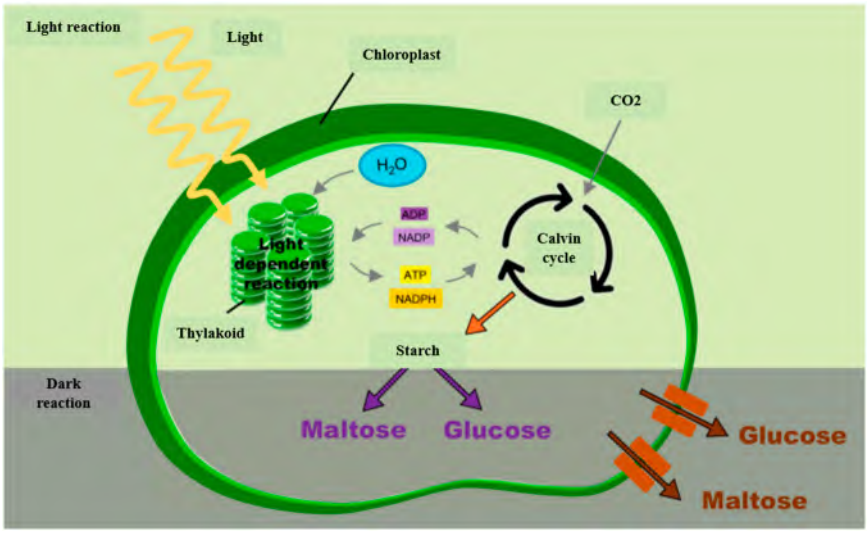

Figure 11. The overall process of photosynthesis at the chloroplast level [107].

Chlorophylls are the primary pigments in crop cells that absorb sunlight in the blue (450 nm) and red (650 nm) wavelengths and give the crop its green color. However, there are other pigments in crop cells, namely carotenoids, which absorb blue light and give the leaves their yellow color. Furthermore, the excitation of ions in the process of photosynthesis is driven by the absorption of specific wavelengths of light in the visible range [103], as shown in Figure 12.

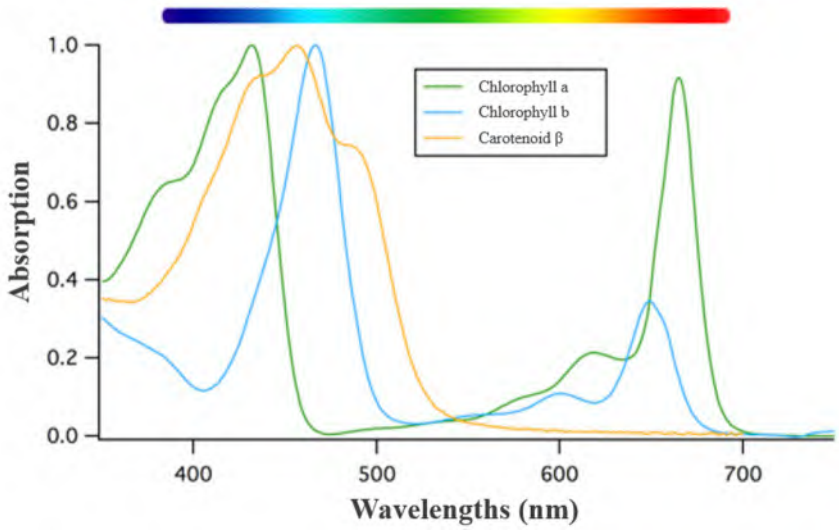

Figure 12. Basic absorption spectra of crops' main chlorophyll and carotenoid pigments [103].

Indeed, wavelengths from 430 to 500 nm are effective in chloroplast development and photosynthetic function [106,108]. In addition to promoting photosynthetic activity, wavelengths from 640 to 670 nm are necessary for leaf growth and crop biomass production [106,109]. Furthermore, according to Wang and Folta [110], the wavelengths 500–600 nm are of great importance in chlorophyll content, photosynthetic function, and consequently crop growth.

This part of the solar radiation of wavelength 400–700 nm is called photosynthetically active radiation and represents the part of solar radiation mainly used for photosynthesis [111,112]. However, the total proportion of solar energy in the photosynthetically active band represents only 48.7% of the average solar spectrum measured at the Earth's surface. At the same time, the chlorophyll pigment is considered as an imperfect radiation absorber

in the 400–700 nm band because it weakly absorbs solar radiation in the green band. Therefore, it is estimated that 90% of the radiation is photosynthetically absorbed by vegetation, and 10% is reflected [113]. According to Amthor [114], the solar radiation intercepted at the Earth's surface depends on the area's location, the presence or absence of clouds in the sky, and the sun's elevation. In addition, the fraction of incident solar radiation intercepted by crops is a function of leaf area and orientation. Furthermore, the total photosynthetically active radiation absorbed by chlorophyll pigments for a crop that has reached whole leaf area development is estimated at 92%.

5.2. Factors That Can Affect Crop Growth in Agrivoltaic Systems

Agrivoltaic systems are systems in which crops are grown, considering factors that may affect crop growth, including the level of shade, climatic factors, and water consumption [115].

Access to the limited amount of sunlight needed for the photosynthetic process is the main challenge for crop productivity under PV panels [24,116], as sunlight is the key factor playing a significant role in crop growth and development [117].

Touil et al. [118] reported that PV panels can cause a reduction of over 40% in the amount of solar radiation received by crops. A coverage rate of 50% or more can also hinder crop growth. For example, a panel-induced shading level of 50% led to a decrease in crop height and stalk diameter, and a decrease in net leaf photosynthesis rate, leaf specific weight, dry matter accumulation on leaves and stalks, and grain number of maize. To this end, the optimal level of shading to ensure energy requirements for photosynthesis consists of a level of photosynthetic photon flux density capable of both saturating CO_2 assimilation and favoring the stabilization of shading conditions and reducing photoinhibition [24].

Nevertheless, the shading induced by the photovoltaic field can be beneficial by reducing the amount of water lost through evaporation and therefore increasing water use efficiency [119]. To this end, these devices are favorable in drought-prone areas during hot periods, as they reduce crop water demands due to reduced evapotranspiration [38,53,54,120]. According to Yue et al. [121], agrivoltaic systems can increase soil moisture by 14.7% for fixed installations and 11.1% for mobile installations. Moreover, based on a study conducted by Adeh et al. [52], panels in agrivoltaic systems allow for more efficient water use (estimated at 328%) by maintaining higher soil moisture levels compared to soil moisture in a full-sun growing area. Barron-Gafford et al. [54] showed that the positive effect of agrivoltaic systems on water conservation is exacerbated by applying water to the crops based on a two-day irrigation frequency that maintains 15% higher soil moisture compared to the soil under full sun. However, although soil moisture remained higher under the panels, it was reduced by 10% based on a daily application of the crop's water requirements. Furthermore, studies conducted in dryland environments on the impact of agrivoltaic systems on specific crops showed that water use efficiency under the panels was estimated at 157%, 65%, and 12% for chili, tomato, and lettuce, respectively, for a 4 m panel elevation [50,118]. Furthermore, a simulation study by Elamri et al. [40] showed a reduction of less than 20% in the water requirement of lettuce as a result of the effect of panel shading.

The shading caused by the panels and the increase in soil moisture affects the microclimate of the area cultivated under the panels. Adeh et al. [52] established that the elevation of the PV panels by 1.2 to 2 m causes a considerable change in air temperature, relative humidity, and wind speed on the surfaces near the PV panels. In a study conducted in the USA on tomato cultivation, it was observed that the air temperature varied between 21.5 °C and 22.3 °C in the subplots cultivated in the open air, whereas it decreased to 19.8 °C under the panels (for an elevation of 2.2 m and a tilt angle of 18°). The rows had the highest average relative humidity at 79.38%, followed by sub-plots cultivated in the open air at 74.63%, and sub-plots located under the panels had an estimated humidity of 73.54%. The soil temperature was estimated to be 20 °C, 24.7 °C, and 25.6 °C under the PV panels, between the panel rows and the control, respectively. In addition, the wind

speed was lower (0.65 m/s) between the rows of panels, whereas it was 0.89 m/s in the open field [119]. According to Noor and Reeza [122], the microclimate under the panels varies differently depending on the area's climate and the land's topography. Their study in the tropics showed that the air temperature was the same in the open field and the higher and middle areas under the panels. However, it was higher in the areas of lower topography under the PV panels. Regarding relative humidity, these studies showed that relative humidity was higher under the PV panels, estimated at 65%, compared to 63.7% between the rows of PV panels and 53.5% in full sun.

The panels reduced the average soil temperature of 5.2 °C in summer with a minimum of 3.5 °C and a maximum of 7.6 °C, and an increase of 1.7 in winter in the UK [21,121]. Abu-Hamdeh [123] showed that the soil temperature under the panels recorded a decrease of 3.1 °C in arid zones and 1.1 in equatorial and temperate zones. Moreso, the soil temperature can vary depending on the installation technology. For example, the ground temperature under fixed panels was found to be lower than under mobile panels since the radiation intercepted by the panels is higher for mobile technologies [51,121]. Weinstock and Appelbaum [124] showed that agrivoltaic systems can lead to a reduction in soil temperature of 4 °C for fixed and 1.5 °C for mobile installations.

5.3. Impact of Solar Panels on Crops

The success of production in agrivoltaic systems is highly dependent on the choice of crops to be grown. Crops grown under PV panels are often subject to different climatic conditions than those grown in full sun because of the shading created by the solar panels. Furthermore, crops of different varieties of the same species may respond differently under the same conditions [29]. For this purpose, the impact of agrivoltaic systems on crops is summarized in Table 2, considering different crops and locations.

Table 2. Impact of photovoltaic panels on different crops in different localities.

Crops	Study Area	Height and/or Spacing or Shading Rate	Impact on Culture	Sources
Durum wheat	Montpelier, France	Height of 4 m Spacing 1.64 m (distance between the lower side of two consecutive panels) Tilt of 25°	• 11–29% reduction in dry matter • 8 to 11% reduction in yield	[24]
Lettuce and cucumber	Montpelier, France	Height of 4 m Tilt of 25°	• Reduction of evapotranspiration by 62% and 70% for lettuce and 73% to 81% for cucumber • Crop cover was significantly higher in the shaded treatments (150% between days 124 and 144)	[50]
Lettuce	Montpelier, France	Height of 4 m Two spacings: 1.6 m in full density and 3.2 m between rows in half density Tilt of 25°	• Crop axis under PV panels was 7.4 cm with 2.0 g dry matter per axis compared to 6.6 cm and 2.5 g per axis in full sun • Significantly reduced number of leaves in the shade • Increased leaf area	[49]
Lettuce	Kansas, USA state	Height of 4 m Two spacings: 6.4 m in half density and 3.2 m between rows in full density	• 42% reduction in yields for the 3.2 m spacing and 19% for the 6.4 m spacing in summer • No impact on yield for the 6.4 m spacing in spring but 21% reduction for the 3.2 m spacing	[38]

Table 2. *Cont.*

Crops	Study Area	Height and/or Spacing or Shading Rate	Impact on Culture	Sources
Chili and tomato	Tucson, USA	Height of 3.3 m above the soil surface at their lowest point Spacing of 1 m Tilt of 32°	• For Capsicum annuum var. glabriusculum, production is three times higher under the panels • For C. annuum var. annuum, there is no impact • For S. lycopersicum var. cerasiforme, production is two times higher under the panels	[54]
Maize	Chiba Prefecture, Japan	Height of 2.7 m Two row spacings: 0.71 m for high-density and 1.67 m for low-density Tilt of 30°	• Yields of 3.54 kg/m^2, 3.35 kg/m^2 and 3.23 kg/m^2 at a distance of 1.67 m in full sun and at a distance of 0.71 m, respectively	[55]
Grape	Ongjin-Gun, Republic of Korea	Height of 2 m Tilt of 15° Shading level of 30 of the total roof area	• Germination period, number of flowers and grape growth are identical in all treatments	[56]
Basil and spinach	Italy	-	• Reduction in marketable biomass yield by 15% and 26% for basil and spinach, respectively	[28]
Sesame, mung bean, kidney bean, corn and soybean	Jeollanam-do, South Korea	Height of 5.42 m Shading rates of 32%, 25.6% and 21.3%	• Yield reductions for all crops except maize at 21.3% shade • At 21.3%, yields increased by 6% for maize and decreased by 7%, 13%, 21% and 26% for sesame, soybean, mung bean and kidney bean, respectively • At 25.6%, yield reduction of 14% for sesame and 35–44% for beans • At 32%, yield reduction of 53% for sesame and 30–44% for other crops	[48]
Oilseed rape, onion, faba bean and forage maize in rotation with potato melon, carrot, onion and dry pea in rotation with tomato	Sevilla, Spain	Height of 5 m Spacing of 9.5 m between suppoted structure Tilt of 27°	• Reduction in crop yields under shade following a correlation of studies already carried out on the effect of shade on the area (reduction of 10%, 7%, 17%, 6%, 20%, 23%, 15% and 5% for carrot, maize, melon, onion, rape, potato, dry pea and tomato, respectively)	[58]
Celery	Southwest Germany	Row distance: 9.5 m (2.8 times module row width)Height (free space in the direction of the work/top edge): 5.5 m/8 m	• Crop height was 30.6% and 14% higher under panels in 2018 and 2017, respectively • Dry matter yield of above-ground biomass was 48% and 31.9% higher under panels • Bulb yield decreased by 18.9% in 2017 and increased by 11.8% in 2018	[59]

Table 2. *Cont.*

Crops	Study Area	Height and/or Spacing or Shading Rate	Impact on Culture	Sources
Red beet, winter wheat, potato and red clover	Southwest Germany	Height of 5 mSpacing of 6.3 mTilt of 20°	• Increase in crop height for all crops • Between 2017 and 2018: −19 to +3% for winter wheat, −20 to +11% for potato and −8 to −5% for red clover and	[125]
Rice, onion, garlic, rye, soybean, bean, maize, forage crop	South Korea	Height of 3.3 mSpacing of 1.5 mShading rate of 30%	• For rice, stem height was 3.8 cm higher under the panels and yields decreased by 18.7% in 2018 and 8.9% in 2019 • For soybeans and beans, yields decreased by 68.7% and 73.3%, respectively • For garlic and onions, yields decreased by 18.7% and 14.6%, respectively • For fodder crops, the height was 7.4 m higher under the panels, nevertheless the yield decreased by 3.1 t/ha	[126]
Rice, potato, sesame, and soybean	South Korea	Height between 4 m and 4.5 m	• No impact on growth except for sesame (lower stem length, number of branches and 1000 seed weight) • Yield reduction of 3% for potato, 19% for sesame, 18–20% for soybean and 13–30% for rice	[42]
Soybean	Monticelli d'Ongina, Italy	Height of 4 to 4.5 mSpacing between rows of trackers of panels of 12 mfour treatments: 27%, 16%, 9% and 18% shading	• Crop height of 98.25 cm at 27%, 90.81 cm at 18%; 86.95 cm at 16% and 85.04 cm at 9% shade under panels and 87.8 cm in full sun • Number of pods reduced by 19.4% at 27% shade and 18.2% at 18% shade compared to treatments with 16% or less shade • Grain yield reduced by 8%, 4.6% and 11.8% for 27%, 9% and 18% shade respectively compared to full sun versus 4.4% increase for 16% shade	[127]

6. Influence of Agrivoltaics Systems on PV Module Performance

Few studies have focused the impact of agrivoltaic systems on the performance of solar panels. This is because crops are most affected by these types of installations. However, Table 3 gives an overview of some of the advantages and disadvantages of these installations on solar panels highlighted by some authors.

Table 3. Impacts of agrivoltaic systems on the performance of solar PV panels.

Advantages/Disadvantages	Description	Source
Advantages on PV panel	Increase energy production due to increased area through the LER	[39,117]
	Decrease in temperature of solar panels could be achieved by using agricultural moisture, evaporation from agricultural activities, and transpiration from crops which results in the increase in electricity generation	[128]
	PV panels in agrivoltaic systems can generate between 3.05% and 3.2% more energy compared to PV installations without cultivated crops	[129]
	Decrease in ambient temperature can cause an increase of 1.29–3.33% in the maximum power output of the PV array	[97]
	The presence of surface green due to vegetation at the bottom of the panels can results in an increase of 0.25 to 0.4% in the efficiency of the solar panels	[99]
Disadvantages on PV panel	Agrivoltaic can reduce the efficiency of electricity generation or agriculture when taken separately	[39]
	Decrease in the electricity produced with the reduction in the density of solar PV panels	[38,48,55]

7. Models Already Developed in the Agrivoltaic Field

One of the first models developed to optimize agrivoltaics was carried out in Montpelier by [24]. This is a model for intercepting the radiation available on the panels (developed on R software) and simulating the crop's development (generic crop model STICS). The light interception model calculates the daily radiation at any point on the ground using a ray-tracing algorithm. The crop simulation model was used to predict the behavior of crops under the panels. For the light simulation, ray tracing algorithm was used to make the simulation. The daily direct and diffuse radiation quantity striking any point of the ground below the array consisted of the output.

The authors of [38] utilized the STICS model, which comprises four primary modules. These modules include the crop growth module, soil interaction module, crop management module, and microclimate module. The crop model determines the effects of climate and soil moisture content on the immediate microclimate surrounding the crops. Indeed, they set up a solar PV system model and a crop model to optimize the performance of the agrivoltaic system. In their PV model, they formulated an optimization problem whose objective was to maximize the incident solar irradiance on the PV, while considering the additional land cost due to minimizing inter-row shading. They proposed to reduce panel density or use semi-transparent panels to reduce the effects of shading. In order to optimize the geometry of an agrivoltaic system, the crop, solar irradiance, mounting height, environmental climate, and tilt angle are crucial. The module production model was developed on PVsyst.

The use of the STICS model is advantageous because it allows the assessment of the impact of the configuration of a given agrivoltaic installation on crop growth. Therefore, real data from field experiments are required to use the model.

Amaducci et al. [120] had developed a software platform on Scilab by coupling the radiation and shading model to the generic crop growth simulator (GECROS). The GECROS crop model predicts crop biomass and yields as a function of climatic factors such as radiation, temperature, wind speed, and partial vapor pressure, as well as the amount of water and nitrogen available in the soil. Regarding the shading radiation model, it consisted of calculating direct and diffuse radiation at ground level with a time step ts = 0.5 h and a spatial resolution of 0.12 m by developing a procedure to calculate whether a portion of soil that is shaded or that receives direct radiation. This study was conducted using a tracking system.

Malu et al. [130] carried out agrivoltaic system modeling to study the electrical performance of agrivoltaic systems when combining grape and energy production in the Nashik

District of Maharashtra State in India using the National Renewable Energy Lab's System Advisory Model (SAM) version 2014.1.14, which uses weather data, location of the study area, PV array size, DC/AC ratio, azimuth angle, required axis type, and tilt angle. Inputs data consist of the weather data, the ratio of DC to AC power, the azimuth angle, the tilt angle, the type of axis required, the size of the system array, and the tilt angle. However, the study focused more on energy production.

Elamri et al. [40] investigated the variations of water in soil and the productivity of crops under PV panels. For this purpose, they used a model called "AVirrig" adapted based on the existing "Optirrig" model. Optirrig was built to generate and optimize irrigation scenarios that operate at a daily time step. The inputs used in this model are rainfall, radiation, air temperature, reference evapotranspiration, soil water reserves, leaf area index, dry matter, and crop yield. "AVirrig", which also includes the "AVrain" model that describes the redistribution of rainfall by solar panels depending on the method of panel installation, consists of a reservoir model that assumes the presence of three water reserves in the soil. This is a specific adaptation of "Optirrig" for AV installations that take into account the fluctuation of the shadow created by the PV modules. In opposition to Malu et al. [130], this study focused more on agricultural production.

Similar to Amaducci et al. [120], Potenza et al. [127], performed modeling to optimize the growth of crops under panels in Italy by coupling the GECROS crop growth model with a set of algorithms to estimate and specialized shading, radiation, and crop-related parameters. The system simulates the entire crop growth cycle, carbohydrate distribution, and grain yield of crops under the panels. Crop height, leaf chlorophyll content, leaf area index, and specific leaf area were measured throughout the experiment. Radiation mapping, calculated on the cells with a resolution of 0.12 m $\times$ 0.12 m and a time step of 30 min, was used to determine the shadow depth. GECROS is advantageous because it allows the prediction of biomass and yield based on the knowledge of climatic parameters. Thus, a knowledge of the variation of climatic parameters under the panels allows to determine the adequate configuration of an agrivoltaic system.

Trommsdorff et al. [43] investigated the electrical efficiency of PV systems applied to crops and the behavior and productivity of crops under panels in Germany's largest agrivoltaic research facility. The study was conducted according to the variation of solar radiation available to the PV panels and the crops. All light simulations for the PV modules were performed with Radiance, which is a back ray tracer for optical calculations in virtual environments that takes into account both direct and diffuse fractions of the irradiance, allowing the simulation of ground reflections to analyze the electrical gains on the back side of the PV panels. In addition, they used ZENIT software tool, which considers, among other things, temperature coefficients, specific efficiency curves, maximum power points, and inverter power limitations to evaluate the overall electrical efficiency. Virtual sensors measured the radiation under the panels. Simulations were performed for different orientations of the APV field between South and South–West (0°, 15°, 30°, 45°) and different distances between rows of panels. Moreso, the photosynthetically active radiation under the panels was converted into biomass yield.

Kim et al. [48] focused on the electricity production of agrivoltaic systems and the increase in revenue when implementing such a system. Thus, they implemented a polynomial regression to develop a model for estimating the system's electricity production using machine learning. The model considered eight (8) parameters, including solar radiation, daily minimum and maximum temperature, daily rainfall, humidity, wind speed, shading ratio, and type of solar panel. However, the shading data used in the study was calculated as panel area over the system area. Therefore, the model does not provide an indication of the optimal configuration in terms of spacing, elevation, and inclination for the crop to be grown.

Pulido-Mancebo et al. [131] have developed a model for optimizing agricultural production under the panels to convert photovoltaic power crops into agrivoltaic systems. It consists of a mathematical model that simulates the solar incidence in a network of

representative points on the ground, depending on the geometry and design of the PV crop to be converted to agrivoltaics. The study focused on photovoltaic installations with rectangular collector planes inclined towards the south and one side of the rectangle (wider) oriented in an east–west direction and parallel to the ground and with the shorter side oriented in a north–south direction. The model is based on the representation of the sun's position with respect to the geometry of the collector array (latitude of the location, solar declination, day angle, and solar time) as well as the geometry of the PV system itself (a rectangle represents the system). The model geometrically determines the shading at any point on the ground by determining the direct and diffuse radiation on the horizontal ground without obstacles. The inputs were the declination, the latitude, solar time, and daily angle. This model is advantageous because it allows a quick overview of the radiation in the ground in agrivoltaic systems.

Nevertheless, these models do not directly give a specific elevation, spacing, and inclination for a given crop and given locality. These models are used to determine whether or not a selected configuration is suitable for a given crop and need to be optimize. All these modeling studies have been set up to study and verify the performance of a specific installation to see the impact of this installation on the yield of the crop being grown in this system. Moreover, Pulido-Mancebo et al. [131] have developed that simulates the solar incidence in a network of representative points on the ground; nevertheless, it does not directly give the optimal spacing between rows of panels and between panels and the elevation to choose for a given crop.

Therefore, considering the limited number of decision support studies that have been conducted to determine the ideal configuration, i.e., elevation, panel row spacing, and panel spacing and tilt for any given crop, this review article has been developed to clearly explain agrivoltaics. We believe that this review can be used as a guide to set up a model that will take into account geometric, geographical, climatic, crop, and PV panel factors which will have as outputs the optimal spacing between panels, elevation, and tilt that will result in maximizing the crop yield and power of the PV system in agrivoltaic systems.

8. Conclusions

The agrivoltaic system was first used in 1980. However, only a few studies were carried out in this field during this period. It is only since 2011 that many have started to work in this field. To this end, several studies have emerged in this field in recent years. These studies have mainly focused on implementing a given configuration of photovoltaic solar panels to reduce the effects of shading on crops. Several panel elevations and spacings were tested on several crops in different areas. However, these proposed arrangements were specific to the site and crop being tested. Thus, no study has been carried out to establish a model that allows for optimal panel elevation and spacing for a given area and crop. It is within this framework that this review was carried out. It gives a clear explanation of the agrivoltaic systems in full sunlight, the principle of operation of the panels, and the photosystem, both of which depend on solar radiation, as well as the factors that can affect their operation. It also shows the key factors that should be considered in an optimization model. This review examined the strengths and weaknesses of each type of installation to better select the system to be used and to optimize both the yield of the crops to be planted under the panels and the yield of the solar panels installed. For this purpose, the choice of an optimal elevation height, spacing, and tilt of the solar panels will reduce the impact of shading and increase crop yields, but also increase the power output of the solar photovoltaic panels, which is a twofold benefit. According to us, setting up a model that can be used for any area to find an optimal panel arrangement in the locality being studied would be an innovative solution that will be of high interest, especially in areas where the agrivoltaic system has never been tested. Furthermore, in the future, other studies may be conducted in the field of agrivoltaics, namely the evaluation of the environmental impact of the use of the panel structure which is becoming more imposing in elevated systems. Moreover, further research could also explore the economic implications of using

agrivoltaics for pumping water to support crop production and generating electricity for sale by small-scale farmers in rural areas where electricity access is limited.

Author Contributions: Conceptualization, A.S., Y.M.S. and A.K.T.; methodology, A.S., Y.M.S. and L.D.; writing—original draft preparation, A.S.; writing—review and editing, A.S., Y.M.S., A.K.T. and L.D. All authors have read and agreed to the published version of the manuscript.

Acknowledgments: Our deepest thanks to the Regional Scholarship and Innovation Fund/Partnership for Skills in Applied Sciences, Engineering and Technology (Rsif/PASET) for supporting us throughout this study.

Conflicts of Interest: The authors declare that they have no conflict of interest.

Nomenclature

β	Slope
γ	Azimuth
α_s	Coordinates of solar altitude
γ_s	Solar azimuth
AC	Alternating current
A_i	Uncultivated agricultural area
A_n	Cultivated agricultural area
ATP	Adenosine triphosphate
CdTe	Cadmium telluride
DC	Direct current
DSSCs	Dye-sensitized solar cells
E	East
GECROS	Genotype-by-Environment interaction on CROp growth Simulator
h_1	Installation height greater than 2.1 m
h_2	Installation height less than 2.1 m
LER	Land Equivalence Ratio
N	North
NADPH	Nicotinamide adenine dinucleotide phosphate
PV	Photovoltaic
S	South
SAM	System Advisory Model
STICS	Simulateur mulTIdisciplinaire pour les Cultures Standard, or multidisciplinary simulator for standard crops
W	West
x	cultivated crop
y	electricity

Abstract

Solar energy is increasingly used to produce electricity in Europe, but the environmental impact of constructing and running solar parks (SP) is not yet well studied. Solar park construction requires partial vegetation removal and soil leveling. Additionally, solar panels may alter soil microclimate and functioning. In our study of three French Mediterranean solar parks, we analyzed:(1) effects of solar park construction on soil quality by comparing solar park soils with those of semi-natural land cover types (pinewood and shrubland) and abandoned croplands (former vineyards); and (2) the effect of solar panels on soil microclimate, CO_2 effluxes, and vegetation. We measured 21 soil properties of physical, chemical, and microbiological soil quality in one solar park and its surroundings to calculate integrated indicators of soil quality. We surveyed soil temperature and moisture, CO_2 effluxes, and vegetation below and outside solar panels of three solar parks. Soil aggregate stability was reduced by SP construction resulting in a degradation of soil physical quality. Soil chemical quality and a general indicator of soil quality were lower in anthropogenic (SP and abandoned vineyards) than in semi-natural (pinewood and shrubland) land cover types. However, differences between abandoned vineyards representing the preconstruction land cover type and solar parks were not significant. Solar panels reduced the soil temperature by 10% and soil CO_2 effluxes by 50% but did not affect early successional plant communities. Long-term monitoring is needed to evaluate the effects of solar panels on vegetation.

KEYWORDS
land cover, microclimate, plant communities, renewable energy, soil functions, soil respiration

1 | INTRODUCTION

The use of solar energy to produce electricity is increasingly common in Europe and requires large areas in order to be cost-effective (Murphy et al., 2015; Ong et al., 2013). Solar park construction involves clearing and grading the soil surface, burying of electric cables, vegetation removal, and soil compaction increasing runoff and erosion. Grading, compaction, and erosion change the physical and chemical properties of the soil and thus reduce its quality. Since solar park construction destroys the vegetation and affects the soil, a careful analysis of the environmental impact of solar parks is needed (Armstrong et al., 2016; Hernandez et al., 2015). Although soil quality is an important indicator of ecosystem functioning, the effect of solar park construction on soil quality has not yet been reported elsewhere. After the installation of solar panels, the vegetation is regularly mown or grazed limiting vegetation height to prevent shading of panels. The solar panels also change the microclimate such as temperature, humidity, and solar radiation (Armstrong et al., 2016; Tanner

et al., 2020). Such changes in microclimate may affect soil processes and plant communities under panels, in particular, in the European Mediterranean with high solar irradiation compared to temperate regions.

Soil quality is "...the capacity of a specific kind of soil to function, within natural or managed ecosystem boundaries, to sustain plant and animal productivity, maintain or enhance water and air quality and support human health and habitation" (Karlen et al., 1997). Three soil quality indicator groups are commonly used: physical, chemical, and biological soil properties (Bünemann et al., 2018; Costantini et al., 2016; Maurya et al., 2020). Physical properties, such as bulk density and texture, influence water holding capacity and plant communities by modulating root growth (Lampurlanés & Cantero-Martínez, 2003; Scarpare et al., 2019). Chemical properties, such as inorganic N, total C, and pH, control plant nutrition and microbiological activity. Biological indicators include the activity of decomposers such as invertebrates or microorganisms. These organisms control organic matter decomposition and nutrient cycling (Maurya et al., 2020).

Velasquez et al. (2007) developed a single general indicator of soil quality (GISQ) that integrates a set of physical, chemical, and biological soil properties. Such soil properties are chosen and measured to evaluate multifaceted aspects of soil functions and further combined to calculate sub-indicators of physical quality, chemical fertility, and biological functioning. The GISQ combines the subindicators to provide a global assessment of soil quality based on soil ecosystem services and facilitates the comparison of soils between different sites/habitats. In a comparative study on four land use types, (Raiesi & Salek-Gilani, 2020) showed, using an adapted GISQ, that soil quality was 1.5-times lower in anthropogenic than in natural soils. Joimel et al. (2016) observed a decrease in soil physico-chemical quality along an anthropization gradient from forest to urban soils, whereas Joimel et al. (2017) did not find any difference in biological quality of these soils. The construction of solar parks on natural and semi-natural land use types (e.g. forest, shrubland, and abandoned vineyards) may reduce soil quality and affect ecosystem functions such as infiltration and storage of water, fertility and plant reestablishment, soil organic matter, and nutrient cycling (Khare & Goyal, 2013; Romero-Díaz et al., 2017; Rutgers et al., 2009; Scarpare et al., 2019; Yin et al., 2020).

Plant communities and soil functioning may also be affected by changes in microclimate under solar panels. Solar panels reduce solar radiation, air humidity, and soil temperatures, but in winter, soil temperatures are generally higher under panels (Armstrong et al., 2016). Adeh et al. (2018) reported highest soil moisture and local heterogeneity of soil water conditions under solar panels. Such changes in microclimate may alter plant community composition and soil respiration that can be measured as CO_2 release. Mediterranean plant communities are dominated by heliophilous plants (Bagella & Caria, 2012). The reduction of solar radiation under solar panels may thus result in a plant community shift toward shade-tolerant species. Seed germination of Mediterranean species may be limited by light reduction (Gresta et al., 2010), and the mortality of heliophilous plants increases in competition to shade-tolerant species. (de Dato et al., 2010; Novara et al., 2012). The change in air and soil microclimate under panels reduced the soil respiration under temperate oceanic climate (Armstrong et al., 2016). Under Mediterranean climate with higher annual temperatures and summer drought, changes in microclimate under solar panels may be higher resulting in a strong disturbance of seasonal soil respiration dynamics (González-Ubierna & Lai, 2019). Plant communities contribute to soil CO_2 release by respiration of roots and rhizosphere microorganisms (Raich & Tufekciogul, 2000) but also by changes in soil structure (Yang et al., 2009; Zou et al., 2005). Furthermore, plants are the principal carbon source of decomposer microorganisms (Wall et al., 2012). Thus, solar panels may also change soil conditions indirectly by a shift in plant community composition since plants are very sensitive to change in microclimate.

The aims of our study were to assess: (1) the effect of solar park construction on soil quality in comparing solar parks with semi-natural land cover types (pinewood and shrubland) and abandoned vineyards; and (2) the effects of solar panels on soil microclimate, CO_2 effluxes, and vegetation under Mediterranean climate. We expected that: (1) solar park construction reduces physical, chemical, and biological soil quality; (2) solar panels change soil microclimate and plant community composition; and (3) solar panels change soil respiration according to the season.

2 | MATERIAL AND METHODS

2.1 | Study sites

Two studies were conducted in three solar parks (SP) located in Southern France (La Calade, Pouzols-Minervois and Roquefort des Corbières, Figure 1a.) with a distance of 10 to 30 km from one another (Table 1). These SP were constructed in 2011, 2014, and 2016, respectively, covered between 8.5 and 16 ha and used ground-fixed photovoltaic (PV) systems carrying the solar panels at a fixed inclination. The solar panels are aligned to form rows (height of 0.6 m min and 2 m max) exposed to the south, with a gap of 4 m between rows. The study region is characterized by typical Mediterranean climate with summer drought and mild, wet winters. The SP are mainly bordered by pinewood (*Pinus halepensis*), shrublands, and vineyards. The soils of the SPs are characterized by carbonatic pedofeatures (i.e., fine calcareous silty clay soil).

2.2 | Sampling designs

2.2.1 | Study 1: Effect of solar park construction

To study the effects of solar park construction on soil quality, four sampling plots (50 × 2 m) separated by 150 m were randomly chosen within the SP at Roquefort des Corbières (inter-rows between solar panels). In the surroundings of the SP, we randomly selected four sampling plots (100 m^2) for each of the three dominant habitat types in the study region: pinewood, shrubland, and abandoned vineyards (Figure 1b).

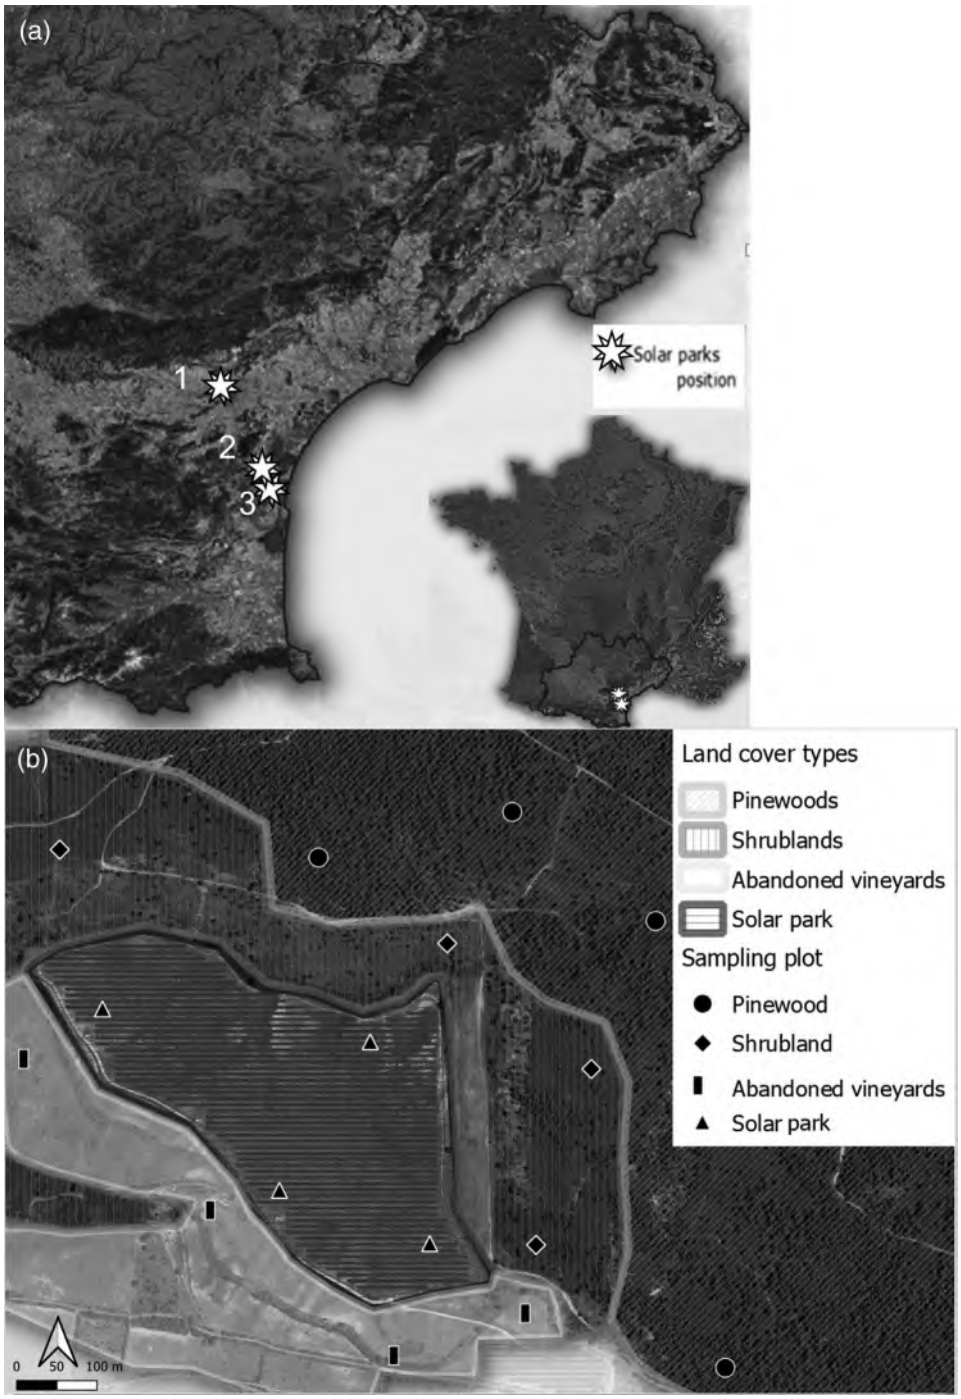

FIGURE 1 (a) Position of the three solar parks with 1: Pouzols-Minervois, 2: Roquefort-des-Corbières, and 3: La Calade (a), (b) the Roquefort-des-Corbières solar park in detail with surrounding land use types and sampling points

These three land cover types are also representative of regional land use (forestry, ancient pastures, and viticulture), and the studied SP was constructed on an abandoned vineyard. The plots were at least 200 m apart from each other and not more than 400 m from the SP. The pinewood is essentially composed of *P. halepensis and Quercus coccifera*. The shrublands are dominated by *Quercus coccifera*, *Pistacia lentiscus*, *Rosmarinus officinalis*, *Myrtus communis*, *Genista scorpius*, *Brachypodium retusum*, and *Cistus monspelliensis*. The vineyards had been abandoned for 5 years before solar park construction and were dominated by grapevine, *Anisantha rubens*, *Dittrichia viscosa*, and *Lysimachia arvensis*. In March 2016, 10 soil samples were randomly collected (10 cm depth) within each plot, mixed to one composite sample per plot. Composite samples were sieved (mesh size: 2 mm) prior to analyses. An aliquot of samples was air-dried (1 week, 30°C). For each sample, another aliquot was stored at 4°C for microbial analyses.

2.2.2 | Study 2: Effect of solar panels

To study the effect of solar panels on soil respiration, temperature, and moisture and on plant communities, we randomly selected within each of the three SP four sampling plots (50 × 2 m) below the solar

1099145x, 2021, 18, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ldr.4101 by University Of Arizona Library, Wiley Online Library on [02/07/2025]. TABLE 1 Environmental and technical characteristics of solar parks

	La Calade	Pouzols-Minervois	Roquefort des Corbières
Altitude (m)	77	100	62
Slope (%)	5	5	5
Temperature (annual mean, °C)	15.5	13.6	15.5.
Precipitation (annual mean, mm)	557	648	557
Sunshine duration (annual mean, hr)	2465	2119	2324
Soil texture	Loamy soil	Loamy soil	Loamy soil
Land cover before construction	Shrubland	Abandoned Vineyards and shrublandsQ	Abandoned Vineyards
Commissioning of the SP	2011	2014	2016
Maximum power (Kwc)	5102	4950	11,152
Solar panel soil localisation	Ground-fixed		
Solar panel cell technologies	Crystalline		
A solar panel power (Wc)	180	250	260
Number of solar panels	26,856	19,800	46,473
Area of the SP (ha)	8.5	10.7	16

panels, both separated by at least 100 m, and four adjacent sampling plots (50 × 2 m) in the inter-rows between the solar panel.

2.3 | Measurements of soil physico-chemical and microbiological quality

2.3.1 | Soil physical properties

Water content (g kg ^{1}) was determined after drying samples (24 h, 105°C). Water holding capacity (WHC) was analyzed according to Saetre (1998) but using a modified protocol. Ten grams of dried soil were weighted in a PVC cylinder and saturated with water. WHC was defined as the water content remaining in the soil after 12 h (4°C). The different soil fractions (i.e., sand, silt, clay) were determined using the Robinson's pipette method (Olmstead et al., 1930) after organic matter removal by oxidation with H_2O_2 (30%, 48 h). Bulk density (BD) was determined by measuring dried soil mass sampled in a Siegrist's cylinder. According to Huang et al. (2004), a value of 2.65 g cm^{-3} was assumed for real soil density (RD). Soil porosity was calculated using the following equation.

$$\text{Soil porosity} = 100 \times \frac{\text{RD} - \text{BD}}{\text{RD}} \quad (1)$$

Mean weight diameter (MWD) of soil aggregates was measured according to Kemper & Rosenau (1986).

2.3.2 | Soil chemical properties

The soil pH was measured in distilled water and KCL (1 M) (Aubert, 1978). Total carbon (TC) and Nitrogen (TN) content were determined by combustion in an elemental analyzer CN FlashEA 1112 (ThermoFisher) (NF ISO 10694, NFISO 13878). Calcium carbonate ($CaCO_3$) content was measured using a Bernard calcimeter (Müller & Gastner, 1971) and the percentage of C in $CaCO_3$ (C—$CaCO_3$) was determined as C—$CaCO_3$ = 11.991/100 × $CaCO_3$. Inorganic nitrogen (NH_4^+ and NO_3^-) was extracted in KCL solution (1 M) and analyzed calorimetrically using the nitroprusside-salicylate and nitrosalicylic acid method according to Mulvaney (1996) and Keeney & Nelson (1983), respectively.

2.3.3 | Soil microbiological properties

Microbial biomass (MB) was measured using substrate-induced respiration (SIR) rates (Anderson & Domsch, 1978). Basal respiration was determined without adding glucose to calculate the metabolic quotient qCO_2 (the ratio of basal respiration to microbial biomass), which is a sensitive ecophysiological indicator of soil stress (Anderson, 2003). Three enzyme activities (i.e., fluorescein diacetate hydrolase, phosphatase and tyrosinase) involved in carbon and phosphorous cycles were assessed (n = 3 per sample) to determine the catabolic potential of microbial communities. Fluorescein diacetate hydrolase (FDase, U g^{-1} dry weight) was measured according to Green et al. (2006), phosphatase (U g^{-1} dry weight) according to Tabatabai and Bremner (1969) and the activity of tyrosinase (μmol min^{-1} g^{-1} dry weight) according to Saiya-Cork et al. (2002).

2.4 | Measurements of solar panel effects on soil moisture, temperature, and in situ respiration

Soil respiration, temperature, and moisture were recorded in March and June 2017 in each sampling plot of the study on solar panel

1099145x, 2021, 18, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ldr.4101 by University Of Arizona Library, Wiley Online Library on [02/07/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

effects. In situ CO_2 release (g CO_2 m^{-1} hr^{-1}) from soils, plant roots, soil organisms, and chemical oxidation of C compounds was measured after removal of aboveground vegetation, using a portable gas analyzer (IRGA, EGM-4, PP-system). The device was connected to a closed soil respiration chamber (SRC-1, PP systems, Massachusetts). To prevent leakage of CO_2 when placing the chamber on the soil, a PVC tube (10 cm × 11 cm) was buried 1 cm deep into the soil prior to measurements. Soil temperature was recorded in a depth of 7 cm using the soil temperature probe (STP-1, PP-system) connected to the respirometer. Soil moisture was recorded on four points at 7 cm depth using a portable time-domain reflectometry (TDR) device (Delta-T Devices, ML2 Theta Probes).

2.5 | Measurements of solar panel effects on vegetation

In the sampling plots of the study on solar panel effects, vegetation surveys were carried out in 2016 and 2017. Three rectangular subplots of 10 m^2 (2 m × 5 m) were placed at the ends and the centre of each plot. Percentage cover of all occurring vascular plant species was estimated as the vertical projection of aboveground plant organs. A ratio of shadow-tolerant (sciaphilous) to hemi-heliophilous and heliophilous plant species (Julve, 2020) was calculated.

2.6 | Statistical analyses

We calculated a general indicator of soil quality (GISQ) according to Velaquez et al. (2007). Information on 21 variables of physical, chemical, and microbiological soil properties was used to create three subindicators related to main soil functions: (1) physical properties that determine the infiltration and storage of water, (2) chemical properties that affect fertility and plant reestablishment in solar parks, and (3) microbiological properties that drive soil organic matter decomposition and nutrient cycling. For each group of variables (physical, chemical, and microbiological), a principal component analysis (PCA) with data scaled to unit of variance was run using "FactoMineR" (Husson et al., 2008) and "Factoextra" (Kassambara & Mundt, 2020) packages. The Kaiser-Meyer-Olkin measure (>0.50) and Bartlett's test of sphericity (0.05) were used to test the sampling adequacy of variables included in the PCA. Variables with communality values <0.05 were removed, and main components were identified using the latent root criterion (eigenvalues >1.0). A synthetic index of quality for each group of variables at a plot *i* (Iq_i) was calculated as the sum of *n* variables (*vi*) multiplied by their respective weight (*wi*) in the determination of axes 1 and 2 of the PCA [Equation (2)].

$$Iq_i = \sum_{i=1}^{n} w_i v_i \quad (2)$$

The values of Iq_i were then reduced to a common range (0.1 to 1.0) using a homothetic transformation to obtain the sub-indicators of physical, chemical, and microbiological soil quality [hereafter pSQ, cSQ, and mSQ, respectively, Equation (3)]. In this equation, a is the maximal and b the minimal *Iq* value for the plot *i*.

$$p,c\,\text{or}\,mSQ = 0.1 + \frac{Iq_i - b}{a - b} \times 0.9 \quad (3)$$

Finally, a PCA was run with the three sub-indicators. The GISQ was obtained by summing the products of the respective contributions of variables to factors 1 and 2 by the % inertia explained by factors, respectively. Finally, the sum of these products gave the following formula for the GISQ [Equation (4)]:

$$\text{GISQ} = 0.29\,\text{pSIq} + 0.28\,\text{cSIq} + 0.33\,\text{mSIq} \quad (4)$$

All data were analyzed using R software (3.6.1, R Core Team, 2013). Effects of land cover type on soil physical, chemical, and microbiological properties, sub-indicators of soil quality, and GISQ were assessed using one way-analysis of variance (ANOVA). In the case of a significant land cover type effect, a Tukey HSD post hoc test was used to analyze differences between specific land cover types. To analyze the effect of solar panels on soil temperature, water content, CO_2 effluxes, and vegetation, linear mixed-effect models (LMMs) (R package "lme4") were applied including month and treatment (below vs outside panels) as fixed factors and solar park identity as a random factor. Assumptions of ANOVA were checked by Shapiro–Wilks test for normality and by Levene test for homoscedasticity. When necessary, data were transformed using the "bestNormalize" package (Peterson, 2021) to meet these assumptions. Effects of solar panels on plant communities were visualized by nonmetric multidimensional scaling (nMDS) based on the Bray–Curtis dissimilarity. Differences in plant community composition were tested using permutational multivariate analysis (PERMANOVA) in R package "vegan" (Oksanen et al., 2007). A subsequent pairwise post hoc test was conducted to analyze differences between factor levels. False discovery rate was used to correct for multiple comparisons.

3 | RESULTS

3.1 | Effects of solar park construction on soil properties

Seven of the eight tested physical soil properties were significantly different between land cover types (Table 2). Among these seven properties, only two showed a significant difference between the two semi-natural (pinewood and shrubland) land cover types and the SP. Soil water content was 5.5% lower in the SP ($p < 0.01$) than in shrubland. The mean weight diameter of aggregates was twice as high in abandoned vineyards as in SP and three times higher in pinewood and shrubland than in SP ($p < 0.001$). Organic carbon was about 2.5 times higher in semi-natural than in anthropogenic land cover types ($p < 0.001$). Sand and silt content, soil porosity, and bulk density were

	Phosphatase (μ g^{-1})	0.0067 (0.0004)	0.0058 (0.0015)	0.0046 (0.0024)	0.0053 (0.0005)	0.28

Note: Mean values with SEs in parentheses. Different letters indicate significant differences between land cover types (significant *p*-values in bold)
Abbreviations: BD, bulk density; BR, basal respiration; FDAse, fluorescein diacetate hydrolase; MB, microbial biomass; MWD, mean weight diameter; OC, organic carbon; qCO_2, metabolic quotient; TC, total carbon; TN, total nitrogen; WC, water content; WHC, water holding capacity

significantly different between abandoned vineyards and pinewood (Table 2). Silt content and soil porosity were 1.4- and 1.3-times lower in abandoned vineyards than in pinewood, respectively. Sand content and BD were about 1.5-times higher in abandoned vineyards than in pinewood. Pinewood and shrubland showed similar physical properties without significant differences.

For most soil chemical properties, SP showed significant differences to pinewood and shrubland but not to abandoned vineyards (Table 2). Total carbon contents were 1.44-times higher in semi-natural land cover types than in anthropogenic land cover types ($p < 0.01$). Organic carbon contents were about 2.76-times higher in semi-natural land cover types than in anthropogenic land cover types ($p < 0.01$). Total nitrogen (TN) content showed the same pattern. TN was twice as high in pinewood and shrubland as in the SP and abandoned vineyards ($p < 0.001$). The water pH ranged between 8.02 and 8.11 and showed a small but significant difference between shrubland and abandoned vineyards.

Two microbiological properties were significantly different between land cover types (Table 2). Land cover type had a significant influence on basal respiration ($p < 0.03$) being two times lower in the SP and abandoned vineyards than in forest and shrubland. The FDAse activity was two times higher in shrubland and pinewood than in the SP and abandoned vineyards. Microbial biomass was twice as low (marginally significant) in SP and abandoned vineyards as in the semi-natural land cover types.

3.2 | Effects of solar park construction on soil quality

The first two axes of the PCA run on physical properties explained 80.56% of the total variance (see A.1.A in Appendix S1). The semi-natural land cover types are separated from the anthropogenic soils along the first axis. Silt, water content, water holding capacity, and mean weight diameter of aggregates had the highest score on the first PCA axis, while soil porosity was strongly correlated with the second axis (see A.1.A, Appendix S1). The highest physical quality index of 0.92 was measured in pinewood and shrubland being two times higher than in abandoned vineyards ($p < 0.001$). The pSQ (Figure 2a) was two times and four- times lower in SP than in the abandoned vineyards and semi-natural land cover types, respectively ($p < 0.01$).

The first two axes of the PCA used to calculate the sub-indicator of soil chemical quality (cSQ) explained 80.98% of the total variance (see A.1.B, Appendix S1). The semi-natural land cover types are

1099145x, 2021, 18, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ldr.4101 by University Of Arizona Library, Wiley Online Library on [02/07/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

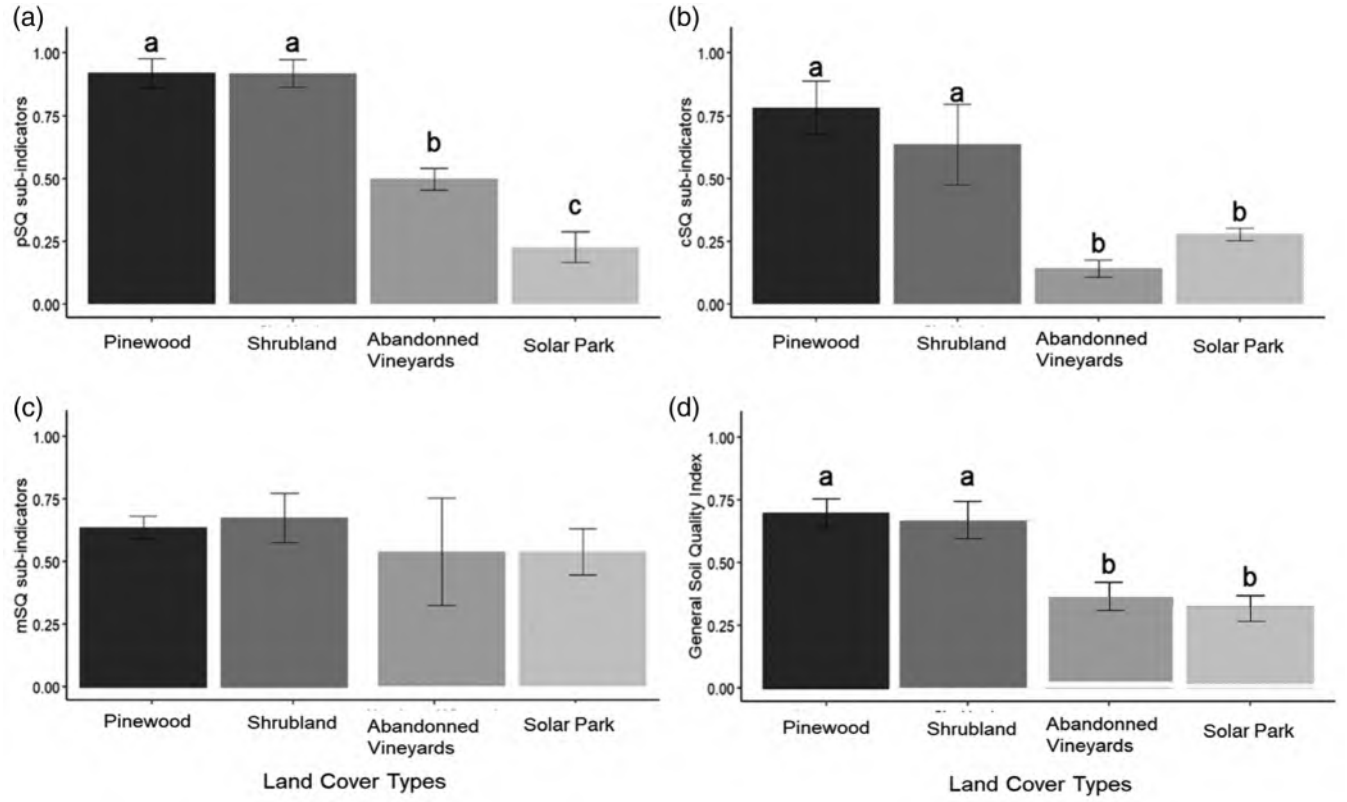

FIGURE 2 Sub-indicators of soil physical (a), chemical (b), and microbiological (c) quality and general soil quality indicator (d) for different types of land cover. Error bars are means ± SE. Different letters indicate significant differences ($p < 0.05$)

separated from the anthropogenic soils along the first axis. Total carbon, organic carbon, TN, and ammonium were most correlated with the first axis and nitrate with the second axis (see A.1.B, Appendix S1). With a value of 0.18, the cSQ was four times lower in the SP and abandoned vineyards than in shrubland and pinewood ($p < 0.001$, Figure 2b).

The first two axes of the PCA used to calculate the sub-indicator of soil microbiological quality explained 80.28% of the total variance (see A.1.C, Appendix S1). Basal respiration, microbial biomass, FDAse, and phosphatase were highly correlated with the first PCA axis, while the qCO_2 was correlated with the second one (see A.1.C, Appendix S1). The mSQ was not significantly different between land cover types ($p = 0.74$) (Figure 2c).

The General Indicator of Soil Quality was four-times lower in the SP and abandoned vineyards than in the pinewood and shrubland ($p < 0.001$).

3.3 | Effects of solar panels on soil temperature, water content and in situ CO_2 effluxes

Soil temperature and water content were significantly different between months ($p < 0.05$; Figure 3a,b). Solar panels significantly decreased soil temperature in March and June (Figure 3a) but did not affect soil water content ($p = 0.79$). Soil CO_2 effluxes did not change between months but were twice as high outside solar panels than below solar panels ($p < 0.001$).

3.4 | Effects of solar panels on plant communities

Neither the species richness nor the total cover of plant community was significantly affected by the solar panels (Table 3). A marginally significant difference was detected for the ratio 'Sciaphile: Heliophile plants,' being higher below than outside solar panels. The NMDS and PEMANOVA did not reveal any significant solar panel effect on plant community composition ($p = 0.3461$, Figure 4). However, community composition was significantly different between the solar parks ($p < 0.001$). No significant difference was detected between observation years (data not shown).

4 | DISCUSSION

Solar park (SP) construction reduced physical and chemical soil quality compared with semi-natural land cover types (forest and shrubland) but not biological soil quality. A change in soil temperature and CO_2 effluxes also demonstrated a negative solar panel effect on soil microclimate and functioning. However, in early stages of plant succession following solar park construction, plant community composition below and outside solar panels was not significantly different.

TABLE 3 Effects of solar panels on plant communities

Parameters	Below solar panels	Outside solar panels	*p*
Species richness	12.56 (5.92)	13.25 (5.49)	0.29
Total cover (%)	351.2 (165.12)	379.97 (183.31)	0.22
Hemi-heliophilous: Heliophilous ratio	0.12 (0.14)	0.10 (0.10)	0.09

Note: Mean values with SEs in parentheses

4.1 | Effects of solar park construction on soil quality

Soil quality assessments require the measurement of a wide range of physical, chemical, and biological properties involving a high complexity of potential analyses (Maurya et al., 2020). In this study, we assessed soil quality using a multiproxy approach including 21 soil properties. The reduction of the number of variables using PCA to group these properties allows an integrated evaluation of soil quality based on their main functions, such as infiltration and storage of water, soil fertility, plant reestablishment and soil organic matter and nutrient cycling. We found that two of three integrated sub-indicators and the general indicator of soil quality were lower in SP than in the semi natural land cover types.

Among the physical soil properties, the aggregate MWD was 1.5-times lower in the SP than in the semi-natural land cover types (Table 2). A low MWD may result in a low aggregate stability. Similarly, Kabir et al. (2017) showed that the MWD decreases in anthropogenic soils associated with a degraded vegetation. In our study, soil leveling and vegetation removal prior to SP construction may have decreased soil organic matter (SOM) content reducing MWD. By binding colloids and stabilizing soil structure, SOM plays a key role in soil physical properties and nutrient cycling (Six et al., 2004). Telak & Bogunovic (2020) showed a decrease in SOM and MWD in a vineyard of Croatia after intensive and frequent tillage. Such mechanical disturbance for many years may have affected soil structure of the vineyard on which the studied SP (Roquefort des Corbières) was constructed. Accordingly, overall physical soil quality of SP was lower than that of abandoned vineyards, which was in turn lower than that of semi-natural land cover types. The physical soil quality index (Figure 2a) revealed that the construction of a SP increased the degradation of the physical soil quality of habitats already degraded by land management (abandoned vineyards). In particular, the stability of the soil, key factor of soil functioning, was lower in SP than in abandoned vineyards. Moreover, a lower SOM affects microbial activity and production of mucus resulting in a decrease of aggregate MWD and thus a soil more sensitive to erosion (Blavet et al., 2009; Le Bissonnais et al., 2018). The soil leveling and vegetation removal during SP

1099145x, 2021, 18, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ldr.4101 by University Of Arizona Library, Wiley Online Library on [02/07/2025]. FIGURE 4 Nonmetric multidimensional scaling (NMDS) plot with polygons indicating the plant species composition of the three solar parks under (hatched polygon) and outside (solid polygon) solar panels, NMDS stress: 0.084. Different letters indicate significant differences after pairwise post hoc test ($p < 0.05$)

construction may have increased surface runoff and soil erosion (Rabaia et al., 2021).

In contrast to our expectations, the SP construction did neither increase soil bulk density nor decrease porosity compared to the abandoned vineyards (Table 2). In our study, soil bulk density was found to be lower in abandoned vineyards than in semi-natural land cover types. The past land management of vineyards may have degraded these properties before SP construction limiting effects of construction work. It is well known that the use of agricultural machinery considerably increases the soil bulk density (Dunjó et al., 2003). Under similar Mediterranean climate and land use history in Spain, the bulk density was 30% higher in vineyards than in pinewood (Dunjó et al., 2003). Such changes in soil physical properties can reduce the infiltration and storage of water. To improve the process of water infiltration and the capacity of water storage, a decompaction of the soil surface may be useful in particular if soils were already compacted by previous land management. Such decompaction also facilitates the germination and establishment of plant species (Bassett et al., 2005). The resulting improved revegetation may limit erosion and protect functions supported by soil physical quality (Beatty et al., 2017).

Soil chemical properties, such as total and organic carbon and TN are directly linked to soil fertility and plant growth (Liu et al., 2014). In our study, these properties showed lower values in anthropogenic soils than in semi-natural land cover types (Table 2). Joimel et al. (2016) obtained similar results along a gradient from natural to anthropogenic habitats in which total carbon and nitrogen decreased significantly from forests to vineyards. Soil disturbance such as soil tillage in vineyards or construction activities increases mineralization of organic matter reducing organic C and N (Brantley & Young, 2010). Accordingly, Choi et al. (2020) found a significantly lower C and N content in SP than in grassland soil. In our study, SP construction did not reduce neither C and N content nor soil chemical quality compared to degraded vineyard soil (Table 2). Consequently, the construction of SP did not further degrade the soil chemical properties. The low index of chemical quality (Figure 2b) is thus most likely related to the past vineyard management. Low C and N content suggest that nutrient cycling was lower in vineyards and SP soils and that several SP soil functions (carbon sequestration, soil structure, biological processes) were hampered compared to semi-natural soils. Appropriate site selection may limit such a loss of key soil functions by SP construction (Choi et al., 2020).

Soil microorganisms (i.e. bacteria and fungi) contribute actively to soil nutrient cycling (Schimel & Schaeffer, 2012). Thus, their genetic and physiologic characteristics are important indicators of ecosystem functioning such as nutrient cycling (Ranjard et al., 2011). Microbiological soil properties showed differences between land cover types for fluorescein diacetate hydrolase (FDAse) activity and basal respiration. FDAse is an appropriate proxy to evaluate soil microbial activities because the ubiquitous esterase enzymes (e.g., lipase, protease) are involved in the hydrolysis of FDA (Schnürer & Rosswall, 1982). In our study, the FDAse was two times lower in anthropogenic soils (Table 2) suggesting a reduction of microbiological activity and nutrient cycling. Soil basal respiration showed the same pattern confirming

1099145x, 2021, 18, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ldr.4101 by University Of Arizona Library, Wiley Online Library on [02/07/2025]. a degradation of soil functions compared to semi-natural soils (Sparling, 1997). Under a similar Mediterranean climate in Italy, basal respiration was three to four-times lower in vineyards than in coniferous forests, mixed forests, and shrublands (Marzaioli et al. (2010). The decrease in soil respiration may be related to the lower organic carbon and nitrogen content or the decrease in microbial biomass (Fernandes et al., 2005). Previous vineyard management, in particular, soil tillage, may have severely decreased microbial biomass resulting in low microbial activity. Five years of abandonment was probably not sufficient to entirely reestablish microbial communities (Quintana et al., 2021). Despite the reduction of microbial properties in abandoned vineyards and solar park soils, the microbiological soil quality index (mSiQ) was not significantly different between land cover types (Figure 2c). Other microbiological properties (BM and phosphatase) mainly contributing to the first PCA axis were hardly affected by land cover type and thus overruled significant response variables in mSiQ calculation.

As a consequence of lower physical and chemical sub-indicators, the general indicator of soil quality was about three times lower in SP compared to semi-natural land cover types (Figure 2d). The key processes involved in degradation of soil quality were soil tillage, partial topsoil removal increasing erosion (Quinton et al., 2010), and organic matter mineralization. Reduced organic matter content and increase of soil compaction decrease water holding capacity (Mujdeci et al., 2017) and soil stability (Simansky et al., 2013). Soil restoration by revegetation may improve soil physical and microbiological qualities of solar parks (Hernandez et al., 2019). Revegetation may increase the stability of aggregates by increasing root biomass and the production of binding agents (Erktan et al., 2016). The root exudates can also stimulate microbial biomass and activity and thus improve nutrient cycling (Eisenhauer et al., 2010; Feng et al., 2019).

4.2 | Effects of solar panels on soil microclimate, vegetation, and in-situ CO_2 effluxes

Climatic conditions influence both soil microbial activities (Shao et al., 2018) and plant communities (García-Fayos & Bochet, 2009). In our study, solar panels reduced the soil temperature in spring and in summer by about 5°C (Figure 3a). Similarly, Armstrong et al. (2016) found a soil temperature reduction of 2°C under solar panels during the summer (UK). The lower temperature under solar panels was the direct effect of shading although night temperatures may be higher (Tanner et al., 2020). Solar panels also intercept precipitation, and Tanner et al. (2020) found a significant reduction in soil humidity under solar panels in the Mojave Desert. However, we did not find any significant soil humidity difference under solar panels and outside (Figure 3b). The result may be explained by a lower evapotranspiration limiting humidity losses during drought periods as suggested by Tanner et al. (2020).

Mediterranean vegetation is dominated by heliophilous plants (Bagella & Caria, 2012). So we expected that light reduction by solar panels strongly affects plant communities. However, we did not find a significant effect of solar panels on plant community composition and structure (Figure 4). The effect of solar panels on the ratio of shadow-tolerant to heliophilous species was only marginally significant and no influence on plant species richness was detected (Table 3). Other studies showed, however, a reduction in plant cover and species richness under solar panels resulting from lower germination and higher mortality (Armstrong et al., 2016). Due to light limitation, heliophilous plants are expected to be less competitive under solar panels (Chen et al., 2004). However, protection against strong solar radiation and drought during Mediterranean summer may have compensated for reduction of light and precipitation in our study. Accordingly, Tanner et al. (2020) observed that in a desert plant richness was marginally greater under their solar panels than in the control. In our study, the absence of a solar panel effect on the vegetation (Figure 4, Table 3) may also be explained by the low age of our solar parks limiting differential effects on the vegetation. In early successional stages, the vegetation is dominated by ubiquitous annual species germinating and developing under a great variety of environmental conditions. Responses to the specific microclimate under solar panels may be slow in Mediterranean vegetation types (Coiffait-Gombault et al., 2012; Kinzig et al., 1999). Long-term monitoring is required to finally evaluate the influence of solar panels on plant communities.

A lower soil respiration is an indicator of lower litter decomposition and nutrient cycling suggesting that these ecosystem functions may be reduced under solar panels (Incerti et al., 2011). In our study, soil respiration was highly affected by solar panels (Figure 3c). Half of the CO_2 fluxes from soils are produced by heterotrophic organisms (Bond-Lamberty et al., 2004). Heterotrophic respiration, but also plant respiration, is driven by environmental factors, mainly temperature and moisture, explaining the strong influence of solar panels (Francioni et al., 2020; Moinet et al., 2019). Accordingly, Armstrong et al. (2016) found a reduction of soil CO_2 effluxes under solar panels in May and June. We already detected a reduced CO_2 efflux from March onward suggesting that the warm Mediterranean spring results in earlier temperature differences between soils under and outside solar panels compared to temperate oceanic climate. This early decrease in temperature under solar panels compared to controls outside solar panels may have reduced microbial activity and thus heterotrophic respiration. The reduction of CO_2 effluxes under solar panels may also be the result of light reduction reducing plant growth and root respiration.

5 | CONCLUSIONS

Physical, chemical, and general soil quality indexes were lower in a solar park than in semi-natural land cover types. Clearing and grading the soil surface during solar park construction resulted in a strong degradation of soil physical quality, especially of soil structure, but did neither disturb soil chemical quality nor global quality compared to abandoned vineyards. These results suggest that solar parks should be preferably constructed on anthropogenic soils or that construction must be accompanied by environmental compensation measures

1099145x, 2021, 18, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ldr.4101 by University Of Arizona Library, Wiley Online Library on [02/07/2025]. and/or ecological restoration. At our Mediterranean study sites, solar panels reduced soil temperature from spring onward. Neither light nor spring temperature reduction under solar panels altered plant communities in early stages of plant succession but reduced CO_2 effluxes. Our study demonstrated that solar park construction and solar panels changed soil quality and microclimate to a magnitude known to affect key soil functions. Long-term monitoring including different seasons is required to evaluate the final response of soil properties and vegetation to solar panels.

ACKNOWLEDGMENTS

Funding was provided by the French Agency for Environmental Transition (ADEME) via a PhD grant to Quentin Lambert and the project PIESO (agreement N°1405C0035). We thank Pierre Illac and Marine David (Total Quadran) for their logistic support. We further thank Mathilde Dionisi, Jean Bigotte, Xavier Fortuny, and Lisa Foli for technical assistance in the lab and in the field.

Dear Certificate Holder and ODOE,

As I have made clear from the beginning my largest concern with the project is the wildfire risk. I strongly believe the only way to reduce this risk to an acceptable level is through vegetation management both with firebreaks and maintaining the overall vegetation height within the project. I have read Sherman County Weed Districts comments recommending a vegetation height of 4-8" for better erosion control/vegetation health. While I understand where the district is coming from in an erosion control perspective, I cannot agree that 8" would be safe from a wildfire standpoint in Sherman County (even a few extra inches of growth can drastically increase fuel load and flame length). Additionally, if there is a fire, due to vegetation not being properly managed, erosion control will be extremely poor that fall/winter. After reading the weed districts comments and doing some research of my own it appears that it is important to not mow native bunch grasses shorter than 3-4" to protect the crown of the plant. While I would prefer to see the vegetation kept to a height of 1-3" for fire mitigation I can concede that a slightly taller vegetation height of 3" to 6" (during fire season June-Oct.) would be what is best when erosion control, vegetation health and fire risk are all taken into consideration together. Vegetation height needs to be as short as possible while still maintaining erosion control and vegetation health. Maintaining this standard would still allow for taller healthy plant growth prior to fire season and not cause plant damage by protecting the crown when mowing.

I have concerns that the certificate holder is still requesting a vegetation height of 10-12" year-round. The fact that certificate holder doesn't see the need to maintain a shorter vegetation height during fire season shows that the certificate holder does not fully understand the wildfire risk for the area. I get that it is being looked at from a cost perspective and maintaining the vegetation will not be cheap, but this view point is one sided. The cost of replacing hundreds of acres of solar panels will dwarf any vegetation management cost. It is in everybody's best interest from the certificate holder to the rate payer to the neighboring farmer to have the vegetation managed to an enhanced standard during fire season.

I am pleased that ODOE is suggesting additional conditions for vegetation management, but I want to make sure they become a permanent requirement for the site. I understand it will be included in the comprehensive solar revegetation and soil management plan but within that document it states that it is only the plan in the interim. The certificate holder also stated the clearances are included in the Operational and Maintenance Framework Plan, but I cannot find where it states the specific vegetation management standards within the O&M Framework Plan (this may be because I am not able to see updated revisions). Additionally, the certificate holder states it will include the vegetation standards in the site-specific Operational WMP but it hasn't been finalized yet. It is frustrating that a plan this important wasn't available for public comment and review. I am hopeful that the vegetation standards and clearances ODOE requires will be built into the site certificate in several places as the site certificate holder has stated. I look forward to seeing a finalized Site-specific Operational WMP and updated O&M Framework plan that include the vegetation management standards and clearances. Thank you for your time and I look forward to hearing your replies.

Sincerely,

Colton McCullough

The Department's responses to all comments provided on the record are attached (Department Response). In the Department's Response, we have included an explanation of how the document is organized, and how to locate the issues identified by the Department as having been raised in

your comments. The certificate holder, Portland General Electric Company, will be providing its responses directly to commenters by February 13, 2026, as required by OAR 345-027-0367.

The Department has also created an OneDrive folder that includes all copies of all comments provided on the Proposed Order. The attached "Amendment Comment Review Process Doc Navigation Help Letter" provides more information on how to access the OneDrive, the Department's file management system, and how to navigate PDF documents. The OneDrive can be accessed via the links in this email or by accessing the Biglow Canyon Wind Farm Webpage.

Please "reply all" to this email message when providing any replies to either the Department's or certificate holder's responses to your comments. Reply and sur-reply documents from the certificate holder and participants can also be uploaded directly to the OneDrive.
Replies must be received by **5:00 pm on February 27, 2026**, to be included in the record. Participants to the public comment process may request more time to submit their replies. The Council Chair may grant a requested extension on a showing of good cause. Please note the Department will only consider replies to issues raised in your own comments in preparing the draft Final Order.

Please note, I will be out of the office from February 13 to February 23, 2026. If you have questions about the process or how to submit replies to the Department or certificate holder's responses to your comments during this timeframe, please contact Sarah Esterson at sarah.esterson@energy.oregon.gov or call (503) 559-9218.

Thank you,

Re: Biglow Canyon RFA 4 - Issue HCA-02 – Construction Phase Tribal Coordination

Dear Mr. Gunn,

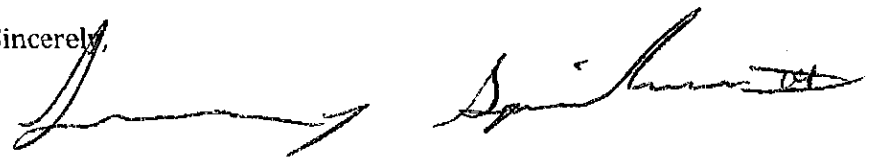
Thank you for your February 13, 2026 correspondence regarding Request for Amendment 4 for the Biglow Canyon Wind Farm Site Certificate.

The Confederated Tribes of the Warm Springs Reservation of Oregon appreciate the applicant's acknowledgment of the project's location within our ceded lands and the cultural sensitivity of the area.

After review of your response, the Tribe's primary concern relates to construction-phase implementation and ensuring appropriate Tribal presence during ground-disturbing activities.

While the applicant has described avoidance buffers, eligibility determinations, and inadvertent discovery procedures, the Tribe believes that real-time Tribal coordination during active construction is essential to ensure that cultural resource protection measures are implemented consistently with the substance of consultation discussions.

Accordingly, CTWSRO requests that a Dedicated Tribal Monitor be incorporated into the construction-phase coordination framework for the Project.



The purpose of this monitor would be to:

- Provide real-time coordination between the Tribe and the construction team;
- Observe implementation of cultural resource protection measures during ground disturbance;
- Facilitate immediate communication in the event of discoveries or unanticipated conditions;
- Maintain government-to-government engagement during construction activities occurring within culturally sensitive areas.

This request is not intended to reopen SHPO concurrence or challenge ODOE's Proposed Order. Rather, it reflects the Tribe's expectation that consultation extends meaningfully into the implementation phase of the Project.

The Tribe remains committed to collaborative engagement and appreciates your continued coordination.

Sincerely,

Lawrence Squiemphen III
Tribal Historic Preservation Officer
Confederated Tribes of the Warm Springs Reservation of Oregon

Good afternoon Christopher,
Attached is the Confederated Tribes of Warm Springs (CTWS) response to Issue HCA-02. Thanks for continued consultation with CTWS on the Biglow project that is within our ceded lands and a Culturally sensitive area to the CTWS. We appreciate you considering our comments and the tribes remain committed to collaborative engagement and continued coordination.

Re: Biglow Canyon Wind Farm Request for Amendment 4 – Certificate Holder Reply to ODOE Response to Certificate Holder Comments on the Proposed Order

Dear Mr. Clark,

Portland General Electric Company (PGE; Certificate Holder) submits the following reply in response to the Oregon Department of Energy's (Department or ODOE) Response to Certificate Holder Comments, issued on February 12, 2026 ("ODOE Response Letter"), that responded to comments PGE had filed with the Department on January 14 and 30, 2026, concerning the Proposed Order on the Request for Amendment 4 (RFA 4) of the Biglow Canyon Wind Farm (BCWF or Facility) Site Certificate.

The ODOE Response Letter indicates areas where additional information may be helpful for ODOE to resolve an issue and documents ODOE's position on certain suggested revisions, all related to the Certificate Holder's comments on the Proposed Order. This reply offers additional information on an issue-by-issue basis, conforming to the issue identification numbers presented in Table 1 of the ODOE Response Letter.

- **GS-06: Request for revision of proposed road dimension width, from 20 to 16 feet**

  The Department's evaluation requested that a site plan showing the location and width of designated emergency access roads and other internal access roads be provided. The Certificate Holder provides additional information related to the locations and widths of roads within the Biglow Solar Micrositing Area in Attachment 1 to this letter. Attachment 1 shows the locations of the 16-foot-wide internal roads (double black lines) and the 20-foot-wide emergency access roads (green lines). Existing wind turbine access roads are shown in blue. The final site plan will show all internal access and emergency access roads on-site. In addition, the water tanks shown on this attachment will be moved outside the fencelines in the 90% design and will be accessed by the emergency access roads.

- **GS-07: Request to allow Temporary Construction Areas outside fenceline, within Solar Micrositing Area**

  The Department's evaluation references representations made in BCWF RFA4 Division 27, Section 4.1.3.7 and requested that the Certificate Holder clarify the locations in the RFA where a request for temporary construction areas outside the fenceline have been

presented and evaluated.

There are inconsistencies in the BCWF RFA4 Division 27, Sections 4.1.3.7 and 4.4.3 regarding the location of temporary construction areas. Section 4.4.3 states:

> "Any temporary disturbance impacts requiring restoration and revegetation will only occur outside of the perimeter fencing for the solar areas, BESS, and collector substation and include temporary impacts from the underground collector lines, laydown areas, installation of perimeter fencing, construction of the O&M building, gen-tie line, and use of any additional temporary construction areas."

Section 4.4.3, Table 2 outlines the following temporary disturbance areas outside the perimeter fenceline:

- Solar Area: Temporary construction disturbance within a 6-foot corridor along the outside of the perimeter fenceline for fence installation.
- Solar Area Gen-Tie Line: Overhead transmission line disturbance amounts include the poles. Assumes a 150-foot temporary disturbance corridor (final corridor pending design) plus 20x20-foot pulling/tensioning areas (temporary disturbance), and 2-foot-diameter permanent disturbance from the poles (steel monopoles). Assumes approximately 700-foot spans between poles.
- Solar Area Road Crossings: Permanent disturbance for road crossings outside the solar area fenceline. Assumes a 16-foot road width, with additional 20-foot width temporary disturbance for construction.
- Temporary disturbance for the laydown area for construction; the construction area will be reclaimed following construction.

Because the layout within RFA4 represents the maximum disturbance scenario for purposes of analyzing land use and habitat impacts, all solar arrays were represented as being fenced in large blocks so that the largest permanent disturbance possible is represented. It was not intended to make a representation that during final design the primary laydown area would be located within a solar array fenceline. All areas within the micrositing area have been evaluated; therefore, regardless of whether the laydown area is within the permanent fenceline, the impacts have been evaluated.

The final site plan will show the locations of all temporary construction areas.

- **OE-05: Request to clarify frequency of inspections using thermal imaging**

The Department's evaluation requests further clarification related to Supervisory Control and Data Acquisition (SCADA) identification of anomalies and generation of work orders, and confirmation of accuracy on the proposed language.

The Certificate Holder appreciates the opportunity to further clarify the language in the Draft Operations and Maintenance (O&M) Plan. The revisions proposed to Section 3.4.2 of the Draft O&M Plan in the Proposed Order as currently framed conflates two different work streams for generating corrective work orders for anomalies detected 1) via routine module inspections and annual infrared/aerial thermal imaging, and 2) via the SCADA system.

The Certificate Holder requests replacing the original language in the Draft O&M Plan Section 3.4.2 (first and fifth bulleted item) with the following language to clarify these processes:

- **Routine module inspections and annual infrared/aerial thermal imaging:** Anomalies detected will generate corrective work orders within 48 hours, and will

be addressed according to level of severity; otherwise, as soon as reasonably possible and according to the final O&M Plan.

- **Routine SCADA monitoring and data analysis:** Anomalies detected will generate corrective work orders within 48 hours and will be addressed according to level of severity; otherwise, as soon as reasonably possible and according to the final O&M Plan.

The Certificate Holder will update this language in the Final O&M Plan submitted to ODOE prior to commencing operation of the solar facility and will provide a redlined version. The Certificate Holder confirms that the language in the Department's evaluation is accurate; the language presented above further clarifies the work streams for generating corrective work orders for detected anomalies.

- **SS-01: Request for flexibility to conduct ground disturbing activities on areas with steep slopes with engineer review**

The Department's evaluation requests additional information regarding the types of ground-disturbing activities on slopes exceeding 20 percent that are under consideration, the locations at the site where they are being considered, and any supporting evidence demonstrating how non-seismic geologic hazards in these areas will be mitigated.

The Certificate Holder addressed geologic conditions and seismic and non-seismic geologic hazards at the Biglow Solar Project site in BCWF RFA4 Exhibit H. Section 8.1 describes the non-seismic geologic hazards related to steep slopes that could affect the Biglow Solar Project, including:

- **Landslides:** There are no mapped landslides within the Solar Micrositing Area. Most of the area is mapped as low susceptibility for landslides, with areas of moderate landslide susceptibility along drainages within the Solar Micrositing Area and areas of high susceptibility for landslides along the drainages and canyons along the eastern and northwestern boundaries of the Solar Micrositing Area. If slope stability issues are identified in the final design geotechnical investigations, the structures will either be relocated during the micrositing process, or remedial measures will be implemented to improve slope stability.
- **Erosion:** Wind erosion hazard at the Project site is generally high to very high, especially on steep slopes, and is mitigated through the use of best management practices as described in the Erosion and Sediment Control Plan submitted with BCWF RFA4 Exhibit I.

Attachment 2 to this letter shows the locations of all slopes greater than 20 percent in the Project Area shaded in red. The majority of these slopes have been completely avoided through the micrositing process. The ground-disturbing activities that would take place on slopes exceeding 20 percent (i.e., the red-shaded areas located within the limits of disturbance [LOD], as shown in Attachment 2 to this letter) include excavation and cut-and-fill to grade the existing slopes above 20 percent to below 20 percent using equipment approved for these activities, industry best practices, and best management practices to prevent erosion. Following grading, the site would be developed as outlined in the designs to install solar facility equipment and structures. Grading these slopes below 20 percent will reduce non-seismic hazards associated with erosion and steep slopes at the Project site; not completing these activities would lead to greater risk of landslides and erosion at the site.

- **SP-09: Requests to Clarify Terms, Clear Brush-Free Area and Vegetation Clearance Area/Zone**

  The Department's evaluation requests specific revisions to the draft Comprehensive Solar Revegetation and Soil Management Plan and draft Construction Wildfire Mitigation Plan and requests a further explanation of how public comments discussed under Issue SP-04, WF-08, and WF-09 were considered. SP-04 and WF-09 issues are related to the height of allowed vegetation and those are addressed in the response to WF-09/WR-10 within this document. The WF-08 issue is related to 20-foot fuel breaks and the request to clarify terms does not include a request to reduce fuel breaks.

  ODOE confirmed during a meeting on January 27, 2026, with the Certificate Holder, BrightNight, and Tetra Tech that the term "clear, brush-free" can include low-growing, fire-resistant vegetation. The Certificate Holder will update the language in the Final Construction Wildfire Mitigation Plan Section 4.6.1 and the Final Comprehensive Solar Revegetation and Soil Management Plan Appendix F to clarify that the 20-foot buffer around the perimeter will be 10 feet on either side of the fenceline

  The Department's evaluation determined that the common term that should be used for all fire buffers is "noncombustible buffer." However, the Certificate Holder requests that the term "low-growing, fire-resistant vegetation" be used in reference to the areas along the solar array fencelines, access roads, and perimeter fenceline in order to:

  1) ensure clarity and consistency regarding vegetation management within these fire buffers, as "noncombustible buffer" refers primarily to gravel or bare dirt, and

  2) address existing erosion concerns while providing wildfire mitigation at the Project site. Low-growing, fire-resistant vegetation protects against soil erosion and prevents the spread of fire following ignition. Maintaining areas completely free of vegetation would contribute to soil erosion.

  The Certificate Holder requests that this language be updated in the following sections of the draft Final Order:

  - III.N.1 Findings of Fact – Wildfire Mitigation Plans – Facility Design
  - III.N.1 Findings of Fact – Wildfire Mitigation Plans – Construction WMP, Wildfire Risk Minimization Preventative Actions, Programs, and Procedures
  - III.N.1 Findings of Fact – Wildfire Mitigation Plans – Operational WMP, Wildfire Risk Minimization Preventative Actions, Programs, and Procedures

  The Certificate Holder will provide redlined versions of the associated plans by the close of the sur-reply period outlining the requested changes.

- **LU-01: Request for reduction in requirements for Site Plan Review**

  Requiring the Certificate Holder to demonstrate compliance with all applicable local ordinances and Site Certificate conditions when applying for a conditional use permit under ORS 469.401(3) is contrary to the plain language and the intent of the statute. Such an obligation requires the County to exercise discretion in making its determination. Issuance of a conditional use permit under ORS 469.401(3) is an administrative procedural step only to give the County dual enforcement authority over the facility; it is not supposed to involve discretion. The condition properly requires the certificate holder to provide the proper forms under the Sherman County Zoning Ordinance (SCZO) 5.4(1) and (3), which are both procedural requirements. SCZO 5.4(1) simply requires a site plan "drawn to scale, and showing the dimensions, arrangement, and intended use of the proposed development." Certificate Holder respectfully requests ODOE reconsider its

interpretation of the SCZO when drafting LU Condition 3(b).

- **LU-02: Objection to Evaluation of Compliance with SCZO 5.2(5)**

  Certificate Holder respectfully disagrees with ODOE's interpretation and conclusion that the Department of Land Conservation and Development (DLCD) Goal 3 exception acreage thresholds are "land standards" within the meaning of the SCZO. The DLCD Goal 3 exception acreage thresholds in OAR 660-033-0130(38) are triggers requiring application of additional criteria. Under ODOE's rationale, because the Certificate Holder demonstrates that a Goal 3 exception is warranted, ODOE should then find that the DLCD land standard in question has been met and Certificate Holder complies with SCZO 5.2(5). The Certificate Holder respectfully requests the Department reconsider its recommended findings under SCZO 5.2(5).

- **LU-04: Objection to Evaluation of Compliance with SCZO Section 5.8(20)(1)**

  SCZO 5.8(20) provides the special conditional use criteria for non-farm uses in the Exclusive Farm Use (EFU) zone. There are six criteria that must be met, three of which explicitly impose geographic extents for evaluating impacts: SZCO 5.8(20)(2) requires consideration of impacts on "adjacent lands"; SCZO 5.8(20)(3) requires consideration of the overall land use pattern of the "area"; and SCZO 5.8(20)(4) requires consideration of the location and size of the "tract" itself. SCZO 5.8(20)(1) has no language describing the geographic extent of the required analysis. Instead, the subpart refers only to farm uses described in ORS 215.203(2). ORS 215.203(2), in turn, refers to the current employment of land for the primary purpose of obtaining profit. Certificate Holder respectfully contends that subpart (1) is intended to require a general analysis, not a specific analysis limited to the subject tract as ODOE contends. If the County had intended to limit the analysis to a geographic area, like the subject tract, it would have specified as it did in subparts (2), (3), and (4). If anything, using ODOE's rationale under LU-05, when a criterion is silent as to the geographic extent of the analysis, it may be proper to apply the EFSC Land Use Analysis Area.

  The relevant sections are provided below:

  - SCZO 5.8(20)(2): Does not interfere seriously with accepted farming practices on adjacent lands devoted to farm use;
  - SCZO 5.8(20)(3): Does not materially alter the overall land use pattern of the area;
  - SCZO 5.8(20)(4): Is situated upon generally unsuitable land for the production of farm crops and livestock, considering the terrain, adverse soil or land conditions, drainage and flooding, vegetation, location and size of the tract, and the availability of necessary support resources for agriculture.

- **LU-05: Objection to Evaluation of Compliance with SCZO 5.8(20)(3)**

  The Department's Evaluation requests that the Certificate Holder provide an analysis of SCZO 5.8(20)(3) based on the established Land Use Analysis Area to support review of our comment. However, the Certificate Holder disagrees with the Department's interpretation that the Land Use Analysis Area is appropriate for this analysis, as explained below.

  SZCO 5.8(20)(3) is one of six special conditional use criteria applicable to non-farm uses in the EFU zone. As described above, three of the six special conditional use criteria impose a geographic extent for consideration. Here, subpart (3) asks the applicant to look at the "overall land use pattern of the area." This is in contrast to other subparts that ask the applicant to look at "adjacent lands" or the "tract" itself. The EFSC Land Use Analysis Area is for evaluating a facility's compliance with the EFSC Land Use Standard, which includes

demonstrating compliance with the applicable substantive criteria from the SCZO. The EFSC Land Use Analysis Area, however, is not determinative of the geographic extent for applying the SCZO criteria. The criteria themselves impose the geographic extent. Certificate Holder respectfully maintains that the geographic extent in SCZO 5.8(20)(3) requires a look beyond the EFSC Land Use Analysis Area at the "overall land use pattern of the area." This is the broadest geographic extent language in SCZO 5.8(20), expanding beyond the adjacent lands or the tract. The EFSC Land Use Analysis Area is frequently used to describe the adjacent or surrounding lands to the project site. When considering changes to overall patterns, that means land use patterns within swaths of the County like North Sherman County, not the surrounding lands within the EFSC Land Use Analysis Area.

- **LU-17: Land Use/Goal Exception – Project Furthers Oregon's Clean Energy Directives and Goals**

  Goal 3 Exception Reason "Directly Furthers Oregon's Clean Energy Directives and Goals"
  ODOE acknowledges that EFSC has discretion to decide when to grant an exception to a statewide planning goal. ODOE also acknowledges that EFSC must balance Oregon's goals and directives to combat climate change and renewable energy development against the State's Goal 3 to protect agricultural lands. Yet ODOE recommends that EFSC disregard any weight for the State's clean energy goals and the Governor's explicit directives when ODOE recommends that EFSC exercise its discretion and balance in favor of Goal 3 agricultural lands. This gives more weight and priority to Goal 3 than the State's clean energy goals and the Governor's explicit directives, which the Certificate Holder respectfully continues to assert warrants reconsideration. The State's own energy department is recommending that EFSC choose to exercise its discretion in a manner that fails to recognize or further the State's clean energy policy and directives.

  ODOE may be misinterpreting the Certificate Holder's proposed findings when concluding that "granting an exception to a Goal 3 based solely on the fact that a proposal would result in the construction or expansion of a renewable energy facility is tantamount to ignoring Goal 3 altogether." Rather, the Certificate Holder is asserting that Biglow Solar will directly further the State's clean energy goals and directives, especially in light of Executive Order 25-29, which requires state agencies to advance the implementation of the state energy strategy and get clean energy projects built, particularly those projects that contribute to energy affordability and reliability. The Certificate Holder maintains that this reason alone is sufficient to justify a Goal 3 exception. While this is not a reason commonly relied upon to grant a Goal 3 exception, it nonetheless is justified. It also does not set precedent or lead to a "slippery slope" for future decisions. This reason is based on specific facts and circumstances that are unlikely to occur repeatedly given the Certificate Holder's unique positioning as a regulated public utility in Oregon.

  In addition, the Certificate Holder has not asked EFSC to consider this reason alone to justify the Goal 3 exception. Instead, the request is coupled with the locational dependency reason and the economic benefits to the agricultural economy reason, which includes implementation of the Community Investment Plan. ODOE is concerned about expressly ignoring Goal 3 in favor of other State policies, but as ODOE recognizes, EFSC has the discretion and the authority to balance the State's goals. We believe EFSC can do so here in a way that grants the Goal 3 exception, recognizes the importance of other reasons like the ones presented here, and reaffirms Goal 3 policies with the implementation of the Community Investment Plan, ensuring that potential impacts to

agricultural lands and related economies are offset

- **LU-18: Land Use/Goal Exception – Minimal impacts to Other Resources**

  Goal 3 Exception Reason "Minimal Impacts on other resources protected by Council standards"
  ODOE appears to be rejecting this reason because of a new rationale related to "double counting" and because the Certificate Holder had already demonstrated sufficient reasons to grant an exception to Goal 3. ODOE recommended EFSC reject the minimal impacts reason, and instead consider those minimal impacts and mitigation per the Oregon Department of Fish and Wildlife Habitat Mitigation Policy as meeting the mitigation requirement in ORS 469.502(2)(c)(B). This approach avoids "double counting" - i.e., finding the same underlying facts and evidence as meeting two separate criteria necessary for granting an exception. The Certificate Holder respectfully disagrees with this approach as Council has previously determined "minimal impacts on other resources protected by Council standards" as a reason for granting an exception under ORS 469.504(2)(c)(A) and did not consider this "double counting" or finding the same underlying facts and evidence under ORS 469.504(2)(c)(B). Furthermore, there are no rules in ORS 469.504(2)(c)(A) that restrict the Council's discretionary determination of what merits a "reason," nor does ORS 469.504 have any regulations indicating that the ODOE may not consider the same underlying facts and evidence to satisfy more than one standard under the rule. Such a policy would not make sense because underlying facts and evidence do not "change" depending on what standard or rule is being considered. ODOE's decision to forego consideration of the project's minimal impacts on other resources protected by Council standards is not grounded in any statutory or rule language or policy and is inconsistent with ODOE's past practices.

- **FW-03: Flexibility on ground clearing activities in Category 2 Habitat**

  The Department's evaluation requests that the Certificate Holder provide reasons why, for the isolated areas of Category 2 habitat, site preparation activities would not be able to be planned and completed at a time that would avoid the critical period for ground-nesting birds.

  The Certificate Holder will make every effort to avoid vegetation removal or ground disturbance in Category 2 habitat from April 15 to September 1. Facility construction is scheduled to begin in June 2026. If vegetation or ground disturbance is restricted in Category 2 habitat during the breeding season, then construction will not be able to begin in Category 2 habitat until after September 1. If avoidance during the specified window is not feasible without impacting the schedule or sequencing of project construction, the Certificate Holder requests the option to complete nest clearance surveys prior to disturbance to avoid impacts to ground-nesting birds. Nest clearance surveys would allow some work to begin in Category 2 habitat in sync with the construction schedule for the rest of the Facility.

- **WF-04: Request for flexibility in road design standards for roads not needed for fire access**

  The Department's evaluation requested the Certificate Holder provide the site plan showing the designated emergency access roads and documentation of any additional correspondence with the North Sherman Rural Fire Protection District other than what was included in RFA4 Attachment U-1.

  Attachment 1 shows the designated emergency access roads. PGE and BN have

conducted extensive outreach in the community and with local emergency responders. On August 12, 2025, BN presented at a North Sherman County Rural Fire Protection District Board meeting, where proposed project details were shared alongside an overview of planned fire prevention and wildfire mitigation measures (the meeting presentation is provided as Attachment 3 to this comment letter which was not previously provided on the record). In addition to this presentation, the project team has been coordinating closely with Sherman County Emergency Services and the North Sherman County Rural Fire Protection District, and has met multiple times, both in person and over the phone, with Fire Chief Burbank to review site-specific fire mitigation measures. Feedback provided by Chief Burbank on the draft Construction Wildfire Mitigation Plan and Biglow Solar site plan indicate the measures are sufficient to address and mitigate wildfire risk during construction and operation of the Biglow Solar facility. BrightNight also plans to invest in the local community and help the North Sherman Fire District build capacity to address wildfire risks within the Fire District boundaries by donating $200,000. To memorialize their intent to donate to the Fire District, BrightNight has shared a draft MOU with Chief Burbank to share with the District for their review and comment.

- **WF-09: Support for recommended vegetation maintenance standards for wildfire season/ WF-10: Objection to Vegetation Maintenance Standards for Wildfire Season**

  The Certificate Holder appreciates ODOE's consideration of vegetation height requirements during the dry season and the input provided by the Sherman County Weed District and other commenters.

  As previously discussed, maintaining vegetation at a height of 1 to 3 inches during the June–October dry season presents practical and ecological challenges. Repeated mowing to that height would likely damage perennial bunchgrasses included in the approved seed mix, reduce long-term stand viability, increase susceptibility to invasive annual grasses, and potentially elevate fine fuel risk over time. In addition, mowing at extremely low heights may increase ignition risk due to equipment contact with rocks or soil surface.

  At the same time, the Certificate Holder acknowledges neighboring non-participating landowner concerns regarding wildfire risk and understands the desire for lower vegetation height during the peak fire season. Based on consultation with vegetation management specialists from Sherman County Weed District and Tetra Tech, and consideration of local Conservation Reserve Program management practices, the Certificate Holder is committed to maintaining vegetation at a target height of approximately 8 inches during the dry season, where practicable to ensure vegetation health. The Certificate Holder further commits that vegetation will be maintained below 10 to 12 inches, consistent with the draft Comprehensive Solar Revegetation and Soil Management Plan.

  An 8-inch target height represents a reasonable middle ground that:

  - Reduces standing fine fuels compared to unmanaged conditions;
  - Maintains bunchgrass crown integrity and long-term vegetation health;
  - Aligns more closely with local vegetation management practices; and
  - Avoids creating conditions that would favor invasive annual grasses.

  The Certificate Holder recognizes that mowing height may vary slightly depending on equipment capabilities, species composition, and site conditions, and commits to implementing vegetation management in coordination with local experts and in accordance with the final approved Comprehensive Solar Revegetation and Soil

Management Plan and Construction Wildfire Mitigation Plan.

This approach reflects the Certificate Holder's willingness to collaborate with ODOE and local stakeholders while ensuring that vegetation management practices remain ecologically sustainable and supportive of long-term wildfire risk reduction objectives.

- **TL-01: Request for additional flexibility in transmission line siting**

  The Department's evaluation requests that the Certificate Holder must present the alternate gen-tie transmission line corridors so that they can be evaluated for compliance with applicable laws, rules and standards.

  The Certificate Holder appreciates the opportunity to update the location of the project substation and 230-kV gen-tie transmission line for the record. As described in RFA 4 and the Proposed Order, the gen-tie transmission line was originally identified as approximately 600 feet in length within a 150-foot corridor and supported by four 80-foot-tall steel monopole structures.

  As design has progressed, refinement of the project substation location has resulted in a corresponding adjustment to the gen-tie transmission line, with an updated alignment of a 230-kV transmission line approximately 1,900 feet in length, supported by three 80-foot-tall steel monopole structures. Attachment 4 shows the new location of the project substation and gen-tie transmission line, all still located within the Solar Micrositing Area.

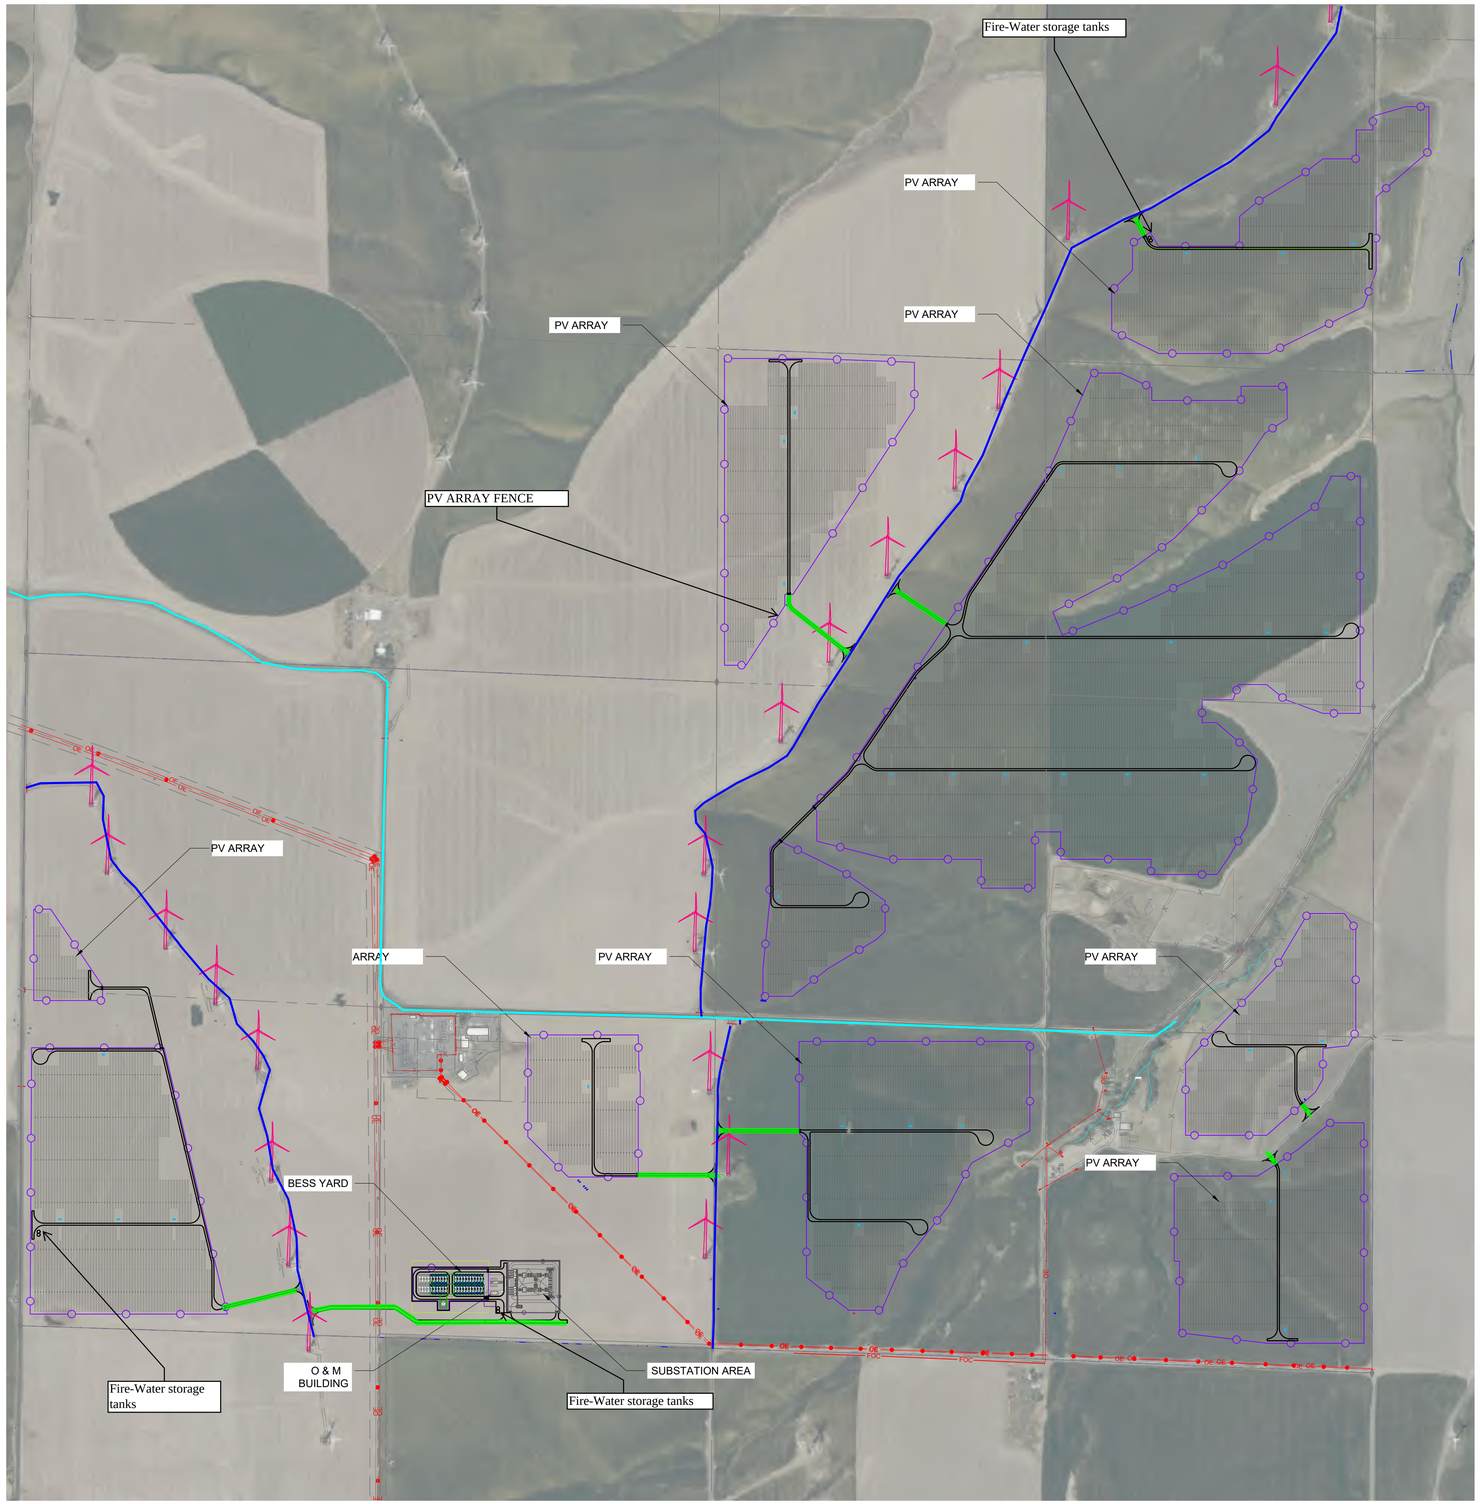
  The refinement resulted from continued engineering evaluation of site conditions and infrastructure layout. During design reviews, it was identified that the originally planned substation area may present constraints relative to the existing infrastructure. Accordingly, the substation location and corresponding gen-tie alignment were adjusted to avoid low elevation areas, better align with existing infrastructure, and improve constructability, long-term operability, and overall infrastructure resilience. This refinement reflects prudent final engineering and results in improved consistency, new and existing infrastructure, rather than a change in project scope.

  Although the revised alignment extends beyond the originally anticipated 150-foot corridor by approximately 500 feet, the alignment remains entirely within the Solar Micrositing Area and within areas previously identified in the RFA 4 application as being subject to permanent impacts. The shift represents a minor refinement in siting based on final engineering and does not introduce permanent impacts outside of those areas already analyzed and disclosed in the application materials.

  Accordingly, the Certificate Holder respectfully requests flexibility in the Final Order to accommodate this refined alignment, while clarifying that the updated configuration remains within the previously anticipated permanent impact area and does not expand the overall footprint of analyzed impacts.

PGE respectfully submits these comment replies for consideration by ODOE and the Energy Facility Siting Council in advance of Council action on the Proposed Order for Request for Amendment 4.

Sincerely,



Lenna Cope

North Sherman County Fire Board

MEETING

AUGUST 2025

TODAY'S GOAL

- **Progress Update:** Share overview of the project and update you on our progress
- **Safety:** Discuss the safety measures planned for construction, design, and operation
- **Experience:** Review how BrightNight has worked with first responders in other project communities
- **Feedback:** Learn what else we can do to align our work with Sherman County's emergency safety preferences. Wrap up with a list of discussion topics.

WHO'S HERE?

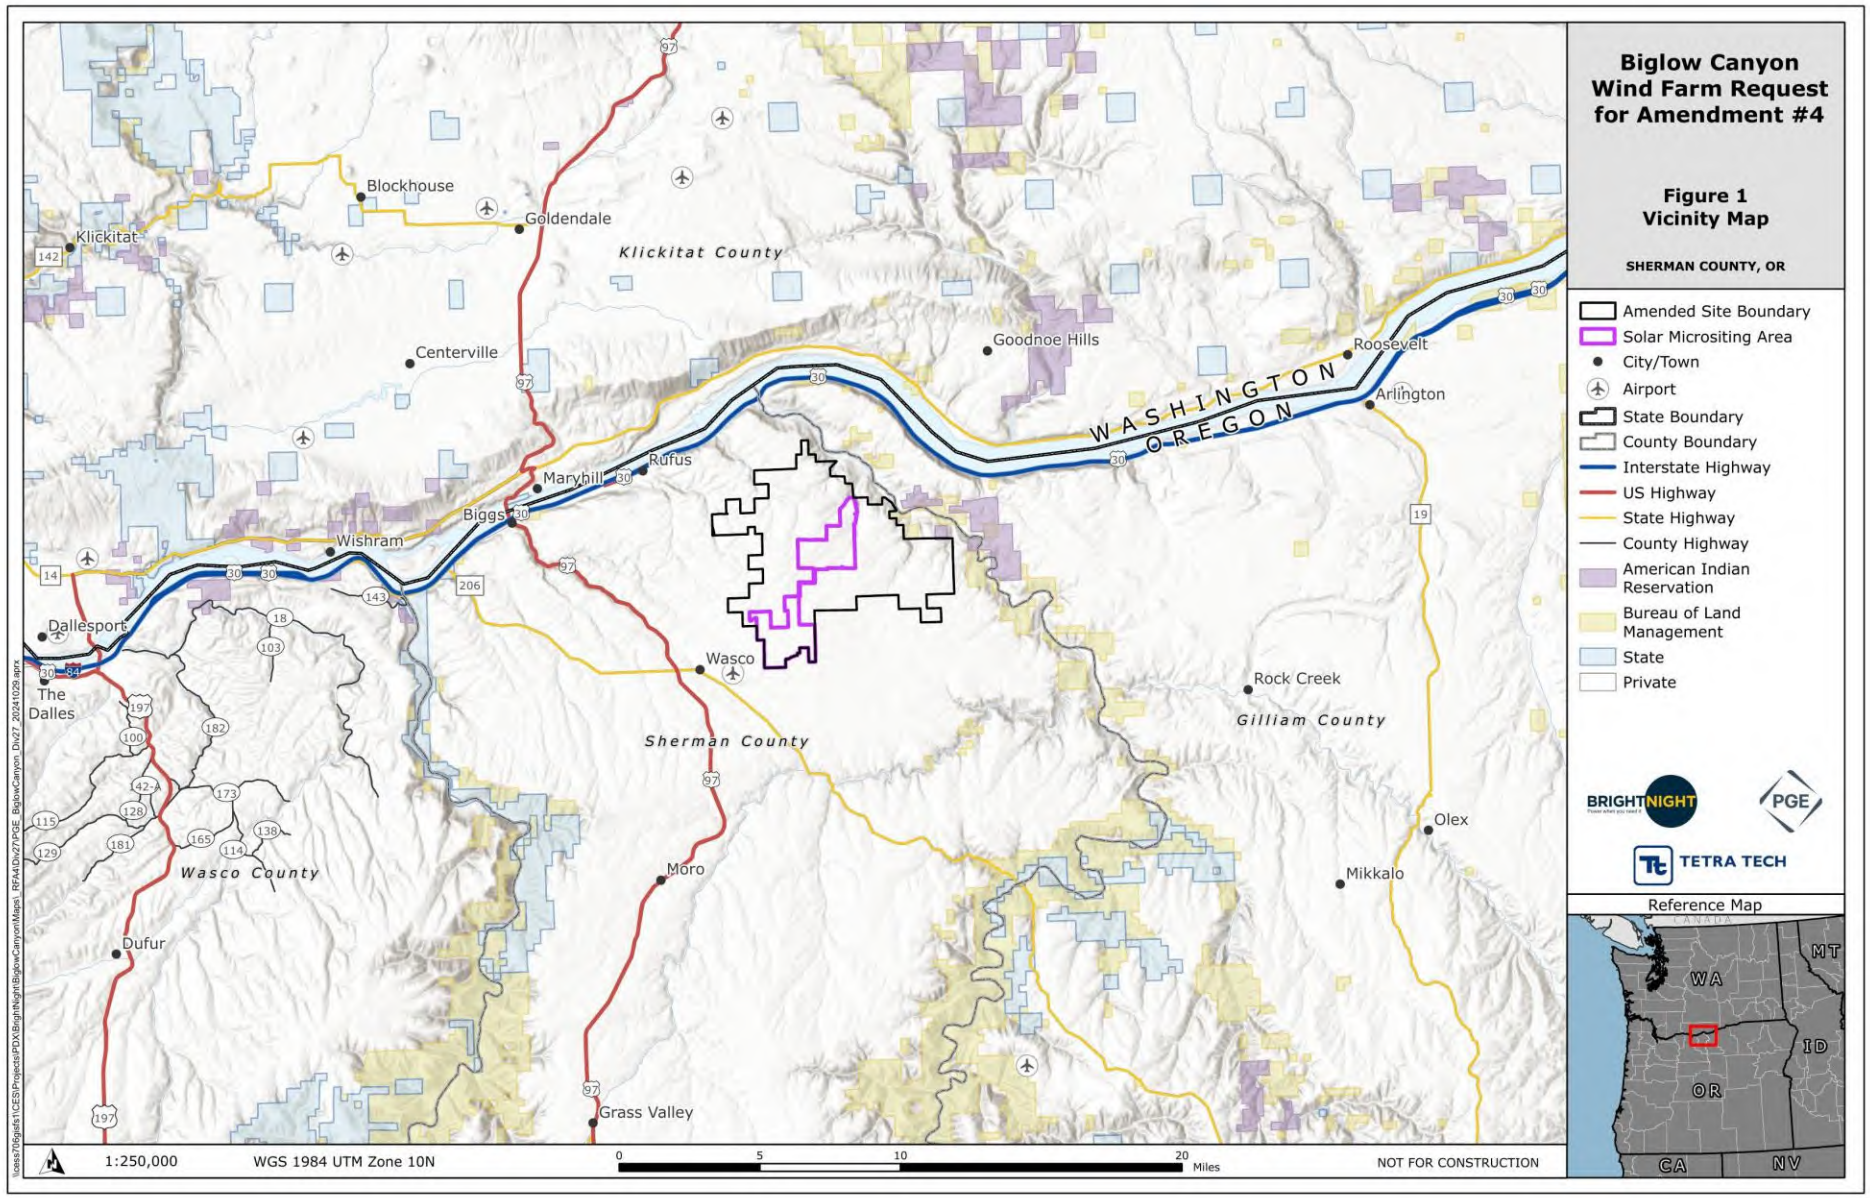
BrightNight

- Kathleen – Lead developer
- Tamara – Development support
- Michael – Project Delivery
- Ranjith – BESS Engineering
- Arturo – Solar Engineering

Coffman Engineers

- Mark Gouveia

AGENDA/PURPOSE



- Project Description
- Site Layout Review
- Schedule Overview
- Emergency Response Plan Overview
- Share Wildfire Mitigation Plan (WMP) measures for construction
- Ensure coordination with Sherman County responders

Project Description

Project Description

Biglow Solar + Storage Project Overview

OVERVIEW
PGE and BrightNight have partnered to bring a solar and storage project to the existing Biglow Canyon Windfarm in Sherman County, Oregon.

CAPACITY
385-Megawatts in two phases. Today, we're discussing phase 1 (125 MW PV and 125 MW BESS).

FOOTPRINT
Study area is 3,980 acres. Actual project footprint is ~676 acres.

INTERCONNECTION
Utilizing the existing Biglow Canyon Substation. Ideal optimization of existing infrastructure to reduce project impact.

PERMITTING
Currently moving through the Oregon EFSC process.

Tax Revenue
At least $40,000,000 in tax revenue generated over the life of the project.

Schedule Overview

2024

April-Sept

Survey Complete (cultural resources, habitat, raptor, wetlands, botanical)

Meetings with community leaders

Initial tribal outreach

2025

April

Application for Amendment for existing EFSC Site Certificated deemed published and complete by ODOE

July

Preliminary layout

Technology selection

Agricultural mitigation meetings

August

Sponsorship of the Sherman County Fair

Open house, Aug. 19

September

Anticipate completing EFSC application submission

November

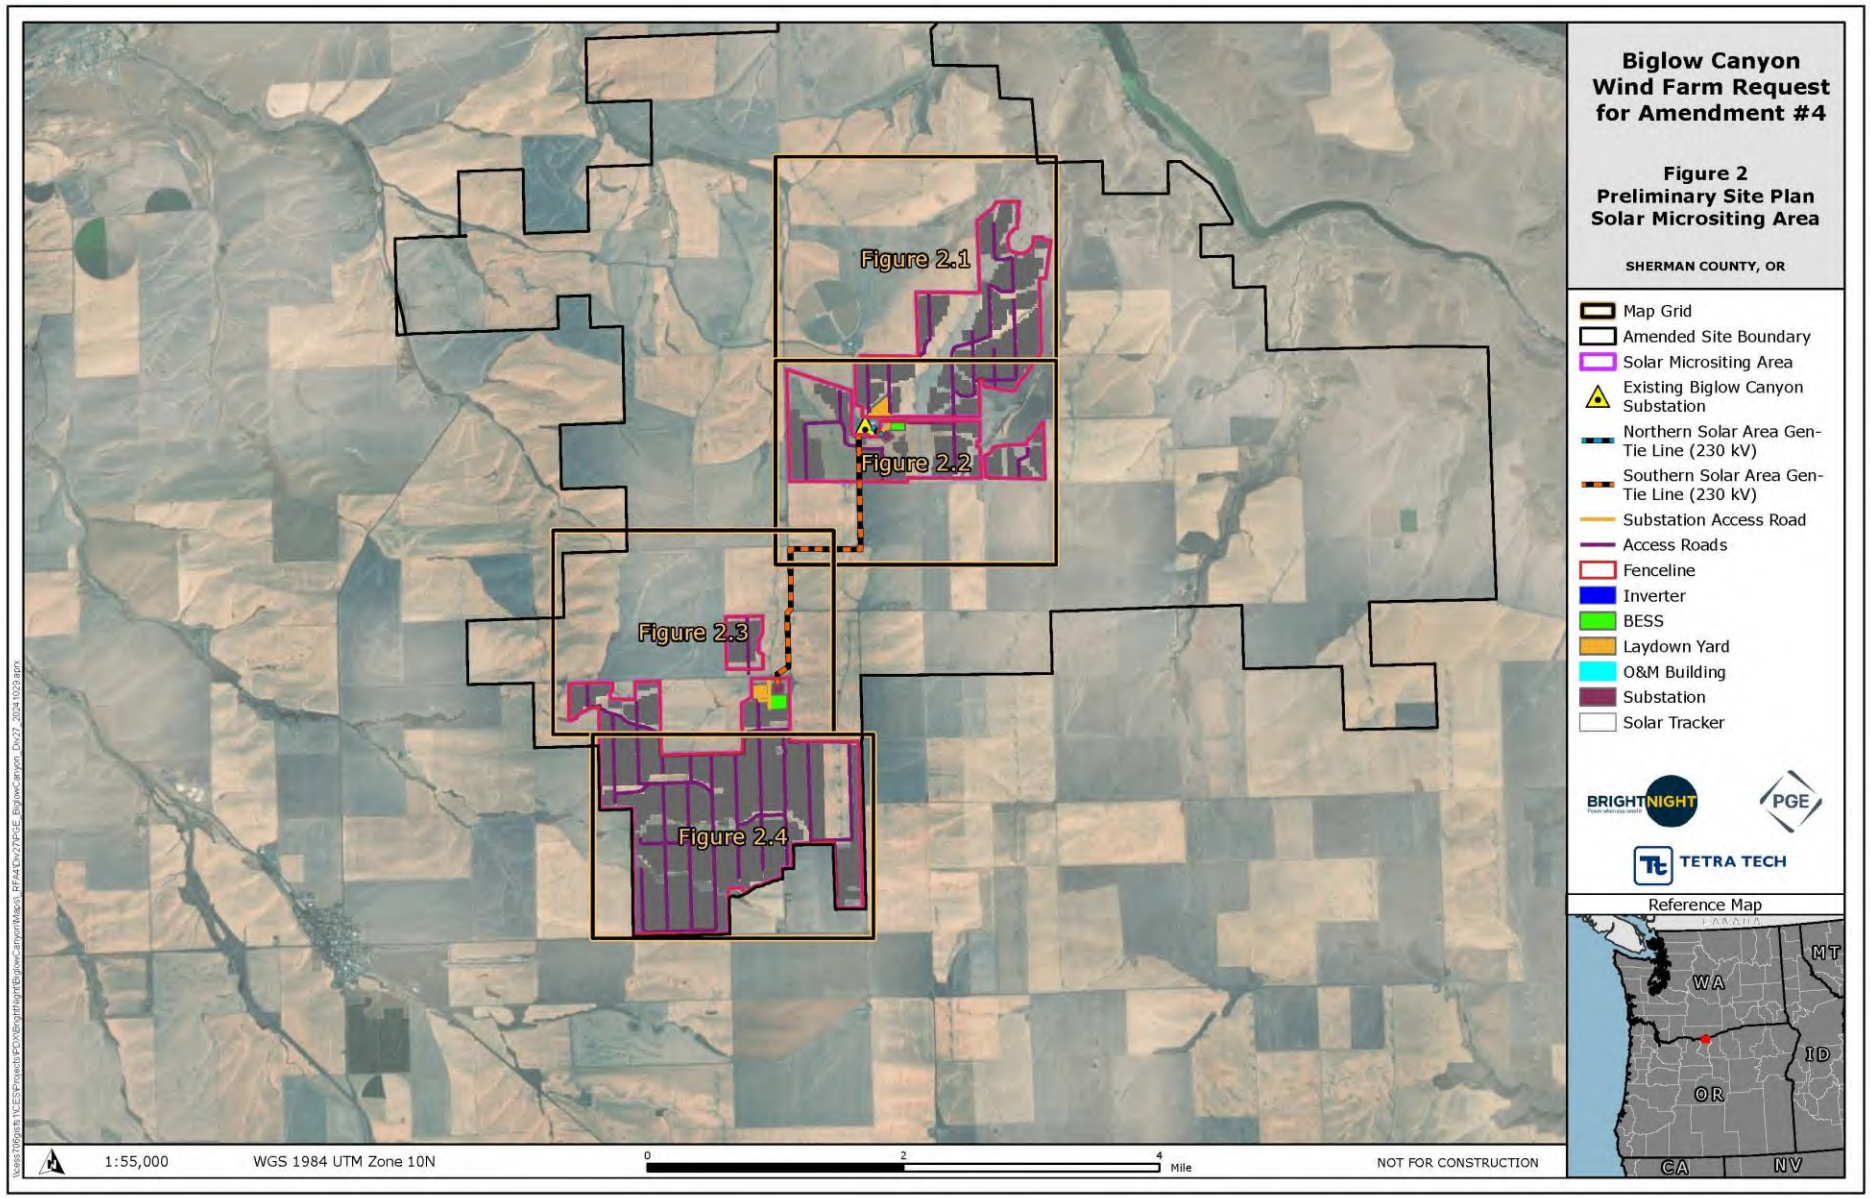
EFSC issues "draft proposed order," tentative hearing date set

2026

January

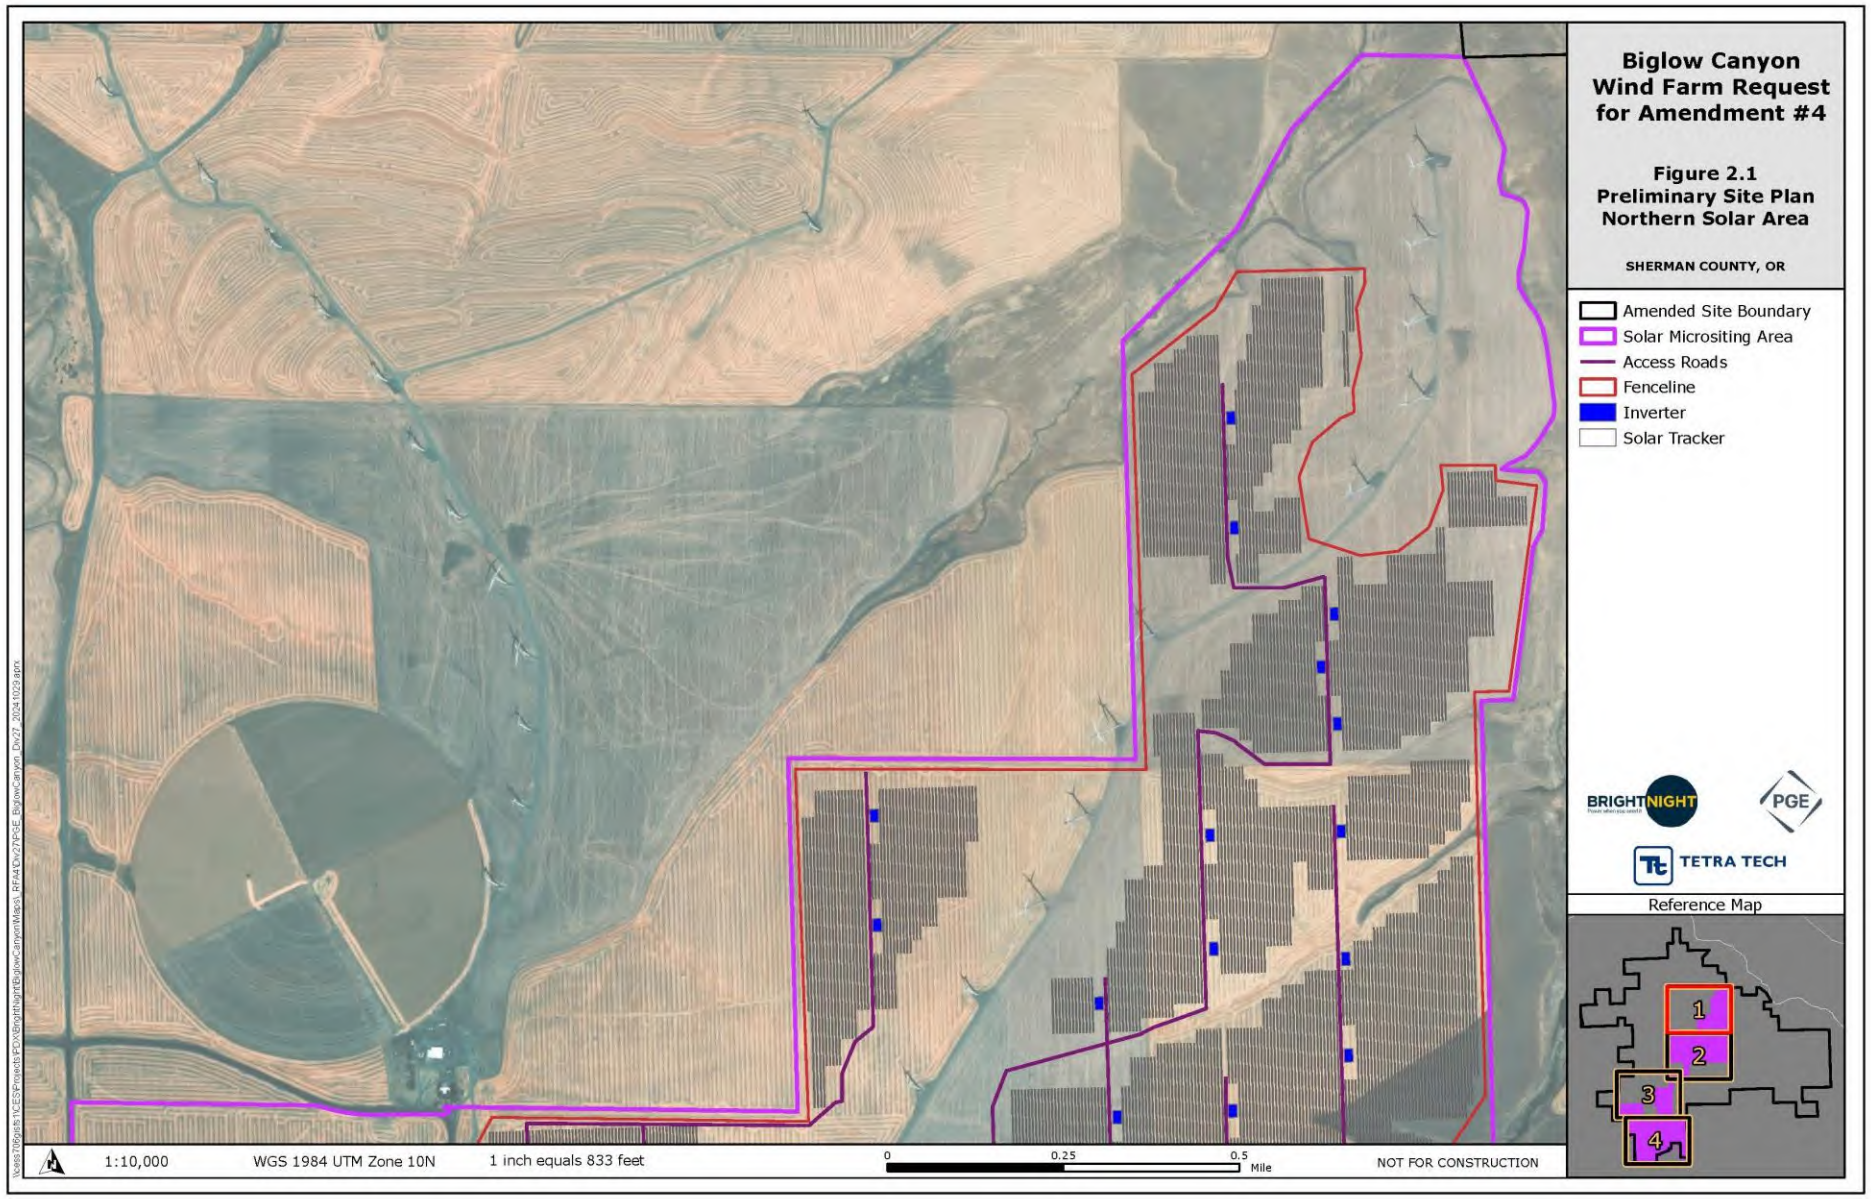
Council review and determination

Q2



Construction of phase 1

2027



Q4

Anticipated construction of phase 2

Equipment Clearances:

- Minimum 8' clearance between front faces of battery enclosures for O&M access and UL 9540A fire propagation prevention guidelines
- Minimum 10' clearance between side faces of battery enclosures

Access Roads

- 24' interior access roads and perimeter road for firetruck access
- 50' internal turning radius

Minimum 10' setback from fence to BESS yard perimeter road

BESS Equipment Details

Subtitle goes here

Manufacturer and Model – Tesla Megapack 2XL

Fully integrated AC battery enclosure with battery modules, string inverters, thermal management system and fire safety systems

Proprietary fire detection and suppression system

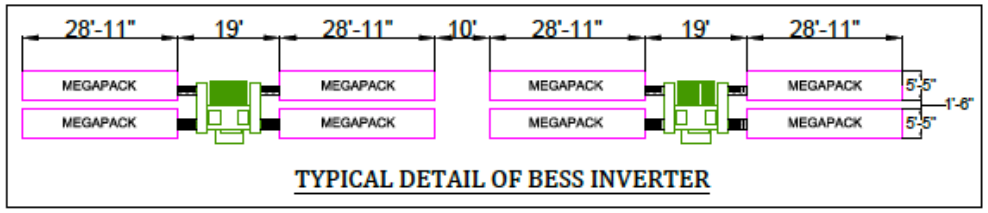
Over 14 GWh in operation

Proposed Equipment Quantities

- Initial Install – 154 Megapacks and 39 Medium Voltage Transformers
- Future Augmentation – 29 Megapacks and 7 Medium Voltage Transformers
- Medium Voltage Transformers – 39
- Note that equipment quantities could change as design progresses

Equipment Specifications:

Mechanical



- IP66/ NEMA 3R
- L x D x H - 8.8m x 1.6m x 2.7m
- 84,000 lbs
- Operating Temperature Range: -30C to 50C

Electrical

- Output voltage: 480V AC 3 phase
- Power Rating: 979 kW
- Energy Rating: 3916 kWh

Codes and Certifications

- System – UL 9540, UL 9540A, UL 1973, UL 1741, IEC 62619, IEEE1547
- Battery Cells – UL 1642

SAFETY & EMERGENCY RESPONSE

Kathleen
Coffman Engineers

BrightNight ensures safety at every level of design and operation

Foundations of BrightNight's Safety Program

- Work closely with customer design and operations teams to exceed customer's safety expectations
- Community engagement
- Rigid procurement and contracting standards with Suppliers, EPCs and Integrators
- In-depth safety review at every phase of project design
- Robust project execution process that considers safety from Cradle to Grave (design, engineering, testing, installation, commissioning, operation, service and disposal)
- 24/7 visibility to personnel, equipment and environment safety, planned PMs and Service during project operation
- Continuous learning through education, training, communication and continuous improvement process

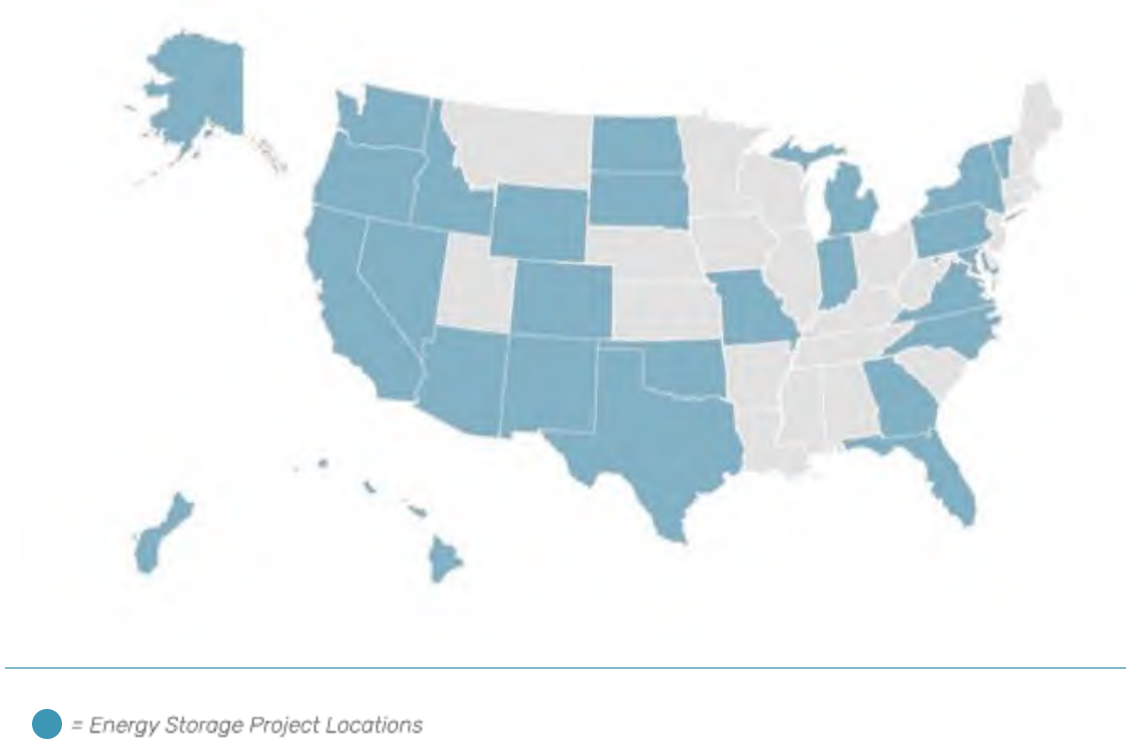
Coffman Energy Storage Experience

Supporting developers, EPCs, utilities, and OEMs

At all stages of the project life cycle

- CUP application, permitting, utility interface
- Configurational design, Third Party Review
- 30-60-90-IFC Construction Documentation
- Fab Shop Inspections / SAT / Commissioning

Experience with all types of energy storage



- Lithium-ion Battery Storage
- Flow Batteries / Metal-air / Non-Lithium
- Gravity Systems, Flywheel
- Compressed Air (CAES)
- Thermal Energy Storage (TES)

Services: Engineer of Record, OE, Third Party Review

Fire Prevention

BrightNight plans to use the "Tesla Megapack" battery system at the Biglow Solar and Storage Project. This industry-leading equipment features exceptional safety and prevention technology:

Noise

The Megapack is self-contained and operational noise levels are designed to minimize noise pollution. The Greenwater project will abide by all local noise ordinances.

Emissions

In the unlikely event of a fire, emissions are extremely limited. Any emissions would originate from the plastic enclosures, not the batteries. Concentrations are so small there would would be no negative impact to air quality in the surrounding area

Proactive Fire Control

Megapack is designed to prevent battery fires and be resilient if they occur. Fires are extremely rare. Testing has shown that if one occurs, Megapack safety systems can control and contain a fire within the unit.

Containment

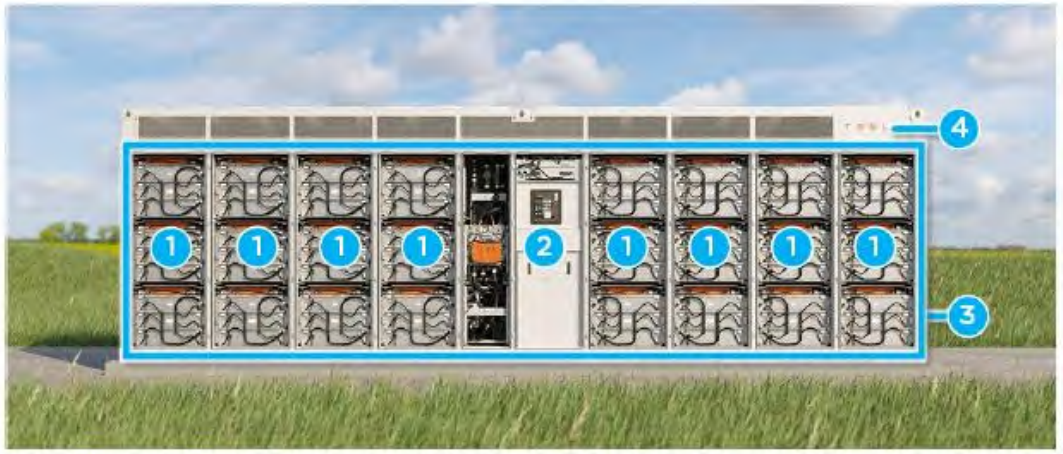
Each Megapack unit is self-contained. This important safety feature helps prevent potential soil or water contamination and prevents the spread of an unlikely fire event.

Water Runoff

Megapacks are designed to make it difficult for water to come in contact with the enclosed battery cells.

Lithium Batteries

Tesla Megapack Fire Protection Systems



BESS projects are safe for the environment. Self contained systems with no emissions during normal operation.

24/7 Monitoring. Megapack installations are remotely monitored by Tesla 24/7, allowing for early detection, diagnosis and troubleshooting of system errors while providing live support to first responders when needed.

Proactive Fire Control. Megapack is designed to prevent battery fires and be resilient if they occur. Fires are extremely rare. Testing shows that if one occurs, Megapack safety systems can control and contain a fire within the unit. Typically contained to a single module with no visible flames on the exterior.

Recyclable at End of Life. At the end of the system's lifetime BrighNight will safely remove the battery enclosures and recycle the majority of components.

1. Battery modules with active and passive fuses – externally serviceable
2. Touch-safe Customer Interface Bay
3. Non-walk-in IP66 enclosure and deflagration mitigation
4. Thermal roof with overpressure vents

UL Listed Equipment. Equipment is fully test and listed by the UL testing company for the products in your house.

Fire Event Gas Byproducts. Gases resulting from a Megapack fire are similar to those of a typical structure fire: hydrogen, carbon dioxide, carbon monoxide and methane. Expected fire size is less than a house or vehicle fire.

Fire Event Water Runoff. Megapack units are designed to make it difficult for water to come in contact with the enclosed battery cells. Fire water runoff testing has shown no harmful levels of contaminants. (Note: Tesla's Emergency Response Guide recommends no direct water application to a Megapack fire.)

Re: Biglow Canyon Wind Farm Request for Amendment 4 – Sur-reply Response to Comments on Proposed Order (BCWAMD4Doc24-09)

Dear Lawrence,

Portland General Electric (PGE) and project developer BrightNight (BN) appreciate receipt of your February 27, 2026, letter on behalf of the Confederated Tribes of Warm Springs Reservation of Oregon (CTWSRO), regarding PGE's letter addressing your comments on the Oregon Department of Energy's (ODOE) Proposed Order on Request for Amendment 4 (RFA 4) to the Biglow Canyon Wind Farm Site Certificate.

PGE and BN acknowledge that the proposed solar components under RFA 4 are located within the ceded lands of CTWSRO and in an area of ongoing cultural, historical, and archaeological importance. We appreciate CTWSRO's continued participation in government-to-government consultation with the State of Oregon.

PGE remains committed to cultural resource protection in a manner consistent with the Amended Site Certificate and the Energy Facility Siting Council's (Council) Historic, Cultural, and Archaeological Resources standard (Oregon Administrative Rule [OAR] 345-022-0090). Archaeological monitoring, inadvertent discovery procedures, and continued Tribal consultation are being integrated to ensure appropriate protection of cultural resources during ground-disturbing activities.

PGE acknowledges and appreciates CTWSRO's request regarding construction-phase Tribal coordination and monitoring. We value the Tribe's continued engagement and view this request as an important continuation of coordination efforts as the project advances toward implementation.

As reflected in the record, the project design was refined based on the results of the GeoVisions report to avoid all archaeological sites determined eligible for, or likely eligible for, listing in the National Register of Historic Places (NRHP), as well as unevaluated sites, by a minimum 20-meter buffer. The Oregon State Historic Preservation Office (SHPO) concurred with the eligibility determinations and the avoidance-based approach. It is PGE's continued understanding that the approved design avoids direct impacts to identified cultural resources.

The construction-phase framework described below is intended to support careful implementation of that avoidance-based design and to ensure continued coordination and responsiveness during ground-disturbing activities. PGE is committed to ensuring that cultural

resource protection measures are implemented consistently and effectively during construction.

To that end, we agree to develop a project-specific Inadvertent Discovery Plan (IDP) and a construction-phase Cultural Resources Coordination and Monitoring Plan (CRCMP) in consultation with CTWSRO and other consulting Tribes. These plans will:

- Confirm avoidance of all known cultural resource sites, including clearly defined buffers;
- Establish notification procedures and timelines in the event of scope modifications or immediate communication protocols in the event of inadvertent discoveries or unanticipated conditions;
- Outline monitoring protocols for areas requiring additional oversight if unanticipated conditions are encountered; and
- Provide for regular coordination and communication throughout construction, including schedule updates, milestone notifications, and opportunities for ongoing engagement (e.g., periodic project update meetings).

PGE agrees to incorporate a Tribal Monitor into the project's construction-phase framework, should the Tribe wish to provide one. We will work collaboratively with CTWSRO to define the role, scope, communication protocols, and scheduling parameters for a Tribal Monitor to support real-time coordination and timely response to discoveries or unanticipated conditions in culturally sensitive areas. This framework will clarify expectations regarding site access, communication pathways, and field coordination with contractors.

To further reduce the potential for inadvertent impacts, PGE commits to clearly flagging or fencing avoidance areas prior to and during construction and ensuring that construction personnel are trained on cultural resource protection measures and appropriate communication protocols.

While PGE welcomes and supports Tribal monitoring participation, construction activities will proceed in accordance with the schedule and scope shared during ongoing coordination and communication throughout the life of the project, regardless of whether a Tribal Monitor is present on-site on a given day. The standing invitation for Tribal monitoring will remain in place throughout ground-disturbing construction activities in accordance with the approved CRCMP.

PGE believes that the avoidance measures incorporated into the refined design, together with SHPO concurrence, the IDP, and compliance with Oregon Revised Statutes (ORS) 358.910–358.920, provide a protective and legally sufficient framework. At the same time, we remain open to continued dialogue to ensure that construction-phase coordination measures are clearly defined, appropriately tailored, and supported by the record.

To ensure that the commitments and coordination framework described above are clearly reflected in the project record, PGE requests that these clarifications be incorporated into the Final Order through revisions to applicable site certificate conditions, consistent with the Proposed Order. The proposed revisions are intended to further clarify avoidance requirements, construction-phase cultural resource coordination and monitoring, and implementation of inadvertent discovery procedures. For the Department's and Council's consideration, PGE provides the following redline revisions to the conditions identified below.

***GEN-HC-02**: The certificate holder must design, construct, and operate the solar facility to avoid archaeological sites (35SH00188, BSP-1-S02, BSP-1-S10, and BSP-1-S12) and archaeological isolate (BSP-1-I04) with a minimum 20-meter avoidance buffer.*

Prior to ground-disturbing activities, avoidance areas must be clearly identified in construction plans and physically flagged or fenced in the field prior to ground-disturbing activities. The Certificate Holder must ensure that the construction personnel are informed of avoidance areas and trained on cultural resource protection requirements prior to initiating ground disturbance.
[Final Order on RFA4, Historic, Cultural, and Archaeological Condition 1]

***GEN-HC-03**: Prior to construction activities ~~that occur within the 20-meter avoidance buffer for archaeological sites (35SH00188, BSP-1-S02, BSP-1-S10, and BSP-1-S12) and archaeological isolate (BSP-1-I04);~~ the certificate holder must submit to the Department for approval, in consultation with SHPO, a Cultural Resources Coordination and Monitoring Plan (CRCMP) and a Project-Specific Inadvertent Discovery Plan (IDP) ~~demonstrating that an Oregon Qualified Archaeologist or Tribal Cultural Resource Monitor will be onsite during ground disturbing activities associated with the resources listed in this condition.~~*
The CRCMP must include at a minimum:

1. *Procedures to ensure avoidance of archaeological sites (35SH00188, BSP-1-S02, BSP-1-S10, BSP-1-S12) and archaeological isolate (BSP-1-I04), including maintenance of the required 20-meter avoidance buffers;*
2. *Procedures for flagging or fencing avoidance areas prior to construction;*
3. *Communication and coordination protocols with consulting Tribes, including construction schedule updates and notification of key construction milestones;*
4. *Procedures for training construction personnel regarding cultural resource protection measures and communication protocols;*
5. *Monitoring procedures to be implemented if ground-disturbing activities occur within avoidance buffers or if unanticipated cultural resources are encountered during construction; and*
6. *A framework allowing interested Tribes the opportunity to provide a Tribal Monitor during ground-disturbing activities.*

The Certificate Holder must implement the Department-approved CRCMP and IDP during construction and shall maintain communication with consulting Tribes regarding cultural resource protection throughout construction activities.
~~The certificate holder shall adhere to the measures approved in the Cultural Resources Monitoring Plan.~~

***OPR-HC-01**: During operations, the certificate holder shall require all onsite employees and contractors to implement and adhere to the requirements of the Inadvertent Discovery Plan, as provided in Condition PRE-HC-01. The IDP shall be reviewed and updated*

annually for current contact information, including current contact information for consulting Tribes. [Final Order on AMD4; Historic, Cultural and Archeological Condition 5]

We appreciate the Tribe's continued partnership and look forward to maintaining respectful, transparent, and collaborative engagement throughout the life of the project. Please do not hesitate to contact us if further discussion would be helpful.

Sincerely,

Kenny Gunn
Cultural Resources Lead

Kevin and Kathy McCullough
Wasco, OR

Re: Biglow Canyon Wind Farm Request for Amendment 4 – Sur-Reply Response to Comments on Proposed Order

Dear Mr. and Mrs. McCullough,

Portland General Electric (PGE) and project developer BrightNight (BN) appreciate your February 24, 2026, responses to our February 13, 2026, reply regarding the Oregon Department of Energy's (ODOE's) Proposed Order on Request for Amendment 4 (RFA 4) of the Biglow Canyon Wind Farm (BCWF) Site Certificate.

PGE and BN carefully reviewed your most recent comment response letters and provide the following responses, based on our interpretation of the concerns raised in your correspondence, which are intended to directly and comprehensively address each issue.

This reply provides additional information on an issue-by-issue basis, consistent with ODOE's issue identification framework and categories identified in Table 1 of the ODOE Response letter dated February 12, 2026.

1. **Facility Maintenance/Organizational Expertise (Issue OE-1)**
   In your letter, you reiterate concerns regarding past maintenance challenges at the existing wind facility and express lack of confidence that the Certificate Holder will safely and reliably operate the proposed Solar Components. The Certificate Holder has addressed your facility maintenance concerns in Section 1of our February 13, 2026, comment response letter. As reflected in ODOE's evaluation of Issue OE-01, ODOE and the Certificate Holder acknowledged past maintenance and operational challenges at the existing wind facility and determined that while those issues warrant enhanced oversight, they do not demonstrate the inability to construct or operate the proposed solar components in compliance with the site certificate conditions.

   ODOE has recommended additional conditions to ensure the operational expertise of the Certificate Holder. These conditions require finalization and implementation of the draft Operations and Maintenance Plan Framework to strengthen oversight, vendor accountability, performance monitoring, and reporting expectations. To provide additional clarity regarding how these enhanced oversight measures will be implemented, the Certificate Holder has included a redlined version of the Draft Operations and Maintenance Plan as Attachment A to this letter. The revisions incorporate ODOE's proposed conditions as well as refinements offered during the public comment process. PGE and BN are committed to adhering to the applicable conditions to ensure improved transparency and operational controls moving forward.

2. **Vegetation Height and Fire Buffers/Setbacks (Issues WF-09, SP-04)**

One of the central themes of your letter is the adequacy of vegetation management and perimeter fire buffers, particularly considering the dry windy conditions characteristic of North Sherman County.

The Certificate Holder acknowledges the concerns that commenters have expressed regarding vegetation height at the proposed Biglow Solar facility and provided the following comment on vegetation height to ODOE in a letter dated February 27, 2026. You may have already seen our comment on the ODOE OneDrive set up for the Project, but we wanted to provide it here in case you have not previously seen it:

> *"The Certificate Holder appreciates ODOE's consideration of vegetation height requirements during the dry season and the input provided by the Sherman County Weed District and other commenters.*
>
> *As previously discussed, maintaining vegetation at a height of 1 to 3 inches during the June–October dry season presents practical and ecological challenges. Repeated mowing to that height would likely damage perennial bunchgrasses included in the approved seed mix, reduce long-term stand viability, increase susceptibility to invasive annual grasses, and potentially elevate fine fuel risk over time. In addition, mowing at extremely low heights may increase ignition risk due to equipment contact with rocks or soil surface.*
>
> *At the same time, the Certificate Holder acknowledges neighboring non-participating landowner concerns regarding wildfire risk and understands the desire for lower vegetation height during the peak fire season. Based on consultation with vegetation management specialists from Sherman County Weed District and Tetra Tech, and consideration of local Conservation Reserve Program management practices, the Certificate Holder is committed to maintaining vegetation at a target height of approximately 8 inches during the dry season, where practicable to ensure vegetation health. The Certificate Holder further commits that vegetation will be maintained below 10 to 12 inches, consistent with the draft Comprehensive Solar Revegetation and Soil Management Plan.*
>
> *An 8-inch target height represents a reasonable middle ground that:*
>
> - *Reduces standing fine fuels compared to unmanaged conditions;*
> - *Maintains bunchgrass crown integrity and long-term vegetation health;*
> - *Aligns more closely with local vegetation management practices; and*
> - *Avoids creating conditions that would favor invasive annual grasses.*
>
> *The Certificate Holder recognizes that mowing height may vary slightly depending on equipment capabilities, species composition, and site conditions, and commits to implementing vegetation management in coordination with local experts and in accordance with the final approved Comprehensive Solar Revegetation and Soil Management Plan and Construction Wildfire Mitigation Plan.*
>
> *This approach reflects the Certificate Holder's willingness to collaborate with ODOE and local stakeholders while ensuring that vegetation management practices remain ecologically sustainable and supportive of long-term wildfire risk reduction objectives."*

In addition, the Certificate Holder provided the following comment regarding vegetation management within wildfire buffers to ODOE in a letter dated February 27, 2026:

"ODOE confirmed during a meeting on January 27, 2026, with the Certificate Holder, BrightNight, and Tetra Tech that the term 'clear, brush-free' can include low-growing, fire-resistant vegetation. The Certificate Holder will update the language in the Final Construction Wildfire Mitigation Plan Section 4.6.1 and the Final Comprehensive Solar Revegetation and Soil Management Plan Appendix F to clarify that the 20-foot buffer around the perimeter will be 10 feet on either side of the fenceline.

The Department's evaluation determined that the common term that should be used for all fire buffers is 'noncombustible buffer.' However, the Certificate Holder requests that the term 'low-growing, fire-resistant vegetation' be used in reference to the areas along the solar array fencelines, access roads, and perimeter fenceline in order to:

1) ensure clarity and consistency regarding vegetation management within these fire buffers, as 'noncombustible buffer' refers primarily to gravel or bare dirt, and

2) address existing erosion concerns while providing wildfire mitigation at the Project site. Low-growing, fire-resistant vegetation protects against soil erosion and prevents the spread of fire following ignition. Maintaining areas completely free of vegetation would contribute to soil erosion.

The Certificate Holder requests that this language be updated in the following sections of the draft Final Order:

- *III.N.1 Findings of Fact – Wildfire Mitigation Plans – Facility Design*
- *III.N.1 Findings of Fact – Wildfire Mitigation Plans – Construction WMP, Wildfire Risk Minimization Preventative Actions, Programs, and Procedures*
- *III.N.1 Findings of Fact – Wildfire Mitigation Plans – Operational WMP, Wildfire Risk Minimization Preventative Actions, Programs, and Procedures*

The Certificate Holder will provide redlined versions of the associated plans by the close of the sur-reply period outlining the requested changes."

We believe these comments and forthcoming redlines thoroughly address the issues raised.

3. Soil Health and Erosion (Issue SP-01)

In your response, you question whether the conversion of agricultural land to solar use will realistically improve conditions in a dryland farming environment such as Sherman County,

The Certificate Holder has addressed your concerns related to soil health and erosion in Section 5 of our February 13, 2026, comment response letter, which included some examples of research regarding the effects of solar energy facilities on vegetation and soil health. The memorandum provided by the Certificate Holder summarizing the effects of Solar Energy Facilities on Vegetation and Soils was originally prepared to support discussions with the Sherman County Soil and Water Conservation District (SWCD) regarding soil health and vegetation management considerations. The research cited describes localized microclimate effects that can occur at ground level beneath photovoltaic (PV) panels, such as moderated soil temperatures, reduced wind exposure at the surface, and reduced evapotranspiration due to shading. These are site-scale soil and vegetation dynamics that have been observed in other regions and may or may not

translate to Sherman County conditions. It was intended to provide context from peer-reviewed research conducted in agricultural and semi-arid environments that may inform broader conversations about land management at Biglow, not to suggest that solar panels increase precipitation or alter regional rainfall patterns.

This information was shared with you to address the statements in your January 29, 2026, letter questioning solar facility contributions to soil quality improvement and to provide research findings that show potential benefits to arid grasslands and shrublands are possible from solar facility operations in other locations that may have some similar ecological characteristics to north-central Oregon. Including this research in the record was meant to provide transparency and to acknowledge that similar agricultural landscapes elsewhere have studied these interactions.

As noted in item 5 below, agrivoltaics research is a pre-screened project in the draft Biglow Solar Community Investment Plan (CIP). If carried out, such a project could provide meaningful insight into the impacts of solar facilities on vegetation and soil health in Sherman County, Oregon.

4. **Right to Farm (Issue LU-07)**
   With respect to liability, you reiterate concerns that local farmers could face wildfire exposure risks and that existing Right to Farm protections may be insufficient in this context.

   As noted by ODOE in their letter to you on February 12, 2026, regarding Issue LU-07 (Right to Farm), "Matters of liability are generally not within the Council's jurisdiction."

5. **Community Investment Plan – Agrivoltaics Research (Issue LU-07)**
   In discussing the CIP, you express skepticism about the agrivoltaics research concept, particularly given the local water constraints and your concern regarding the structure of the project selection process.

   The pre-screened agrivoltaics concept referenced in Section 5.1 of the CIP (BCWF RFA4 Proposed Order Attachment E) is an optional research opportunity; it does not presume irrigation or additional water use, and it would only proceed if supported locally and selected through the Community Investment process. The proposed budget for the pre-screened agrivoltaics research project would be a one-time investment of $100,000 to $300,000 to fund a full-time research assistant and necessary equipment. Annual expenses for the proposed project would be paid from the account established with that one-time investment.

   All pre-screened CIP projects would need to be approved by the Sherman County Court before being selected to receive mitigation funding. Regardless of whether such research is pursued, vegetation management and soil protection at the Biglow Solar facility will ultimately be governed by the final approved Comprehensive Solar Revegetation and Soil Management Plan and applicable site certificate conditions.

   Regarding your concerns on the selection committee that would review applications for the mitigation funding and make recommendations to the Sherman County Court: The make-up of the selection committee is based on other similar boards formed for agricultural mitigation programs in Morrow County but updated to be reflective of Sherman County's agricultural community needs and to consider input from ODOE, the

County, and other stakeholders. However, the Certificate Holder is open to suggestions for committee membership and has added a representative from the Oregon Wheat Growers League in response to public comment on the Draft Proposed Order.

A redlined version of the CIP is included as Attachment B. The revisions reflect refinements made during the Proposed Order process and additional commitments offered during public comment to enhance transparency in project selection, eligibility criteria, and reporting to Sherman County. The draft Memorandum of Understanding between PGE and the Mid-Columbia Economic Development District, has been added as an attachment to the CIP, which outlines the terms for implementation of the CIP, including membership on the selection committee and the process for selecting projects for funding.

6. **Wildfire Risk Analysis (Issue WF-02)**
   Your most recent comment reiterates your concern with the datasets and assumptions used in the wildfire risk analysis, including reliance on climate normals, burn probability modeling, and fuel classifications.

   The Certificate Holder has addressed your previous concerns related to the climate data used in the BCWF RFA4 wildfire risk analysis in Section 2.d. of our letter to you on February 13, 2026; your comment in your February 24, 2026, reply letter does not include enough information for us to provide an additional response.

7. **Wildfire Mitigation (Issue WF-12)**
   Throughout your letter, wildfire prevention remains your primary concern, and you urge development of a robust, project-specific Operations Wildfire Mitigation Plan (WMP). In response, the Certificate Holder is submitting an Operations WMP Outline as Attachment C to this letter.

   The Proposed Order (PO) and ODOE's draft proposed conditions require that a final Operations WMP be completed and approved prior to operation of the solar facility, phase, or component, as applicable (PRO-WF-01). The Certificate Holder acknowledges this requirement and remains committed to timely development and submittal of the final Operations WMP consistent with the PO and the Energy Facility Siting Council (EFSC)'s final site certificate conditions.

   In advance of that requirement, and in recognition of public and agency interest in this topic, PGE is providing an Operations WMP Outline in Attachment C to this letter that lists anticipated commitments and establishes a clear framework for development of the final Operations WMP. This outline is intended to demonstrate continued progress and provide EFSC and members of the public with transparency regarding how wildfire risk will be addressed during facility construction and operations.

   In both the Draft Construction WMP and Operations WMP Outline, the Certificate Holder has committed to the following measures to support wildfire prevention and response during construction and operation of the Biglow Solar facility:

   - Facility operator emergency response training (Draft Construction WMP Section 3.1)
   - Maintaining multiple on-site water sources with a minimum of 500 gallons of water each and operator training on how to use water hoses, pumps, and related

equipment (Draft Construction WMP Sections 3.1 and 4.2); and

- Providing pre-screened financial support in the Biglow Solar CIP for Sherman County firefighting equipment, staffing, and training, as well as community wildfire mitigation projects, as described in item 8 below.

A redlined version of the Draft Construction WMP is also included as Attachment D. The revisions incorporate refinements made during the Proposed Order process and provide additional specificity regarding fire prevention protocols, equipment standards, on-site water availability, and coordination with local fire districts.

We agree that wildfire mitigation planning for a facility of this scale and location must be robust and carefully developed. As a public utility, PGE is subject to additional operational, safety, and reliability obligations that extend beyond those applicable to many standalone private facilities. Accordingly, the Operations WMP is being developed to align not only with EFSC site certificate requirements, but also with PGE's broader wildfire risk mitigation framework, utility safety standards, and public safety responsibilities.

For this reason, development of the final Operations WMP requires careful coordination across engineering, operations, emergency response, and utility compliance teams. While a draft or final Operations WMP is not required at this stage of the amendment review, PGE is committed to ensuring that the completed plan reflects a comprehensive, utility-level approach to wildfire risk prevention, preparedness, and response. The Operations WMP Outline provides for the record the elements that must be accounted for in the final Operations WMP and our commitment to develop a robust final Operations WMP.

8. **Firefighter Training and Fire Department Capacity (Issues PS-01 and PS-02)**
You raise important questions about the capacity and preparedness of local volunteer fire responders and whether facility personnel will be equipped to respond effectively to a fire event.

   The Certificate Holder has identified a pre-screened project in Sherman County to build firefighting capacity (including upgrading, maintaining, or adding firefighting equipment and facilities; additional training for volunteers; additional funding for staff; and funding for projects to develop fuel breaks, reduce wildfire hazards, and provide firefighting water) in Section 5.2 of the CIP (BCWF RFA4 Proposed Order Attachment E). In addition, the Certificate Holder has committed to ensuring all facility personnel are fully trained in emergency response (Draft Operations and Maintenance Framework Plan, Section 3.6), including the use and maintenance of fire protection equipment (Draft Construction WMP Section 3.1).

9. **Lithium Battery Fire Safety**
Although not directly addressed in your comment letter, we reviewed the article you submitted with your comment response letter that discusses a recent lithium-ion battery fire at the Moss Landing Vistra Power Plant, a natural gas-powered energy generation plant and battery energy storage facility located outside of San Francisco.

   We acknowledge your ongoing concerns regarding fire risks associated with lithium-ion batteries used to store electricity at facilities like the one planned for the Biglow Solar facility. As reflected in our prior correspondence and materials submitted to the record,

PGE and BrightNight have addressed the design, engineering, and operational measures proposed to minimize fire risk at the facility. This has included providing opportunities for direct discussion with Coffman Engineers, Inc., as well as sharing presentations and supporting documentation describing applicable codes and standards, fire detection and suppression systems, emergency response coordination, and operational safeguards.

The letter included as Attachment E to this letter summarizes our prior communications and outreach efforts related to battery fire safety and outlines our efforts to communicate with you regarding battery storage fire risk and the steps we are taking to prevent fires at the proposed Biglow Solar facility.

Regarding the comparison to the Moss Landing 2023 incident: Below is some additional context regarding the key distinctions between indoor battery buildings and state-of-the-art containerized battery energy storage facilities, including current building codes that were not in existence or adopted at the time of construction for facilities involved in some of these more significant battery building fires (IFC, NFPA 855 and UL9540/9540A). This information is being provided so that the EFSC record contains a complete understanding of the inherent differences in fire and life-safety risks associated with different types of lithium-ion battery systems, particularly BESS facilities inside buildings vs. those in non-occupiable, outdoor facilities constructed to 2026 industry standards and best practices.

Over the past 5 years, the BESS industry has moved almost exclusively towards outdoor, non-occupiable containers (enclosures) for lithium-ion battery deployment. While some limited indoor battery facilities continue to be developed, they are typically for very specific, niche, or smaller applications.

The Moss Landing 2023 incident involved a thermal runaway and fire event at an indoor battery building, which is considerably different in configuration, risk profile and fire performance relative to the type of outdoor lithium-ion battery facility being proposed at Biglow. The Moss Landing battery building began construction (and retrofit to BESS facility) in December 2019, using NMC (Nickel Manganese Cobalt) lithium-ion battery chemistry first developed, tested, and produced in 2017/2018. The most current fire code including specific BESS information was not included at the Moss Landing facility until 2019. NFPA 855 was not published until August 2019.

Containerized BESS facilities utilize modular, typically pre-assembled enclosures and have the following specific differences from indoor installations:

1. **Separation** – Containerized BESS typically have 8 to 10 feet of aisles, which in all but the most extreme scenarios limits potential fire size to a single enclosure. Note that the more probable fire event would only involve a few cells and no flaming would be expected on the exterior of the cabinet.
2. **Occupiable Spaces** – Containerized BESS have no occupiable spaces inside. As such the risk to maintenance personnel is significantly reduced.
3. **Physical Size** – The standard for Energy Storage Systems (NFPA 855) limits the size of outdoor enclosures/cabinets to 53 ft in length x 8.5 ft in width x 9.5 ft in height. This naturally limits the fuel load of the containerized BESS.
4. **Unit Level Factory Testing / Certification** – Containerized BESS are tested and listed as a complete unit. No additional safety systems are required to be added

in-field and the performance of the factory designed/constructed safety systems is known. In addition to other rigorous testing and listing requirements, this equipment is UL tested and listed according to UL9540 at the cell, module, unit, and installation level (Large Scale Fire Test, LSFT). These tests evaluate multiple factors of the equipment during an incident, including heat flux, temperature, toxic and flammable gas release, and potential to propagate to other cells, modules, or units.

For the reasons stated above, past incidents at indoor battery buildings are not comparable to the planned Biglow Solar facility.

We are committed to continuing to work with you and your family constructively. Given the accommodations implemented and the enhanced regulatory requirements included in the Proposed Order, we believe the record demonstrates that substantial and meaningful efforts have been made to address the concerns raised.

Please reach out if you have questions or would like to discuss further. We are committed to continuous engagement of the community and neighbors as this project moves forward.

Sincerely,

Dan Wilson

Table 1: Department Recommended Requirements

Summary	Timing	Requirement
Prior to Operations - Plan Finalization		
Action Based Plan	This plan shall be finalized based on actions that can be monitored, tracked, and recorded. Detailed narrative or explanation that is not a specific action must be removed. Filter for clarity and remove unnecessary high-level narrative.	
Qualifications and Contact Information	In the Plan: Include the contact information for: 1. The individuals that will manage and oversee vendors and contractors. 2. The individuals that will perform design-phase safety reviews. Evidence to Support Plan Review: Certificate must provide to the Department the names, contact information and qualifications of the individuals that will manage and oversee vendors and contractors; and of the individuals that will perform design-phase safety reviews. The Department may request additional information or justification for any individuals where the experience or qualifications is inadequate.	
Incorporation of requirements/citations from applicable site certificate conditions, protocols and technical plans	In the Plan: Identify all technical and site management plans applicable to operations and compliance for the solar components; incorporate relevant action items into the plan. At a minimum, the plan must reference and incorporate the Emergency Operations Responses Plan, Operational Spill Prevention Control and Countermeasure Plan, Operational Wildlife Mitigation Plan, and Comprehensive Revegetation, Noxious Weed and Soil Reclamation Plan.	
Inspection and maintenance	In the Plan: Identify all inspections and maintenance activities, schedule, protocol and inspection documentation format. Evidence to Support Plan Review: Provide documentation to be used to track maintenance and inspection activities. If information will be tracked via software, explain, demonstrate and provide available data.	
Vendor Performance Scoring System	In the Plan: The final plan shall include details about the Certificate Holder's vendor performance scoring system. The scoring system must, at a minimum, evaluate vendor response time, corrective maintenance scoring rates and inspection completion.	

Summary	Timing	Requirement
Operations and Maintenance Budget Tracking and Forecasting	In the Plan: The final plan shall include a section for Operations and Maintenance Budget Tracking, including but not limited to, a summary of the basis for the amount estimated in the initial maintenance reserve, and an explanation of the 5-year life cycle cost modeling. The plan shall include information about the estimated and available budget. Future plan updates must include 5-year life cycle cost modeling results.	
Third-Party O&M Budget Audit	In the Plan: The final plan shall include information about annual third-party condition assessments, and ensure that the scope of the assessment includes annual review of vendor/contractor performance against warranty and reliability benchmarks.	
Build Transfer Agreement	Evidence to Support Plan Review: Provide a copy of the executed Build Transfer Agreement	
Community Outreach	In the Plan: The final plan shall include names and addresses of participating landowners, and shall detail the schedule, agenda and outreach efforts for annual coordination meetings, to be conducted by the Certificate Holder. The final plan shall require that the Certificate Holder invite Sherman County emergency responders and ODOE to each annual meeting. The plan shall require minutes from each meeting. Any issues will be tracked and evaluated to determine the appropriate response.	
Reporting	In the Plan: Require reporting to the Department of the following: 1. Within 72-hours of a change in contractors, vendors or contract terms, report the change, the reasons for the change, and the identification, contact information and qualifications to the Department. 2. Monthly, report to the Department a summary of performance monitoring results (Vendor Performance Scoring System), including identification of any significant performance issues and corrective actions taken by or for the participating entity, contractor(s) and vendor(s). Certificate holder shall identify corrective actions, including stop work or removal from site, required of the vendor(s) for any performance scores less than 95% percent on-time inspection and repair completion rate. 3. Annually, provide to the Department a written report from a third-party contractor evaluating whether the established or forecasted operations and maintenance budget is adequate for site operations. 4. Annually, provide the agenda, attendees list and meeting minutes from the community outreach meetings. Certificate holder shall report any issues identified at the meeting and shall provide their response and/or resolution of the identified issue.	

1.0 Introduction

This draft outline of the Operations and Maintenance (O&M) Plan for the amended Biglow Canyon Wind Farm (BCWF) integrates the Solar Components as identified in the BCWF Request for Amendment 4 (RFA 4) into the existing wind facility. It has been jointly developed by Portland General Electric Company (PGE; the Certificate Holder) and BIGL bn, LLC (BIGL), a subsidiary of BrightNight, LLC, to establish the preliminary framework for how the Solar Components of the Amended BCWF will be operated, maintained, and managed in compliance with the Site Certificate and applicable regulatory standards.

This O&M Plan applies exclusively to the Solar Components and associated infrastructure introduced through the BCWF RFA 4. It does not govern the O&M of the existing wind energy infrastructure, which continues to be managed under the previously coordinated PGE Operational Safety Monitoring Program. The O&M Plan reflects lessons learned from legacy wind operations at BCWF and current best practices for utility-scale solar and storage projects.

The O&M Plan framework described in Section 3.0 outlines the structure of operational responsibilities, long-term maintenance protocols, quality assurance processes, environmental compliance measures, and integration with emergency response and monitoring systems. The Certificate Holder will provide an O&M Plan that will use this framework to further detail the specific actions required to operate and maintain the Solar Components. The final O&M plan will be submitted to the Oregon Department of Energy (ODOE) prior to the start of operation of the Solar Components.

The final O&M Plan will reference and incorporate several other technical and site management plans relevant to operations and compliance for the Solar Components at the amended BCWF. These include, but are not limited to, the following plans developed for the BCWF RFA 4:

- The standalone Emergency Operations Response Plan (EOP) specific to solar and battery energy storage system (BESS) components;
- The Construction-phase Wildfire Mitigation Plan (WMP) and the Operations-phase WMP, which outline prevention and response protocols for wildfire risk during all project phases;
- The Comprehensive Solar Revegetation and Soil Management Plan, which details vegetation establishment, monitoring, and long-term maintenance;
- The Dust Abatement Plan, which governs dust control measures during both construction and operations; and
- Other resource-specific plans (e.g., the Decommissioning Plan, Spill Prevention and Control protocols) as required by the Site Certificate.

These documents will be cross-referenced with the final O&M Plan to ensure consistent implementation and clarity of responsibilities. The final O&M Plan will remain a living document, subject to regular review and revision in response to design changes, regulatory updates, and lessons learned during implementation.

2.0 Facility Partnership: Roles and Responsibilities

The Amended BCWF reflects a project delivery model that combines PGE's regulatory responsibility and long-term ownership with development and technical execution support from BIGL. This structure is designed to ensure compliance with Site Certificate conditions while leveraging external technical expertise to deliver the proposed Solar Components efficiently and to current industry standards.

PGE, as the Certificate Holder, retains ultimate oversight and responsibility for the Amended BCWF, including the Solar Components as outlined in RFA 4. BIGL has been engaged to support the initial development and construction of these components under a Build Transfer Agreement and will also provide O&M services for a minimum of the first 5 years of project operation. This approach allows for continuity between construction and early stage operation, while ensuring that all long-term operational accountability remains with PGE.

BrightNight and its subsidiary BIGL will implement a long-term O&M strategy grounded in industry best practices, internal experience, and a robust safety-first culture. While specific vendors have not yet been selected, BrightNight's team draws on a strong national track record in solar and battery storage project delivery and management. The Solar Components of the Amended BCWF will be supported by comprehensive O&M protocols that include scheduled preventive maintenance, real-time monitoring, remote diagnostics, and rapid response to equipment issues. BrightNight's O&M program, which emphasizes cradle-to-grave execution, 24/7 visibility into system performance, and continuous learning, will guide all operational phases. Quality assurance will be embedded through stringent contracting standards, rigorous design-phase safety reviews, and direct oversight by experienced internal personnel. Over the first 5 years of the project, BIGL will manage a third-party ~~party~~ experienced O&M provider, who will serve as the primary entity responsible for day-to-day maintenance and performance monitoring, while PGE's role will be defined in coordination with project milestones, interconnection requirements, NERC compliance, and long-term asset management planning.

BrightNight is committed to working in partnership with qualified local vendors whenever possible, fostering regional economic benefits and ensuring on-the-ground responsiveness throughout the project's operational life. All third-party vendors, whether local or national, will be selected through a rigorous procurement process that evaluates technical qualifications, safety performance, environmental compliance, and proven experience with utility-scale solar and storage facilities. Selected vendors will be required to adhere to industry best practices, such as:

- Implementing detailed preventive maintenance schedules,
- Providing trained and certified personnel,
- Using real-time monitoring and fault detection systems,
- Following all original equipment manufacturers' maintenance and service guidelines,
- Maintaining transparent documentation and reporting protocols,
- Using digital maintenance management systems,
- Conducting regular quality assurance/quality control (QA/QC) inspections,

- Establishing clear escalation procedures for unplanned outages, and
- Participating in site-specific safety trainings and continuous improvement processes.

BrightNight is also acutely aware of the community concerns stemming from historical O&M challenges at the BCWF. Based on conversations with local stakeholders, a key feature of the O&M strategy, though not highly technical, demonstrates the commitment to maintaining consistent communication with community members over the life of the BCWF Solar Components. The Project Developer and Certificate Holder will provide direct contact information and conduct regular check-ins to ensure residents feel empowered to raise questions or concerns. Any issues brought forward will be relayed promptly to the appropriate O&M teams for timely response and resolution. While BrightNight and PGE do not anticipate concerns of this nature, we believe creating a clear, accessible escalation path is an important part of building lasting community trust.

This structured approach ensures that any vendor engaged in the Amended BCWF will operate with the same high standards of safety, reliability, and performance that define BrightNight's operational philosophy.

This partnership structure does not alter the Certificate Holder's regulatory obligations or diminish its responsibility for compliance with the Energy Facility Siting Council (EFSC) and other applicable state and federal requirements. Rather, it provides a defined and managed pathway for project delivery that integrates third-party expertise into a framework that remains under PGE's control. Any third-party permits associated with construction activities will be secured through BIGL or its contractors but will be limited to standard, project-level requirements (e.g., encroachment, transport, building permits) and do not change the scope or structure of the existing site certificate.

Overall, the division of responsibilities between PGE and BIGL maintains clear regulatory accountability while enabling technically competent execution of the amended facility. This model is consistent with industry practices for utility-owned renewable infrastructure and is expected to support a timely and orderly expansion of the BCWF site in accordance with certificate conditions.

3.0 Integrated Operations and Maintenance Plan Framework

The Certificate Holder will submit a final version of the O&M Plan to ODOE prior to the commencement of operations. This Plan is intended to meet regulatory obligations, and to serve as the foundational framework guiding day-to-day operations of the Solar Components at the Amended BCWF.

To ensure consistency between compliance documentation and real-world implementation, the Plan will be updated as needed to fully incorporate the procedures, protocols, and tools adopted by the selected long-term O&M service provider. This integrated approach is designed to maintain a single, authoritative document that governs both regulatory compliance and operational execution, which eliminates the risk of conflicting or duplicative guidance.

3.1 Purpose and Applicability

The framework described in this section outlines the intended procedures for managing and maintaining the Solar Components of the Amended BCWF. It incorporates requirements from the Site Certificate, applicable codes, and protocols from the EOP, Decommissioning Plan, and supporting exhibits. This Plan applies to the Certificate Holder, BIGL, its contractors, and subcontractors. The final O&M Plan will be a living document. It shall be reviewed annually and revised in coordination with design changes, operational updates, or regulatory amendments.

3.2 Facility Description and Roles

The Amended BCWF includes legacy wind infrastructure and new solar photovoltaic (PV) and BESS systems. These additions are constructed under a Build Transfer Agreement by BIGL, with PGE retaining long-term ownership and regulatory oversight as the Certificate Holder.

- The facility will have ~~3~~three FTE onsite employees, ~~2~~two techs, and a ~~BN Services~~BIGL O&M Manager ~~is typically unmanned~~; operations also rely on remote supervisory control and data acquisition (SCADA) systems.
- Initial O&M management services for solar and BESS components will be performed by BIGL for 5 years.

3.3 Design and Equipment Selection

The Certificate Holder and BIGL are going through the design and equipment selection process. During final design, PGE will consider all solar technologies available to ensure the most efficient and productive solar array layout and BESS equipment. The final O&M plan will incorporate O&M activities specific to the equipment selected, based on the manufacturers' instructions.

3.4 Preventative Maintenance and Asset Monitoring

BIGL or the Certificate Holder will identify preventative maintenance measures and supporting equipment monitoring efforts to ensure safe and reliable operation of the facility.

3.4.1 Substation

- Thermal imaging for termination and buswork
- Visual inspection of structure foundation and conduit
- Lubrication of moving parts (breakers, switches, etc.)
- Cooling system checks
- Control room inspections visual and tests
- Label and nameplate check
- Vegetation management

3.4.2 PV System

- ~~Routine module inspections and annual infrared/aerial thermal imaging with anomalies detected via SCADA generating corrective work orders as soon as reasonably possiblewithin 48 hours~~

- Routine module inspections and annual infrared/aerial thermal imaging: Anomalies detected will generate corrective work orders within 48 hours, and will be addressed according to level of severity; otherwise, as soon as reasonably possible and according to the final O&M Plan.
- Routine SCADA monitoring and data analysis: Anomalies detected will generate corrective work orders within 48 hours and will be addressed according to level of severity; otherwise, as soon as reasonably possible and according to the final O&M Plan.
- Torque checks per manufacturers' recommendations
- Panel washing with water use logs (per Exhibit O limits)
- ~~The more frequent of either OEM recommendations, annual, and/or semiannual v~~Visual inspection of inverters, combiner boxes or load break disconnects, trackers, and all major equipment according to manufacturers' recommendations
- ~~SCADA tests and inspections~~
- Vegetation management

3.4.3 BESS

- ~~Quarterly I~~infrared inspections of power conversion system units per OEM recommendations~~,~~
- Inspections of heating, ventilation, and air conditioning, battery management system (BMS), and fire suppression systems per OEM recommendations.
- SCADA/BMS remote monitoring for anomalies
- Response procedures tied to EOP protocols for thermal runaway (EOP Section 3.2.1)
- Vegetation management

3.5 Compliance, Controls, and Reporting

The Certificate Holder will implement O&M practices that support compliance with applicable regulatory requirements and Site Certificate conditions. This will include operational controls, oversight procedures, and alignment with supporting plans that address vegetation management, spill prevention, wildfire mitigation, air and water quality, and other environmental and safety considerations.

Compliance measures will be scaled to site activities and updated as operations evolve. Documentation of inspections, incidents, and maintenance activities will be maintained. Reporting will follow applicable requirements and timeframes outlined in the Site Certificate and coordinating agency permits.

This section will be updated in the final O&M Plan to reflect specific commitments based on Site Certificate conditions and reporting requirements identified by ODOE and coordinating agencies. The final version will define required reporting content, frequencies, responsible parties, and coordination procedures to demonstrate ongoing compliance.

3.6 Emergency Preparedness Integration

The Certificate Holder will take the following actions to address emergency preparedness:

- Inspect and test all safety equipment.
- Review and update the EOP regularly, and ensure all personnel are fully trained in emergency response.
- Perform all Spill Prevention, Control, and Countermeasure Plan requirements, including maintaining spill kits.
- Develop and maintain a Hazardous Materials Management Plan if required by state or federal regulations.
- If applicable, prepare and maintain an Emergency Planning and Community Right-to-Know Act (EPCRA) Tier I or II form, plus a list and quantities of chemicals that exceed reporting thresholds for EPCRA Tier 2.
- Conduct an audit that includes a review of site compliance with the facility's safety program and onsite observation for proper implementation of safety policies, including Lock Out-Tag Out, and a review of the facility's safety program and any recommended revisions.
- Perform a root cause analysis, corrective actions taken, and recommended corrective work related to injuries or illness requiring medical attention other than first aid, injuries or illness requiring restricted duty or days away from work, or a fatality.
- Notify the operator as soon as possible, not to exceed 1 hour, of any of the following events:
    1) Emergency responders contacted for an emergency or law enforcement response.
    2) Injury on site requiring medical attention more than first aid.
    3) Unplanned outage of one or more medium-voltage (MV) collection or high-voltage circuits.
    4) Onsite fire.
    5) Conditions that necessitate an evacuation of onsite personnel.
    6) Awareness of an impending weather event that has a reasonable probability of causing significant damage or any of the preceding 1) through 5) events.

3.7 Contractor and Staff Oversight

BrightNight, on behalf of PGE, will oversee and facilitate the O&M of the BCWF Solar Components with an O&M service provider experienced in operating and maintaining large-scale PV solar systems and balance-of-plant systems for a large-scale BESS. There will be a long-term service agreement with the Solar Component BESS supplier. The O&M service provider will be responsible for the operation of the Solar Components, maintenance of the PV solar system to the point of interconnection, and maintenance of equipment/circuits from the BESS inverter AC output terminals to the point of interconnection. The O&M service provider's scope will cover equipment, including the PV array, PV system inverters, low-voltage cables, MV transformers (including auxiliary transformers), MV feeders, MV switchgear, site meters, ~~substation equipment, generation tie line,~~ and the O&M building equipment. PGE will perform maintenance on the substation equipment and gen-tie line.

4.0 Long-term Maintenance and Operational Continuity

To support the proposed 40-year operational life of the Solar Components, the Certificate Holder has developed a long-term maintenance and operations framework that evolves over time and ensures continuous compliance with site certificate conditions.

Years 1–5: BIGL will lead O&M activities under the Build Transfer Agreement. ~~This includes~~The O&M service provider will have full responsibility for inspections, corrective maintenance, and warranty compliance~~.~~ BIGL's scope will also include preventive maintenance scheduling and vendor oversight.

Post-Year 5: PGE will assume full O&M responsibilities, integrating solar and BESS oversight into its internal asset management systems. This transition will be guided by a detailed handover plan including training, document transfer, and performance reviews conducted in Year 4.

Continuity of Practice: Regardless of ownership stage, O&M will be conducted in accordance with procedures established in this document, including vendor management, EOP training, and incident reporting protocols. Performance metrics and component reliability will be tracked in PGE's asset management software and reviewed annually.

4.1 Personnel and Quality Assurance Oversight

The Amended BCWF will be supported by experienced operations personnel through all phases of its operating life.

Operations Roles:

- SCADA/Performance Analyst
- Field Technician Team (PV/BESS certified)
- Asset Manager (PGE)
- QA/QC Lead (during and post-handoff)

Quality Assurance Protocols:

- Annual third-party condition assessments (PV and BESS)
- Annual SCADA data audit for performance anomalies
- Compliance inspections linked to EOP protocols
- Maintenance records retained and reviewed for trends

4.2 Budget Planning and Lifecycle Management

PGE will incorporate the solar and BESS components into its existing capital planning processes. The following measures support financial assurance and long-term reliability:

- Maintenance Budgeting:
  - O&M budgets for the first 5 years are embedded in the Build Transfer Agreement.

  - Post-transfer, expenses are forecasted annually by the Asset Management Team and tracked against site-specific performance.
- Lifecycle Planning:
  - A major maintenance reserve will be included in financial modeling to support inverter replacement, battery module refresh (anticipated at 12–15 years), and other long-term needs.
  - PGE's decommissioning cost estimates (Exhibit X) will be updated every 5 years to reflect equipment aging and market conditions.

5.0 Plan Updates and Reporting

The O&~~I~~M Plan shall be reviewed and revised annually, if applicable, by the Certificate Holder based on design changes, operational updates, or regulatory changes; and to incorporate the procedures, protocols, and tools adopted by the selected long-term O&M service provider.

SWCD	Soil and Water Conservation District

1.0 Introduction

The Portland General Electric Company (PGE or Certificate Holder) owns and operates the Biglow Canyon Wind Farm (BCWF or Existing Facility) under Site Certificate on Amendment 3, issued October 31, 2008 (Site Certificate). PGE has filed a Request for Amendment 4 (RFA 4) to add photovoltaic (PV) solar energy generation and battery storage (Solar Components[1]) to the Existing Facility.

BCWF currently consists of 217 wind turbines, with a peak generating capacity of 450 megawatts (MW). RFA 4 adds up to 125 MW alternating current (AC) generating capacity from PV solar arrays and 125 MW in battery storage capacity (Solar Components) in approximately 1,445 acres (Solar Area) sited within the existing BCWF site boundary Solar Micrositing Area (RFA 4 Site Boundary). The Solar Micrositing Area is approximately 1,924 acres and provides a conservative estimate of the maximum acreage needed for development, micrositing, and temporary disturbances from the Solar Components during construction, rather than the anticipated disturbance footprint. The permanent disturbance[2] area impacted by the Solar Components within the Solar Micrositing Area is up to 1,455 acres (Solar Area) and the final footprint will be confirmed during pre-construction compliance.

The Solar Micrositing Area is zoned entirely Exclusive Farm Use (EFU) by Sherman County and is currently cultivated for dryland wheat. Because the permanent disturbance area from the Solar Components will exceed 12 acres and 20 acres of high-value and arable farmland, respectively, RFA 4 requires an exception to Oregon Statewide Planning Goal 3 (Agricultural Lands).

This Community Investment Plan (CIP) supports PGE's Goal 3 exception request and helps justify why a Goal 3 exception is warranted for the BCWF, as amended. The CIP is a mitigation plan that, once implemented, will ensure that any potential adverse impacts to the local agricultural economy from the removal of cultivated wheat land are offset to a level acceptable to Sherman County and the community.

PGE will own and operate the Solar Components as a part of the BCWF, which, to date, have been developed by BIGL bn, LLC (BIGL, or Project Developer). BIGL, in its capacity as the project developer, is supporting PGE in the RFA 4 and may construct and temporarily operate the Solar

[1] Solar Components will include solar arrays, inverters, and inverter step-up transformers. Related or supporting facilities include underground medium voltage collector lines, a collector substation, battery energy storage system (BESS) facilities and their subcomponents (i.e., inverters), approximately 600 feet of a new 230-kV generation tie transmission line, operations and maintenance structures, site access roads, internal roads, perimeter fencing, facility entry gates, and temporary laydown areas. The maximum generating capacity from the Solar Components will be 125 MW AC, and the infrastructure will be fenced within the Solar Micrositing Area creating a permanent impact area of up to 1,445 acres (i.e., Solar Area).
[2] Permanent disturbance includes areas and infrastructure (trackers, inverters, internal roads, buildings, stormwater basins, and parking) inside the perimeter fence for the Solar Micrositing Area.

Components on behalf of PGE under a Build-Transfer Agreement and may implement components of the CIP including providing mitigation fund payments on behalf of PGE.

1.1 Project Layout and Construction Schedule

The proposed layout for the Solar Components includes a primary area of infrastructure improvements within the Solar Micrositing Area. The Solar Area will connect to the electrical grid through the existing point of interconnection (POI) at the Biglow Canyon Substation, which is situated within the Solar Micrositing Area.

Solar Micrositing Area: The Solar Micrositing Area is a continuous area of land that covers approximately 1,924 acres, fully within the approved BCWF site boundary, within which construction of the Solar Components may occur, subject to site certificate conditions. This area includes the Existing Facility's current POI and may be expanded to add a new 230-kilovolt (kV) line terminal, all Solar Components, and the fenced area for where such components will be located (1,445 acres; Solar Area).

Solar Area: This area falls within both the approved BCWF site boundary and the Solar Micrositing Area. It will host new solar arrays using tracking systems, a new BESS, a new collector substation, a new operations and maintenance building, a temporary laydown yard for construction, new access roads, perimeter fencing, the Existing Facility's current POI, approximately 600 feet of new 230-kV generation tie line, and other associated project components.

The Solar Components located within this area will add approximately 125 MW AC generating capacity on a total of up to 1,445 acres that would be fenced within the approved BCWF site boundary. All Solar Components will be set back at least 520 feet from the existing wind turbines per PGE requirements.

Construction is expected to begin in Q2 of 2026 and continue through Q4 of 2027 for a duration of approximately 17 to 19 months from mobilization to final completion.

1.2 Goal 3 Exception and Need for Mitigation Plan

Oregon Statewide Planning Goal 3 (Agricultural Lands) (Goal 3) requires counties to identify farmland on its comprehensive plan map, and zone those lands as EFU. An EFU zone places certain restrictions on developments to minimize uses that conflict with farming (DLCD 2023). Oregon Administrative Rule (OAR) Chapter 660, Division 33 and similar provisions under Sherman County Zoning Ordinance (SCZO) Article 3 regulate EFU lands and permitted uses on these lands. The SCZO has not been amended since 2003 and does not reflect the current list of uses and standards provided by OAR 660-033-0130. As a result, PGE directly applied OAR 660-033-0130(38)(g), which states that a PV solar power generation facility shall not use, occupy, or cover more than 12 acres of high-value farmland unless certain criteria under OAR 660-033-0130(38)(h) are met or an exception is taken pursuant to Oregon Revised Statutes (ORS) 194.732. Similarly, per OAR 660-033-0130(38)(i), a PV solar power generation facility shall not use, occupy, or cover more than 20 acres of arable lands unless certain criteria under OAR 660-033-0130(38)(i) are met or an exception is taken pursuant to ORS 194.732.

As the Solar Components will occupy more than 12 acres of high-value farmland and more than 20 acres of arable land, it does not meet the acreage standards under OAR 660-033-0130(38)(g) and (i) and requires a Goal 3 exception. The Energy Facility Siting Council (Council or EFSC) may approve an exception to Goal 3 for an energy facility that meets the criteria listed under ORS 469.504(2)(c) and OAR 345-022-0030(4)(c). These criteria include the following:

- Reasons justify why the state policy embodied in the applicable goal should not apply;
- The significant environmental, economic, social and energy (EESE) consequences anticipated as a result of the proposed facility have been identified and adverse impacts will be mitigated in accordance with rules of the Council applicable to the siting of the proposed facility (EESE consequences); and
- The proposed facility is compatible with other adjacent uses or will be made compatible through measures designed to reduce adverse impacts.

This CIP supports the approval of PGE's Goal 3 exception request by supporting the "reasons" to justify the Goal 3 exception and ensuring that potential adverse impacts under the EESE consequences are properly mitigated. Measures to address the Amended Facility's compatibility are outlined in RFA 4 Exhibit K, Sections 6.2 and 8.3.

PGE justifies a Goal 3 exception by demonstrating that reasons justify removing up to 1,445 acres of dryland wheat from agricultural production for 40 years. One of the reasons is that the Amended Facility will result in rural local economic development benefits. This CIP ensures that the rural local economic benefits will offset potential adverse impacts the Solar Components may have on Sherman County's agricultural economy. In addition, participating landowners—many of whom represent multigenerational farm families—have emphasized that solar development provides an opportunity to diversify income and strengthen long-term financial stability. This landowner perspective reinforces the rationale for a Goal 3 exception, as the Amended Facility not only contributes to rural economic development but also supports the continuity of agricultural operations across generations.

2.0 Development of the Plan

To help inform the development of the CIP and to identify example projects that could be funded through the mitigation fund (see Section 4.0), PGE and the Project Developer spent considerable time and effort coordinating with the local agricultural community to understand what potential projects/investments would be most beneficial to support the local agricultural economy. Meetings were held with local wheat farmers, the Oregon Watershed Enhancement Board (OWEB), Oregon State University (OSU) including its extension service in Sherman County and the College of Agricultural Sciences, the Oregon Wheat Commission, the Sherman County Fire District, Sherman County Emergency Services, the Rural Sherman County Fire Board, the Weed Master, the Road Master, the County Planning office, and County Judge

Engagement also included targeted discussions with project landowners and surrounding landowners, who underscored the importance of financial resilience in maintaining viable farm operations. Coordination with the Sherman County Soil and Water Conservation District (SWCD) has not yet occurred in person because the SWCD indicated they did not wish to engage unless the project was approved; the Project Developer remains committed to continued outreach with the SWCD once the project is approved.~~While coordination with the Sherman County Soil and Water Conservation District (SWCD) has not yet occurred in person, the Project Developer remains committed to continued outreach.~~

Fire safety emerged consistently as the most pressing community concern—not only in relation to the Solar Components, but as a broader and growing threat to Sherman County's agricultural economy. In response, the Project Developer has prioritized coordination with local fire districts, including a presentation to the North Sherman Fire Board on August 12, 2025, and a follow-up meeting with Chief Burbank of the North Sherman County Fire District on September 9. These meetings provided an opportunity to review site layout and engineering plans, incorporate feedback, and identify opportunities to strengthen local fire response capacity.

Several key themes for possible agricultural mitigation investments emerged from this coordination:

1. Investments in minimizing wildland fire risk to agricultural crops, properties, and infrastructure and minimizing risk of liability to farmers from farm activities igniting fires and impacting non-farm uses in the agricultural district;
2. Research into agrivoltaics techniques in the context of dryland farming in central and eastern Oregon;
3. Research into long-term effects to soils that have been removed from cultivation and placed in long-term vegetation management programs within solar array areas;
4. Maintaining and/or improving weed control county-wide on agricultural lands and minimizing costs for weed control;
5. Technical assistance training for heavy equipment operation and repairs for farmers and laborers in the County to provide uplift in firefighting support, construction, and farming;
6. Providing funding for 4H, National Future Farmers of America Organization, or other youth programs; and
7. Providing additional funds to supplement Natural Resources Conservation Service and SWCD cost share programs for technical assistance programs such as improving haul routes, weed control, establishing fire breaks, etc.

As described further in Section 4.0, the final decision on what projects would be funded and/or what organizations would be awarded mitigation funds will be determined by the Sherman County Court. The mitigation projects identified in Section 5.0 and the selection criteria identified in Section 4.2.4 are unique to the Sherman County agricultural community and its specific needs. The

projects identified in this plan are in direct response to community feedback and will bring economic benefit to the County's agricultural community, which is primarily composed of dryland wheat farmland.

3.0 Overview of Project Impacts on Agricultural Economy

PGE evaluated the potential adverse impacts to Sherman County's agricultural economy from removing up to 1,445 acres of dryland wheat from production for the life of the project. For details of this evaluation, see RFA 4 Exhibit K, Attachment K-1. The removal of 1,445 acres of winter wheat would have an estimated reduction in annual output of $281,300 in the grain sector. Putting this into context, $281,300 is equivalent to 0.8 percent of the Sherman County's average value of production of winter wheat and 0.1 percent of the State's average value of production of winter wheat. This highlights the small percent of the county and state's winter wheat production value impacted by the Solar Micrositing Area.

Using a worst-case scenario impact analysis of a full build out of the Solar Components resulting in the loss of 1,445 acres of dryland wheat over 40 years, PGE estimates that the Amended Facility may result in a loss of annual indirect economic output of $100,000 over the life of the Facility, as amended. This loss of indirect economic output represents decreases in spending on wheat farming inputs like seeds, fertilizer, and fuel and contract services.

Calculated over a period of 40 years of operation, and adjusting for inflation, the estimated indirect output would be $2,315,218 or $1,600 per acre of farmland taken out of production. The final mitigation payments will be based on the actual acres identified in the final design of the Solar Components, which may be less than the full 1,445 acres identified in the Goal 3 exception request.

4.0 Mitigation Fund

PGE and the Project Developer have partnered with Sherman County and the Mid-Columbia Economic Development District (MCEDD) to establish an agricultural mitigation fund that will administer and distribute dollars for projects having a benefit to the Sherman County agricultural economy. The fund will ensure that any potential adverse impacts from the Solar Components are offset to levels acceptable to Sherman County and the community. Maintaining local control over investment decisions was identified as an essential element of trust-building during stakeholder engagement. For this reason, all mitigation fund allocations will ultimately be directed by the Sherman County Court to ensure alignment with community priorities and accountability to local stakeholders.

4.1 Establishing the Biglow Community Investment Fund

MCEDD will administer the Biglow Community Investment Fund under an Administrative Agreement among Sherman County, MCEDD, PGE, and BIGL. MCEDD, PGE, and BIGL have prepared a draft Memorandum of Understanding (MOU) describing their intended coordination and

framework for administering the Community Investment Fund. The draft MOU is included as an attachment to this Community Investment Plan. The Parties anticipate that the MOU will be executed prior to the start of construction of the Solar Components. ~~(as described in the Memorandum of Understanding among Sherman County, MCEDD, and PGE, dated [add]).~~

Prior to construction, $1,600 per acre for each acre the Solar Components removed from agricultural production will be placed into the Biglow Solar Account that will then be used to fund mitigation projects under the CIP. The total number of acres removed will be determined based on the final layout confirmed during the Oregon Department of Energy pre-construction compliance review. The mitigation payment may be provided by PGE or the Project Developer (or other entity) on behalf of PGE.

4.2 Administration of the Biglow Community Investment Fund

MCEDD will administer the Biglow Community Investment Fund, which will be funded prior to construction of each phase of the Solar Components. MCEDD will also oversee the following administrative steps.

4.2.1 Selection Committee

MCEDD will form and oversee a five-person advisory committee (Selection Committee) to review applications for funding and make recommendations to Sherman County BOC on funding projects. The Selection Committee will comprise the following individuals:

- One representative from Sherman County government;
- One representative from an academic institution engaged in agriculture research in Sherman County or an agricultural-related nonprofit entity located in Sherman County;
- One dryland farm producer in the County;
- One community member; and
- One representative with expertise in wildfire as it relates to agricultural lands.
- One representative from the Oregon Wheat Growers League.

Sherman County will have the ability to propose candidates for the Selection Committee in accordance with the aforementioned criteria, provided that the County proposes candidates within 30 calendar days of the formation of the committee. If the County elects not to propose candidates to the Selection Committee, MCEDD shall make any remaining necessary appointments.

In addition to the members above, the Selection committee shall include one non-voting member with subject matter expertise over statewide or regional agriculture issues selected by the Energy Facility Siting Council.

4.2.2 Applications for Funding

MCEDD shall issue a notice of available funding for mitigation projects as provided by the administrative agreement and contemplated in the Memorandum of Understanding. The notice will identify the selection criteria for qualifying projects and include an application form. All applications for funding would need to be filed with MCEDD at a time determined by the parties, ahead of the Start of Construction (Application Deadline).

4.2.3 Awarding Funds

The Selection Committee will review applications, rank the projects against the selection criteria, and make recommendations to the Sherman County BOC within 3 months of the Application Deadline. The BOC will aim to make a decision on funding within 60 days of receipt of the Selection Committee's recommendation. MCEDD will award funds within 30 days of the County's decision.

4.2.4 Selection Criteria

The selection criteria for a qualified mitigation project are to ensure that projects provide uplift of the Sherman County agricultural economy and are responsive to community needs as described in Section 2.0 and as may be identified by the community in the future. These selection criteria were identified after significant community engagement and listening sessions.

Except as provided in Section 4.2.5 below, the Selection Committee will apply and balance the selection criteria when recommending projects for funding. The five selection criteria are as follows:

1. Improving resiliency and efficiency of Sherman County's agricultural economy;
2. Improving agricultural wildfire protection and risk management capacity;
3. Investing in research to further agrivoltaics for dryland wheat lands;
4. Investing in agricultural education for next-generation farmers; and
5. Subsidizing the price of wheat produced in Sherman County

4.2.5 Pre-Screened Projects

A preliminary list of pre-screened projects is included in Section 5.0. These projects have been identified by Sherman County and the community as having a direct benefit to the rural agricultural economy of Sherman County and are deemed to meet, on balance, the selection criteria. A project proponent of a pre-screened project must still apply for funding through MCEDD and provide a project plan to identify the project's fiscal contribution to the rural agricultural economy and confirm that the selection criteria will be satisfied. A pre-screened project application goes directly to the BOC for consideration and bypasses review by the Selection Committee.

4.3 Reporting Obligations

Award recipients shall provide an annual report to the County, MCEDD, and PGE, as further described in the MOU.

5.0 Pre-Screened Projects

The five pre-screened projects were developed based on extensive outreach and coordination with key stakeholders from the Sherman County agricultural community, as well as state-wide agricultural-related organizations (see Section 2.0). These projects have the support of both the County and the community, who agree they will provide meaningful benefits to Sherman County's agricultural economy. In particular, they include initiatives that support essential services such as wildfire mitigation. For Sherman County, wildfire mitigation is especially critical, as it helps protect wheat farms—the primary land use in the county—and their supporting infrastructure, including roads, equipment, grain elevators and storage facilities, as well as urban areas tied to farm operations.

5.1 Project 1: Dryland Wheat Agrivoltaics Research in Sherman County

Project Sponsors: OSU Foundation, OSU Extension Office, OSU Nexus of Energy, Water, and Agriculture Lab

Project Description: This project would involve research into agrivoltaics techniques in the context of dryland farming in central and eastern Oregon. Research may include an agrivoltaics test project in Sherman County where different dryland crops, including wheat, are grown within a solar array and studied. Research may include investigation in panel layout/row dimension design to facilitate farm equipment, cropping trials, differences in crop yields based on panel shading, and effects on soils within different vegetation regiments within panel arrays. Research study will be further defined by the project ~~sponsor~~sponsor, and project sponsor will seek input from Sherman County stakeholders, including Oregon Wheat Growers League in developing the scope of the research study.

Project Benefit: Researching achievable agrivoltaics strategies in eastern Oregon would generate valuable insights to guide project siting decisions and identify potential legislative or regulatory changes that could further incentivize compatible farming practices alongside solar power generation. Based on information provided by OSU Associate Professor Chad Higgins, partial shading from solar panels has shown increase in crop production while using less water (Hassanpour Adeh et al. 2018). Research on agrivoltaics in the context of central and eastern Oregon dryland farming could create opportunities for Sherman County farmers to diversify their operations. By capturing more soil moisture, solar panel shading may allow farmers to maintain current dryland crop yields, such as winter wheat, within a smaller footprint.

Proposed Budget: To be provided by project sponsor. Project budget is anticipated to range from $100,000 to $300,000 to fund a full-time research assistant and any necessary equipment.

5.2 Project 2: Agricultural Wildfire Risk Minimization and Capacity Building

Project Sponsors: North Sherman County Rural Fire Department

Project Description: Sherman County has experienced large-scale wildfires that have burned thousands of acres and have destroyed more than 1 million bushels of wheat in a single fire resulting in more than $5 million in damage (Sherman County 2024). In response to increased community support for fire mitigation and prevention efforts, Sherman County developed and adopted a Community Wildfire Protection Plan (CWPP) in 2024 to identify and mitigate wildfire risk and to develop a strategy to reduce those risks. The CWPP is also meant to assist the county, its communities, and fire districts by making them eligible for certain grants or other funding sources. Grants and funding sources may include National Fire Plan grants, U.S. Forest Service Community Wildfire Defense Grants, and other funding sources to treat hazard fuel situations and to better prepare residents for wildfires that may occur.

The CWPP[3] identifies several projects such as:

1. Upgrading, maintaining, or adding firefighting equipment for Sherman County's Rural Fire Protection Districts.
    a. See Project #7 in CWPP Section XIII.
    b. See Project #31 in CWPP Section XIII.
2. Upgrading and developing new facilities at Rufus Fire Hall, North Sherman Rural Fire Protection District Station, and/or South Sherman Rural Fire Protection District Station
    a. See Project #6 in CWPP Section XIII.
3. Training for volunteers
    a. See Project #13 in CWPP Section XIII.
4. Funding for additional staff
    a. See Project #2 in CWPP Section XIII – develop paid seasonal county firefighting positions.
    b. Fund administrative staff to support all projects identified in CWPP Section XIII.
5. Fund projects to develop fuel breaks, reduce wildfire hazards, provide firefighting water.
    a. See Projects #14, #15, #22 through #30 in CWPP Section XIII.

The County could allocate mitigation funding to support either partial or full implementation of the projects identified in the CWPP, as well as other initiatives aimed at supporting the County's agricultural community in wildfire mitigation and response.

Project Benefit: Section V.E. of the County's CWPP identifies the probability of wildfire in Sherman County as high, with significant vulnerability to grain fields, pastures, and utility infrastructure. As noted in the CWPP, previous fires in the county have burned one million bushels of wheat and caused over $5 million in damages. Any project that reduces the risk or extent of wildfire damage to dryland wheat crops and their supporting infrastructure would provide a direct economic benefit to the County's agricultural community. Stakeholder feedback reinforced that agricultural mitigation and wildfire mitigation are deeply interconnected in Sherman County. Farmers

[3] See Section XII of the CWPP (Sherman County 2024) for a list of identified wildfire mitigation projects.

repeatedly emphasized that their livelihoods depend on the resilience of their land and crops, and that wildfire protection must be addressed alongside agricultural investments. Accordingly, the coordination on behalf of RFA4 with the North Sherman Fire District demonstrates a proactive approach to integrating agricultural and fire mitigation needs.

Proposed Budget: To be provided by project sponsor. Project budget is anticipated to range from $100,000 to $500,000.

5.3 Project 3: Funding matching for SWCD programs for wheat farmers

Project Sponsors: Sherman County SWCD

Project Description: Provide funding to supplement funding of SWCD County Cost Share (CCS) program. The Sherman County SWCD CCS program is funded from county tax dollars and includes projects such as improving farming haul roads with gravel, solar well developments, border fencing, terrace and water and sediment control basin reshaping, weed control, pasture/range planting, and creation and maintenance of fire breaks (Sherman County SWCD 2025). As funding for this program is limited, mitigation funds could be directed to SWCD to supplement this program's funding and provide additional opportunities for Sherman County farmers to participate in this program.

Project Benefit: Benefits to farmers participating in the SWCD CCS program would depend on the project but would result in offsetting costs to farmers for soil conservation, weed control, fire mitigation, etc.

Proposed Budget: To be provided by project sponsor. The current annual budget for this program is $100,000 allocated at $25,000 quarterly. For conservation projects, landowners provide 25 percent of the cost while SWCD provides 75 percent of the cost share rate with projects up to $20,000.[4] Mitigation funds allocated to this program could increase the annual budget to provide capacity to fund more projects in the county depending on demand by Sherman County farmers.

5.4 Project 4: Next-Generation Farming Innovation and Technology Training Program

Project Sponsors: To be determined. Sponsors could be individual wheat farmers seeking funding for precision agricultural technology investments, school district seeking funding for heavy equipment training programs, or other community programs such as 4H or National Future Farmers of America Organization seeking funding for youth programs focused on wheat farming.

Project Description: A variety of projects could be included, such as:

- Grant program for county wheat farmers to invest in precision agricultural technology such as weed management equipment, remote sensing technology to assist with weed mapping

[4] See CCS grant application:
https://www.shermancountyswcd.com/files/a1235c3b6/CCS_Application_2024.pdf

or soil mapping, variable rate technology to collect data on soil variability to inform application of fertilizers, and other technologies.

  - The precision agricultural technology grant program is intended to increase Sherman County wheat farmer's access to this technology through a cost-sharing agreement between farmers and MCEDD.
  - The cost-share agreement would be determined by the County BOC but is assumed to be 50 percent of the total cost of the precision tech equipment and installation. A cost-share program ensures prospective recipients of the program are fully invested in the use and maintenance of the precision agricultural technology.

- Grant program to offset tuition costs for Sherman County residents to participate in heavy equipment training and receive large equipment operator certification.

Project Benefit:

- The cost-share grant program for precision agricultural technology is assumed to increase the number of farmers who otherwise would not have access to precision management technology due to the significant upfront cost barrier. Investments in this technology could help county wheat farmers decrease costs to expensive farming inputs such as chemicals, fertilizers, and fuel resulting in economic benefits to these farmers.
- The grant program for heavy equipment operation training would directly relate to increasing local capacity to operate farm equipment, firefighting equipment, and construction equipment. This increased capacity would economically benefit farmers in the County by providing additional labor capacity.

Proposed Budget: To be provided by project sponsor. Project budget is anticipated to range from $200,000 to $1,000,000 depending on the number of grants allocated.

5.5 Project 5: Capacity Building for Wheat Growers

Project Sponsor: Sherman County, individual wheat farmers.

Project Description: This project proposes a per-bushel support mechanism to strengthen the financial resilience of Sherman County's wheat growers. For every bushel of wheat produced in the County, an additional $0.05 would be paid directly to farmers on top of the prevailing market price. This payment is intended to help offset the rising costs of inputs such as seed, fertilizer, fuel, machinery, and labor.

Project Benefits: The benefit of this project is that it directly places funds into the hands of Sherman County wheat farmers at a time when input costs are rising and market prices remain unpredictable. More specifically, the project would:

- Support farm income by providing an additional payment linked to production levels.
- Help offset rising input costs such as seed, fertilizer, and fuel.

- Provide flexibility for reinvestment in farm operations, equipment, or practices that improve efficiency.
- Contribute to the local agricultural economy by supplementing the revenue available to wheat growers.
- Offer modest support for community stability, as additional farm income can help sustain agricultural operations in the County.

Proposed Budget: To be provided by project sponsor. At a rate of $0.05 per bushel, the project could cost up to approximately $282,550 in a single harvest season, assuming an annual production of 5.65 million bushels. The actual budget would vary depending on annual yield volumes and prevailing market conditions.

Attachment 1 – Draft Memorandum of Understanding for the Community Investment Fund

MEMORANDUM OF UNDERSTANDING
FOR
BIGLOW SOLAR AGRICULTURAL MITIGATION

This Memorandum of Understanding ("MOU") is entered into on _____, 2025 ("Effective Date"), among Sherman County ("County"), Mid-Columbia Economic Development District ("MCEDD"), and _____, ("Project Sponsor"), collectively the "Parties."

Recitals

A. Project Sponsor is developing solar photovoltaic and battery energy storage components on up to ~~3,234~~1,925 acres on private land zoned exclusive farm use in Sherman County, Oregon ("Solar Components").

B. The Solar Components will be subject to review by the Oregon Energy Facility Siting Council ("EFSC") as an amendment to the Portland General Electric's existing Biglow Canyon Wind Farm Site Certificate on Amendment 3, dated October 31, 2008 ("Biglow Solar RFA").

C. The Biglow Solar RFA provides reasons upon which EFSC may grant an exception to Oregon's Statewide Planning Goal 3 and authorize the removal of up to 3,234 acres from dryland wheat production for the life of the Solar Components.

D. Project Sponsor performed an agricultural economic impact analysis ("AIA") to evaluate the direct, indirect, and induced impacts from removing up to ~~3,234~~1,445 acres of land from dryland wheat production. The AIA concluded that the quantifiable agricultural impacts on Sherman County's agricultural economy from permanent footprint of the Solar Components may be approximately $1,531 per acre.

E. Project Sponsor anticipates mitigating the Project's quantifiable agricultural impacts through the implementation of the Biglow Solar Community Investment Plan ("CIP"). Project Sponsor and the County wish to support the agricultural economy in Sherman County with projects ("Mitigation Projects") that advance priorities of the local agricultural community ("Mitigation Selection Criteria"). The draft CIP is included in the Biglow Solar RFA and identifies the Mitigation Selection Criteria and potential Mitigation Projects.

F. Project Sponsor and the County wish to work with MCEDD to implement the CIP, and the Parties enter into this MOU to document their anticipated coordination efforts under the CIP and to outline a general framework by which the Parties may establish future commercial arrangements and related implementation efforts (the "Potential Arrangement").

G. The Parties hereby acknowledge and agree that further negotiation and evaluation are required and that additional material provisions and additional details are required before a final agreement might be drafted ("Definitive Agreement"). Except for Section 4, this MOU does not constitute a binding agreement between the Parties or their respective affiliates, and only such a mutually executed Definitive Agreement would be binding on them if such a Definitive Agreement can be reached. This MOU is intended solely as a statement of preliminary intent by the Parties as an aid to their further discussions and negotiations towards

PGE Internal

the Potential Arrangement and Definitive Agreement.

NOW THEREFORE, in pursuit of the Potential Arrangement, it is anticipated that the Parties will use the next several months to discuss, evaluate and negotiate the specific terms and parameters of such Potential Arrangement and Definitive Agreement. Any terms, conditions, roles and responsibilities in support of such Potential Arrangement will be mutually agreed to and approved by the Parties in a separate Definitive Agreement. The preliminary objectives and of the Parties include the following:

1. Party Contributions and Responsibilities.

a. It is anticipated that Project Sponsor is responsible for finalizing the draft CIP, managing the implementation of the CIP, and facilitating the Potential Arrangement negotiations that may give rise to the Definitive Agreement.

b. It is anticipated that MCEDD helps implement the CIP by administering the Community Investment Fund as further described below.

c. It is anticipated that the County through the Board of Commissioners is the decision-maker for selecting Mitigation Projects for funding.

2. Establishing the Community Investment Fund. It is anticipated that the Community Investment Fund would be funded as follows:

a. Project Sponsor will pay $1,531 per acre into the Community Investment Fund for each acre that the Solar Components remove from dryland wheat production ("Mitigation Payment"). The total number of acres removed from production for purposes of calculating the Mitigation Payment shall be determined prior to construction based on the final layout of the Solar Components proposed for construction ("Start of Construction"), which may be constructed in whole or in part depending on phasing.

b. There may be more than one Start of Construction and therefore more than one Mitigation Payment depending on Project phasing. The Community Investment Fund is intended to fund Mitigation Projects with the entire amount of one Mitigation Payment, meaning if there is more than one Mitigation Payment because of phasing, there would be more than one round of funding under the Community Investment Fund.

c. The Mitigation Payment needs to be paid into the Community Investment Fund prior to the Start of Construction for each respective phase.

3. Administering the Community Investment Fund. It is anticipated that MCEDD will administer the Community Investment Fund on behalf of the County and Project Sponsor, as contemplated in the CIP and ultimately, as provided in the Definitive Agreement, which the Parties contemplate may address, without limitation, the following:

a. Term. The Definitive Agreement will commence upon its execution and

PGE Internal

terminate at the earlier of (i) five years or (ii) the day by which all the funds are allocated and the reporting completed to satisfy the Project Sponsor's mitigation obligations under the CIP.

b. Selection Committee. It is anticipated that MCEDD will form and oversee a ~~five~~six-person advisory committee ("Selection Committee") to review applications for funding and make recommendations to the County on which Mitigation Projects should receive funding. It is anticipated that the Selection Committee will be comprised of: (i) one representative from Sherman County government; (ii) one representative from an academic institution engaged in agriculture research in Sherman County or an agricultural-related nonprofit entity located in Sherman County; (iii) one dryland farm producer in the County; (iv) one community member; ~~and~~ (v) one representative with expertise in wildfire as it relates to agricultural lands; and (vi) one representative from the Oregon Wheat Growers League. The Selection Committee may be formed following EFSC's approval of the Biglow Solar RFA. The County may propose candidates for appointment to the Selection Committee in accordance with the aforementioned criteria. If the County elects not to propose candidates for the Selection Committee, MCEDD shall make any remaining necessary appointments.

c. Applications for Funding. All applications for funding would need to be filed with MCEDD at a time determined by the parties, ahead of the Start of Construction ("Application Deadline"). MCEDD, in coordination with the County and Project Sponsor, will work to develop a Mitigation Project funding application. Notice of available funding and the application form would be released at least four months prior to the Application Deadline.

d. Awarding Funds. It is anticipated that the Selection Committee will recommend to the County which Mitigation Projects to fund through the Community Investment Fund by applying the Mitigation Selection Criteria and issuing a recommendation within 90 days of the Application Deadline. It is anticipated that the County would select Mitigation Projects for funding based on the Selection Committee's recommendations, subject to Section 3.e below, and award funds within 60 days of being presented with the Selection Committee's recommendations. MCEDD will award funds within 30 days of the County's decision.

e. Pre-Screened Mitigation Projects. The CIP identifies five potential Mitigation Project that were scoped based on feedback from the agricultural community and stakeholders ("Pre-Screened Mitigation Projects"). The parties intend that the Pre-Screened Mitigation Projects may bypass the Selection Committee and be deemed recommended for funding upon MCEDD receiving a complete funding application.

f. Reporting. It is anticipated that any recipient of funds from the Community Investment Fund would provide an annual report to the County, the Project

PGE Internal

Sponsor, and MCEDD, to be further detailed in the Definitive Agreement.

g. Administration Fee. It is anticipated that the Project Sponsor will pay MCEDD a fee for administering the Community Investment Fund. Members of the Selection Committee will be nonpaid volunteers.

4. Term. This MOU shall be effective upon execution by all the Parties ("Effective Date") and shall run for three years from the Effective Date or until (a) the mutual executive of the Definitive Agreement or (b) termination by mutual written consent of all the Parties.

[add three party signature block]

PGE Internal

Attachment C: Operations Wildfire Mitigation Plan Outline

PGE Biglow Canyon Wind Farm Operations Wildfire Mitigation Plan Outline

This document outlines Portland General Electric Company's (PGE) approach to a Draft Operations Wildfire Mitigation Plan (Operations WMP) for the Biglow Canyon Wind Farm Solar Components. The plan will satisfy the approval standards under OAR 345-022-0115(1)(b), will follow the template provided by the Oregon Department of Energy on January 28, 2025, and will be aligned with the structure, terminology, and risk-based mitigation framework contained in PGE's 2026–2028 Wildfire Mitigation Plan (WMP) filed with the Oregon Public Utility Commission, including any future Commission-approved updates.

Key Components of the Plan:

Wildfire Risk Assessment and Prevention

- PGE's proposed 2026-2028 Wildfire Mitigation Plan Appendix H contains PGE's Generation Wildfire Risk Assessment, including the Biglow facility with Solar Components added. Figure H-1 of PGE's 2026-2028 Wildfire Mitigation Plan shows the areas in an Outlying Fire Risk Zone (OFRZ), which are considered at a higher risk of wildfire.
- Prevention measures are expected to include inspection and correction practices, vegetation management, defensible space requirements, fire-season operational protocols, and other mitigation strategies consistent with PGE's Commission-filed 2026–2028 WMP. The Operations WMP will define specific procedures, standards, and implementation timelines during facility operations, similar to those described in Section 4.1.3 of the Draft Construction WMP.
- The Operations WMP will describe fire detection systems, thermal management controls, monitoring systems, emergency response protocols, and integration with situational awareness systems to mitigate fire risk and support safe facility operations, similar to those described in Section 4.1.4 of the Draft Construction WMP.

Fire Season Readiness

- During PGE-declared Fire Season, personnel performing operational or maintenance activities will follow wildfire mitigation procedures designed to reduce ignition risk and maintain safe working conditions. The Operations WMP will describe Fire Season readiness protocols applicable to facility operations.
- Consistent with Fire Season readiness operational protocols outlined in PGE's proposed 2026-2028 Wildfire Mitigation Plan, field personnel and suppliers will be equipped with appropriate fire suppression tools and equipment during fire season, which may include properly rated fire extinguishers, round-pointed shovels, Pulaskis, and other firefighting equipment identified in company standards. Supplemental fire suppression resources, such as mobile fire trailers equipped with water supply, hose, and pump systems, may be deployed when conditions warrant.

- The Operations WMP will also outline requirements to ensure fire suppression tools and equipment remain functional and readily accessible during operations in fire-prone areas. These requirements will be consistent with applicable fire prevention rules and other relevant jurisdictional requirements.
- Fire Season field operational restrictions will be defined in the Operations WMP and are expected to align with PGE's Fire Season Readiness operating procedures. During periods of elevated fire danger, PGE may implement additional operational controls based on wildfire risk indicators such as National Weather Service Red Flag Warnings, Industrial Fire Precaution Levels (IFPL), National Fire Danger Rating System conditions, or other jurisdiction-specific fire restrictions.
- Depending on conditions, these measures may include restrictions on spark-producing activities, time-of-day limitations on certain work activities, enhanced fire watches, pre-positioning of fire suppression tools and equipment, or temporary suspension of non-essential activities.
- If a fire occurs during operations, personnel will follow company emergency response procedures, including notification of emergency services and PGE's Control Center/s, coordination with local fire authorities, and implementation of appropriate response actions consistent with site-specific Emergency Response Plans.

Inspections and Maintenance

- Comprehensive inspection and maintenance schedules for all facility components will follow manufacturer recommendations associated with each type of facility component, will be summarized in a table within the Plan, and documentation of inspections will be submitted to ODOE for compliance evaluation.

Vegetation Management

- Maintenance of low-growing, fire-resistant vegetation within 20-foot defensible space around site perimeter (10 feet inside the fence and 10 feet outside the fence) (or as specified by ODOE in the Final Order).
- Vegetation under solar arrays maintained at 8 inches maximum height during fire season and 10 to 12 inches outside of fire season (or as specified by ODOE in the Final Order).
- Bi-annual vegetation assessments with additional monitoring as needed.

Training and Monitoring

- Start-of-operations and annual safety training will be provided for all personnel covering electrical safety and equipment use. The Operations WMP will describe the content and delivery methods of these training programs.
- Additionally, identified PGE field personnel and Suppliers (contractors and vendors) will be required to complete mandatory Fire Season Training through computer-based training or

other company-approved training methods prior to performing field activities during fire season.

- 24/7 remote monitoring via SCADA system with smoke/fire detectors throughout facility.
- Coordination with local fire departments and emergency services.

Plan Updates and Reporting

- Annual reporting per OAR 345-026-0080 to Oregon Department of Energy.
- Annual review of the Operations WMP to determine if updates are necessary, including evaluation of changes in standards, policies, future technologies or best practices.
- Provisions for Operations WMP amendments as needed.

The Operations WMP will establish a comprehensive framework for preventing wildfires, maintaining appropriate equipment and vegetation management, and responding effectively to wildfire emergencies at the expanded Biglow Canyon facility.

Attachment 1. Residence/Landowner Outreach Letter

1.0 Introduction

The Energy Facility Siting Council (EFSC) approved Portland General Electric Company's (PGE or Certificate Holder) Draft Construction Wildfire Mitigation Plan (WMP) as part of the Request for Amendment (RFA) 4 to the Site Certificate for the Biglow Canyon Wind Farm (BCWF or Existing Facility) which added photovoltaic solar energy generation and battery storage (Solar Components) to the operating BCWF in Sherman County, Oregon.

This plan is intended to satisfy the approval standards under OAR 345- 022-0115(1)(b), which requires the Plan to:

> *(A) Identify areas within the site boundary that are subject to a heightened risk of wildfire, using current data from reputable sources, and discuss data and methods used in the analysis;*
>
> *(B) Describe the procedures, standards, and time frames that the applicant will use to inspect facility components and manage vegetation in the areas identified under subsection (a) of this section;*
>
> *(C) Identify preventative actions and programs that the applicant will carry out to minimize the risk of facility components causing wildfire, including procedures that will be used to adjust operations during periods of heightened wildfire risk;*
>
> *(D) Identify procedures to minimize risks to public health and safety, the health and safety of responders, and damages to resources protected by Council standards in the event that a wildfire occurs at the facility site, regardless of ignition source; and*
>
> *(E) Describe methods the applicant will use to ensure that updates of the plan incorporate best practices and emerging technologies to minimize and mitigate wildfire risk.*

This plan is submitted in adherence to the following Site Certificate Conditions relating to RFA 4:

> Wildfire Prevention and Risk Mitigation Condition 1 (PRE): Prior to facility construction, the certificate holder shall finalize and submit a Construction Wildfire Mitigation Plan (WMP), Attachment XX to the Final Order on AMD4 to the Department for review and approval.
>
> [PRE-WF-01; Final Order on AMD4]
>
> Wildfire Prevention and Risk Mitigation Condition 2 (CON): During facility construction, the certificate holder shall require onsite contractors and employees to adhere to the Construction Wildfire Mitigation Plan (WMP) approved under PRE-WF-01.
>
> [CON-WF-01; Final Order on AMD4]

2.0 Final Wildlife Mitigation Plan Checklist (Prior to Construction)

2.1 Update Applicable Sections of Construction WMP

To finalize this Construction WMP prior to construction of the Solar Components, the following sections will be updated:

- Update Section 4.0 based on final Solar Component design including a brief description of areas within the site that are subject to high wildfire risk, fire prevention features at the site, such as road~~s~~ dimensions, setbacks, fire breaks, entry/exit locations, location of water trucks and fire protection equipment locations.
- Update Section 4.1 and include in this WMP the facility site maps described in Section 4.1.6.
- Update Section 4.3 with contact information and emergency response procedures for the fire department, Certificate Holder, and operational manager. Update Section 4.3 with analysis area residence contact information and confirm analysis area residence contact letter sent to residences within site boundary and 0.5 miles from the facility.
- Update S~~s~~ection 4.6 to describe vegetation management and areas that will be managed to be vegetation-free, noncombustible space, or gravel surface.

3.0 Prior to Construction Task List (PRE)

Prior to construction of the facility, the activities in Sections 3.1 and 3.2 will be completed.

3.1 Training

The Certificate Holder will organize and hold an on-site training with Certificate Holder, contractors and construction personnel, inviting specialty contractors, local fire departments, participating and adjacent landowners, emergency management office personnel, ODOE, and any other emergency management agency that covers:

- Description of construction phasing;
- The type, location, and proper use of fire protection equipment;
- Fire protection equipment usage and maintenance requirements;
- The locations of water sources and proper usage, storing and maintenance for the pump, hose nozzle; and water hose;
- Overview of smoking policy and locations;
- Overview of procedures and restrictions of construction maintenance activities during Fire Season and Red Flag Warnings designated in this Plan;
    - Rescue, Alarm, Contain and Extinguish RACE procedures including:
    - Rescue anyone in danger (if safe to do so);
    - Alarm – call the control room, who will then determine if 911 should be alerted;
    - Contain the fire (if safe to do so); and
    - Extinguish the incipient fire stage (if safe to do so).
- Provide information and encourage attendees to sign up for the County's emergency management notification system.

The training attendee list and training materials will be provided to ODOE to demonstrate compliance. The Certificate Holder will fill out and submit to ODOE the template residence outreach letter provided as Attachment 1 of this WMP. Once ODOE confirms the letter to be sufficient, the letter will be mailed to each residence within the 0.5-mile analysis area. The mailing will be confirmed and submitted to ODOE.

3.2 Solar Micrositing Area Site Maps Submission

The Certificate Holder will update site maps from Section 4.1.6 concurrently to local fire departments and ODOE.

4.0 Construction Wildfire Mitigation Plan (CON)

The information in Section 4.0 will be updated in the finalized WMP.

4.1 Summary of Solar Component Design Features and Fire Protection Equipment

4.1.1 Construction Phasing

The Certificate Holder and contractors will maintain vegetation within the Solar Micrositing Area and will also maintain a defensible space clearance along Facility features. Defensible space will be free of combustible vegetation or other materials. Roads and parking areas will be maintained to be free of vegetation tall enough to contact the undercarriage of the vehicle.

During construction clearing, grubbing, and grading, the contractor will establish ~~create noncombustible~~a buffer managed with low-growing, fire-resistant vegetation ~~buffer zone~~ extending a minimum of 10 feet inside the fence line and another minimum 10-foot limits of disturbance buffer outside the fence line for a total of a minimum of 20 feet of ~~noncombustible~~ buffer around the perimeter of the site.

While hot work permits are not generally anticipated for the construction of the Solar Components, such permits or formal approval will be required during fire season if any hot work is to be conducted.

Fuel storage and handling protocols include the following:

- Any equipment or vehicles carrying fuel must remain parked at a designated location along a county-right-of way.
- Vehicles leaving the right-of-way must not carry fuel containers, with the exception of a
- single five-gallon container used to operate the water truck pump.
- Smoking will be restricted to designated areas within the Facility only.

4.1.2 Wildfire Risk

The data sources used in this Plan to identify areas within the Solar Micrositing Area subject to heightened risk of wildfire include the Oregon CWPP Planning Tool (ODF and USFS 2024) and the Sherman County Multiple-Jurisdictional Natural Hazards Mitigation Plan (Sherman County 2024).

This section will be updated in the finalized WMP.

The Sherman County Multiple-Jurisdictional Natural Hazards Mitigation Plan describes a county-wide risk assessment of wildfire as “high” probability and identifies many areas in the county as “conducive for large and fast-moving wildfires” due to high winds typical for regional dry conditions and terrain. The plan identifies risk factors for starting wildfires in the county as highways, railroads, lighting, power lines, debris burning, and equipment.

4.1.3 Fire Prevention

The greatest risk of fire is during construction, when welding and metal cutting will take place, and vehicles and construction equipment may be used in areas of tall, dry grass. To prevent fires from occurring, the construction contractor will implement a number of systems and procedures. These will include requirements to conduct welding or metal cutting only in areas cleared of vegetation, and to keep firefighting equipment on-site as discussed in Section 4.4. Construction workers will keep vehicles on roads during the dry months of the year, unless offroad activities are required for emergency purposes, in which case fire precautions will be observed. Construction workers will be prohibited from parking vehicles in areas of tall, dry vegetation to prevent fires caused by contact with hot mufflers or catalytic converters. In the event of a large fire, emergency responders will be dispatched.

Fire prevention specific to solar arrays is dependent on proper installation and maintenance of electrical equipment to prevent short-circuits and consequent sparking, and reduction in fuel to reduce the chance of fire spreading. Qualified staff will be employed to install and maintain electrical equipment. The solar array will have shielded electrical cabling, as required by applicable code, to prevent electrical fires. All electrical equipment will meet National Electrical Code and Institute of Electrical and Electronics Engineers standards. With proper maintenance and safety checks, the electrical collection system and gen-tie lines are unlikely to cause a fire. The substrate on the ground inside the solar array fence line will be gravel where needed for maintenance and access roads or where gravel already exists, and vegetation where gravel isn't needed or already present. Weeds will be managed in accordance with the weed management procedures described in the ~~Amended Revegetation Plan and Biglow Solar Noxious Weed Plan (see Exhibit P, Attachments P-2 and P-4, respectively~~Comprehensive Solar Revegetation and Soil Management Plan~~)~~.

~~The new roads proposed within the Solar Micrositing Area, shall be sufficiently sized for emergency vehicle access in accordance with 2022 Oregon Fire Code requirements, including Section 503 and Appendix D - Fire Apparatus Access Roads. Specifically, the n~~New roads proposed within the solar area fence lines will be at least ~~20~~16 feet in width. The areas immediately around the O&M buildings, proposed substation, and BESS will be graveled, with no vegetation present.

Additionally, the RFA 4 solar arrays, BESS, and associated project components will be setback at least 50 feet from all property lines of non-participating landowners.

4.1.4 Battery Energy Storage System Fire Prevention

The Certificate Holder will implement the following fire prevention and control methods to minimize fire and safety risks for the Li-ion batteries proposed for the BESS:

- The batteries will be stored in completely contained, leak-proof modules.
- The Li-ion battery system will be kept in a temperature-controlled facility with individual
- battery modules isolated to prevent the spread of fire if it were to occur.

- The batteries will be based on Lithium Iron Phosphate chemistry, which has a lower risk of fire.
- The Li-ion battery system will be comprised of multiple temperature-controlled battery enclosures, each with its own fire detection, monitoring and fire protection systems. The battery enclosures will be spaced at a minimum recommended distance from each other as required by the battery supplier, AHJ requirements and applicable codes and standards. Minimum spacing isolates each battery enclosure and reduces the risk of fire propagation between battery enclosures in the unlikely event of a fire.
- Ample working space will be provided around the BESS for maintenance and safety purposes.
- Twenty-four-hour monitoring of the BESS will be implemented and will include shutdown capabilities.
- Transportation of Li-ion batteries is subject to 49 CFR 173.185 – Department of Transportation Pipeline and Hazardous Material Administration. This regulation contains requirements for prevention of a dangerous evolution of heat, prevention of short circuits, prevention of damage to the terminals, and prevention of batteries coming into contact with other batteries or conductive materials. Adherence to the requirements and regulations, personnel training, safe interim storage, and segregation from other potential waste streams will minimize any public hazard related to transport, use, or disposal of batteries.
- Design of the BESS will be in accordance with applicable Underwriters Laboratories (UL 2023; specifically 1642, 1741, 1973, 9540A), National Electric Code, and National Fire Protection Association (specifically 855) standards, which require rigorous industry testing and certification related to fire safety and/or other regulatory requirements applicable to battery storage at the time of construction.
- Additionally, the Certificate Holder will employ the following design practices, as applicable to the available technology and design at time of construction:
    - Employment of an advanced and proven battery management system;
    - Qualification testing of battery systems in accordance with UL 9540A (Revision 4) at the batter cell, module, and unit level;
    - Installation of fire sensors, smoke and hydrogen and/or carbon monoxide detectors, alarms, emergency ventilation systems, cooling systems within each battery enclosure;
    - Employment of fire control panels with 24-hour battery backup;
    - Installation of doors that lock with restricted access to authorized personnel only;
    - Implementation of locks and fencing to prevent entry of unauthorized personnel;
    - Installation of remote power disconnect switches; and

- Clear and visible signs to identify remote power disconnect switches.

4.1.5 Facility Access

The locations of specific access points and gates will depend on the final configuration of the solar areas and related infrastructure. The perimeter fencing will have lockable vehicle access gates. As currently designed, five gates are included for the ~~Northern~~ Solar Area ~~and three gates for the Southern Solar Area~~. Additional gates may be included for emergency exits or for removal of wildlife. Each solar array, with any collocated related or supporting facility components, would be enclosed by seven-foot-tall chain-link perimeter fencing with one foot of razor or barbed wire at the top. Alternatively, ~~W~~wire mesh, or similar, perimeter fencing, up to 8 feet in height may be used~~., will enclose each of the two solar areas as shown on Figure 2 of the RFA 4 Division 27 document~~.

4.1.6 Facility Site Maps

This Construction WMP includes facility site maps that identify:

- The phasing for construction of facility features and components;
- During construction clearing, grubbing, and grading, the contractor will establish a ~~low-growing vegetation~~ buffer zone managed with low-growing, fire-resistant vegetation extending a minimum of 10 feet inside the fence line and another minimum 10-foot limit~~s~~ of disturbance buffer outside the fence line for a total of a minimum of 20 feet of buffer around the perimeter of the site.
- Location and dimensions of facility roads;
- Solar arrays, BESS, and associated project components will be setback at least 50 feet from all property lines of non-participating landowners;
- Location of vegetation free, noncombustible, defensible spaces;
- Wildfire risk at the site;
- High-fire consequence areas/resources (includes existing infrastructure, residences, sensitive habitat, or cultural resources)
- The location of facility access points;
- A description and the location of emergency access procedures, including how emergency responders and/or adjacent landowners may access site for fire protection equipment or to extinguish an on-site fire when personnel will not be onsite;
- The type and location of fire protection equipment on site;
- The locations of water sources that will be on-site during construction.

Facility site maps will be included in the finalized WMP~~.~~.

The final Construction WMP will include a site map detailing specific access points, location of fire protection equipment, and location of water sources.

4.2 Specifications for Fire Protection Equipment

The following fire suppression equipment will be carried in vehicles conducting maintenance activities and stored on-site at the O&M building at all times:

- Fire Extinguisher: Dry chemical. 2A:10BC (5 pound), properly mounted or secured;
- Pulaski;
- Hand Shovel: Round point. 26 to 28 in "D" Handle, blade - 12 inches long and 10 inches wide; and
- Collapsible Pail or Backpack Pump: 5-gallon capacity~~; and~~.
- ~~Drip Can: 5-gallon capacity.~~

During fire season (designated Fire Season or June to October each year) water trucks/water source, water buffalo, or tank with minimum 500-gallon capacity must be on site. The water truck or water supply shall include the following, unless approved by ODOE:

- Pump should be maintained ready to operate and capable to provide a discharge of not less than 20 gallons per minute at 115 psi at pump level. Note: Volume pumps will not produce the necessary pressure to effectively attack a fire start. Pressure pumps are recommended.
- Provide enough hose (500 feet minimum) not less than 3/4" inside diameter to reach areas where power driven machinery has worked.
- Water supply, pump, and at least 250 feet of hose with nozzle must be maintained as a connected, operating unit ready for immediate use.

All internal combustion engines must be equipped with exhaust systems, mufflers and screens, or include an appropriate spark arrestor; and must be kept in good operating condition. All combustion engines (including but not limited to off road vehicles, chainsaws, and generators) will be equipped with a spark arrester that meets U.S. Forest Service Standard 5100-1.

All power-driven machinery will be kept free of excess flammable material which may create a risk of fire.

4.3 Solar Component Contact Information and Emergency Response Procedures

Local fire department and county emergency management contact information:

- North Sherman County Rural Fire Protection District: (541) 442-5252 or 911
- Sherman County Emergency Services: (541) 565-3100 or 911

Fire department response times to the site:

- The Project Developer and Certificate Holder will work with North Sherman County RFPD to determine response times to the site and this will be included in the final Construction WMP.

Certificate holder primary contact and contact of construction contractor managers:

Certificate Holder Primary Contact Information	
Name	Dan Wilson
Company	Portland General Electric Company
Street Address	121 SW Salmon Street, 3WTC0403
City/State/Zip	Portland, OR 97204
Phone	503-630-8138
Email	Dan.Wilson@pgn.com
Construction Contractor Manager Contact Information	
Name	Construction contractor managers contact information will be provided in the final Construction WMP.
Title	
Street Address	
City/State/Zip	
Phone	
Email	

Residence addresses within the site boundary and 0.5 miles from the site boundary:

- Attachment XX of the finalized WMP will include a list of property owners within the RFA 4 Site Boundary and a 0.5-mile radius.
- Residence/landowner outreach letter is provided as Attachment 1 of this WMP. Use this letter to provide to new or updated residences with the analysis area as designated in Section 5.0, Plan Updates and Reporting Requirements.

Contact 911 in the event of:

- A fire or emergency on-site that cannot be addressed by personnel on-site and requires the
- assistance of fire or emergency medical personnel;
- A fire ignition on-site that spreads out of the fence line;
- Any fire off-site that does not have emergency responders on site.
    - To the extent that construction personnel can safely assist and/or provide equipment to help extinguish off-site fires until emergency responders are on site, it is encouraged to do so to assist in the spread of the fire, loss of life, property and damage to the environment.

4.4 Use of Vehicles and Power Driven Machinery at Site

The following best management practices (BMPs) to minimize fire risk from vehicle travel, equipment use, and fueling activities will be implemented at the site during construction:

- The movement of vehicles will be planned and managed to minimize fire risk.
- The contractors will be responsible for identifying and marking paths for all off-road vehicle travel. All off-road vehicle travel will be required to stay on the identified paths. No off-road vehicle travel will be permitted while working alone. Travel off road or parking in vegetated areas will be restricted during fire season as designated in this Plan.
- Areas with grass that are as tall or taller than the exhaust system of a vehicle must be wetted or mowed before vehicles travel through it.
- Workers will be instructed to shut off the engine of any vehicle that gets stuck, and periodically inspect the area adjacent to the exhaust system for evidence of ignition of vegetation. Stuck vehicles will be pulled out rather than "rocked" free and the area will be inspected again after the vehicle has been moved.
- The contractors will designate a location for field fueling operations at the temporary construction yards. Any fueling of generators, pumps, etc. shall take place at this location only.
- Fuel containers, if used, shall remain in a vehicle or equipment trailer, parked at a designated location alongside a county right-of-way. No fuel containers shall be in the vehicles that exit the right-of-way except the five-gallon container that is required for the water truck pump.
- All power--driven machinery will be kept free of excess flammable material which may create a risk of fire.

4.5 Fire Weather Monitoring and Restrictions during Fire Season

4.5.1 Definitions

- **Non-Fire Season –** Approximately October - May
- **Fire Season –** Approximately June-September, formally designated by the Oregon Department of Forestry (ODF). Under ORS 478.960 (4), a Fire Chief can establish Fire Season within a Fire District when ODF, under ORS 477.505, declares Fire Season. Begins seasonal restrictions for public and industry.
- **Fire Weather Watch –** A fire weather watch is issued when there is a high potential for the development of a red flag event. A watch is issued 18 to 96 hours in advance of the expected onset of criteria. Intent of a fire weather watch is to alert forecast users at least a day in advance for the purposes of resource allocation and fire fighter safety. A watch means critical fire weather conditions are possible but not imminent or occurring.

- **Red Flag Weather Warning –** A red flag warning is used to warn of impending or occurring red flag conditions. Its issuance denotes a high degree of confidence that weather and fuel conditions consistent with local red flag event criteria will occur in 48 hours or less. Specific Red Flag criteria differ for each situation and district in Oregon. Be extremely careful with open flames and other activities that emit sparks.
- **Hot Work –** Any cutting, grinding, welding, or other activity that creates spark or open flame.

4.5.2 Fire Watch Service

Fire watch shall:

- Be physically capable and experienced to operate firefighting equipment.
- Have facilities for transportation and communications to summon assistance.
- Observe portions of the facility where equipment activity occurred during the day.

Upon discovery of a fire, fire watch personnel must: First report the fire, summon any necessary firefighting assistance, describe intended fire suppression activities; then, after determining a safety zone and an escape route that will not be cut off if the fire increases or changes direction, immediately proceed to control and extinguish the fire, consistent with firefighting training and safety.

4.5.3 Fire-Prevention Measures and Restrictions

Certificate holder shall maintain a log when construction activities are impacted by Fire Restrictions during Fire Season as designed in this Section. The log will include:

- The date;
- Fire Precaution Level;
- Description of actions taken, including if any measures were taken to reduce wildfire risk that are not identified in this Plan.

4.5.3.1 Non-Fire Season

- All hot work (must be conducted on roads or on non-combustible surfaces.
- Smoking in designated areas only.

4.5.3.2 Fire Season

- All hot work (any cutting, welding, or other activity that creates spark or open flame) must be conducted on roads or on non-combustible surfaces.
- Water source meeting specifications in this Plan will be on site during fire season.
- Following the completion of hot work, the Certificate Holder or contractors must maintain a fire watch for 60 minutes to monitor for potential ignition.

- Fire watch shall be on duty during any breaks and for one hour after all power driven machinery used by the operator has been shut down for the day.
- Smoking in designated areas only.

4.5.3.3 Fire Weather Watch

- No hot work permitted.
- Driving and parking only permitted on graveled or paved surfaces.
- Fire watch shall be on duty during any breaks and for one hour after all power driven machinery used by the operator has been shut down for the day.
- No smoking on site.

4.5.3.4 Red Flag Weather Warning

- No hot work permitted.
- On-site personnel must be aware of Red Flag Warning.
- Driving and parking only permitted on graveled or paved surfaces.
- Fire watch shall be on duty during any breaks and for one hour after all power driven machinery used by the operator has been shut down for the day.
- No smoking on site.

Table 1. Fire Prevention Measures during Fire Season

Requirement	Non-Fire Season	Fire Season	Fire Weather Watch	Red Flag Warning
Fire weather advisory	Not required	Not required	Not required	On-site personnel must be aware of Red Flag Warning.
On-site water source	N/A	As specified in Section 4.2	As specified in Sections 4.2 and 4.3.	As specified in Sections 4.2 and 4.3.
Hot work	Only permitted on roads or on non-combustible surfaces.	Only permitted on roads or on non-combustible surfaces; fire watch required for 60 minutes after completion	Not Permitted	Not Permitted
Fire Watch Service	Not required	During breaks and for 60 minutes after all power-driven machinery has been shut down for the day.	During breaks and for 60 minutes after all power-driven machinery has been shut down for the day.	During breaks and for 60 minutes after all power-driven machinery has been shut down for the day.

Requirement	Non-Fire Season	Fire Season	Fire Weather Watch	Red Flag Warning
Driving and Parking	As described in Section 4.4.	As described in Section 4.4.	Only permitted on roads or on non-combustible surfaces and Section 4.4.	Only permitted on roads or on non-combustible surfaces and Section 4.4.
Smoking	Designated areas only	Designated areas only	Not permitted	Not permitted

4.6 Vegetation Management

4.6.1 Vegetation-free, Noncombustible Space, and Vegetation Standards

Vegetation within the fence line and below the solar arrays will be maintained in accordance with the approved Revegetation and Reclamation Plan for the facility.

- Vegetation will be limited to a height of 10-12 inches during the wet season (November-May) and 8 inches during the dry season (June-October), with a minimum vertical clearance of 12 inches from electrical equipment.
- Vegetation near, at, or taller than the maximum height shall be removed or mowed. Mowing must be done in advance of fire season or in accordance to any fire restrictions.
- 20 feet of low-growing, fire-resistant vegetation buffer around the perimeter of the site (10 feet on each side of the fenceline)
- Vegetation within 10 feet of each side of all service roads will be managed ~~by mowing or other vegetation removal~~with low-growing, fire-resistant vegetation.
- At no point shall vegetation come in contact with electrical equipment.
- Any vegetation removed from the site will be disposed of and not stored onsite.
- The Certificate Holder and contractors will prevent the accumulation of combustible "burn piles" on site.

The following areas will be managed to be vegetation-free, noncombustible space, or gravel surface:

- ~~16-foot wide~~16-foot-wide ~~service roads within solar fence line – all weather compacted soil or graveled~~
- ~~20 feet of noncombustible buffer around the perimeter of the site~~ (10 feet on each side of the fenceline)
- Fenced areas around the collector substation, operations and maintenance structure, and meteorological stations will be graveled, with no vegetation present.
- All newly constructed roads will be graded and graveled to meet load requirements for all equipment.

~~Vegetation within 10 feet of eitherach side of all service roads will be managed by mowing or other vegetation removal~~

Vegetation in these areas will be managed by the following techniques:

- Mechanical Clearing: mowing, brushing, chipping, tree trimming/felling
- Manual Clearing: hand tools (chainsaws, machetes, handsaws)
- Chemical Treatment: use of approved herbicides by licensed applicators to control or suppress vegetation growth (broadcast spray, spot treatment, cut-stump/basal bark)

4.7 Construction Trainings

4.7.1 Safety Training

Once per year after construction begins, organize and hold an on-site training with Certificate Holder and construction personnel, inviting equipment manufacturers, specialty contractors, local fire departments, participating and adjacent landowners, emergency management office personnel, ODOE, and any other emergency management agency that covers:

- The location of electrical facility components and the fire safety measures associated with each component that have been constructed;
- Description of remaining construction phasing;
- The type, location, and proper use of fire protection equipment;
- Fire protection equipment usage and maintenance requirements;
- The locations of water sources and proper usage, storing and maintenance for the pump, hose nozzle; and water hose;
- Overview of smoking policy and locations;
- Overview of procedures and restrictions of construction activities during Fire Season, Fire Weather Watches, and Red Flag Warnings designated in this Plan;
- Rescue, Alarm, Contain and Extinguish (RACE) procedures including:
    - Rescue anyone in danger (if safe to do so);
    - Alarm – call the control room, who will then determine if 911 should be alerted;
    - Contain the fire (if safe to do so); and
    - Extinguish the incipient fire stage (if safe to do so).
- Provide information and encourage attendees County's emergency management notification system.

5.0 Plan Updates: Amendments and Reporting Requirements:

The following will be provided to ODOE in the semi-annual construction report required per OAR 345-026-0080:

- Sections 4.1 and 4.2, any changes in wildfire risk at the site or changes in facility components or preventative features.
- Section 4.3, any changes in local fire protection agency personnel and operational managers.
- Section 4.3, any changes in analysis area residence/landowner addresses or contact information.
- A copy of the Fire Season Restriction Log identified in Section 4.5.3.
- Changes in wildfire risk if different from the Site Plan provided prior to construction. Evaluation of wildfire risk will be consistent with the requirements of OAR 345-022--0115(1) using current data from reputable sources.

This information may be used to establish the performance of the Construction WMP. If determined by certificate holder or ODOE, adjustments or improvements must be proposed to ensure the Construction WMP provides wildfire mitigation. Any ODOE required updates shall be implemented within 14 days, unless otherwise agreed to by ODOE based on a good faith effort to address wildfire hazard.

This Plan may be amended from time to time by agreement of the certificate holder and the Oregon Energy Facility Siting Council (EFSC) or ODOE, acting within its delegated authority of EFSC. Such amendments may be made without amendment of the site certificate. EFSC authorizes ODOE to agree to amendments to this Plan. ODOE will notify EFSC of all amendments, and EFSC retains the authority to approve, reject, or modify any amendment of this Plan agreed to by ODOE.

Attachment E: Certificate Holder Communications and Outreach Related to Battery Fire Safety

Correspondence and Engagement Log – Battery Fire Safety

Stakeholder: Ms. Kathy McCullough
Engagement Period: May – October 2025

Date	Engagement Type	Initiated By	Participants	Subject / Purpose	Outcome / Notes
September 17, 2025	Virtual Meeting (Scheduled)	Project Team	Coffman Engineers; Project Team; Ms. McCullough	BESS / fire risk discussion	Not attended[1]
September 17, 2025	Email / Phone Follow-Up	Project Team	Ms. McCullough	Follow-up regarding missed meeting; presentation shared	Meeting rescheduled
September 18-19, 2025	Email	Ms. McCullough	Coffman Engineers; Project Team	Technical follow-up questions	Addressed in subsequent meeting
September 2025	Virtual Meeting	Project Team	Coffman Engineers; Ms. McCullough	Fire safety discussion	Technical questions addressed
September 23, 2025	Virtual Meeting	Project Team	Coffman Engineers; Project Team; Ms. McCullough	Follow-up coordination meeting	Continued engagement

Footnotes

1. A meeting was scheduled with Ms. McCullough to discuss any questions she had regarding fire risk/safety. The project team and Coffman Engineers waited for Ms. McCullough at the agreed upon scheduled time, but she did not attend. Follow-up contact was attempted via phone and text. Ms. McCullough later apologized, and materials were provided in writing.

Dear Kathy And Kevin,

Thank you for your responses to our February 13, 2026 reply regarding the Proposed Order on Request for Amendment 4 of the Biglow Canyon Wind Farm Site Certificate, please find attached Portland General Electric's and the project developer, BrightNight's, sur-reply.

All the best.

Re: Biglow Canyon Wind Farm Request for Amendment 4 – Proposed Order Response to Comment (BCWAMD4Doc25-03-P3)

Dear Mr. McCullough,

Portland General Electric (PGE) and the project developer BrightNight (BN) appreciate your February 27, 2026, response to our reply regarding the Proposed Order on Request for Amendment 4 (RFA 4) of the Biglow Canyon Wind Farm (BCWF) Site Certificate.

PGE and BN carefully reviewed your most recent comment response letter and provide the following responses, based on our interpretation of the concerns raised in your correspondence, which are intended to directly and comprehensively address each issue.

This reply provides additional information on an issue-by-issue basis, consistent with the Oregon Department of Energy (ODOE)'s issue identification framework and categories identified in Table 1 of the ODOE Response Letter dated February 12, 2026.

1. Vegetation Height (Issues WF-09, SP-04)

PGE and BN acknowledge the concerns that you have expressed regarding vegetation height at the proposed Biglow Solar facility and share the following comment on vegetation height that we provided to ODOE in a letter dated February 27, 2026. You may have already seen our comment on the ODOE OneDrive set up for the Project, but we wanted to provide it here in case you have not previously seen it:

> *The Certificate Holder appreciates ODOE's consideration of vegetation height requirements during the dry season and the input provided by the Sherman County Weed District and other commenters.*
>
> *As previously discussed, maintaining vegetation at a height of 1 to 3 inches during the June–October dry season presents practical and ecological challenges. Repeated mowing to that height would likely damage perennial bunchgrasses included in the approved seed mix, reduce long-term stand viability, increase susceptibility to invasive annual grasses, and potentially elevate fine fuel risk over time. In addition, mowing at extremely low heights may increase ignition risk due to equipment contact with rocks or soil surface.*
>
> *At the same time, the Certificate Holder acknowledges neighboring non-participating landowner concerns regarding wildfire risk and understands the desire for lower vegetation height during the peak fire season. Based on consultation with vegetation management specialists from Sherman County Weed District and Tetra Tech, and*

consideration of local Conservation Reserve Program management practices, the Certificate Holder is committed to maintaining vegetation at a target height of approximately 8 inches during the dry season, where practicable to ensure vegetation health. The Certificate Holder further commits that vegetation will be maintained below 10 to 12 inches, consistent with the draft Comprehensive Solar Revegetation and Soil Management Plan.

An 8-inch target height represents a reasonable middle ground that:

- *Reduces standing fine fuels compared to unmanaged conditions;*
- *Maintains bunchgrass crown integrity and long-term vegetation health;*
- *Aligns more closely with local vegetation management practices; and*
- *Avoids creating conditions that would favor invasive annual grasses.*

The Certificate Holder recognizes that mowing height may vary slightly depending on equipment capabilities, species composition, and site conditions, and commits to implementing vegetation management in coordination with local experts and in accordance with the final approved Comprehensive Solar Revegetation and Soil Management Plan and Construction Wildfire Mitigation Plan.

This approach reflects the Certificate Holder's willingness to collaborate with ODOE and local stakeholders while ensuring that vegetation management practices remain ecologically sustainable and supportive of long-term wildfire risk reduction objectives.

2. Wildfire Risk Mitigation (Issue WF-12)

Your February 27, 2026, comment response letter expressed continued concern regarding the fact that an Operations Wildfire Mitigation Plan (WMP) has not yet been provided.

The Proposed Order (PO) and ODOE's draft proposed conditions require that a final Operations WMP be completed and approved prior to operation of the solar facility, phase, or component, as applicable (PRO-WF-01). The Certificate Holder acknowledges this requirement and remains committed to timely development and submittal of the final Operations WMP consistent with the PO and the Energy Facility Siting Council (EFSC)'s final site certificate conditions.

In advance of that requirement, and in recognition of public and agency interest in this topic, PGE is providing an Operations WMP Outline as Attachment A to this letter. Attachment A outlines anticipated commitments and establishes a clear framework for development of the final Operations WMP. This outline is intended to demonstrate continued progress and provide EFSC and members of the public with transparency regarding how wildfire risk will be addressed during facility construction and operations.

In both the Draft Construction WMP and Operations WMP Outline, the Certificate Holder has committed to the following measures to support wildfire prevention and response during construction and operation of the Biglow Solar facility:

- Facility operator emergency response training (Draft Construction WMP Section 3.1);
- Maintaining multiple on-site water sources with a minimum of 500 gallons of water each and operator training on how to use water hoses, pumps, and related equipment (Draft Construction WMP Sections 3.1 and 4.2); and
- Identifying a pre-screened project in Sherman County to build firefighting capacity (including upgrading, maintaining, or adding firefighting equipment and facilities;

additional training for volunteers; additional funding for staff; and funding for projects to develop fuel breaks, reduce wildfire hazards, and provide firefighting water) in Section 5.2 of the Community Investment Plan (BCWF RFA4 Proposed Order Attachment E).

We agree that wildfire mitigation planning for a facility of this scale and location must be robust and carefully developed. As a public utility, PGE is subject to additional operational, safety, and reliability obligations that extend beyond those applicable to many standalone private facilities. Accordingly, the Operations WMP is being developed to align not only with EFSC site certificate requirements, but also with PGE's broader wildfire risk mitigation framework, utility safety standards, and public safety responsibilities.

For this reason, development of the final Operations WMP requires careful coordination across engineering, operations, emergency response, and utility compliance teams. While a draft or final Operations WMP is not required at this stage of the amendment review, PGE is committed to ensuring that the completed plan reflects a comprehensive, utility-level approach to wildfire risk prevention, preparedness, and response. The Operations WMP Outline provides for the record the elements that must be accounted for in the final Operations WMP and our commitment to develop a robust final Operations WMP.

Our communities' concerns are very important to us, and we are committed to operating this facility in a way that reflects our shared interest in protecting people, property, and the landscape we all value.

Please reach out if you have questions or would like to discuss further. As previously discussed, there will be continued engagement of the community and neighbors as this project moves forward.

Sincerely,

Lenna Cope

Attachment A: Operations Wildfire Mitigation Plan Outline

PGE Biglow Canyon Wind Farm Operations Wildfire Mitigation Plan Outline

This document outlines Portland General Electric Company's (PGE) approach to a Draft Operations Wildfire Mitigation Plan (Operations WMP) for the Biglow Canyon Wind Farm Solar Components. The plan will satisfy the approval standards under OAR 345-022-0115(1)(b), will follow the template provided by the Oregon Department of Energy on January 28, 2025, and will be aligned with the structure, terminology, and risk-based mitigation framework contained in PGE's 2026–2028 Wildfire Mitigation Plan (WMP) filed with the Oregon Public Utility Commission, including any future Commission-approved updates.

Key Components of the Plan:

Wildfire Risk Assessment and Prevention

- PGE's proposed 2026-2028 Wildfire Mitigation Plan Appendix H contains PGE's Generation Wildfire Risk Assessment, including the Biglow facility with Solar Components added. Figure H-1 of PGE's 2026-2028 Wildfire Mitigation Plan shows the areas in an Outlying Fire Risk Zone (OFRZ), which are considered at a higher risk of wildfire.
- Prevention measures are expected to include inspection and correction practices, vegetation management, defensible space requirements, fire-season operational protocols, and other mitigation strategies consistent with PGE's Commission-filed 2026–2028 WMP. The Operations WMP will define specific procedures, standards, and implementation timelines during facility operations, similar to those described in Section 4.1.3 of the Draft Construction WMP.
- The Operations WMP will describe fire detection systems, thermal management controls, monitoring systems, emergency response protocols, and integration with situational awareness systems to mitigate fire risk and support safe facility operations, similar to those described in Section 4.1.4 of the Draft Construction WMP.

Fire Season Readiness

- During PGE-declared Fire Season, personnel performing operational or maintenance activities will follow wildfire mitigation procedures designed to reduce ignition risk and maintain safe working conditions. The Operations WMP will describe Fire Season readiness protocols applicable to facility operations.
- Consistent with Fire Season readiness operational protocols outlined in PGE's proposed 2026-2028 Wildfire Mitigation Plan, field personnel and suppliers will be equipped with appropriate fire suppression tools and equipment during fire season, which may include properly rated fire extinguishers, round-pointed shovels, Pulaskis, and other firefighting equipment identified in company standards. Supplemental fire suppression resources, such as mobile fire trailers equipped with water supply, hose, and pump systems, may be deployed when conditions warrant.

- The Operations WMP will also outline requirements to ensure fire suppression tools and equipment remain functional and readily accessible during operations in fire-prone areas. These requirements will be consistent with applicable fire prevention rules and other relevant jurisdictional requirements.
- Fire Season field operational restrictions will be defined in the Operations WMP and are expected to align with PGE's Fire Season Readiness operating procedures. During periods of elevated fire danger, PGE may implement additional operational controls based on wildfire risk indicators such as National Weather Service Red Flag Warnings, Industrial Fire Precaution Levels (IFPL), National Fire Danger Rating System conditions, or other jurisdiction-specific fire restrictions.
- Depending on conditions, these measures may include restrictions on spark-producing activities, time-of-day limitations on certain work activities, enhanced fire watches, pre-positioning of fire suppression tools and equipment, or temporary suspension of non-essential activities.
- If a fire occurs during operations, personnel will follow company emergency response procedures, including notification of emergency services and PGE's Control Center/s, coordination with local fire authorities, and implementation of appropriate response actions consistent with site-specific Emergency Response Plans.

Inspections and Maintenance

- Comprehensive inspection and maintenance schedules for all facility components will follow manufacturer recommendations associated with each type of facility component, will be summarized in a table within the Plan, and documentation of inspections will be submitted to ODOE for compliance evaluation.

Vegetation Management

- Maintenance of low-growing, fire-resistant vegetation within 20-foot defensible space around site perimeter (10 feet inside the fence and 10 feet outside the fence) (or as specified by ODOE in the Final Order).
- Vegetation under solar arrays maintained at 8 inches maximum height during fire season and 10 to 12 inches outside of fire season (or as specified by ODOE in the Final Order).
- Bi-annual vegetation assessments with additional monitoring as needed.

Training and Monitoring

- Start-of-operations and annual safety training will be provided for all personnel covering electrical safety and equipment use. The Operations WMP will describe the content and delivery methods of these training programs.
- Additionally, identified PGE field personnel and Suppliers (contractors and vendors) will be required to complete mandatory Fire Season Training through computer-based training or

other company-approved training methods prior to performing field activities during fire season.

- 24/7 remote monitoring via SCADA system with smoke/fire detectors throughout facility.
- Coordination with local fire departments and emergency services.

Plan Updates and Reporting

- Annual reporting per OAR 345-026-0080 to Oregon Department of Energy.
- Annual review of the Operations WMP to determine if updates are necessary, including evaluation of changes in standards, policies, future technologies or best practices.
- Provisions for Operations WMP amendments as needed.

The Operations WMP will establish a comprehensive framework for preventing wildfires, maintaining appropriate equipment and vegetation management, and responding effectively to wildfire emergencies at the expanded Biglow Canyon facility.

Subject: Biglow Canyon RFA4 Certificate Holder Sur-reply - Colton McCullough
Attachments: BIGL RFA4_Comment Sur-Reply Letter to Colton McCullough_03.06.2026.pdf

---

Dear Mr. McCullough,

Thank you for your responses to our February 13, 2026 reply regarding the Proposed Order on Request for Amendment 4 of the Biglow Canyon Wind Farm Site Certificate, please find attached Portland General Electric's and the project developer, BrightNight's, sur-reply.

Thank you.

Attachment B-3: Department Evaluation of Public Comments

Table 1: List of Issues, Commenters and Comment Evaluation Process Summary

Issue ID	Issue Summary	Commenter	Change Incorporated into Draft Final Order
General Standard of Review (OAR 345-022-0000)			
Issue GS-01	Concern about single hearing for a complex amendment	Kathryn McCullough	No
Issue GS-02	Request for correction to Existing Facility Site Location	Certificate Holder	Yes, minor changes to findings or conditions
Issue GS-03	Request for correction to Turbine Dimensions in Existing Energy Facility Description	Certificate Holder	Yes, minor changes to findings or conditions
Issue GS-04	Request for correction to Existing Related or Supporting Facilities Description	Certificate Holder	Yes, minor changes to findings or conditions
Issue GS-05	Request for correction to Existing O&M Building Description	Certificate Holder	Yes, minor changes to findings or conditions
Issue GS-06	Request for revision of proposed road dimension width, from 20 to 16 feet	Certificate Holder	Yes, changes to Facility Description and draft Construction Wildfire Mitigation Plan
Issue GS-07	Request to allow Temporary Construction Areas outside fenceline, within Solar Micrositing Area	Certificate Holder	Yes, minor changes to findings or conditions
Issue GS-08	Request for flexibility in perimeter fencing design	Certificate Holder	Yes, minor changes to findings or conditions
Issue GS-09	Request for correction of description of Solar Micrositing Area	Certificate Holder	Yes, minor changes to findings or conditions
Issue GS-10	Property owner does not consent to project being developed on his private property, as currently proposed.	Jered Reid/Donald Hilderbrand	No
Organizational Expertise (OAR 345-022-0060)			
Issue OE-01	Maintenance issues at existing wind facility	Kathryn and Kevn McCullough	No

Table 1: List of Issues, Commenters and Comment Evaluation Process Summary

Issue ID	Issue Summary	Commenter	Change Incorporated into Draft Final Order
Issue OE-02	Request to amend recommended Amended Condition 3 (CON-OE-01), removing reference to fax number as contact method for construction managers.	Certificate Holder	Yes, minor changes to findings or conditions
Issue OE-03	Request to revise requirement to provide executed Build Transfer Agreement in draft Operations and Maintenance Plan Framework, allowing for submission of redacted copy	Certificate Holder	Yes, minor changes to findings or conditions
Issue OE-04	Request to amend frequency of performance monitoring reports	Certificate Holder	Yes, minor changes to findings or conditions
Issue OE-05	Request to clarify frequency of inspections using thermal imaging	Certificate Holder	Yes, minor changes to findings or conditions
Structural Standard (OAR 345-022-0020)			
Issue SS-01	Request for flexibility to conduct ground disturbing activities on areas with steep slopes with engineer review	Certificate Holder	Yes, changes to Condition 68
Soil Protection (OAR 345-022-0022)			
Issue SP-01	Questions the type and height of weeds required to be controlled	Kathryn McCullough	No
Issue SP-02	Requests to clarify statement referring to the use of Sherman County for weed control.	Certificate Holder	Yes, minor changes to findings or conditions
Issue SP-03	Requests Revisions to Mapped Soil Units in Analysis Area	Certificate Holder	Yes, minor changes to findings or conditions
Issue SP-04	Concerns related to 1-3" veg height under WMP and ability of that height to provide erosion control	Sherman County Weed District	Yes, changes made to Section IV.D Soil Protection, IV.N Wildfire Prevention and Risk Mitigation, Appendix F of the draft Comprehensive Revegetation and Soil Management Plan and

Issue ID	Issue Summary	Commenter	Change Incorporated into Draft Final Order
Issues HCA-02	Adequacy of archaeological monitoring and protective measures	Confederated Tribes of Warm Springs	Yes, changes to Section III.K Historic, Cultural and Archaeological Resources, and Condition GEN-HC-03.
Public Services (OAR 345-022-0110)			
Issue PS-01	Concerns about capacity of local fire responders to fight fire at energy facility	Kathryn McCullough	No
Issue PS-02	Concern that local fire responders do not have adequate training to respond to fire at energy facility or BESS	Kathryn McCullough	No
Wildfire Prevention and Risk Mitigation (OAR 345-022-0115)			
Issue WF-01	Concerns about burn probability data used in fire risk analysis	Kathryn McCullough	No
Issue WF-02	Concerns about use of climate normal for fire risk analysis In Exhibit V	Kathryn McCullough	No
Issue WF-03	Concerns about fuel models used for fire risk analysis	Kathryn McCullough	No
Issue WF-04	Request for flexibility in road design standards for roads not needed for fire access	Certificate Holder	Yes, changes to draft Construction Wildfire Mitigation Plan, draft Amended Site Certificate and dFO Section I.D.3, description of roads.
Issue WF-05	Recommendations for BESS design criteria to minimize fire risk	Kathryn McCullough	No
Issue WF-06	Request for clarification of setback requirement	Certificate Holder	Yes, minor changes to findings or conditions
Issue WF-07	Concerns about adequacy of 50-foot fire setbacks	Kathryn McCullough; Kevin McCullough	No
Issue WF-08	Concern about adequacy of 20-foot fuel breaks	Sherman County Soil and Water Conservation District; Irene Gilbert	No

Table 1: List of Issues, Commenters and Comment Evaluation Process Summary

Issue ID	Issue Summary	Commenter	Change Incorporated into Draft Final Order
Issue WF-09	Support for recommended vegetation maintenance standards for wildfire season	Colton McCullough	Yes, changes made to Section IV.D Soil Protection, IV.N Wildfire Prevention and Risk Mitigation, Appendix F of the draft Comprehensive Revegetation and Soil Management Plan and draft Construction Wildfire Mitigation Plan.
Issue WF-10	Objection to recommended vegetation maintenance standards for wildfire season	Certificate Holder	
Issue WF-11	Request to remove requirement to include drip can with fire suppression equipment.	Certificate Holder	
Issue WF-12	Concern about lack of availability of Operational Wildfire Mitigation Plan.	Kathryn McCullough, Irene Gilbert	No
Siting Standards for Transmission Lines (OAR 345-024-0090)			
Issue TL-01	Request for additional flexibility in transmission line siting	Certificate Holder	Yes, changes made to draft Amended Site Certificate and dFO Section I.D.3, description of 230 kV transmission line.
Noise Control Regulation (OAR 340-035-0035)			
Issue NC-01	Requests Proposed Order Table 26 be revised to add NSR13 and reference to RFA Exhibit Y Table Y-7.	Certificate Holder	Yes, minor changes to findings or conditions
Issue NC-02	Requests revisions to recommended Noise Control Condition 2 (PRE-NC-02) allowing for general waiver versus solar specific	Certificate Holder	Yes, changes made to Condition PRE-NC-02.
Water Rights			
Issue WR-01	Requests revisions to recommended Amended Water Rights Condition 1 (PRE-WR-01) to Clarify Well Log Submission Timing	Certificate Holder	Yes, changes made to Condition PRE-WR-01 (now CON-WR-01)

Table 1: List of Issues, Commenters and Comment Evaluation Process Summary

Issue ID	Issue Summary	Commenter	Change Incorporated into Draft Final Order
Issue WR-02	Requests revisions to recommended Amended Condition 75 (OPR-WR-01) on Applicability of Groundwater Usage Monitoring and 5,000 gallon/day limit	Certificate Holder	Yes, changes made to Condition OPR-WR-01.
Issue WR-03	Requests revisions to recommended Amended Condition 75 (OPR-WR-01) on Applicability of 5,000 gallon/day limit	Certificate Holder	Yes, changes made to Condition OPR-WR-01.

Issue WF-12 (McCullough, Kathryn; Gilbert, Irene); Concern about lack of availability of Operational Wildfire Mitigation Plan 61

III.I. Siting Standards for Transmission Lines (OAR 340-035-0090) 61

Issue TL-01 (Certificate Holder); Request for additional flexibility in transmission line siting 61

III.J. Noise Control Regulation (OAR 340-035-0035) 63

Issue NC-01 (Certificate Holder) Requests Proposed Order Table 26 be revised to add NSR13 and reference to RFA Exhibit Y Table Y-7. 63

Issue NC-02 (Certificate Holder) Requests revisions to recommended Noise Control Condition 2 (PRE-NC-02) allowing for general waiver versus solar specific 64

III.K. Water Rights (OAR Ch. 690) 65

Issue WR-01 (Certificate Holder); Requests Revisions to recommended Amended Water Rights Condition 1 (PRE-WR-01) to Clarify Well Log Submission Timing 65

Issue WR-02 (Certificate Holder); Requests Revisions to recommended Amended Condition 75 (OPR-WR-01) on Applicability of Groundwater Usage Monitoring 65

Issue WR-03 (Certificate Holder); Requests Revisions to recommended Amended Condition 75 (OPR-WR-01) on Applicability of 5,000 gallon/day limit 66

I. Introduction

Portland General Electric Company (certificate holder) filed Request for Amendment 4 of the Site Certificate for the Biglow Canyon Wind Farm (RFA4) to the Energy Facility Siting Council (EFSC or Council) seeking authorization to expand the existing 450-megawatt (MW) wind power generation facility to allow construction and operation of a 125-MW solar power generation facility and related or supporting facilities within a 1,924-acre solar micrositing area.

On December 16, 2025, the Oregon Department of Energy (Department or ODOE) issued its Proposed Order on RFA4. On the same date, in accordance with OAR 345-027-0367(4), the Department issued a Public Notice, initiating a 45-day comment period, to conclude on January 30, 2026. The Notice also established deadlines for the subsequent comment evaluation process, including:

- February 13, 2026, for the Department and certificate holder responses to comments;
- February 27, 2026, for commenters to reply to Department/certificate holder responses; and,
- March 6, 2026, for the Department/certificate to file sur-replies.

II. Public Comment Process Overview

The Council adopted changes to the Site Certificate Amendment comment process (OAR 345-027-0367) in September 2025, effective October 2025. This is the first amendment request under the new rules.

The purpose of the rule changes was to make the site certificate amendment review process more efficient and effective, improve the public comment process and increase the public's understanding of how to participate in the process. As presented above, the new process includes a step for the certificate holder and the Department to respond to comments; allows for those commenters to then reply; and then concludes with an opportunity for the Department and certificate holder to offer sur-reply.

The rules require that the certificate holder respond to all comments received during the comment period; the Department does not have the same obligation but may choose to respond. As presented in the document below, the Department has provided responses to commenters in a manner that provides organization for the public, the Department and the Council.

The intent of this new comment process is for each commenter to receive feedback from the Department and the certificate holder on the nature of their comments – specifically, whether they were raised with sufficient specificity so that the commenters can then reply with additional information or clarification. Where comments were raised with sufficient specificity,

the process is intended to provide each commenter with feedback on whether those issues warrant remedy or change to a recommended finding of fact or recommended new or amended condition, and provide an opportunity for commenters to further explain and provide factual reasoning to support the Department and Council's evaluation of whether the certificate holder has met their burden of proof that they either can or have satisfied the requirements of applicable Council standards and other laws.

III. Evaluation of Issues by Standard

III.A. General Standard of Review (OAR 345-022-0000)

Issue GS-01 (McCullough, Kathryn): Concern about single hearing for a complex amendment
Comment ID: BCWAMD4Doc24-06 Proposed Order Public Comment McCulloughK-6 2026-01-09
Response ID: BCWAMD4Doc26-01 Proposed Order Public Comment ODOE Responses 2026-02-12

Comment Summary
Commenter raises concern about single hearing for complex amendment.

Department Evaluation
On December 16, 2025, the Department issued public notice of the complete RFA4 and the Proposed Order on RFA4 which included notice of a 45-day comment period closing on January 30, 2026. The public notice included information for the in-person and remote public hearing held in Grass Valley on January 15, 2026.

The Department followed procedural rules and no requests were made to Council with a good-cause justification for time extensions or additional hearings, therefore, the Department recommends no further action is needed on this issue.

Issue GS-02 (Certificate Holder): Request for correction to Existing Facility Site Location
Comment ID: BCWAMD4Doc24-08 Proposed Order Public Comment Certificate Holder 2026-01-14Response ID: BCWAMD4Doc26-01 Proposed Order Public Comment ODOE Responses 2026-02-12

Comment Summary
Certificate holder requests correction to description of facility site location. The Proposed Order Cover Letter identifies the Facility Site Location being 4.8 miles northeast of the City of Wasco. The proposed Solar Micrositing Area is 4.8 miles northeast of the City of Wasco, but the Facility Site Location is 2.5 miles northeast of the City of Wasco.

Department Evaluation
The Department's draft Final Order will not include the Cover Letter with the referenced discrepancy. However, the Department agrees that the corrections should be incorporated into

the Proposed Order Section I.C., Approved Site Description and in Section I.D.4., Proposed Solar Micrositing Area; and, in Section 3.3. of the draft Amended Site Certificate, as presented below.

> Proposed Order Section I.C. The site is located approximately 2.5 miles northeast of the City of Wasco in Townships 1 and 2 North, Ranges 17 and 18 East, Willamette Meridian.
>
> Proposed Order Section I.D.4. The facility components proposed in RFA4 would be located within a proposed 1,924-acre Solar Micrositing Area. The Solar Micrositing Area is located approximately 4.8 miles northeast of the City of Wasco.
>
> Draft Amended Site Certificate Section 3.3. The facility is located about 2.5 miles northeast of the City of Wasco in Townships 1 and 2 North, Ranges 17 and 18 East, Willamette Meridian, Sherman County, Oregon. The Solar Micrositing Area is located approximately 4.8 miles northeast of the City of Wasco.

Issue GS-03 (Certificate Holder): Request for correction to Turbine Dimensions in Existing Energy Facility Description
Comment ID: BCWAMD4Doc24-08 Proposed Order Public Comment Certificate Holder 2026-01-14
Response ID: BCWAMD4Doc26-01 Proposed Order Public Comment ODOE Responses 2026-02-12

Comment Summary
The Certificate Holder requests the following corrections be made to the description of turbine dimensions in the Proposed Order, Section I.B.1, to reflect the facility as built:

> ~~The wind turbines are located on private land that the certificate holder has leased from the affected landowners.~~ The Siemens 2.3 MW turbines are mounted on tubular steel towers with a ~~hub~~ height of ~~280~~ 262 feet at the hub and ~~maximum blade tip~~ an overall height of ~~445~~ 413 feet including the turbine blades. The wind turbines are located on private land that the certificate holder has leased from the participating landowners.

Department Evaluation
The certificate holder seeks to clarify the description in the Proposed Order and draft Amended Site Certificate of the dimensions of existing, operational wind turbines based on actual dimensions. Because the certificate holder has the best information about actual turbine dimensions at the facility, the Department agrees to amend Section I.B.1. of the Proposed Order and Section 3.1 of the draft Amended Site Certificate accordingly.

Issue GS-04 (Certificate Holder): Request for correction to Existing Related or Supporting Facilities Description
Comment ID: BCWAMD4Doc24-08 Proposed Order Public Comment Certificate Holder 2026-01-14

Response ID: BCWAMD4Doc26-01 Proposed Order Public Comment ODOE Responses 2026-02-12

Comment Summary
The certificate holder requests the following revisions to Table 1 of the Proposed Order be made to reflect existing facility components as built:

- Collector line length, underground: ~~106~~75 miles
- Collector line length, overhead: ~~3.9~~5 miles
- O&M Building Quantity: ~~2~~3 each

Department Evaluation
The certificate holder seeks to clarify the description in the Proposed Order Table 1 and draft Amended Site Certificate Section 3.1, Subsection 2.a of existing facility components, consistent with final design. Because the certificate holder has the best information about existing facility components/final design, the Department agrees to amend the Proposed Order Table 1 and draft Amended Site Certificate Section 3.1, Subsection 2.a, based on the changes presented above.

Issue GS-05 (Certificate Holder): Request for correction to Existing O&M Building Description
Comment ID: BCWAMD4Doc24-08 Proposed Order Public Comment Certificate Holder 2026-01-14
Response ID: BCWAMD4Doc26-01 Proposed Order Public Comment ODOE Responses 2026-02-12

Comment Summary
The certificate holder requests that the total square footage of the as built O&M buildings total identified in Section 3.1, Subsection 2.d of the site certificate be changed from 17,500 square feet to 19,500 square feet due to the building evaluated through ODOE's Change Request process.

Department Evaluation
Based on review of the record, the Department confirms that on January 12, 2017, it issued a determination under previous rules referring to a Change Request process, confirming that construction of an additional warehouse at the O&M site could occur without being reviewed through the site certificate process. The square footage of the additional warehouse was 3,600 feet (the amount reflected in the certificate holder's revision).

It is the Department's intent to incorporate changes reviewed through Change Requests, Facility Modifications and Amendment Determination Requests into a Site Certificate when the Site Certificate is open through the amendment process. Therefore, the Department agrees to incorporate changes in the O&M square footage reference, consistent with the dimensions reviewed through the Change Request process, into the draft Amended Site Certificate Section 3.1, Subsection 2.d.

Issue GS-06 (Certificate Holder): Request for revision of proposed road dimension width, from 20 to 16 feet
Comment ID: BCWAMD4Doc24-08 Proposed Order Public Comment Certificate Holder 2026-01-14
Response ID: BCWAMD4Doc26-01 Proposed Order Public Comment ODOE Responses 2026-02-12
Reply: BCWAMD4Doc28-04 Proposed Order Public Comment CH Reply to ODOE 2026-02-28

Comment Summary
The certificate holder requests that the Proposed Order Section I.D.3 be amended to clarify that all new facility access roads will be 16, rather than 20, feet in width.

Department Evaluation
In RFA4, Section 4.1.3.6, the certificate holder represented that "all newly constructed roads within the Solar Micrositing Area will be graveled to meet load requirements for all equipment. These internal access roads are expected to be approximately 20 feet in width." In RFA4, Exhibit V, Attachment V-1, the Draft Construction Wildfire Mitigation Plan states that "new roads proposed within the Solar Micrositing Area shall be sufficiently sized for emergency vehicle access in accordance with 2022 Oregon Fire Code requirements, including Section 503 and Appendix D - Fire Apparatus Access Roads. Specifically, the new roads proposed within the solar area fence lines will be 20 feet in width." In a subsequent comment, the certificate holder stated that this representation was only intended to apply to certain external access roads and other roads needed for emergency access (See Issue WF-04.)

In its response to this issue, the Department requested that the certificate holder provide a site plan showing the location and width of designated emergency access roads and other internal access roads to support the evaluation.

In reply to the Department's response to comments, the certificate holder provided a map showing that new roads connecting the existing facility access roads to the proposed substation, O&M building and solar array access gates would be designed to allow fire access (e.g. 20-foot roads) but all roads within solar array fencelines would be 16 feet.

Compliance with 2022 Oregon Fire Code Requirements is not required for all roads, only those that are intended to provide emergency vehicles access to structures and buildings in the event of a fire-related emergency. In addition, during a brief call on March 4, 2026, the Department discussed the road width changes with Chief Burbank of the North Sherman County Rural Fire Protection District (RFPD). Chief Burbank confirmed that fire response within the proposed solar array perimeter fencelines would be limited, and that the RFPD would primarily seek to contain any fire that started within or spread into a solar array from outside of the perimeter fences and that response vehicles have off-road capabilities. Because there would be limited need to ensure access by full-size emergency vehicles to portions of the facility within the perimeter fencelines, the Department recommends the Council grant the additional flexibility requested; however, under the Construction Wildfire Mitigation Plan attached to the draft Final

Order, the final site plan must be reviewed and approved by the Department in consultation with local fire and emergency management officials.

Issue GS-07 (Certificate Holder): Request to allow Temporary Construction Areas outside fenceline, within Solar Micrositing Area
Comment ID: BCWAMD4Doc24-22 Proposed Order Public Comment Certificate Holder-2 2026-01-30
Response ID: BCWAMD4Doc26-01 Proposed Order Public Comment ODOE Responses 2026-02-12
Reply: BCWAMD4Doc28-04 Proposed Order Public Comment CH Reply to ODOE 2026-02-28

Comment Summary
Certificate holder requests clarification in the Proposed Order Section I.D.3 that temporary construction areas may be placed anywhere within the proposed Solar Micrositing Area, not only within perimeter fencelines. The certificate holder indicates that this clarification is consistent with the RFA and ensures construction logistics are not inadvertently limited.

Department Evaluation
In RFA4, Section 4.1.3.7., the certificate holder represented that temporary construction yards would be located within the fenceline (permanent disturbance footprint) of the proposed facility:

> "During construction, one 8.7-acre temporary construction area (laydown area) within the perimeter fencing will be used to support construction, store supplies and equipment, and facilitate the delivery and assembly of materials and equipment…Additional temporary construction areas may be used as determined by the construction contractor, but these would be within the solar areas considered permanent disturbance; therefore, maximum impact is evaluated in RFA4"

Certificate holder indicates that the proposed clarification is consistent with the RFA. In its reply to the Department's initial response, the certificate holder explains that **t**here are inconsistencies in the BCWF RFA4 Division 27, Sections 4.1.3.7 and 4.4.3 regarding the location of temporary construction areas. Section 4.4.3 states:

> "Any temporary disturbance impacts requiring restoration and revegetation will only occur outside of the perimeter fencing for the solar areas, BESS, and collector substation and include temporary impacts from the underground collector lines, laydown areas, installation of perimeter fencing, construction of the O&M building, gen-tie line, and use of any additional temporary construction areas."

Section 4.4.3, Table 2 explains that temporary disturbance areas outside the perimeter fenceline include, among other things "…Temporary disturbance for the laydown area for construction" and states that "…the construction area will be reclaimed following construction."

The certificate holder further explains that because the layout within RFA4 represented the maximum disturbance scenario, solar arrays were represented as being fenced in large blocks so that the largest permanent disturbance possible was represented, but this was not intended to represent that the primary laydown area would be located within a solar array fenceline. All areas within the micrositing area have been evaluated; therefore, regardless of whether the laydown area is within the permanent fenceline, the impacts have been evaluated.

The Department appreciates the certificate holder's clarification and agrees to make the following changes in Section I.D.3 of the Draft Final Order. Similar changes are presented in Section 3.2 of the Draft Amended Site Certificate:

An approximately 8.7 acre, temporary construction area would be ~~established within the perimeter fenceline,~~ used to store supplies and equipment and facilitate the delivery and assembly of materials and equipment during construction. Additional temporary construction areas may be utilized within the ~~permanent footprint of the proposed solar arrays~~ Solar Micrositing Area. The areas would consist of a crushed gravel surface that will be removed following construction and revegetated, crushed gravel surface that will remain following construction because that was the pre-existing surface condition, or vegetation that is left in place for which the need to revegetate would be evaluated following construction.

Issue GS-08 (Certificate Holder): Request for flexibility in perimeter fencing design
Comment ID: BCWAMD4Doc24-22 Proposed Order Public Comment Certificate Holder-2 2026-01-30
Response ID: BCWAMD4Doc26-01 Proposed Order Public Comment ODOE Responses 2026-02-12

Comment Summary
Certificate holder requests additional flexibility in perimeter fencing materials, including use of wire mesh or similar perimeter fencing up to 8 feet in height.

Department Evaluation
The description of perimeter fencing in the draft Site Certificate is consistent with information provided in RFA4, Section 4.1.3.6; however, the Department agrees that flexibility in the final design and type of fencing is allowable as long as the fencing is constructed and grounded in accordance with NESC Rule 110, would maintain public health and safety by preventing unauthorized entrance to the site, and would not create an unnecessary hazard for wildlife. The Department will incorporate changes in the draft Final Order Section I.D.3, draft Amended Site Certificate Section 3.2, and Section 4.1.5 of the Construction Wildfire Mitigation Plan, to allow the additional flexibility requested.

Issue GS-09 (Certificate Holder): Request for correction of description of Solar Micrositing Area
Comment ID: BCWAMD4Doc24-22 Proposed Order Public Comment Certificate Holder-2 2026-01-30

Response ID: BCWAMD4Doc26-01 Proposed Order Public Comment ODOE Responses 2026-02-12

Comment Summary
Certificate holder requests changes to a footnote in Facility Component Table to clarify Solar Micrositing Area is larger than permanent disturbance footprint, as presented below:

> ~~The Solar Micrositing Area would occupy approximately 1,445 acres within fenced areas and transmission line corridor. The entire solar facility footprint is considered a permanent disturbance area for the purposes of evaluating and mitigating impacts to resources such as Fish and Wildlife Habitat; however, soil reclamation and weed management is applicable to the solar facility footprint as discussed in applicable section in this order.~~
>
> The approved BCWF site boundary encompasses approximately 25,000 acres and includes all existing and approved BCWF components. The Certificate Holder proposes to modify the use of approximately 1,924 acres within the approved BCWF site boundary (Figure 3) to accommodate the Solar Components. These 1,924 acres comprise the Solar Micrositing Area (also referred to as the RFA 4 Site Boundary), within which construction of the Solar Components may occur.

Department Evaluation
The Department agrees with the certificate holder that the description of the Solar Micrositing Area and maximum permanent disturbance of the Solar Facility, as provided in the Proposed Order Section I.D, Table 2 footnote 1, should be clear and consistent with the table itself, (e.g. 1,924 acre Solar Micrositing Area and 1,445 acre maximum permanent disturbance.)

The footnote is intended to clarify the term "permanent footprint" from an impact assessment perspective. For example, impacts within the perimeter fence of a solar facility are a permanent impact under the Fish and Wildlife Habitat standard. But that does not mean impacts to soils and vegetation within the fenceline are permanent. In fact, impacts to soils and vegetation within the fenceline are not permanent and these impacts need to be minimized and mitigated under other standards, such as Soil Protection and Land Use.

The certificate holder's proposed revisions are providing a different intent – of clarifying that the existing site boundary is being used to accommodate solar, which has nothing to do with the impact assessment under Fish and Wildlife, Soil Protection or Land Use for this amendment. The Department disagrees with the incorporating the certificate holder's proposed language, but agrees to make the following change:

> Solar facility components would permanently occupy up to 1,445 acres within the 1,924 acre ~~The~~ Solar Micrositing Area~~would occupy approximately 1,445 acres within fenced areas and transmission line corridor~~. Areas within the perimeter fenceline of the solar facility ~~The entire solar facility footprint is~~ are considered a permanent ~~disturbance area~~

~~for the purposes of evaluating and mitigating impacts to resources such as~~ impact under the Fish and Wildlife Habitat standard; however, impacts within the perimeter fenceline to soils, vegetation and noxious weeds are not considered permanent under the Soil Protection and Land Use standards and must be minimized and mitigated, ~~soil reclamation and weed management is applicable to the solar facility footprint~~ as discussed in applicable sections in this order.

Issue GS-10 (Jered Reid/Donald Hilderbrand): Property owner does not consent to project being developed on his private property, as currently proposed.
Comment ID: BCWAMD4Doc24-16 Proposed Order Public Comments HilderbrandD via Law Office of Jered Reid 2026-01-29
Response ID: BCWAMD4Doc26-01 Proposed Order Public Comment ODOE Responses 2026-02-12; BCWAMD4Doc27-04 Proposed Order Public Comment CH Response to Donald Hilderbrand 2026-02-13
Comment Summary
Mr. Hilderbrand, a person with an ownership interest in real property included in the proposed site, commented that he does not consent to his property being included in the project.

Department Evaluation
Matters related to property rights, including land access, purchasing, and leasing are generally outside of EFSC jurisdiction, meaning that EFSC cannot resolve disputes associated with these issues between landowners and the certificate holder, or between individual owners of a property.

In its responses to this issue, the Certificate Holder further clarified that no portion of the proposed facilities described in RFA4, or associated infrastructure, is planned on property owned by Mr. Hilderbrand, nor does the request contemplate the inclusion of non-participating landowners' property.

Because the commenter has not raised an issue related to a matter within the Council's jurisdiction, the Department does not intend to make any changes to the draft of the Final Order based on this comment.

III.B. Organizational Expertise (OAR 345-022-0060)

Issue OE-01 (McCullough, Kathryn; McCullough, Kevin); Maintenance issues at existing wind facility
Comment ID: BCWAMD4Doc24-01 Proposed Order Public Comment McCulloughK-1 2025-12-23
Response ID: BCWAMD4Doc26-01 Proposed Order Public Comment ODOE Responses 2026-02-12; BCWAMD4Doc27-09 Proposed Order Public Comment CH Response to Kathy and Kevin McCullough 2026-02-13.
Reply ID: BCWAMD4Doc28-01 Proposed Order Public Comment McCulloughK Reply 2026-02-24
Sur-reply ID: BCWAMD4Doc29-02 Proposed Order Public Comment CH Sur-Reply to Kathy and Kevin McCullough 2026-03-06

Comment Summary
Commenters object to approval of RFA4 until maintenance issues at the existing wind facility are addressed, stating that the certificate holder "should not be allowed to build solar until the Vestas towers are fixed." Commenter provides documentation of ongoing maintenance issues at existing wind facility, including blade throw, leaks of hydraulic oil from nacelles and turbine towers, transformer failures, multiple fallen bolts, hatch doors, nose cones, and other objects from turbines.

Department Evaluation
In its responses to this issue, the certificate holder also acknowledges the operational incidents documented at the BCWF and explains that it has implemented targeted improvements specific to the BCWF, including changes to internal management structure and personnel; a change in the turbine operations and maintenance provider with a newly negotiated contract to mitigate future technical challenges and better align with site-specific performance goals; and improved monitoring of contractor performance. Improved preventative maintenance, robust monitoring, and corrective action planning will be the result of these changes, which are still ongoing. The certificate holder represents that "lessons learned from past challenges have resulted in more robust preventative maintenance and corrective action protocols, stronger vendor performance accountability, clearer performance standards tied to equipment health, and improved quality assurance and quality control oversight" and that the lessons "have informed the design, operational planning, and compliance framework for the proposed solar and battery energy storage systems under RFA4…" The certificate holder further maintains that recommended new and amended conditions in the Proposed Order and the implementing plans and conditions address the commenters concerns through mandatory reporting, defined timelines, corrective action tracking and inspection authority.

In replies, the commenter expressed their continuing concern with this issue.

As discussed on page 40 of the Proposed Order, the Department acknowledges that the existing wind facility has experienced substantial equipment and maintenance issues over the past several years.

While the Department does not agree that the maintenance issues demonstrate that the certificate holder, in partnership with BIGL, LLC, cannot operate or maintain a solar facility in compliance with site certificate conditions, the issues do demonstrate a deficiency in the adequacy of the existing site certificate conditions in ensuring systematic oversight of vendor performance, preventive maintenance, and safe, reliable construction and operation.

The Department has recommended the Council adopt additional conditions of approval to improve oversight and ensure the safe operation of the proposed solar components, including recommended Organizational Expertise Conditions 1 and 2 which require the finalization of the Draft O&M Framework Plan included as Attachment C to the Proposed Order. Based on comments and information provided on the record, the Department does not recommend any changes to the draft Final Order.

Issue OE-02 (Certificate Holder): Request to amend recommended Amended Condition 3 (CON-OE-01), removing reference to fax number as contact method for construction managers.
Comment ID: BCWAMD4Doc24-08 Proposed Order Public Comment Certificate Holder 2026-01-14
Response ID: BCWAMD4Doc26-01 Proposed Order Public Comment ODOE Responses 2026-02-12

Comment Summary
Certificate holder requests changes to recommended Amended Condition 3 (CON-OE-01) to remove requirement to provide fax numbers for construction managers.

Department Evaluation
The Department agrees that requiring a fax number is unnecessary given the other communication methods included in the recommended amended condition, including phone number and email address. The Department agrees to remove reference to "fax number" in recommended Amended Condition 3 (CON-OE-01) in the draft Final Order.

Issue OE-03 (Certificate Holder): Request to revise requirement to provide executed Build Transfer Agreement in draft Operations and Maintenance Plan Framework, allowing for submission of redacted copy
Comment ID: BCWAMD4Doc24-08 Proposed Order Public Comment Certificate Holder 2026-01-14
Response ID: BCWAMD4Doc26-01 Proposed Order Public Comment ODOE Responses 2026-02-12

Comment Summary
Certificate holder requests changes to recommended Organizational Expertise Condition 1 and Proposed Order Table 5, which requires submittal of an executed Build Transfer Agreement (BTA) as part of finalization of the O&M Framework Plan. Specifically, certificate holder requests that they be authorized to submit a redacted copy, redacting confidential terms and conditions.

Department Evaluation
The Department agrees that there are likely confidential terms and conditions of the BTA which do not have a nexus with the Organizational Expertise standard and therefore do not need to be included in the version submitted to the Department. Receipt by the Department of an executed BTA is a recommended requirement because it is the mechanism that will establish the certificate holder's role and responsibility for oversight and control over a third-party; and, the third-party's role and responsibility in selecting and managing construction contractors, construction and operation of the proposed solar components. The Department proposes to incorporate the following language in Proposed Order Table 5 and Table 1 of the draft O&M Framework Plan.

Confidential terms and conditions, unrelated to the roles, responsibilities, oversight and control of the certificate holder, third-parties, site certificate and facility, may be redacted from the executed BTA provided to the Department.

Issue OE-04 (Certificate Holder): Request to amend frequency of performance monitoring reports
Comment ID: BCWAMD4Doc24-22 Proposed Order Public Comment Certificate Holder-2 2026-01-30
Response ID: BCWAMD4Doc26-01 Proposed Order Public Comment ODOE Responses 2026-02-12

Comment Summary
Certificate holder requests changes to recommended Organizational Expertise Condition 1 (PRO-OE-01) through Table 1 of the O&M Framework Plan (Proposed Order Attachment C) and Proposed Order Table 5, to reduce the frequency of reporting results of vendor performance from monthly to quarterly. Certificate holder states that monthly reporting may over-emphasize short-term variability that does not reflect underlying performance trends, while quarterly reporting allows for more meaningful evaluation of system performance and provides sufficient time for the certificate holder and O&M contractors to address identified issues.

Department Evaluation
As presented in Table 1 of the O&M Framework Plan (Proposed Order Attachment C) and Proposed Order Table 5, under the heading "Reporting," the proposed monthly reporting requirement applies to identification of any significant performance issues and corrective actions taken by or for the participating entity, contractor(s) and vendor(s). Further, monthly reporting shall identify corrective actions, including stop work or removal from site, required of the vendor(s) for any performance scores less than 95% percent on-time inspection and repair completion rate.

The Department understands the certificate holder's concerns but disagrees that a lessor frequency be established prior to establishing a cadence or implementation and evaluation of the plan. The Department's experience with the existing operating facility demonstrates that more frequency is necessary to track and understand operational and maintenance issues and status and/or plan for repairs.

The draft O&M Framework Plan allows for annual review and update of the plan (see Proposed Order Attachment C, Section 5, Conclusions. The Department maintains that changes in monitoring and reporting frequency be evaluated once the plan is implemented, based on revisions necessary to support effective review and understanding of vendor performance.

The Department recommends an additional change to Section 5.0 of the draft O&M Framework Plan, stating that:

All changes are subject to review and approval by the Department.

Issue OE-05 (Certificate Holder): Request to clarify frequency of inspections using thermal imaging
Comment ID: BCWAMD4Doc24-22 Proposed Order Public Comment Certificate Holder-2 2026-01-30
Response ID: BCWAMD4Doc26-01 Proposed Order Public Comment ODOE Responses 2026-02-12
Reply ID: BCWAMD4Doc28-04 Proposed Order Public Comment CH Reply to ODOE 2026-02-28

Comment Summary
Certificate holder requests to modify Proposed Order Attachment C, draft O&M Framework Plan, Section 3.4.2 as presented below:

> Routine module inspections and annual infrared/aerial thermal imaging with anomalies detected via SCADA generating corrective work orders ~~within 48 hours~~ according to the final Operations and Maintenance Plan.

Certificate holder requests this change stating that it is unlikely that SCADA will detect module-level anomalies for work order creation.

Department Evaluation
The Department accepts the certificate holder's clarification on the frequency of thermal imaging because it is the certificate holder's proposal, but requests further clarification related to SCADA's identification of anomalies and generation of work orders.

In its responses, the Department requested clarification of the intent of the change. In its replies, the certificate holder explained that the current language in Section 3.4.2 of the Draft O&M Plan conflates two different work streams for generating corrective work orders for anomalies detected 1) via routine module inspections and annual infrared/aerial thermal imaging, and 2) via the SCADA system. The certificate holder provided revised language replacing the original language in the Draft O&M Plan Section 3.4.2 (first and fifth bulleted item) with the following language to clarify these processes:

> o **Routine module inspections and annual infrared/aerial thermal imaging:** Anomalies detected will generate corrective work orders within 48 hours, and will be addressed according to level of severity; otherwise, as soon as reasonably possible and according to the final O&M Plan.
>
> o **Routine SCADA monitoring and data analysis:** Anomalies detected will generate corrective work orders within 48 hours and will be addressed according to level of severity; otherwise, as soon as reasonably possible and according to the final O&M Plan.

Because the proposed language merely clarifies that inspections and SCADA monitoring are two different pathways for identifying anomalies and potential issues occurring within the PV system, the Department agrees to make the proposed changes.

III.C. Structural Standard (OAR 345-022-0022)

Issue SS-01 (Certificate Holder): Request for flexibility to conduct ground disturbing activities on areas with steep slopes with engineer review
Comment ID: BCWAMD4Doc24-22 Proposed Order Public Comment Certificate Holder-2 2026-01-30
Response ID: BCWAMD4Doc26-01 Proposed Order Public Comment ODOE Responses 2026-02-12

Comment Summary
Certificate holder requests that recommended Amended Condition 68 be changed to allow ground disturbing activities in areas with slopes exceeding 20 percent when reviewed and approved by the Geotechnical Engineer of Record and designed to adequately address non-seismic hazard risks, as presented below.

> **Proposed Clarified Condition 68 (CON-SS-03):**
> The Certificate Holder shall design, engineer, and construct the solar facility to avoid dangers to human safety presented by non-seismic hazards, including but not limited to settlement, landslides, flooding, erosion, and collapsible soils. Ground-disturbing activities shall be avoided in areas with slopes exceeding 20 percent unless such activities are reviewed and approved by the Geotechnical Engineer of Record and designed to adequately address non-seismic hazard risks.

Department Evaluation
Recommended Amended Condition 66 requires that the certificate holder complete and submit a final Geotechnical Investigation prepared, which must be prepared for Geotechnical Engineer of Record and would evaluate seismic and non-seismic hazards at the site, based on final design. The language proposed by the certificate holder therefore is duplicative. Any changes to recommended Amended Condition 68 must be reviewed in tandem with recommended Amended Condition 66.

To assist in the evaluation of relaxing the prohibition of ground disturbing works on slopes exceeding 20%, the Department requests additional information regarding the types of ground disturbing activities on slopes exceeding 20 percent that are under consideration, the locations at the site where they are being considered, and any supporting evidence demonstrating how non-seismic geologic hazards in these areas will be mitigated. Please note that the recommended Condition 68 was intended to ensure compliance with the requirements of Sherman County's Natural Hazards (NH) Combining Zone and SCZO Section 3.7. If work on steep slopes within the NH Combining Zone is proposed, all information required under SCZO 3.7(5) must be included in RFA4.

In its reply, the certificate holder provided an additional map showing locations where cut and-fill on existing slopes above 20 percent would occur.

Based on this additional information, the Department acknowledges that there are some areas within the proposed Solar Micrositing Area outside of Sherman County's Natural Hazard Combining Zone where cut and fill to grade existing slopes to below 20 percent would not present a significant hazard, but the Department continues to have concerns about the certificate holder's proposal to locate facility components on or near the steep edges of Biglow Canyon and other areas within the County's Natural Hazard Combining Zone (see RFA4 Land Use Exhibit, Figure K-2).

To ensure these areas are avoided, while providing additional flexibility on the remainder of the site, the Department suggests Recommended Amended Condition 68 be further revised. Changes to the condition as presented in the Proposed Order are shown in underline, strikethrough, black font; additional changes recommended as a result of the comment evaluation process are shown un underline, strikethrough, red font.

> **Recommended Amended Condition 68:** The certificate holder shall design, engineer and construct the solar facility to avoid dangers to human safety presented by non-seismic hazards~~. As used in this condition, "non-seismic hazards",~~ include~~e~~ing but not limited to ~~settlement~~, landslides, flooding~~, and~~ erosion, and collapsible soils. Ground disturbing activities are not permitted in areas within Sherman County's Natural Hazard Combining Zone~~, nNo ground disturbing activity may occur in areas~~ where slopes exceed~~ing~~ 20 percent.

III.C. Soil Protection (OAR 345-022-0022)

Issue SP-01 (McCullough, Kathryn); Questions the type and height of weeds required to be controlled
Comment ID: BCWAMD4Doc24-06 Proposed Order Public Comment McCulloughK-6 2026-01-09
Response ID: BCWAMD4Doc26-01 Proposed Order Public Comment ODOE Responses 2026-02-12; BCWAMD4Doc27-09 Proposed Order Public Comment CH Response to Kathy and Kevin McCullough 2026-02-13

Comment Summary
Commenter questions whether weeds are allowed to be a foot in height and whether noxious weeds, or all weeds, are required to be controlled/mitigated.

Department Evaluation
Noxious weeds will not be allowed to be 1-foot in height. The vegetation height limit of 1-foot established in the draft Construction Wildfire Mitigation Plan (WMP) Section 4.6.1. applies to beneficial vegetation, not noxious weeds.

Noxious weeds and invasive annual grass are required to be treated, controlled and monitored during construction and operation (see recommended Soil Protection Conditions 1 to 3).

In its responses to this issue, the certificate holder also commented that it believes the concerns are already addressed by the Proposed Order and its recommended plans and conditions.

The Department considers this issue resolved.

Issue SP-02 (Certificate Holder); Requests to clarify statement referring to the use of Sherman County for weed control.
Comment ID: BCWAMD4Doc24-08 Proposed Order Public Comment Certificate Holder 2026-01-14
Response ID: BCWAMD4Doc26-01 Proposed Order Public Comment ODOE Responses 2026-02-12

Comment Summary
Certificate Holder requests to clarify that while there is intent to contract the Sherman County Weed Control District to implement measures of the Weed Control Plan, the District may not have sufficient capacity to manage implementation, in which case other qualified vendors may be contracted to implement the measures of the Weed Control Plan.

Department Evaluation
RFA4 Exhibit K Land Use, Section 8.1.3.1 states, "The Certificate Holder currently contracts with the Sherman County Weed Control District to inspect and treat weeds at BCFW and will continue to use their staff's services to treat the Solar Micrositing Area." This representation was incorporated into the Proposed Order Section D.1. Soil Protection; however, it was not expressly incorporated into a condition or weed-related mitigation requirement.

Recommended Soil Protection Conditions 1 to 3 require finalization and implementation of the draft Comprehensive Solar Vegetation and Soil Management Plan (Proposed Order Attachment D). Weed control requirements applicable prior to and during construction and operation are included in this plan. The plan does not require that the certificate holder contract with Sherman County Weed Control District to implement and monitor the requirements of the plan but rather requires that it be implemented by a qualified Weed Control Contractor.

The Department agrees that the recommended findings of fact can be updated based on the certificate holder's revised representation. Rather than revising the facts to refer to the potential of contracting with Sherman County Weed District or qualified vendors for weed control, the Department recommends that the findings of fact be revised to refer to the requirements of the draft Comprehensive Solar Revegetation and Soil Management Plan, as presented below:

~~The certificate holder has indicated that the District will be contracted to implement the measures of the Weed Control Plan.~~[1] Prior to and during construction and operation of the facility components proposed in RFA4, the certificate holder will be required to hire a Weed Control Contractor responsible for performing weed control in accordance with the Comprehensive Solar Revegetation and Soil Management Plan under recommended Soil Protection Conditions 1 through 3.[2]

The Department considers this issue resolved.

Issue SP-03 (Certificate Holder); Requests Revisions to Mapped Soil Units in Analysis Area
Comment ID: BCWAMD4Doc24-08 Proposed Order Public Comment Certificate Holder 2026-01-14
Response ID: BCWAMD4Doc26-01 Proposed Order Public Comment ODOE Responses 2026-02-12

Comment Summary
Certificate holder requests revision of percentage of Solar Micrositing Area in Soil Unit 16D in Proposed Order Table 7. Commenter recommends amount should be 0.1%, not 0.2%.

Department Evaluation
Based on review of AMD4 Exhibit I, the Department agrees to correct Table 7 in the draft Final Order, as requested.

The Department considers this issue resolved.

Issue SP-04 (Sherman County Weed District) Concerns related to 1-3" veg height under WMP and ability of that height to provide erosion control
Comment ID: BCWAMD4Doc24-15 Proposed Order Public Comment Sherman County Weed District 2026-01-28
Response ID: BCWAMD4Doc26-01 Proposed Order Public Comment ODOE Responses 2026-02-12; BCWAMD4Doc27-02 Proposed Order Public Comment CH Response to Colton McCullough 2026-02-13; BCWAMD4Doc27-09 Proposed Order Public Comment CH Response to Kathy and Kevin McCullough 2026-02-13; BCWAMD4Doc27-13 Proposed Order Public Comment CH Response to Sherman Co Weed District 2026-02-13;

Comment Summary
Sherman County Weed District (SCWD) recommends vegetation be maintained at 4-8 inch height during dry season to support erosion control. SCWD suggests that a vegetative height of

[2] BCWAMD4DocXX. Proposed Order on AMD4 Attachment D, Table A-2, pg. A-3. The draft Comprehensive Solar Revegetation and Soil Management Plan includes additional experience requirements for the Weed Control Contractor.

1-3 inches will not support erosion control. SCWD also expresses concerns with the viability of bunchgrass species if maintained at the 1-3 inch height.

Department Evaluation
The Department is evaluating several comments related to the recommendation that vegetation within the solar facility and other vegetation clearance areas be maintained at 1 to 3 inches during fire season to mitigate fire risk. Mr. McCullough recommends the recommendation be implemented throughout the life of the facility (Issue WF-09). SCWD recommends that the vegetation height standard be increased to 4 to 8 inches to support erosion control and enhance viability of bunchgrass species.

In its comments, the certificate holder requested that the height standard be increased to 10 to 12 inches year-round but in reply to the Sherman County Weed District, requested that ODOE take the District's professional recommendation into consideration and revise the Proposed Order and implementing plans accordingly to require management of grass height at 4 to 8 inches during dry season. Mr. McCullough commented that he did not agree that 8" vegetation would be safe from a wildfire standpoint, but acknowledged the importance of not mowing native bunch grasses shorter than 3-4" to protect the crown of the plant. He conceded that a slightly taller vegetation height (3" to 6" during fire season June-Oct) would be acceptable considering erosion control, vegetation health, and fire risk together.

The Department maintains that vegetation management is a critical tool for minimizing wildfire risk associated with the proposed facility but defers to the professional recommendation of the County Weed Control District as to the appropriate standard to best balance wildfire risk mitigation and soil protection. Consistent with the District's recommendation, the Department revised Section III.N.I Wildfire Prevention and Risk Mitigation of the draft Final Order, Attachment G draft Construction Wildfire Mitigation Plan, and Appendix F of the draft Comprehensive Revegetation and Soil Management Plan to include reference to vegetation requirements below:

a. **Vegetation Height and Clearance**

Vegetation within and adjacent to the Solar Components will be maintained as follows:

- During the dry season (June to October), vegetation height will be limited to 4 to 8 inches. Vegetation will be mowed to a height of 4 inches prior to June of each year.
- Outside of the dry season (November to May), vegetation will be maintained at a maximum height of less than 12 inches~~,~~.
- ~~with a~~ A minimum vertical clearance of 12 inches from all electrical and mechanical equipment will be maintained at all times.
- Vegetation exceeding ~~this~~ the heights listed above will be mowed or removed ~~prior to local~~ in accordance with any ODF- or County-issued fire restrictions.

…

Issue SP-05 (McCullough, Kathryn); Long-term soil health
Comment ID: BCWAMD4Doc24-17 Proposed Order Public Comment McCulloughK-10 2026-01-29
Response ID: BCWAMD4Doc26-01 Proposed Order Public Comment ODOE Responses 2026-02-12

Comment Summary
Ms. McCullough raises concerns about lack of evidence supporting claims related to long-term soil improvement following use of the site for solar after 50 years.

Department Evaluation
Ms. McCullough does not identify a specific recommended finding, condition, or conclusion for which she objects Vegetation management and erosion control is required under the Draft Comprehensive Revegetation and Soil Management Plan established under recommended Soil Protection Conditions 1 to 3, however commenter has not explained how plan is deficient or could be improved.

In its responses on this issue, the certificate holder provides a memo summarizing some recent published literature outlining some of the ecosystem service benefits that can result from native vegetation management practices at solar photovoltaic facilities, such as the creation of microhabitats around solar panels with lower air temperatures and evapotranspiration rates, higher soil water content, and additional surface roughness that slows wind speeds and protects against erosion. The certificate holder also highlighted conditions of approval related to soil protection and the provisions of the draft Comprehensive Revegetation and Soil Management Plan for vegetation management and erosion control at the site.

The Department does not recommend revisions to the draft Final Order based on this comment because the commenter did not identify the recommended findings of fact, conclusions of law or conditions of approval identified in the proposed order to which they object.

Issue SP-06 (Sherman County Soil and Water Conservation District, A. Whitman); Requests to develop a strong working relationship with certificate holder/BrightNight to ensure soil protection measures are in place.
Comment ID: BCWAMD4Doc24-21 Proposed Order Public Comment Sherman SWCD 2026-01-30
Response ID: BCWAMD4Doc26-01 Proposed Order Public Comment ODOE Responses 2026-02-12; BCWAMD4Doc27-14 Proposed Order Public Comment CH Response to SWCD 2026-02-13

Comment Summary
Ms. Whitman of Sherman County Soil and Water Conservation District (SCSWCD) requests to develop a strong working relationship with certificate holder/BrightNight to ensure soil protection measures are in place.

Department Evaluation
In its responses to the Sherman County SWCD on this issue, the certificate holder emphasized previous attempts to engage with Ms. Whitman and highlighted the conditions related to soil protection included in the Proposed Order.

In the Department's responses, the Department requested that Ms. Whitman identify specific recommended findings, conditions, or conclusions of law to which she objects and explain the regulatory nexus for requiring consultation, and adherence to recommendations provided during consultation.

Ms. Whitman did not reply to either the certificate holder or Department. Because the commenter did not identify the specific recommended findings, conditions, or conclusions of law to which she objects, the Department does not believe the commenters issue was raised with sufficient specificity to afford the Council, Department, or certificate holder an opportunity to respond. Accordingly, the Department does not recommend any changes to the draft Final Order in response to this issue.

Issue SP-07 (Sherman County Soil and Water Conservation District, A. Whitman); Potential soil contamination from fire-damaged photovoltaic modules or battery components.
Comment ID: BCWAMD4Doc24-21 Proposed Order Public Comment Sherman SWCD 2026-01-30
Response ID: BCWAMD4Doc26-01 Proposed Order Public Comment ODOE Responses 2026-02-12; BCWAMD4Doc27-14 Proposed Order Public Comment CH Response to SWCD 2026-02-13

Comment Summary
Ms. Whitman of SCSWCD raises concerns about potential for panels or batteries damaged by fire or other cause to release toxins into soils and waterways.

Department Evaluation
In its responses to the Sherman County SWCD on this issue, the certificate holder emphasized previous attempts to engage with Ms. Whitman and highlighted the conditions related to soil protection included in the Proposed Order.

In its responses, the Department notes that Ms. Whitman does not identify a specific recommended finding, condition, or conclusion for which she objects. Control of noxious weeds and annual grasses is required under the Draft Comprehensive Revegetation and Soil Management Plan established under recommended Soil Protection Conditions 1 to 3, however Ms. Whitman has not explained how the plan is deficient or could be improved. Wildfire minimization and mitigation are required under Wildfire Prevention and Risk Mitigation Conditions 1 to 3, however commenter has not explained how plan is deficient or could be improved.

Because the issue was not raised with sufficient specificity to afford the Council, Department, or certificate holder an opportunity to respond, the Department does not recommend any changes to the draft Final Order in response to this issue.

Issue SP-08 (Sherman County Soil and Water Conservation District, A. Whitman); Enforcement of requirements for natural resource protection.
Comment ID: BCWAMD4Doc24-21 Proposed Order Public Comment Sherman SWCD 2026-01-30
Response ID: BCWAMD4Doc26-01 Proposed Order Public Comment ODOE Responses 2026-02-12; BCWAMD4Doc27-14 Proposed Order Public Comment CH Response to SWCD 2026-02-13

Comment Summary
Ms. Whitman of SCSWCD raises concerns about enforcement of measures to protect environment and natural resources. She suggests that the State hold the certificate holder accountable for controlling weeds, preventing soil erosion, promoting fire prevention, and any other practices that ensure the health of the surrounding community and watersheds.

Department Evaluation
In its responses to this issue, the certificate holder highlights conditions of approval related to soil protection in the Proposed Order and provisions related to weed control, erosion control, and fire prevention in the draft Comprehensive Solar Revegetation and Soil Management Plan included as Attachment D of the Proposed Order.

In its responses, the Department noted that Ms. Whitman did not identify a specific recommended finding, condition, or conclusion of law to which she objects, and that Ms. Whitman had not explained how the draft Comprehensive Solar Revegetation and Soil Management Plan is deficient or could be improved.

Because the issue was not raised with sufficient specificity to afford the Council, Department, or certificate holder an opportunity to respond, the Department does not recommend any changes to the draft Final Order in response to this issue..

Issue SP-09 (Certificate Holder); Requests to Clarify Terms, Clear Brush Free and Vegetation Clearance Area/Zone
Comment ID: BCWAMD4Doc24-22 Proposed Order Public Comment Certificate Holder-2 2026-01-30
Response ID: BCWAMD4Doc26-01 Proposed Order Public Comment ODOE Responses 2026-02-12
Reply ID: BCWAMD4Doc28-04 Proposed Order Public Comment CH Reply to ODOE 2026-02-28

Comment Summary
Certificate holder provides the following clarification to ensure consistent interpretation of buffer area requirements along roads and perimeter fencelines within the Solar Micrositing Area. The terms “clear, brush-free area” and “vegetation-clearance area/zone” are used in

multiple locations in the Proposed Order and Attachments D and G without consistent definition. To improve the clarity and avoid misinterpretation, the certificate holder requests that these terms be replaced with "low-growing, fire-resistant vegetation," or that the documents otherwise clarify that these buffer areas are intended to be maintained with low-growing, fire-resistant vegetation rather than fully devoid of vegetation.

In addition, the certificate holder notes an inconsistency regarding whether the required buffer along the perimeter fenceline is intended to be 10 feet on each side or 20 feet measured along the exterior or interior and requests clarification from ODOE to ensure consistent understanding and implementation of the buffer requirement.

Department Evaluation
In the Proposed Order Attachment G Section 4.1.6 (draft Construction WMP), the Department recommended the following:

> During construction clearing, grubbing, and grading, the contractor will establish a noncombustible buffer zone extending a minimum of 10 feet inside the fenceline and another minimum 10-foot limits of disturbance buffer outside the fenceline for a total of a minimum of 20 feet of noncombustible buffer around the perimeter of the site.

Also as presented in the draft Amended Site Certificate Table 1 attached to the Proposed Order, the vegetation management buffer for the perimeter fenceline is established at 20 feet. These requirements were based on the draft Construction Wildfire Mitigation Plan and draft Comprehensive Revegetation and Soil Management Plan provided by the certificate holder.

In its responses, the Department agreed that the varying terms used in Section III.D.1 and draft Amended Site Certificate should be replaced with a consistent term, "noncombustible buffer" and be further clarified that for the perimeter fenceline, the buffer extends 10-feet on either side.

In replies, the certificate holder provided additional information to support its request to replace all references to a "noncombustible buffer" with the term ""low-growing, fire-resistant vegetation." The certificate holder requests that this change be applied to areas along the solar array fencelines, access roads, and perimeter fenceline. While the certificate holder does not request to reduce the size of the 20-foot fuel breaks around the perimeter of the site the certificate holder does request to change the standards for vegetation management in this zone. The certificate holder argues that these changes are necessary to address existing erosion concerns while providing wildfire mitigation at the Project site.

In sur-replies to Kevin and Kathryn McCullough, the certificate holder provided a redlined of the draft Construction Wildfire Mitigation Plan which removes the perimeter buffer from the list of areas the certificate holder previously represented would be "managed to be vegetation-free, noncombustible space, or gravel surface" and instead represents that "20 feet of low-growing, fire-resistant vegetation buffer [would be maintained] around the perimeter of the site (10 feet

on each side of the fenceline)." The revised draft Construction Wildfire Mitigation Plan further represents that "Vegetation within 10 feet of each side of all service roads will be managed with low-growing, fire-resistant vegetation" rather than a vegetation free, noncombustible, zone.

Section 1205.5.1 of the Oregon Fire Code provides:

> *"A clear brush free area of 10 feet shall be required around the perimeter of the ground-mounted photovoltaic arrays or as determined by the fire code official. A maintained vegetative surface or noncombustible base, approved by the fire code official, shall be installed and maintained under the photovoltaic arrays and associated electrical equipment installations."*

The Department acknowledges the need to balance wildfire protection with erosion control, particularly given the presence of highly erodible soils at the site. Given this need, as well as the inconsistencies in the record, the Department will defer to the requirements of the Oregon Fire Code and will insert the term "clear, brush free area." The Department acknowledges that this term may include either a noncombustible, non-vegetated area or an area of low-growing, fire resistant vegetation, and requests that the certificate holder consult with local fire officials on specific management criteria and provide documentation of the local fire officials determination of what standard is appropriate as part of the pre-construction compliance review process.

The following changes are incorporated into Section III.D.1 Soil Protection, draft Construction Wildfire Mitigation Plan and Appendix F of the draft Comprehensive Solar Revegetation and Soil Management Plan attached to the draft Final Order:

> •A minimum 20-foot ~~non-combustible buffer~~ clear, brush free area will be maintained around the ~~interior or exterior~~ perimeter of fenced solar array areas (10-feet inside the fence and 10-feet outside the fence); activities necessary to maintain the area as clear, brush free shall be based on consultation with the local fire code official.~~, and~~

Issue SP-10 (Certificate Holder); Requests revisions to Draft Comprehensive Revegetation and Solar Management Plan
Comment ID: BCWAMD4Doc24-22 Proposed Order Public Comment Certificate Holder-2 2026-01-30
Response ID: BCWAMD4Doc26-01 Proposed Order Public Comment ODOE Responses 2026-02-12

Comment Summary
Certificate holder provides additional recommended edits to the draft Comprehensive Revegetation and Solar Management Plan presented as Attachment D to the Proposed Order.

Department Evaluation

The Department reviewed the certificate holder's proposed changes to the draft Comprehensive Revegetation and Solar Management Plan and generally agrees to administrative changes and clarifications. As presented for Issue FW-03, the Department does not agree to the certificate holder's request for flexibility in ground disturbing activities during the sensitive ground nesting bird season.

The Department reviewed the certificate holder's requested changes to the seed mix presented in Appendix F Table 2 in consultation with ODFW. ODFW confirmed that the proposed seed mix is acceptable, but recommend ensuring the forbs are available, as some of those species can be difficult to find and have appropriate alternates or additions to the seed mix.

Comment Summary

Ms. Whitman of SCSWCD raises general concerns about the spread of noxious weeds and annual grass at the site and their potential to increase wildfire risk.

Department Evaluation
In its responses to this issue, the certificate holder highlights conditions of approval related to soil protection in the Proposed Order and provisions related to weed control in the draft Comprehensive Solar Revegetation and Soil Management Plan included as Attachment D of the Proposed Order.

In its response, the Department notes that Ms. Whitman did not identify a specific recommended finding, condition, or conclusion of law to which she objects. Ms. Whitman has not explained how the draft Comprehensive Solar Revegetation and Soil Management Plan is deficient or could be improved.

Because the issue was not raised with sufficient specificity to afford the Council, Department, or certificate holder an opportunity to respond, the Department does not recommend any changes to the draft Final Order in response to this issue.

III.D. Land Use (OAR 345-022-0030)

Issue LU-01 (Certificate Holder); Request for reduction in requirements for Site Plan Review
Comment ID: BCWAMD4Doc24-22 Proposed Order Public Comment Certificate Holder-2 2026-01-30
Response ID: BCWAMD4Doc26-01 Proposed Order Public Comment ODOE Responses 2026-02-12
Reply ID: BCWAMD4Doc28-04 Proposed Order Public Comment CH Reply to ODOE 2026-02-28

Comment Summary
Certificate holder requests the following changes be made to recommended Land Use Condition 3:

a. Prior to construction of any component or phase of the solar facility, the certificate holder shall submit, to the Department and the Sheman County Planning Commission, an application for Conditional Use Permit ~~pursuant to ORS 469.401(3) meeting the requirements of SCZO Section 5.4(1) and (3).~~
b. ~~The Site Plan required under SCZO 5.4(1) must demonstrate compliance with all applicable local ordinances and site certificate conditions.~~
[Final Order on AMD4]

The certificate holder asserts that because it has elected to seek a Council determination of compliance with statewide land use planning goals under ORS 469.504(1)(b), Sherman County would not have discretionary approval of a CUP or Site Plan, and compliance with applicable sections of the Sherman County Zoning Code (SCZO) would be determined by Council and memorialized in the Final Order and Site Certificate.

Department Evaluation
The certificate holder is correct that under ORS 469.401(3), an affected County does not have general discretion to reject a permit addressed in an amended site certificate, the statute explicitly authorizes the County to consider whether the permit is consistent with the terms and conditions of the amended site certificate. The statute also requires the certificate holder to submit "proper applications and payment of the proper fees" for any permit addressed in the site certificate, including the Conditional Use Permit. In its responses to this issue, the Department requested additional information on why the certificate holder believed requiring a site plan would not be needed, or why, the condition, as written would be inconsistent with ORS 469.401(3).

In its reply, the certificate holder argues that requiring a demonstration of compliance with all applicable local ordinances and site certificate conditions when applying for a conditional use permit is contrary to the plain language and the intent of the statute because it would require the County to exercise discretion in making its determination. The certificate holder that issuance of a conditional use permit under ORS 469.401(3) is not supposed to involve discretion. Here, the Department disagrees. The statute provides as follows:

> "…After the site certificate or amended site certificate is issued, the only issue to be decided in an administrative or judicial review of a state agency or local government permit for which compliance with governing law was considered and determined in the site certificate or amended site certificate proceeding *shall be whether the permit is consistent with the terms of the site certificate or amended site certificate*." (emphasis added)

In addition, ORS 469.401(5) provides that

> "Nothing in ORS chapter 469 shall be construed to preempt the jurisdiction of any state agency or local government over matters that are not included in and governed by the site certificate or amended site certificate. Such matters include but are not limited to employee health and safety, building code compliance, wage and hour or other labor regulations, local government fees and charges *or other design or operational issues that do not relate to siting the facility."*

Taken together, these provisions establish a limited scope of local review to ensure that a facility is consistent with the terms and conditions of a site certificate, and with any applicable local ordinances that were not included in and governed by the site certificate. While this review is generally limited to ministerial level decisions, some level of discretion on part of the County planning staff is necessary.

The Department and the County will need a final site plan in order to verify that the facility will comply with setback, dimensional requirements, and other restrictions imposed through site certificate conditions and applicable local ordinances. While the Department believes the

condition is appropriate as written, the following clarifying edits have been made in the draft Final Order:

Recommended Land Use Condition 3

a. Prior to construction of any component or phase of the solar facility, the certificate holder shall submit, to the Department and the Sheman County Planning Commission, an application for Conditional Use Permit ~~pursuant to ORS 469.401(3)~~ meeting the requirements of SCZO Section 5.4(1) and (3).
b. The Site Plan required under SCZO 5.4(1) must demonstrate compliance with all ~~applicable local ordinances and~~ site certificate conditions and the applicable substantive criteria addressed in the Final Order on AMD4.

[Final Order on AMD4]

Issue LU-02 (Certificate Holder); Objection to Evaluation of Compliance with SCZO 5.2(5)

Comment ID: BCWAMD4Doc24-22 Proposed Order Public Comment Certificate Holder-2 2026-01-30

Response ID: BCWAMD4Doc26-01 Proposed Order Public Comment ODOE Responses 2026-02-12

Reply ID: BCWAMD4Doc28-04 Proposed Order Public Comment CH Reply to ODOE 2026-02-28

Comment Summary

Certificate holder objects to the Department's recommended finding that the proposed facility would not comply with SCZO 5.2(5) and requests that the Department reconsider its recommended finding that the acreage thresholds under OAR 660-033-0130(38)(k) are a "land standard" within the meaning of the SCZO, arguing instead that they are thresholds that, if triggered, require the application of more stringent review criteria under the exceptions test. The certificate holder restated its position in its reply but did not provide new argument or evidence.

Department Evaluation

In the Proposed Order, the Department recommends the Council find:

> "…the facility components proposed in RFA4 would generally comply with applicable air, water, and solid waste standards; however, as described in the evaluation of directly applicable state rules and laws under ORS 197.646, below, the facility components proposed in RFA4 would exceed the maximum amounts of arable and high-value farmland allowed under OAR 660-033-0130(38), and for this reason cannot be approved without an exception to Statewide Planning Goal 3."

OAR 660-033-0130 establishes the minimum standards applicable to the schedule of permitted and conditional uses under OAR 660-033-0120. OAR 660-033-0130(38)(g) provides as follows: "For high-value farmland described at ORS 195.300(10), a photovoltaic solar power generation facility shall not use, occupy, or cover more than 12 acres" unless certain standards are met. A similar standard is established under OAR 660-033-0130(38)(i) which provides; "For arable

lands, a photovoltaic solar power generation facility shall not use, occupy, or cover more than 20 acres..."

Similar to all other standards set in the rule and the SCZO, if a facility would use, occupy, or cover, more land than allowed by the rule, then the facility cannot be approved as a conditional use. Instead, the project proponent must seek an exception to the standards and the Statewide Planning Goal the standards implement. Because the acreage thresholds in OAR 660-033-0130(38) are used to determine whether a facility can be approved as a Conditional Use, and because they are directly applicable to any Sherman County Land Use decision under ORS 197.646, the Department maintains that they are effectively land use standards within the meaning of SCZO 5.2.

Issue LU-03 (Certificate Holder); Objection to Evaluation of Compliance with SCZO 5.2(6)
Comment ID: BCWAMD4Doc24-22 Proposed Order Public Comment Certificate Holder-2 2026-01-30
Response ID: BCWAMD4Doc26-01 Proposed Order Public Comment ODOE Responses 2026-02-12

Comment Summary
Certificate holder objects to the Department's recommended finding that the proposed facility would not comply with SCZO 5.2(6) and requests that the Department reconsider its finding that failure to comply with acreage threshold under OAR 660-033-0130(38)(k) is a "use violation" within the meaning of the SCZO.

Department Evaluation
The Department agrees with the certificate holder that the obligation to receive approval of a Goal 3 exception does not constitute a "use violation" of the SCZO and agrees to revise the analysis.

Issue LU-04 (Certificate Holder); Objection to Evaluation of Compliance with SCZO Section 5.8(20)(1)
Comment ID: BCWAMD4Doc24-22 Proposed Order Public Comment Certificate Holder-2 2026-01-30
Response ID: BCWAMD4Doc26-01 Proposed Order Public Comment ODOE Responses 2026-02-12
Reply ID: BCWAMD4Doc28-04 Proposed Order Public Comment CH Reply to ODOE 2026-02-28

Comment Summary
Certificate holder objects to the Department's recommended finding that the proposed facility would not comply with SCZO 5.8(20)(1) and request that the Department reconsider its finding that failure to comply with acreage threshold under OAR 660-033-0130(38) would result in the proposed facility being incompatible with farm use. The certificate holder restated its position in its reply.

Department Evaluation
The Department interprets the "compatibility with farm use" standard under SCZO 5.8(20)(1) to mean that the non-farm use is compatible with farm uses on the subject tract, which is a distinct issue from the compatibility with adjacent uses criteria found in SCZO 5.8(20)(2) and in the Council's exception criteria under ORS 469.504(2)(c)(C). The Department maintains that the minimum standards applicable to conditional uses under OAR 660-033-0130 are an appropriate measure of whether a proposed facility is compatible with farm use when the County has not adopted its own standards or criteria.

Issue LU-05 (Certificate Holder) Objection to Evaluation of Compliance with SCZO 5.8(20)(3)
Comment ID: BCWAMD4Doc24-22 Proposed Order Public Comment Certificate Holder-2 2026-01-30
Response ID: BCWAMD4Doc26-01 Proposed Order Public Comment ODOE Responses 2026-02-12
Reply: BCWAMD4Doc28-04 Proposed Order Public Comment CH Reply to ODOE 2026-02-28

Comment Summary
Certificate holder objects to the Department's recommended finding that that proposed facility would not comply with SCZO 5.8(20)(3) and requests that the Department reconsider its finding that conversion of approximately 1,445 acres of cultivated land, including 1,006 acres of high-value farmland, to a non-farm use has the potential to materially alter the overall land use pattern of the analysis area by reducing the number of tracts available for farmland and potentially affecting the local agricultural economy.

Department Evaluation
The Department disagrees with the scope of the analysis provided by the certificate holder, including 130 square miles. The Land Use analysis area includes the area within and extending ½-mile from the site boundary. In its response on this issue, the Department requested that the certificate holder provide an analysis of SCZO 5.8(20)(3) based on the established Land Use analysis area, to support review of this comment. In its reply, the certificate holder declined to provide the requested analysis, arguing that the geographic extent in SCZO 5.8(20)(3) requires a look beyond the EFSC Land Use Analysis Area at the "overall land use pattern of the area." This is the broadest geographic extent language in SCZO 5.8(20), expanding beyond the adjacent lands or the tract. The EFSC Land Use Analysis Area is frequently used to describe the adjacent or surrounding lands to the project site. When considering changes to overall patterns, that means land use patterns within swaths of the County like North Sherman County, not the surrounding lands within the EFSC Land Use Analysis Area.

The Department maintains that the Analysis Area is the appropriate scale on which to evaluate stability of the overall land use pattern, particularly considering the 1-mile study radius for smaller projects that is required under OAR 660-033-0130(38)(h)(G) and (i)(D). The Department does not recommend any changes to the draft Final Order based on this issue.

Issue LU-06 (von Borstel, Alan); Concern with cumulative impacts of solar development in Sherman County
Comment ID: BCWAMD4Doc24-11 Proposed Order Public Comment Von BorstelA 2026-01-20

Response ID: BCWAMD4Doc26-01 Proposed Order Public Comment ODOE Responses 2026-02-12; BCWAMD4Doc27-00 Proposed Order Public Comment CH Response to Alan von Borstel 2026-02-13

Comment Summary
Mr. Von Borstel raises concern that cumulative impacts of solar development in Sherman County may adversely affect wildlife, wildfire protection, cultural, historic and scenic the agricultural community, and supporting industries.

Department Evaluation
Mr. Von Borstel raises concerns about the cumulative impact of solar development in Sherman County. He did not identify a specific standard or legal requirement or a specific impact that would result from the construction and operation of the proposed facility under consideration.

As such, the Department does not believe the commenters issue was raised with sufficient specificity to afford the Council, Department, or certificate holder an opportunity to respond. If the commenter objects to one or more findings of fact, conclusions of law, or conditions of approval in the Proposed Order, the Department requests that commenter identifies these findings, conclusions, or conditions in their reply.

Issue LU-07 (Multiple Commenters); Recommendation that "Right to Farm" protections are needed to protect farmers from wildfire liability
Comment ID: BCWAMD4Doc24-02 Proposed Order Public Comment McCulloughK-2 2025-12-24; BCWAMD4Doc24-04 Proposed Order Public Comment McCulloughK-4 2026-01-05; BCWAMD4Doc24-22 Proposed Order Public Comment Certificate Holder-2 2026-01-30; BCWAMD4Doc25-03 Proposed Order Public Hearing Transcript 2026-01-15
Response ID: BCWAMD4Doc26-01 Proposed Order Public Comment ODOE Responses 2026-02-12; BCWAMD4Doc27-05 Proposed Order Public Comment CH Response to Irene Gilbert 2026-02-13; BCWAMD4Doc27-09 Proposed Order Public Comment CH Response to Kathy and Kevin McCullough 2026-02-13
Reply ID: BCWAMD4Doc28-01 Proposed Order Public Comment McCulloughK Reply 2026-02-24Sur-Reply ID: BCWAMD4Doc29-02 Proposed Order Public Comment CH Sur-Reply to Kathy and Kevin McCullough 2026-03-06
Comment Summary
Commenters raise concerns about the increased risk of liability to farmers that could arise if a fire started by farming practices damaged the solar facility. Commenters object to recommended approval of solar facility in "high fire risk area" without hold harmless clause. Commenters assert that potential liability for a wildfire started by normal farming practices could result in bankruptcy, and without protections from liability the project infringes on the commenters "right to farm" under ORS 30.930 to 30.947.

Department Evaluation
Matters of liability are generally not within the Council's jurisdiction. Providing farmers the suggested liability protections would be a matter to take up with the state legislature. There

was no new argument or evidence provided in the commenter's reply, as such, the Department does recommend any revisions in the draft of the Final Order based on this comment because the comment raises an issue that is not within the scope of Council's authority.

Issue LU-08 (Certificate Holder); Objection to Evaluation of OAR 660-033-0130(38)(G)
Comment ID: BCWAMD4Doc24-22 Proposed Order Public Comment Certificate Holder-2
Response ID: BCWAMD4Doc26-01 Proposed Order Public Comment ODOE Responses 2026-02-12

Comment Summary
Certificate holder objects to Departments recommended findings under evaluation of OAR 660-033-0130(38)(h)(G).

Department Evaluation
In its evaluation of this criteria, the Department states, "No solar facilities have been constructed or have been approved within the study area identified by rule, so no further analysis is necessary; however, the rule was intended to apply to a facility less than 12 acres in size and does not accurately capture the proposed facilities' potential impacts on the stability of the overall land use pattern..."

As stated, the Department's recommended finding is that no further analysis of the criteria is needed. The additional explanation is intended to provide context for recommended findings under the evaluation of SCZO 5.8.20(3). The Department will include clarifying changes in both sections to clarify that the Department's evaluation of the proposed facilities potential impacts on the stability of the overall land use pattern of the area is informed by, but independent of, the test required under OAR 660-033-0130(38)(h)(G).

Issue LU-09 (Oregon Wheat Growers League); Recommendation to include impact of lost assessments in economic impact analysis
Comment ID: BCWAMD4Doc24-20 Proposed Order Public Comment OWGL 2026-01-30
Response ID: BCWAMD4Doc26-01 Proposed Order Public Comment ODOE Responses 2026-02-12; BCWAMD4Doc27-10 Proposed Order Public Comment CH Response to Oregon Wheat Growers 2026-02-13

Comment Summary
Commenter raises a concern that the certificate holder's analysis of economic impacts of the RFA4 facility changes does not account for lost agricultural assessments that fund research, market development, and grower services. Recommends updating the impact analysis to account for lost assessment revenues.

Department Evaluation
The commenter has not objected to a Department recommended finding of fact, conclusion of law or condition of approval in the Proposed Order, but rather to the scope of the certificate holder's analysis of the indirect economic impacts of the proposed RFA4 changes.

In its responses the certificate holder explains that, while wheat assessment revenues were not evaluated as a discrete category, the indirect impacts to the local agricultural economy in Sherman County associated with changes in production were estimated and mitigated through the sector-based approach reflected in the record (Attachment K-2, Agricultural and Fiscal Impact Analysis).

The Department does not recommend any changes to the draft Final Order based on this issue because the comment does not identify the recommended findings of fact, conclusions of law or conditions of approval identified in the proposed order to which they object.

Issue LU-10 (Oregon Wheat Growers League); Objection to claim that Community Investment Plan will offset impacts to agricultural economy

Comment ID: BCWAMD4Doc24-20 Proposed Order Public Comment OWGL 2026-01-30
Response ID: BCWAMD4Doc26-01 Proposed Order Public Comment ODOE Responses 2026-02-12; BCWAMD4Doc27-10 Proposed Order Public Comment CH Response to Oregon Wheat Growers 2026-02-13

Comment Summary

Commenter contends the draft Community Investment Plan (CIP) "does not deliver" on a statement by the certificate holder that the CIP will "ensure any negative economic impacts that could result from the decrease in total acres of wheat production in the county will be offset by investments in the local agricultural community."[3] Contends that mitigation cannot fully offset the loss of agricultural land into an industrial use.

Department Evaluation

The commenter has not objected to a Department recommended finding of fact, conclusion of law or condition of approval in the Proposed Order regarding the CIP, but rather to a statement the certificate holder made about the CIP. Council must consider whether the proposed CIP supports a "rural economic benefits" reason for granting an exception to statewide planning Goal 3, which seeks to preserve agricultural land. The Department has not contended the CIP will fully offset any/all negative economic impacts to the local agricultural community. Rather, the Department has recommended the Council find the proposed CIP "*reasonably addresses* the indirect impacts of converting agricultural lands in the proposed Solar Micrositing Area to nonfarm use"[4] and recommended Council find that implementation of the CIP supports a rural economic benefits reason for granting an exception to Goal 3.

In its responses on this issue, the certificate holder restated that the economic modeling supporting the CIP adequately accounted for indirect and induced impacts to the agricultural economy. And that the evidence provided in the record, and the stakeholders consulted, adequately informs the market conditions for Sherman County wheat growers.

[3] RFA4, Exhibit K, Land Use, p. 71.
[4] Proposed Order, pp. 139-140.

The Department does not recommend any revisions to the draft Final Order based on this comment because the comment does not identify a recommended findings of fact, conclusions of law or conditions of approval identified in the proposed order to which the commenter objects.

Issue LU-11 (Oregon Wheat Growers League): Recommendation to include Oregon Wheat Growers League in Community Investment Selection Committee

Comment ID: BCWAMD4Doc24-20 Proposed Order Public Comment OWGL 2026-01-30
Response ID: BCWAMD4Doc26-01 Proposed Order Public Comment ODOE Responses 2026-02-12; BCWAMD4Doc27-10 Proposed Order Public Comment CH Response to Oregon Wheat Growers 2026-02-13

Comment Summary

Commenter recommends that farmer representatives should be included in decision making process. Recommends Oregon Wheat Growers League be included in structure.

Department Evaluation

The commenter expresses concern there is no guarantee a farmer representative will be "built into the decision-making process" and proposes to "update the structure to include a representative from the Oregon Wheat Growers League."

To help inform the development of the CIP and to identify potential projects that would support the local agricultural economy the certificate holder met with, among other persons and groups, local wheat farmers and the Oregon Wheat Commission. That coordination led to the certificate holder including in the CIP five "pre-screened" projects that would qualify for funding. For other proposals, a five-person advisory committee (Selection Committee) would review applications and make recommendations to the Sherman County Board of Commissioners on funding. The Selection Committee would include one representative from Sherman County government; one representative from an academic institution engaged in agriculture research in Sherman County or an agricultural-related nonprofit entity located in Sherman County; *one dryland farm producer in the County*; one community member; and one representative with expertise in wildfire as it relates to agricultural lands.[5]

In its response to this issue, the certificate holder responded that they supported revising the final CIP to include a representative from the OWGL on the Selection Committee. The certificate holder requested that ODOE acknowledge this request and recommend to EFSC that the CIP be revised in Section 4.2.1 to identify the addition of one representative from the OWGL. The Department agrees with the certificate holder's request.

Issue LU-12 (Oregon Wheat Growers League): Need for engagement with Market Development Organizations in developing Community Investment Plan

Comment ID: BCWAMD4Doc24-20 Proposed Order Public Comment OWGL 2026-01-30

[5] Proposed Order, p. 139 and Attachment E (the draft CIP), Section 4.2.1.

Response ID: BCWAMD4Doc26-01 Proposed Order Public Comment ODOE Responses 2026-02-12; BCWAMD4Doc27-10 Proposed Order Public Comment CH Response to Oregon Wheat Growers 2026-02-13

Comment Summary

Commenter recommends that further consultation with market development organizations (e.g. , Oregon Wheat Commission, U.S. Wheat Associates, National Association of Wheat Growers and Northwest Grain Growers) seeking to understand the long-term markets in domestic and international capacities "is needed to clarify statements listed in the market statements."

Department Evaluation

In its response on this issue, the Department is not clear on what "market statements" the commenter is referring, nor what further consultation with the recommended organizations would achieve. As such, the Department does not recommend any changes be made to the draft Final Order based on this issue because the commenter does not identify the recommended findings of fact, conclusions of law or conditions of approval identified in the proposed order to which they object.

Issue LU-13 (Oregon Wheat Growers League): Concern with inclusion of agrivoltaics research as pre-screened project in Community Investment Plan

Comment ID: BCWAMD4Doc24-20 Proposed Order Public Comment OWGL 2026-01-30
Response ID: BCWAMD4Doc26-01 Proposed Order Public Comment ODOE Responses 2026-02-12; BCWAMD4Doc27-10 Proposed Order Public Comment CH Response to Oregon Wheat Growers 2026-02-13

Comment Summary

Commenter raises concern with inclusion of agrivoltaics research in pre-screened mitigation project list, alleging "[t]his areas is overstated" and the project "would not produce meaningful results." Recommends producer-led analysis of research proposals would allow research investments to match the growing area most effectively.

Department Evaluation

Dryland wheat agrivoltaics research is one of five pre-screened projects identified in the draft Community Investment Plan (CIP) as having a direct benefit to the rural agricultural economy of Sherman County. These five projects were developed based on outreach and coordination with key stakeholders from the Sherman County agricultural community, as well as state-wide agricultural-related organizations including local wheat farmers, the Oregon Watershed Enhancement Board (OWEB), Oregon State University (OSU) including its extension service in Sherman County and the College of Agricultural Sciences, the Oregon Wheat Commission, the Sherman County Fire District, Sherman County Emergency Services, the Rural Sherman County Fire Board, the Weed Master, the Road Master, the County Planning Office, and County Judge. Further, as noted above, the Selection Committee for CIP mitigation projects will include one representative one dryland farm producer in the County.

In its responses to OWGL's comments, the certificate holder commented that it agreed the League's input would be valuable in the development of a proposal for an agrivoltaics project and that it anticipates that the proponent of this project would seek the input from OWGL when developing the proposal to ensure that the research directly benefited the Sherman County wheat economy. The certificate holder requested that the Department acknowledge this request and recommend to the Council that the final CIP be revised at Section 5 to require the project proponent to consult OWGL when developing the project proposal to include in the CIP funding application.

Given the concerns of OWGL, and the certificate holder's acknowledgement that additional input in the development of a proposal would be beneficial, the Department recommends the Council reject the Dryland Wheat Agrivoltaics Research in Sherman County as a pre-screened project. The project sponsor would continue to be able to apply for funding through the normal selection process and investing in research to further agrivoltaics for dryland wheat lands would continue to be one of the selection criteria for review. The Department recommends that having this project go through the full selection process is the best way to incentivize successful stakeholder engagement in the project design process.

Issue LU-14 (Oregon Wheat Growers League): Concern with including weed management projects as pre-screened project in Community Investment Plan
Comment ID: BCWAMD4Doc24-20 Proposed Order Public Comment OWGL 2026-01-30
Response ID: BCWAMD4Doc26-01 Proposed Order Public Comment ODOE Responses 2026-02-12; BCWAMD4Doc27-10 Proposed Order Public Comment CH Response to Oregon Wheat Growers 2026-02-13

Comment Summary
Commenter raises concern with inclusion of weed management projects in the pre-screened mitigation project funding list. Asserts the project adds burden to neighboring properties and recommends weed management be incorporated into the project requirements rather than diminishing agricultural mitigation funds.

Department Evaluation
The commenter contends "the project should ensure that a weed management plan that can be reasonably enforced is completed outside of ag mitigation efforts."

Weed control is a requirement under Proposed Order. The certificate holder has prepared the Comprehensive Solar Revegetation and Soil Management Plan (Comprehensive Plan) to serve as a primary source of commitments related to revegetation, soil management, dust control, stormwater management, and noxious weed control through the pre-construction, construction, and operations phases for the photovoltaic solar energy generation and battery storage (Solar Components) associated with RFA4. In its responses to this issue, the certificate holder also confirmed that they agree with the League that weed control is not a separate mitigation effort, but a mandatory and integral part of project construction and operation

Under the Proposed Order recommended Soil Protection Conditions 1 through 3, the certificate holder would be required to finalize the draft Comprehensive Plan (included as Attachment D), and construct and operate the solar facility in compliance with the Plan. As with all site certificate conditions, the Department and Council maintain authority to enforce these condition requirements. The commenter has not raised any issues related to the adequacy of the draft Comprehensive Plan or Recommended Soil Protection Conditions 1 through 3.

The weed control measures funded under the draft CIP would not address weeds related to the Biglow facility but rather would provide a grant program for county wheat farmers to invest in precision agricultural technology such as weed management equipment, remote sensing technology to assist with weed mapping or soil mapping.

The draft CIP Project 4 is a "[g]rant program for county wheat farmers to invest in precision agricultural technology such as weed management equipment, remote sensing technology to assist with weed mapping or soil mapping, variable rate technology to collect data on soil variability to inform application of fertilizers, and other technologies." The description further states "[t]he cost-share grant program for precision agricultural technology is assumed to increase the number of farmers who otherwise would not have access to precision management technology due to the significant upfront cost barrier."[6]

The Department does not recommend any revisions in the draft Final Order based on this comment because recommended conditions in the Proposed Order would already require the certificate holder to take weed control measures, and the weed control funding measures described under the draft CIP would not be used to control weeds related to the certificate holder's project but rather would be utilized by county wheat farmers.

Issue LU-15 (Oregon Wheat Growers League): Concern with including fire mitigation projects as pre-screened project in Community Investment Plan
Comment ID: BCWAMD4Doc24-20 Proposed Order Public Comment OWGL 2026-01-30
Response ID: BCWAMD4Doc26-01 Proposed Order Public Comment ODOE Responses 2026-02-12; BCWAMD4Doc27-10 Proposed Order Public Comment CH Response to Oregon Wheat Growers 2026-02-13

Comment Summary
Commenter raises concern with inclusion of investments in minimizing fire risk in the pre-screened mitigation project funding list. Recommends fire mitigation should be considered separately from agricultural mitigation.

Department Evaluation

[6] Proposed Order Attachment E, Draft Community Investment Plan, pp. 10-11.

Under Council's Wildfire Prevention and Risk Mitigation standard, OAR 345-022-0115, Council must find the certificate holder has adequately characterized wildfire risk within the analysis area and that the proposed facility will be designed, constructed, and operated in compliance with a Wildfire Mitigation Plan approved by the Council.

In the Proposed Order, the Department recommends the Council impose new conditions requiring the certificate holder to submit plans addressing wildfire risks associated with the construction and operation of the solar facility. Recommended Wildfire Prevention and Risk Mitigation Conditions 1 and 2 require the certificate holder to submit to the Department, for review and approval, a Construction Wildfire Mitigation Plan (WMP), (consistent with Attachment G to the Order) and to adhere to the WMP during construction of the solar facility. And Recommended Wildfire Prevention and Risk Mitigation Conditions 3 and 4 require the certificate holder to submit to the Department for review and approval an Operational Wildfire Mitigation Plan and adhere to it during operations.

In its responses, the certificate holder also confirms that fire risk minimization and mitigation is not a separate mitigation effort, but a mandatory and integral part of project construction and operation.

In 2024, separate from the Council process related to the proposed Biglow solar facility, Sherman County developed and adopted a Community Wildfire Protection Plan (CWPP) to identify and mitigate wildfire risk in the county and to develop a strategy to reduce those risks. The CWPP identifies several projects that would assist the County in mitigating wildfire risk (e.g., upgrading, maintaining, or adding firefighting equipment for Sherman County's Rural Fire Protection Districts and training for volunteers).

In the certificate holder's draft CIP, "Agricultural Wildfire Risk Minimization and Capacity Building" is one of the five pre-screened projects identified as having a direct benefit to the rural agricultural economy of Sherman County. Under the draft CIP Project 2, the County could allocate mitigation funding to support either partial or full implementation of the projects identified in its CWPP, as well as other initiatives aimed at supporting the County's agricultural community in wildfire mitigation and response.

The Department does not recommend any revisions in the draft Final Order based on this comment because recommended conditions in the Proposed Order already require the certificate holder to take measures to comply with the Council's Wildfire Prevention and Risk Mitigation standard. Separately, the wildfire risk minimization measures described under the draft CIP would not be used to address wildfire risks related to the certificate holder's project but rather would benefit the County overall.

Issue LU-16 (Oregon Wheat Growers League): Objection to statement that lease payments will compensate for lost agricultural revenue

Comment ID: BCWAMD4Doc24-20 Proposed Order Public Comment OWGL 2026-01-30

Response ID: BCWAMD4Doc26-01 Proposed Order Public Comment ODOE Responses 2026-02-12; BCWAMD4Doc27-10 Proposed Order Public Comment CH Response to Oregon Wheat Growers 2026-02-13

Comment Summary
Commenter objects to a statement by the certificate holder that lease payments will compensate for any lost agricultural revenue incurred by a landowner/farmer due to conversion of farmland to energy use[7]; the commenter contends that the farm operator may not own the subject parcel and may not benefit from lease payments and suggests clarification is needed to determine if the persons who provided statements are only landowners or if they are also farm operators.

Department Evaluation
In its responses on this issue, the certificate holder notes that the agricultural economic analysis presented in BCWF RFA 4 Attachment K-2 of Exhibit K and referenced the Proposed Order evaluates direct, indirect, and induced impacts from removing land from agricultural production. Impacts to the agricultural economy are assessed in terms of employment, labor income, and economic output using the IMPLAN economic modeling package The Community Investment Plan (CIP) then ensures that the local rural economic benefits will offset potential adverse impacts the development of BCWF RFA 4 may have on Sherman County's agricultural economy. Mitigation under the Energy Facility Siting Council (EFSC) Land Use Standard and the CIP address local agricultural community and economic impacts at a county and community level, rather than compensating individual producers for lost production. That type of impact is handled by private agreement, as mentioned above.

In its responses, the Department noted that the commenter had not objected to a Department recommended finding of fact, conclusion of law or condition of approval in the Proposed Order, but rather to a statement the certificate holder made that lease payments will offset the direct loss of agricultural production resulting from its proposed solar facility.

As discussed in the Proposed Order, because the proposed solar facility would use, occupy, or cover more farmland than allowed under state laws and regulations, for Council to approve the facility, it would have to provide an exception to Statewide Planning Goal 3, which seeks to preserve and maintain agricultural lands for farm use.

The certificate holder argues that one reason Council should provide an exception to Goal 3 is because its proposed solar facility will promote rural economic development in several ways including through lease payments to affected landowners. The Department analyzed this argument in the Proposed Order and, while it agreed that some aspects of the proposal support Council granting an exception to Goal 3 because of the rural economic development that will result (e.g., through the proposed Community Investment Plan), the Department

[7] RFA4, Exhibit K, Land Use, p. 18.

recommended Council find that the certificate holder has not provided sufficient evidence to demonstrate that lease payments will benefit agricultural operations because the participating landowner or individuals farming the land have not demonstrated, or even indicated, they intend to use the lease payments from the proposed solar facility to make or allow for new farm investment.[8]

Therefore, it is not necessary to seek clarification regarding the landowner statements, and the Department does not intend to make any revisions in the draft of the Final Order based on this comment because the Department has recommended Council reject the certificate holder's position that the lease payments support Council granting an exception to Goal 3.

Issue LU-17 (Certificate Holder); Land Use/Goal Exception – Project Furthers Oregon's Clean Energy Directives and Goals

Comment ID: BCWAMD4Doc25-03 Proposed Order Public Hearing Transcript 2026-01-15; BCWAMD4Doc24-23 Proposed Order Public Comment Certificate Holder-3 2026-01-30
Response ID: BCWAMD4Doc26-01 Proposed Order Public Comment ODOE Responses 2026-02-12
Reply ID: BCWAMD4Doc28-04 Proposed Order Public Comment CH Reply to ODOE 2026-02-28

Comment Summary

Certificate holder objects to the Department recommending Council reject their argument that an exception to Goal 3 is justified because authorizing the facility components proposed in RFA4 is consistent with State policies and goals addressing climate change and encouraging the acceleration of Oregon's clean energy transition.

In their comments on the Proposed Order, the certificate holder provides additional evidence and argument in support of its position. The certificate holder discusses state legislation (SB 1547, ORS 469A.005-469A.210) mandating that large investor-owned utilities, including PGE, meet Renewable Portfolio Standard targets. The certificate holder also addresses two recent Executive Orders issued by Governor Kotek, Executive Order 25-25, *Accelerating Wind and Solar Energy Development in Advance of Elimination of Federal Clean Energy Tax Credits* (EO 25-25), and Executive Order 25-29 *Reducing Greenhouse Gas Emissions and Advancing Oregon's Clean Energy Future* (EO 25-29). The certificate holder contends "a Goal 3 exception is justified because the facility, as amended, directly furthers Oregon's clean energy directives and goals."

Department Evaluation

The Department does recommend any revisions to the draft of the Final Order based on this comment.

The State of Oregon has taken several measures to combat climate change and encourage the development of renewable energy, including those discussed by the certificate holder. At the same time, Oregon has a rigorous land use system that seeks, among other goals, to preserve

[8] Proposed Order on RFA4, pp. 141-142.

the state's agricultural lands, via Goal 3. None of the statutes or Executive Orders the certificate holder cites require EFSC to grant an exception to Goal 3 for a renewable energy facility. Indeed, per statute, EFSC "*may* find goal compliance for a facility that does not otherwise comply with one or more statewide planning goals by taking an exception to the applicable goal" (ORS 459.504(2), emphasis added). Therefore, as the certificate holder has noted, EFSC has the discretion to decide when to grant an exception to a statewide planning goal.

In recent years, most projects reviewed by EFSC have sought an exception to Goal 3. That is because large renewable energy facilities, in particular solar photovoltaic power generation facilities, require significant amounts of land and that land is often zoned for Exclusive Farm Use. Therefore, it is up to EFSC to balance Oregon's goals and directives to combat climate change/encourage renewable energy against the state's Goal 3, seeking to preserve agricultural land. This is a responsibility the Department and EFSC take seriously. The Department believes that granting an exception to Goal 3 based solely on the fact that a proposal would result in the construction or expansion of a renewable energy facility, without specific evidence demonstrating that a site or facility is particularly well suited to meeting those goals or policies, is tantamount to ignoring Goal 3 altogether.

Indeed, EFSC has consistently rejected arguments that a proposed facility's potential contributions toward meeting Oregon's climate change and renewable energy policies is a reason justifying taking an exception to Goal 3. Rather, the Department and Council have sought to identify the specific impacts a proposed facility would have on agricultural lands and the agricultural economy. This is a location-specific and project-specific analysis. Council has regularly approved exceptions to Goal 3 where the project proponent can demonstrate the facility is located near existing energy or transportation infrastructure (and thus would displace less agricultural land than a facility farther from such infrastructure), will have minimal impacts to agriculture and/or provide a benefit to the rural/agricultural economy.
In the Proposed Order the Department recommends Council find that the certificate holder has provided sufficient evidence to justify an exception to Goal 3 based on the RFA4 facility components being locationally dependent on nearby major transmission infrastructure and transportation corridors and because the proposed Community Investment Plan funds are likely to be used in a manner that benefits the local agricultural economy and provide rural economic development benefits. Therefore, should Council agree with the Department's recommendation, it would grant an exception to Goal 3 for the proposed additions to the facility, not based solely on the fact that those additions will further Oregon's clean energy directives and goals, but because it makes sense to site an energy facility at that location, given the presence of nearby energy and transportation infrastructure and because the certificate holder will implement measures that will benefit the rural/agricultural economy.

The Department maintains its recommendation that Council not base a goal exception on the proposed facility components furthering Oregon's clean energy directives and goals because the certificate holder has failed to provide any specific or unique reasons that demonstrate that the proposed solar facility or the Biglow site is particularly well suited to meeting the states goals or the certificate holders' legal obligations other than the locational dependence on the

availability of excess interconnection capacity resulting from the underperforming wind facility. Were Council to acknowledge that the existence of state energy policies and priorities alone are an adequate reason to override state policies protecting farmland, proponents of future renewable energy projects may cite such a decision as a basis for Council to grant an exception to Goal 3 even if their projects, unlike this one, are not locationally dependent, would not provide a benefit to the rural/agricultural economy and/or would have greater impact on agricultural lands and productivity.

Issue LU-18 (Certificate Holder); Land Use/Goal Exception – Minimal impacts to Other Resources
BCWAMD4Doc24-23 Proposed Order Public Comment Certificate Holder-3 2026-01-30
Response ID: BCWAMD4Doc26-01 Proposed Order Public Comment ODOE Responses 2026-02-12
Reply ID: BCWAMD4Doc28-04 Proposed Order Public Comment CH Reply to ODOE 2026-02-28

Comment Summary
Certificate holder objects to recommended rejection of Minimal Impacts to Other Resources Reason to support an exception to Statewide Planning Goal 3. Provides comparison of potential impacts compared to other recent orders.

Department Evaluation
The Department does recommend any changes to the draft Final Order based on this comment and recommends Council not make changes in its Final Order based on this comment.

The certificate holder maintains that an exception to Goal 3 is justified because their proposed Solar Micrositing Area would have minimal impacts on other resources protected by Council standards since it would avoid sensitive environmental features, including Washington ground squirrel occupied habitat, FEMA 100-year floodplains, U.S. Fish and Wildlife Service-designated critical habitat, and ODFW-designated big game winter ranges, and wetlands and waters. They contend their proposal would impact less Category 2 through 4 habitats than three other facilities to which Council granted a Goal 3 exception and that the permanent habitat loss that would occur will be mitigated according to ODFW Habitat Mitigation Policy goal. While the overall acreages may be greater, the Department notes that the construction and operation of the proposed facility would result in permanent impacts to up to 21 acres of Category 2 Sagebrush Shrub-Steppe habitat that is in or adjacent to a Priority Wildlife Connectivity Area. Two of the three facilities which the certificate holder used for comparison in its comments affected no Category 2 habitat, while the remaining facility affected 0.1 acres. The Department maintains that this level of impact on essential, limited, habitat is, in itself, more than a "minimal impact."

Per ORS 469.504(2)(c) the Council may take an exception to a statewide planning goal if it finds the following standards are met:

(A) Reasons justify why the state policy embodied in the applicable goal should not apply;
(B) The significant environmental, economic, social and energy consequences anticipated as a result of the proposed facility have been identified and adverse impacts will be mitigated in accordance with rules of the council applicable to the siting of the proposed facility; and
(C) The proposed facility is compatible with other adjacent uses or will be made compatible through measures designed to reduce adverse impacts.

Thus, for Council to grant an exception to Goal 3, in addition to finding there are sufficient reasons to justify taking an exception, ORS 469.504(2)(c)(B) requires Council to also find that the significant environmental, economic, social and energy consequences anticipated as a result of the facility components proposed in RFA4 have been identified and adverse impacts will be mitigated in accordance with rules of the Council. Here, because the Department believes the certificate holder had already demonstrated sufficient reasons to grant an exception to Goal 3, it recommended Council reject minimal impacts as a reason for granting an exception under ORS 469.504(2)(c)(A) and instead consider those minimal impacts and mitigation per the ODFW Habitat Mitigation Policy as meeting the mitigation requirement in ORS 469.502(2)(c)(B).[9] This approach avoids "double counting" - *i.e.*, finding the same underlying facts and evidence as meeting two separate criteria necessary for granting an exception. Accordingly, the Department recommends Council not make any changes to the Draft Final Order in response to the certificate holder's comments.

III.E. Fish and Wildlife Habitat (OAR 345-022-0060)

Issue FW-01 (McCullough, Kathryn); Adequacy of Exhibit P and Evaluation of Impacts to Wildlife
Comment ID: BCWAMD4Doc24-03 Proposed Order Public Comment McCulloughK-3 2026-01-01
Response ID: BCWAMD4Doc26-01 Proposed Order Public Comment ODOE Responses 2026-02-12; BCWAMD4Doc27-09 Proposed Order Public Comment CH Response to Kathy and Kevin McCullough 2026-02-13

Comment Summary
Ms. McCullough raises concerns regarding the adequacy of RFA4 Exhibit P and the evaluation of impacts to wildlife. She states that the Exhibit P (to the preliminary RFA4) is incomplete and appears to apply only to birds and bats, arguing that other mammals should be addressed. She provides photographic documentation of other animals in the vicinity of the site.

[9] See Proposed Order, p. 146: ". . . the construction and operation of the facility components proposed in RFA4 could have significant adverse impacts on soils, fish and wildlife habitat, cultural resources, and waters of the State, but the Department recommends the Council find that existing and recommended conditions of approval are adequate to avoid, minimize, or mitigate these impacts."

Department Evaluation
The Department believes RFA4 Exhibit P, and associated findings in the Proposed Order, adequately address potential impacts to fish and wildlife species, including the species identified by Ms. McCullough. Because impacts to all wildlife and wildlife habitat, not just bird and bat species, were considered in the evaluation of the RFA4, the Department does not recommend any additional changes to the Proposed Order are warranted at this time.

Under OAR 345-022-0060(3)(d) [formerly OAR 345-021-0010(1)(p)(D)], Exhibit P must identify all *state sensitive species* that might be present in the analysis area, based on consultation with ODFW and appropriate field study and literature review. Information about state sensitive species is required to be included in the Fish and Wildlife Exhibit, in part, to inform habitat categorization based and determine appropriate measures to avoid and minimize impacts in accordance with ODFW's Habitat Mitigation Policy, but the importance and use of habitat to wildlife more generally is also considered when making these determinations.

In Exhibit P, Section 6.1, of the final RFA4, the certificate holder identifies that 16 *state sensitive species* that have the potential to occur in the analysis area. This list is not intended to be a list of all species that are potentially present at the site, only those species identified by ODFW as State Sensitive, or Sensitive-Critical, which for the proposed Solar Micrositing Corridor, includes primarily bird and bat species and two reptile species.

As referenced by the commenter, the biologists conducting field surveys of the site also recorded non-listed species encountered during surveys in the Biological Survey Reports included in Attachment P-1, including some of the species identified in the comments and associated photographs. Impacts to non-listed species were further addressed in Exhibit P, and the Proposed Order, through the consideration of mapped Big Game Winter Range (for Elk and Mule Deer) and Priority Wildlife Connectivity Areas (based on connectivity needs for 54 surrogate species) in the categorization of habitat, which resulted in additional areas shrubland-steppe and grassland habitat being considered Category 2 "essential and limited" habitat. ODFW also recommended additional measures to protect wildlife and habitat which were incorporated into the draft Comprehensive Solar Revegetation and Soil Management Plan included as Attachment D to the Proposed Order.

The Department does not recommend any changes in the draft Final Order based on this comment, for the reasons described above.

Issue FW-02 (Certificate Holder); Srivener's Error
Comment ID: BCWAMD4Doc24-08 Proposed Order Public Comment Certificate Holder 2026-01-14
Response ID: BCWAMD4Doc26-01 Proposed Order Public Comment ODOE Responses 2026-02-12

Comment Summary
Certificate holder requests correction of a Scrivener's error in Condition GEN-FW-02. Notes that GEN-FW-02 references Condition 63 (should now be GEN-FW-03)

Department Evaluation
The Department agrees to make the recommended change, applicable language where the change would be presented is shown below, in red underline, strikethrough font:

Condition GEN-FW-02:…

a. …
b. ….
c. … If the construction would result in additional permanent impacts, the certificate holder shall increase the area of mitigation for permanent loss of Category 3 and Category 4 habitat as described in the Habitat Mitigation Plan incorporated herein by ~~Condition 63~~ GEN-FW-03.

Issue FW-03 (Certificate Holder) Flexibility on ground clearing activities in Category 2 Habitat
Comment ID: BCWAMD4Doc24-08 Proposed Order Public Comment Certificate Holder 2026-01-14
Response ID: BCWAMD4Doc26-01 Proposed Order Public Comment ODOE Responses 2026-02-12

Comment Summary
The certificate holder comments that the proposed restrictions on vegetation removal in Category 2 habitat during the critical period for ground nesting birds (Apr 15 to Sept 1) would preclude almost all work in those areas and would incentivize grading instead of mowing or drive and crush. The certificate holder requests that the Department make the following changes to Section 5.0, Table 4 of the draft Comprehensive Solar Revegetation and Soil Management Plan included as Attachment D to the Proposed Order:

~~On or before April 15 of any year in which construction occurs within Category 2 habitat, all mowing, vegetation removal and/or ground disturbance associated with site preparation must be completed. No mowing, vegetation removal and/or ground disturbance associated with site preparation may occur within Category 2 habitat between April 15 through September 1.~~

To the extent practical, mowing or other vegetation removal activities in Category 2 habitat will be scheduled to occur outside the critical period for ground nesting birds (April 15 – September 1), to avoid disturbing active nests. If mowing or other vegetation removal activities in Category 2 habitat are necessary between April 15 to September 1, the Certificate Holder shall hire a qualified biologist to conduct a clearance survey for nesting birds prior to vegetation removal. The Certificate Holder shall ensure that active nest sites identified during the clearance survey are flagged and marked as sensitive areas for avoidance on construction maps.

Department Evaluation

As explained on page 181 of the Proposed Order, the language in the draft Comprehensive Solar Revegetation and Soil Management Plan was intended to require the certificate holder to complete all initial mowing, vegetation removal and ground disturbance *associated with site preparation* in Category 2 habitat before April 15 or after September 1, and not to prohibit any subsequent vegetation management activities such as mowing. The location and extent of Category 2 habitat is isolated, within a distinct location expanding 20 acres. In response to this comment, the Department agreed to evaluate the proposed change, but requested that the certificate holder provide reasons why, for the isolated area of Category 2 habitat, site preparation activities would not be able to planned and completed at time that would avoid the critical period for ground nesting birds.

In its reply, the certificate holder noted that Facility construction is scheduled to begin in June and that if vegetation or ground disturbance is restricted in Category 2 habitat during the breeding season, then construction will not be able to begin in Category 2 habitat until after September 1. It remains unclear why the certificate holder would not be able to mobilize vegetation management crews for the limited area of Category 2 habitat prior to construction, or if waiting until September to work in the habitat area would. In addition, the Department consulted with ODFW on the proposed change. ODFW commented that clearance surveys are ineffective for accurate identification and requested that vegetation removal activities occur prior to the beginning of nesting season (April 15).

Based on ODFW's recommendation and the information on the record, the Department does not recommend any changes in the draft Final Order based on this issue.

Issue FW-04 (Certificate Holder); Recommended edits to Draft Habitat Mitigation Plan
Comment ID: BCWAMD4Doc24-22 Proposed Order Public Comment Certificate Holder-2 2026-01-30
Response ID: BCWAMD4Doc26-01 Proposed Order Public Comment ODOE Responses 2026-02-12

Comment Summary
Certificate holder provides additional recommended edits to the Draft Habitat Mitigation Plan presented as Attachment F to the Proposed Order.

Department Evaluation
The Department reviewed the certificate holder's proposed changes to the draft Habitat Mitigation Plan and considers the changes not to modify the substantive intent of the plan but rather clarify to ensure appropriate approach for evaluating success for noxious weed control and shrub planting. The Department is reviewing the proposed changes with ODFW and will provide any agreed upon changes in the draft Final Order.

III.F. Historic, Cultural and Archaeological Resources (OAR 345-022-0090)

Issue HCA-01 (Certificate Holder): Supplement Record with Tribal Consultation Details
Comment ID: BCWAMD4Doc24-08 Proposed Order Public Comment Certificate Holder 2026-01-14

Comment Summary
Certificate holder requests additional details about its outreach to Tribes be incorporated into the Proposed Order.

Department Evaluation
The Department appreciates the certificate holder's efforts to engage with Tribes regarding this project; however, we do not agree with the proposed additions for the draft Final Order. The Tribes themselves have had the opportunity to provide input on the record, and as described under Issue HCA-02, the Confederated Tribes of the Warm Springs Reservation of Oregon have expressed concerns with recommended conditions of approval. The Department has included clarifying changes to Section III.K.1 of the draft Final Order explaining that additional information regarding the certificate holder's and Department's outreach efforts is provided in Exhibit S and comments on the Proposed Order.

Issue HCA-02 (Confederated Tribes of Warm Springs) Adequacy of archaeological monitoring and protective measures
Comment ID: BCWAMD4Doc24-09 Proposed Order Public Comment CTWS 2026-01-15
Response ID: BCWAMD4Doc26-01 Proposed Order Public Comment ODOE Responses 2026-02-12

Comment Summary
CTWS express concerns that the certificate holder characterized archaeological monitoring as limited in scope and duration, focused on a single location, rather than implementing monitoring for all ground-disturbing activities, as recommended in the Cultural Resources Survey Report. CTWS requests that the full suite of cultural resource protection measures identified through survey and consultation be implemented."

Department Evaluation
There are two proposed conditions that require avoidance and monitoring.

- Recommended Historic, Cultural, and Archaeological Condition 1 (GEN-HC-02) requires the certificate holder to avoid ground disturbing activities within 20-meters of all sites and isolates identified as eligible for, or likely eligible for, listing on the National Register of Historic Places during construction and operation of the proposed solar facility.
- Recommended Historic, Cultural, and Archaeological Condition 2 (GEN-HC-03) requires the certificate holder to submit a Cultural Resources Monitoring Plan demonstrating that an Oregon Qualified Archaeologist or Tribal Cultural Resource Monitor will be onsite during ground disturbing activities that would occur within the 20-meter buffer.

The Cultural Resources Survey Report provided as Attachment S-1 to RFA4 Exhibit S, includes several recommendations for monitoring, including the following:

> "GeoVisions recommends a monitoring plan and Inadvertent Discovery Plan be in place prior to Project construction, that an archaeological monitor who meets the standards of "qualified archaeologist" as defined by the existing site certificate be present during and observe all ground disturbing activities, as well as construction activities in and around recorded archaeological sites and isolates, as well as the probable location of the Oregon Trail, and that a tribal monitor is present for all construction activities within 20 meters of sites and isolates with precontact or culturally important material to ensure that no identified or unidentified archaeological sites are "excavat[ed], injur[ed], destroy[ed] or alter[ed]," (ORS 358.920(1)(a) to identify and to ensure that any subsurface archaeological objects, sites, and/or historic properties be properly identified and preserved over the course of Project construction activities and uphold the intent of the State of Oregon (ORS 358.910(2))." RFA4, Att S-1, pg. 102.

In its responses to this issue, the Department acknowledged that the monitoring requirements of these conditions are more limited than what was recommended by GeoVisions, which recommends that a Qualified Archaeologist be on site during all ground disturbing activities and that a Tribal Cultural Resource Monitor be present when ground disturbing activities occur within a 20-meter avoidance buffer. The Department requested that the certificate holder provide a draft Cultural Resources Monitoring Plan that is consistent with the recommendations included in the GeoVisions Report.

In the certificate holder's responses, they restated their commitment to cultural resource protection but disagreed with the recommendation for additional monitoring. The certificate holder emphasized that archaeological monitoring, if required, would not be focused on a single location; it would be focused for all ground-disturbing actions within 20- meters of eligible and unevaluated sites, as defined by the GeoVisions report and the State Historic Preservation Office's (SHPO) concurrence. The certificate holder noted that the project has been designed to avoid all such sites with a 20-meter buffer; thus, monitoring of the 20-meter buffers is not expected to be necessary. If project design changes, or in the event of inadvertent discoveries during construction, then monitoring would be implemented and impacts would be evaluated. The certificate holder further asserts that while GeoVisions' recommendations for avoidance of NRHP-ineligible resources and for archaeological monitoring during all ground-disturbing activities, including within 20 meters of those resources, may be in line with conditions imposed for the existing wind facility, those conditions are inconsistent with the SHPO concurrence. The certificate holder commented that it did not have record of a request from CTWSRO, through informal coordination or at our November 2025 meeting at CTWSRO's offices or formal government-to-government consultations, for protective measures beyond those reflected in the Proposed Order and draft Amended Site Certificate and noted that if the Tribal Historic Preservation Officer (THPO) believed that certain resources should be managed differently or that additional protection measures should be required, the certificate holder would support continued government-to-government consultation between CTWSRO THPO

and ODOE, as determinations regarding applicable standards, conditions, and mitigation requirements fall within the Council's and ODOE's purview.

In reply to the certificate holder, the CTWS THPO reiterated the importance of ensuring appropriate Tribal presence during ground-disturbing activities and requested that a Dedicated Tribal Monitor be incorporated into the construction-phase coordination framework for the Project to:

- Provide real-time coordination between the Tribe and the construction team;
- Observe implementation of cultural resource protection measures during ground disturbance;
- Facilitate immediate communication in the event of discoveries or unanticipated conditions;
- Maintain government-to-government engagement during construction activities occurring within culturally sensitive areas.

The CTWSRO noted that its request was not intended to reopen SHPO concurrence or challenge ODOE's Proposed Order but rather to reflect the Tribe's expectation that consultation extends meaningfully into the implementation phase of the Project.

The Department notes that, while the certificate holder may have preferred this issue to have been raised by the Tribes at an earlier point in time, the CTWS THPO did raise this issue on the record with sufficient specificity for the issue to be evaluated. The Department appreciates the Tribes' engagement in the review process. The Department further notes that the recommendation for a Qualified Archaeologist to be present during all ground-disturbing activities included in the GeoVisions' report is consistent with SHPO's July 10, 2025 concurrence letter, which was based on the certificate holder's own representations in the preliminary Request for Amendment that it would comply with existing Site Certificate Condition 71 during construction of the solar components.

The Department believes the request to have a Dedicated Tribal Monitor present during all ground disturbing activities goes beyond the recommendations in the GeoVisions Report, and beyond what was requested in the initial comment; however, the Department believes the Tribes' request to have a qualified archaeologist on site during ground disturbing activities is reasonable given the history of the area and potential for additional unidentified pre-contact sites or isolates to be present at the site documented in the cultural resources survey report. The Department further recommends that the requirements are consistent with the recommendations made in SHPO's concurrence letter.

> Accordingly, in the draft Final Order the Department will include the following changes to Recommended Historic, Cultural, and Archaeological Condition 2 (GEN-HC-03):
>
> Prior to construction~~ activities that occur within the 20-meter avoidance buffer for archaeological sites (35SH00188, BSP-1-S02BSP-1-S10, and BSP-1-S12) and~~

~~archaeological isolate (BSP-1-I04)~~, the certificate holder must submit to the Department for approval, in consultation with SHPO, a Cultural Resources Monitoring Plan demonstrating that an Oregon Qualified Archaeologist or Tribal Cultural Resource Monitor will be onsite during ground disturbing activities ~~associated with the resources listed in this condition~~ at the site. The plan may provide for exceptions to monitoring scope and frequency, subject to approval by the Department, in consultation with the Confederated Tribes of Warm Springs. The certificate holder shall adhere to the measures approved in the Cultural Resources Monitoring Plan.

III.G. Public Services (OAR 345-022-0110)

Issue PS-01 (McCullough, Kathryn); Concerns about capacity of local fire responders to fight fire at energy facility
Comment ID: BCWAMD4Doc24-05 Proposed Order Public Comment McCulloughK-5 2026-01-06
Response ID: BCWAMD4Doc26-01 Proposed Order Public Comment ODOE Responses 2026-02-12; BCWAMD4Doc27-09 Proposed Order Public Comment CH Response to Kathy and Kevin McCullough 2026-02-13
Reply ID: BCWAMD4Doc28-01 Proposed Order Public Comment McCulloughK Reply 2026-02-24
Sur-Reply ID: BCWAMD4Doc29-02 Proposed Order Public Comment CH Sur-Reply to Kathy and Kevin McCullough 2026-03-06

Comment Summary
Commenter raises concerns about the adequacy of fire protection services at the site and potential risks to volunteer firefighters, particularly risks associated with fighting fire involving BESS components. Provides examples of risks, including toxic fumes, thermal runaway, and the ineffectiveness of water-based firefighting, in combination with challenging fire environment and rural setting.

Department Evaluation
In Section 4.4.7 of RFA4 Exhibit V, PGE explains that it would provide the North Sherman County Rural Fire Protection District with construction plans, schedules, and locations prior to the start of construction and that the Construction and Operations Wildfire Management Plans required under Wildfire Prevention and Risk Mitigation Condition 1 to 4 would address structural, BESS, and wildfire scenarios, and would include provider training on facility-specific hazards, established communication channels, site access, and firefighting resources.

In responses to this comment, the certificate further explained that on August 12, 2025, BrightNight presented details about the project and wildfire mitigation measures to the North Sherman County Rural Fire Protection District Boar and represents that it has been coordinating closely with Sherman County Emergency Services, the North Sherman County Rural Fire Protection District (RFPD), and Fire Chief Burbank of the North Sherman RFPD.

The certificate holder also indicates that BrightNight also plans to donate $200,000 to the RFPD to help build capacity to address wildfire risks but no additional details on when this donation would occur or how it would be spent were provided on the record of RFA4.

On March 4, 2026, the Department had a brief call with Chief Burbank and confirmed that he was familiar with the facility and Wildfire Mitigation Plan. Chief Burbank concerned that he did not have any concerns, but was clear that volunteer firefighters would not be expected to respond to fires at the BESS and that fire response within the proposed solar array perimeter fencelines would be limited, and that the RFPD would primarily seek to contain any fire that started within or spread into a solar array from outside of the perimeter fences.

The certificate holder's responses also identifies that the proposed BESS would utilize Tesla Megapack battery systems, which are equipped with an internal fire suppression system. The BESS is also designed in compliance with spacing standards intended to limit the propagation of fire between units and other features to prevent spread beyond the BESS yard.

Because the role of local firefighters in responding to a BESS would be limited to actions to prevent the propagation and spread of a fire outside of the BESS yard, the Department does not recommend any revisions to the draft Final Order be made in response to this issue.

Issue PS-02 (McCullough, Kathryn); Concern that local fire responders do not have adequate training to respond to fire at energy facility or BESS
Comment ID: BCWAMD4Doc24-05 Proposed Order Public Comment McCulloughK-5 2026-01-06
Response ID: BCWAMD4Doc26-01 Proposed Order Public Comment ODOE Responses 2026-02-12; BCWAMD4Doc27-09 Proposed Order Public Comment CH Response to Kathy and Kevin McCullough 2026-02-13
Reply ID: BCWAMD4Doc28-01 Proposed Order Public Comment McCulloughK Reply 2026-02-24
Sur-Reply ID: BCWAMD4Doc29-02 Proposed Order Public Comment CH Sur-Reply to Kathy and Kevin McCullough 2026-03-06

Comment Summary
Ms. McCullough provides specific recommendations for improving training and recruitment of volunteer firefighters:

- Provide specialized (NFPA-855 compliant) training to local firefighters for BESS response.
- Fund and/or create a dedicated BESS response unit within existing RFPDs.
- Conduct annual drills at BESS site, simulating windy conditions.
- Conduct outreach to improve volunteer recruitment/retention.
- Conduct community outreach to increase awareness/transparency around BESS Safety Issues.
- Require facility staff to have BESS-fire response capability until firefighters arrive.
- Provide insurance coverage and financial incentives to volunteer firefighters that respond to BESS fires.

- Supply RFPDs with SCBA, foam kits, and hazmat suits
- Create a community fund to cover:
    - Emergency payouts for injured/killed volunteers' families.
    - Training and equipment upgrades.
    - Community wildfire prevention (e.g., vegetation control).

Department Evaluation
As described in the Proposed Order Section III.M, the certificate holder provided a record of correspondence documenting coordination with the North Sherman Rural Fire Protection District (NSRFPD) Fire Board and Chief Jacob Burbank indicating that NSRFPD raised several concerns about access considerations, training, and equipment needed to address fire risk associated with the facility components proposed in RFA4. In response the certificate holder indicated that they intend to provide annual training that would cover response procedures, the risks associated with PV and BESS systems, and protocols for both fire and non-fire emergencies. Training would be provided by Coffman Engineers.

Some of the mitigation proposed by Ms. McCullough, such as providing insurance coverage, financial incentives, and emergency payouts to volunteer firefighters that respond to BESS fires, may be outside of the scope of the Council's authority, but others, including providing training and equipment needed to respond to fires at the site would be established under the Wildfire Mitigation Plans required under recommended Wildfire Prevention and Risk Mitigation Conditions 1 to 4.

In responses to this comment, the certificate further explained that on August 12, 2025, BrightNight presented details about the project and wildfire mitigation measures to the North Sherman County Rural Fire Protection District Boar and represents that it has been coordinating closely with Sherman County Emergency Services, the North Sherman County Rural Fire Protection District (RFPD), and Fire Chief Burbank of the North Sherman RFPD.

On March 4, 2026, the Department had a brief call with Chief Burbank and confirmed that he was familiar with the facility and Wildfire Mitigation Plan. Chief Burbank concerned that he did not have any concerns, but was clear that volunteer firefighters would not be expected to respond to fires at the BESS and that fire response within the proposed solar array perimeter fencelines would be limited, and that the RFPD would primarily seek to contain any fire that started within or spread into a solar array from outside of the perimeter fences.

The certificate holder's responses also identifies that the proposed BESS would utilize Tesla Megapack battery systems, which are equipped with an internal fire suppression system. The BESS is also designed in compliance with spacing standards intended to limit the propagation of fire between units and other features to prevent spread beyond the BESS yard.

Because the role of local firefighters in responding to a BESS would be limited to actions to prevent the propagation and spread of a fire outside of the BESS yard, the Department does not recommend any revisions to the draft Final Order be made in response to this issue.

III.H. Wildfire Prevention and Risk Mitigation (OAR 345-022-0115)

Issue WF-01 (McCullough, Kathryn); Concerns about burn probability data in fire risk analysis
Comment ID: BCWAMD4Doc24-04 Proposed Order Public Comment McCulloughK-4 2026-01-05
Response ID: BCWAMD4Doc26-01 Proposed Order Public Comment ODOE Responses 2026-02-12; BCWAMD4Doc27-09 Proposed Order Public Comment CH Response to Kathy and Kevin McCullough 2026-02-13
Reply ID: BCWAMD4Doc28-01 Proposed Order Public Comment McCulloughK Reply 2026-02-24
Sur-Reply ID: BCWAMD4Doc29-02 Proposed Order Public Comment CH Sur-Reply to Kathy and Kevin McCullough 2026-03-06

Comment Summary
Ms. McCullough raises concerns about the adequacy of the wildfire risk analysis provided in RFA4, Exhibit V. Specifically, she takes issue with the estimate of burn probability in Section 2.1.5. of Exhibit V.

Department Evaluation
Commenter takes issue with the description of burn probability in RFA4 Exhibit V, stating "high burn probability is much higher than 66%, but 66% is very high, especially in an area that already has 6-10 fires in a normal year…"

Ms. McCullough did not identify a recommended finding of fact, conclusion of law or condition of approval identified in the Proposed Order to which she objects but instead takes issue with evidence in the record provided to support the evaluation of wildfire risk at the site. In preliminary RFA4 Exhibit V, the certificate holder noted that 66 percent of the Solar Micrositing Area was rated with "a High to Very High (1-in-100 to 1-in-50) burn probability." In the complete RFA4, this estimate was revised to 98 percent of the wildfire analysis area based on the refined Solar Micrositing Area. In its responses to the comment, the certificate holder also explains that the fuel models used to describe the site likely overestimate the fuel load on site due to current fallow practices and the resulting estimate of burn probability may therefore be greater than actual conditions.

The certificate holder and Department notes that the revised estimate is derived from the 2023 Pacific Northwest Quantitative Wildfire Risk Assessment (McEvoy, Andy; Dunn, Christopher; Rickert, Ian), and not the certificate holder's own data or methods.

The Department generally considers the Pacific Northwest Quantitative Wildfire Risk Assessment to be a reputable source of data for wildfire risk, and as noted above, the revised estimate that resulted from its use includes a larger portion of analysis area than the initial estimate. As a result, the Department does not recommend any changes to the draft Final Order based on this issue.

Issue WF-02 (McCullough, Kathryn); Concerns about use of climate normal for fire risk analysis
Comment ID: BCWAMD4Doc24-04 Proposed Order Public Comment McCulloughK-4 2026-01-05
Response ID: BCWAMD4Doc26-01 Proposed Order Public Comment ODOE Responses 2026-02-12; BCWAMD4Doc27-09 Proposed Order Public Comment CH Response to Kathy and Kevin McCullough 2026-02-13
Reply ID: BCWAMD4Doc28-01 Proposed Order Public Comment McCulloughK Reply 2026-02-24
Sur-Reply ID: BCWAMD4Doc29-02 Proposed Order Public Comment CH Sur-Reply to Kathy and Kevin McCullough 2026-03-06

Comment Summary
Ms. McCullough objects to use of "climate normal" to reflect temperature data of site in RFA4 Exhibit V Section 2.1.4 and Table V-4. Ms. McCullough asserts that use of the climate normals "effectively lower the high temperatures" experienced in the area. As an example, the she provides data showing high temperatures of 101 – 103° F measured at the Arlington Weather Station in July 2018, compared to the 1991-2020 Average (normal) maximum temperature for July of 88.9° F at the Arlington Station.

Department Evaluation
The Department believes that climate normals, published by the National Oceanic and Atmospheric Administration in accordance with global climate data reporting standards, are a reputable source of climate data. As an average, the data does not reflect extreme temperatures that may occur in a given year, but they still provide valuable data on seasonal conditions at the site that can be used to inform the overall risk analysis. The Department also notes that the draft Construction Wildfire Mitigation Plan also accounts for extreme weather events by imposing work restrictions and additional requirements during fire weather watches and red flag warning events.

As such, no substantive changes are recommended in the draft Final Order, but the Department has including clarifying changes in section explaining the limitations on the climate normal data.

Issue WF-03 (McCullough, Kathryn); Concerns about fuel models used for fire risk analysis
Comment ID: BCWAMD4Doc24-04 Proposed Order Public Comment McCulloughK-4 2026-01-05
Response ID: BCWAMD4Doc26-01 Proposed Order Public Comment ODOE Responses 2026-02-12; BCWAMD4Doc27-09 Proposed Order Public Comment CH Response to Kathy and Kevin McCullough 2026-02-13
Reply ID: BCWAMD4Doc28-01 Proposed Order Public Comment McCulloughK Reply 2026-02-24
Sur-Reply ID: BCWAMD4Doc29-02 Proposed Order Public Comment CH Sur-Reply to Kathy and Kevin McCullough 2026-03-06

Comment Summary

Ms. McCullough objects to fuel models used in RFA4 Exhibit V Section 2.1.2. She notes that Fuel Models 102 and 93 used for agricultural lands in the site do not reflect fallow conditions at the site.

Department Evaluation
In the complete RFA4, the certificate holder notes that 93 percent of the proposed solar Micrositing Area is described by Fuel Model 102 or 242, which reflect low load, dry climate grasses and burnable wheat fields, respectively. These fuel models are derived from data from the Community Wildfire Protection Plan (CWPP) Planning Tool (Oregon Explorer 2025), which in turn, is based on the 2023 Pacific Northwest Quantitative Wildfire Risk Assessment (McEvoy, Andy; Dunn, Christopher; Rickert, Ian).

The Department generally considers the Pacific Northwest Quantitative Wildfire Risk Assessment to be a reputable source of data for wildfire risk. Accordingly, the Department does not recommend any changes in the draft Final Order based on this issue.

Issue WF-04 (Certificate Holder); Request for flexibility in road design standards for roads not needed for fire access
Comment ID: BCWAMD4Doc24-22 Proposed Order Public Comment Certificate Holder-2 2026-01-30
Response ID: BCWAMD4Doc26-01 Proposed Order Public Comment ODOE Responses 2026-02-12

Comment Summary
Certificate holder requests clarification of design standards for internal access roads. States that exterior roads and other roads designated for emergency access will be designed in accordance with 2022 Oregon Fire Code Section 503. Certificate holder requests that other interior roads not intended for fire access not be required to comply with Oregon Fire Code Standards.

Department Evaluation
The Department appreciates the clarification of conflicting statements in RFA4. To assist in the evaluation of this issue, the Department requests the certificate holder provide the site plan showing the designated emergency access roads and documentation of any additional correspondence with the North Sherman Rural Fire Protection District other than what was included in RFA4 Attachment U-1.

In its response to this issue, the Department requested that the certificate holder provide a site plan showing the location and width of designated emergency access roads and other internal access roads to support the evaluation.

In reply to the Department's response to comments, the certificate holder provided a map showing that new roads connecting the existing facility access roads to the proposed substation, O&M building and solar array access gates would be designed to allow fire access (e.g. 20-foot roads) but all roads within solar array fencelines would be 16 feet.

Compliance with 2022 Oregon Fire Code Requirements is not required for all roads, only those that are intended to provide emergency vehicles access to structures and buildings in the event of a fire-related emergency. In addition, during a brief call on March 4, 2026, the Department discussed the road width changes with Chief Burbank of the North Sherman County Rural Fire Protection District (RFPD). Chief Burbank confirmed that fire response within the proposed solar array perimeter fencelines would be limited, and that the RFPD would primarily seek to contain any fire that started within or spread into a solar array from outside of the perimeter fences and that response vehicles have off-road capabilities. Because there would be limited need to ensure access by full-size emergency vehicles to portions of the facility within the perimeter fencelines, the Department recommends the Council grant the additional flexibility requested; however, under the Construction Wildfire Management Plan attached to the draft Final Order, the final site plan must be reviewed and approved by the Department in consultation with local fire and emergency management officials.

Issue WF-05 (McCullough, Kathryn); Recommendations for BESS design criteria to minimize fire risk

Comment ID: BCWAMD4Doc24-05 Proposed Order Public Comment McCulloughK-5 2026-01-06
Response ID: BCWAMD4Doc26-01 Proposed Order Public Comment ODOE Responses 2026-02-12; BCWAMD4Doc27-09 Proposed Order Public Comment CH Response to Kathy and Kevin McCullough 2026-02-13
Reply ID: BCWAMD4Doc28-01 Proposed Order Public Comment McCulloughK Reply 2026-02-24
Sur-Reply ID: BCWAMD4Doc29-02 Proposed Order Public Comment CH Sur-Reply to Kathy and Kevin McCullough 2026-03-06

Comment Summary

Ms. McCullough recommends specific design criteria that could be incorporated into the design of the BESS to minimize fire risk. Specifically, the commenter recommends:

- That BESS enclosures be made of metal or fiberglass with steel reinforcements to resist turbine debris impacts
- That windbreaks (e.g., berms, fences) be installed around BESS components to reduce debris and ember spread
- That multiple generators/solar-powered cooling units be installed to prevent overheating.

Department Evaluation

In its responses to this issue, the certificate holder asserted that Ms. McCullough's concerns are addressed by the Proposed Order and its recommended plans and conditions. Specifically, the certificate holder provided the following information:

- BESS enclosures are manufactured to meet applicable building, electrical, and fire code standards, including resistance to environmental stressors. The centralized BESS yard

layout further reduces exposure to potential turbine debris compared to dispersed configurations and site design maintains appropriate setbacks from turbines (520 feet).

- Each BESS unit includes thermal sensors, continuous monitoring, alarm systems, and automatic shutdown capabilities. These systems are designed to detect overheating or abnormal operating conditions early and initiate protective measures. The system is UL 9540A tested, meaning it has undergone rigorous fire propagation testing under nationally recognized safety standards.
- BESS will be housed in enclosed, containerized units located within a centralized BESS yard. Each unit includes internal separation and dedicated monitoring systems designed to detect abnormal conditions and isolate potential thermal events before propagation. The containerized configuration localizes any potential incident within an individual unit.

The certificate holder's responses also identifies that the proposed BESS would utilize Tesla Megapack battery systems, which are equipped with an internal fire suppression system. The BESS is also designed in compliance with spacing standards intended to limit the propagation of fire between units and other features to prevent spread beyond the BESS yard.

The Department believes that while concerns about fire safety are valid, a preponderance of the evidence on the record shows that the proposed BESS can be designed to minimize risks to public health and safety and that there is not adequate justification to impose the additional requirements raised in this comment. As such, the Department does not recommend any changes to the draft proposed order as a result of this issue.

Issue WF-06 (Certificate Holder); Request for clarification of setback requirement
Comment ID: BCWAMD4Doc24-22 Proposed Order Public Comment Certificate Holder-2 2026-01-30
Response ID: BCWAMD4Doc26-01 Proposed Order Public Comment ODOE Responses 2026-02-12

Comment Summary
Certificate holder requests clarification that perimeter fencing must be set back 50 feet from property line of *non-participating* landowner.

Department Evaluation
The Department agrees to make the requested change in Section III.N.1 of the draft Final Order and Section 4.1.3 of the draft Construction Wildfire Mitigation Plan.

Issue WF-07 (Multiple Commenters); Concerns about adequacy of 50-foot fire setbacks
(Commenters include: Kathryn McCullough; Kevin McCullough; Colton McCullough; Sherman County Soil and Water Conservation District, Whitman, A.; Irene Gilbert)
Comment ID: BCWAMD4Doc25-03 Proposed Order Public Hearing Transcript 2026-01-15
Response ID: BCWAMD4Doc26-01 Proposed Order Public Comment ODOE Responses 2026-02-12; BCWAMD4Doc27-09 Proposed Order Public Comment CH Response to Kathy and Kevin McCullough 2026-02-13

Comment Summary
Commenters raise concerns with the adequacy of 50-foot setbacks imposed in recommended Land Use Condition 1. Suggests that larger setbacks may be needed.

Department Evaluation
In its response to this issue the Department noted that the commenters have identified an issue related to a condition of approval but have not provided sufficient evidence to 1) support the claim that the 50-foot setback does not provide adequate protection from wildfire or access to emergency responders; or 2) support the imposition of a greater setback.

The certificate holder restated requirements in the Proposed Order and Draft Site Certificate in its responses but did not provide additional information. No additional evidence supporting larger setbacks was provided in replies.

Because there is not adequate evidence on the record, the Department does not recommend any changes to the draft Final Order based on this issue.

Issue WF-08 (Multiple Commenters); Concern about adequacy of 20-foot fuel breaks
(Sherman County Soil and Water Conservation District, Irene Gilbert)
Comment ID: BCWAMD4Doc25-03 Proposed Order Public Hearing Transcript 2026-01-15
Response ID: BCWAMD4Doc26-01 Proposed Order Public Comment ODOE Responses 2026-02-12; BCWAMD4Doc27-09 Proposed Order Public Comment CH Response to Kathy and Kevin McCullough 2026-02-13

Comment Summary
Commenters raise concern about adequacy of 20-foot fire break around the perimeter of the facility to stop fire from spreading from the facility. Recommends additional research is needed. Sherman County Soil and Water Conservation District suggests that 30-foot is minimum recommended by NRCS. Ms. Gilbert recommends that 30-feet may not be adequate, and that additional research is needed.

Department Evaluation
In its responses to this issue the Department noted that the commenters have identified an issue related to a condition of approval but have not provided sufficient evidence to 1) support the claim that the 20-foot fuel break does not provide adequate protection from wildfire; or 2) support the imposition of a greater setback. The Department also requested clarification on what NRCS standard was referenced or how it is applied to utility facilities.

The certificate holder restated requirements in the Proposed Order and Draft Site Certificate in its responses but did not provide additional information. No additional evidence supporting larger setbacks was provided in replies.

Because there is not adequate evidence on the record, the Department does not recommend any changes to the draft Final Order based on this issue.

Issue WF-09 (McCullough, Colton); Support for recommended vegetation maintenance standards for wildfire season
Comment ID: BCWAMD4Doc25-03 Proposed Order Public Hearing Transcript 2026-01-15
Response ID: BCWAMD4Doc26-01 Proposed Order Public Comment ODOE Responses 2026-02-12

Comment Summary
Mr. McCullough supports recommendation that vegetation be maintained at 1 to 3 inches during fire season to mitigate fire risk. The recommended finding in the Proposed Order, pg. 233, for a 1 to 3 inch vegetation height is not reflected in the draft Comprehensive Solar Revegetation and Soil Management Plan. He requests that the requirement be binding through construction and operation.

Department Evaluation
The Department is evaluating several comments related to the recommendation that vegetation within the solar facility and other vegetation clearance areas be maintained at 1 to 3 inches during fire season to mitigate fire risk. Mr. McCullough recommends the recommendation be implemented throughout the life of the facility. The Sherman County Weed Control District recommends that the vegetation height standard be increased to 4 to 8 inches to support erosion control and enhance viability of bunchgrass species.

In its comments, the certificate holder requested that the height standard be increased to 10 to 12 inches year-round but in reply to the Sherman County Weed District, requested that ODOE take the District's professional recommendation into consideration and revise the Proposed Order and implementing plans accordingly to require management of grass height at 4 to 8 inches during dry season. Mr. McCullough commented that he did not agree that 8" vegetation would be safe from a wildfire standpoint but acknowledged the importance of not mowing native bunch grasses shorter than 3-4" to protect the crown of the plant. He conceded that a slightly taller vegetation height (3" to 6" during fire season June-Oct) would be acceptable considering erosion control, vegetation health, and fire risk together.

The Department maintains that vegetation management is a critical tool for minimizing wildfire risk associated with the proposed facility but defers to the professional recommendation of the County Weed Control District as to the appropriate standard to best balance wildfire risk mitigation and soil protection. Consistent with the District's recommendation, the Department revised Section III.N.I Wildfire Prevention and Risk Mitigation of the draft Final Order, Attachment G draft Construction Wildfire Mitigation Plan, and Appendix F of the draft Comprehensive Revegetation and Soil Management Plan to include reference to vegetation requirements below:

a. **Vegetation Height and Clearance**

- Vegetation within and adjacent to the Solar Components will be maintained as follows:
- During the dry season (June to October), vegetation height will be limited to 4 to 8 inches. Vegetation will be mowed to a height of 4 inches prior to June of each year.
- Outside of the dry season (November to May), vegetation will be maintained at a maximum height of less than 12 inches~~,~~.
- ~~with a~~ A minimum vertical clearance of 12 inches from all electrical and mechanical equipment will be maintained at all times.
- Vegetation exceeding ~~this~~ the heights listed above will be mowed or removed ~~prior to local~~ in accordance with any ODF- or County-issued fire restrictions.

Issue WF-10 (Certificate Holder); Objection to Vegetation Maintenance Standards for Wildfire Season
Comment ID: BCWAMD4Doc24-22 Proposed Order Public Comment Certificate Holder-2 2026-01-30
Response ID: BCWAMD4Doc26-01 Proposed Order Public Comment ODOE Responses 2026-02-12

Comment Summary
Certificate holder objects to the Department's recommendation that vegetation be maintained at 1 to 3 inches during fire season to mitigate fire risk. Requests that the vegetation height requirements be set to limit a height of 10 to 12 inches year-round.

Department Evaluation
The Department is evaluating several comments related to the recommendation that vegetation within the solar facility and other vegetation clearance areas be maintained at 1 to 3 inches during fire season to mitigate fire risk. Mr. McCullough recommends the recommendation be implemented throughout the life of the facility. The Sherman County Weed Control District recommends that the vegetation height standard be increased to 4 to 8 inches to support erosion control and enhance viability of bunchgrass species.

In its comments, the certificate holder requested that the height standard be increased to 10 to 12 inches year-round but in reply to the Sherman County Weed District, requested that ODOE take the District's professional recommendation into consideration and revise the Proposed Order and implementing plans accordingly to require management of grass height at 4 to 8 inches during dry season. Mr. McCullough commented that he did not agree that 8" vegetation would be safe from a wildfire standpoint, but acknowledged the importance of not mowing native bunch grasses shorter than 3-4" to protect the crown of the plant. He conceded that a slightly taller vegetation height (3" to 6" during fire season June-Oct) would be acceptable considering erosion control, vegetation health, and fire risk together.

The Department maintains that vegetation management is a critical tool for minimizing wildfire risk associated with the proposed facility but defers to the professional recommendation of the

County Weed Control District as to the appropriate standard to best balance wildfire risk mitigation and soil protection. Consistent with the District's recommendation, the Department revised Section III.N.I Wildfire Prevention and Risk Mitigation of the draft Final Order, Attachment G draft Construction Wildfire Mitigation Plan, and Appendix F of the draft Comprehensive Revegetation and Soil Management Plan to include reference to vegetation requirements below:

a. **Vegetation Height and Clearance**

- Vegetation within and adjacent to the Solar Components will be maintained as follows:

- ~~with a~~ A minimum vertical clearance of 12 inches from all electrical and mechanical equipment will be maintained at all times.
- Vegetation exceeding ~~this~~ the height~~s~~ listed above will be mowed or removed ~~prior to local~~ in accordance with any ODF- or County-issued fire restrictions.

…

Issue WF-11 (Certificate Holder); Request to remove requirement for drip can with fire suppression equipment.
Comment ID: BCWAMD4Doc24-22 Proposed Order Public Comment Certificate Holder-2 2026-01-30
Response ID: BCWAMD4Doc26-01 Proposed Order Public Comment ODOE Responses 2026-02-12

Comment Summary
Certificate holder requests that the Department remove a requirement in the Construction WMP that a 5-gallon Drip Can be carried in maintenance vehicles and stored on-site at the O&M building. Certificate holder clarifies that the project would not conduct activities requiring use of drip cans, and that workers would not have adequate experience to use drip cans.

Department Evaluation
Inclusion of drip cans in the draft Construction WMP was a representation made by the certificate holder, versus a recommended requirement. Given that the certificate holder seeks to clarify equipment that would not be needed or appropriate for the site, the Department agrees to remove the requirement as requested.

Issue WF-12 (McCullough, Kathryn; Gilbert, Irene); Concern about lack of availability of Operational Wildfire Mitigation Plan.
Comment ID: BCWAMD4Doc25-03 Proposed Order Public Hearing Transcript 2026-01-15; BCWAMD4Doc24-06 Proposed Order Public Comment McCulloughK-6 2026-01-09
Response ID: BCWAMD4Doc26-01 Proposed Order Public Comment ODOE Responses 2026-02-12; BCWAMD4Doc27-09 Proposed Order Public Comment CH Response to Kathy and Kevin McCullough 2026-02-13

Comment Summary
Commenters raise concern about lack of availability of Operational Wildfire Mitigation Plan for review as part of Proposed Order.

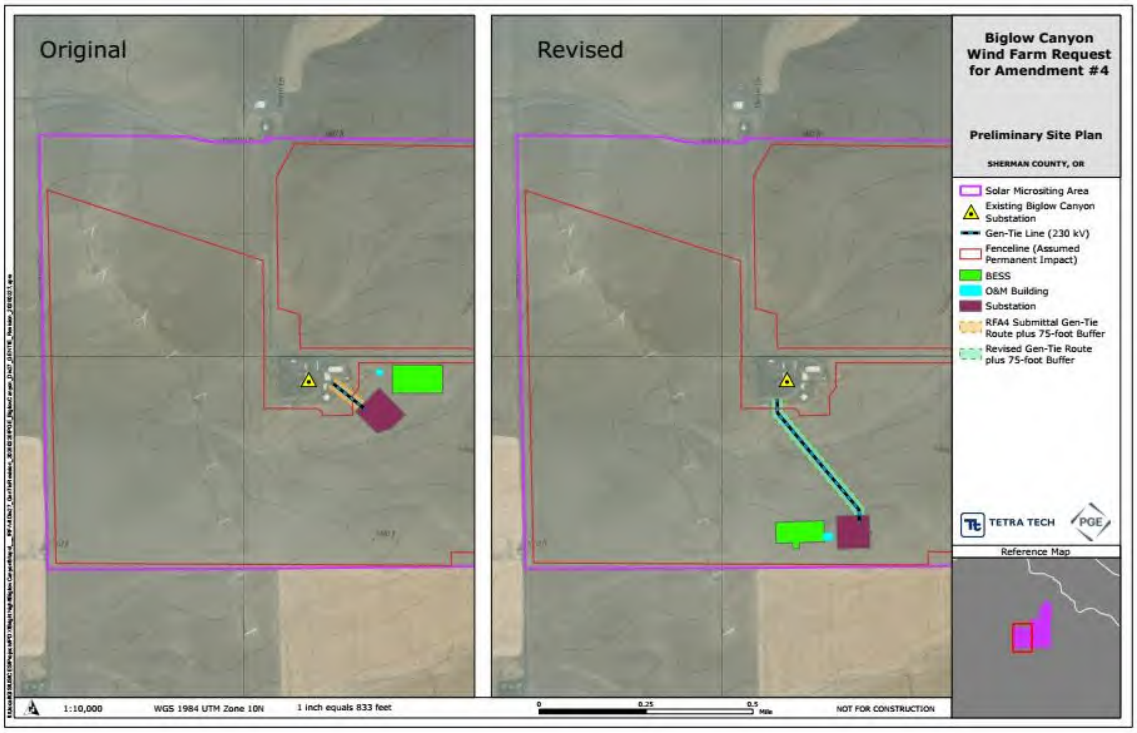
Department Evaluation
Under OAR 345-022-0115(1)(b), the Council must find that a proposed facility will be designed, constructed, and operated in compliance with a Wildfire Mitigation Plan approved by the Council. The rule sets forth the requirements that must be met in the plan. While it is preferred that draft plans for both the construction and operations phases of a facility be included in an application or request for amendment, it is not required by the standard. The Department has described the requirements that must be satisfied in Section III.N of the Proposed Order.

In its responses to this issue, the certificate holder explained that it is developing a site-specific Operational WMP, which will provide any site-specific information outlined in ODOE's Operational WMP template that is not already addressed in PGE's 2026-2028 Corporate WMP which was filed with the Oregon Public Utility Commission on December 31, 2025. The Operational WMP will include the same components as described for the Construction WMP with construction specific actions will be replaced with site-specific operations and maintenance actions. The certificate holder also provided an outline of the Operational WMP with generic examples of information that would be included.
The Department does not recommend any revisions to the draft Final Order based on this comment because the comment has not Identified a specific legal deficiency.
III.I. Siting Standards for Transmission Lines (OAR 340-035-0090)

Issue TL-01 (Certificate Holder); Request for additional flexibility in transmission line siting
Comment ID: BCWAMD4Doc24-08 Proposed Order Public Comment Certificate Holder 2026-01-14
Response ID: BCWAMD4Doc26-01 Proposed Order Public Comment ODOE Responses 2026-02-12
Reply ID: BCWAMD4Doc28-04 Proposed Order Public Comment CH Reply to ODOE 2026-02-28

Comment Summary
Certificate holder requests changes to recommended Amended Condition 119 to provide additional flexibility in transmission line siting, as presented in red underline, strikeout font below:

~~(119) OAR 345-027-0023(5): If the proposed energy facility is a pipeline or a transmission line or has, as a related or supporting facility, a pipeline or transmission line, the Council shall specify an approved corridor in the site certificate and shall allow t~~ The certificate holder ~~to~~ shall construct the ~~pipeline or~~ 230-kV transmission line connecting the Biglow Canyon Substation to the Solar Substation ~~anywhere~~ within a 150-foot corridor, as identified in the final site design ~~presented in Figure 2 of the Amended Site Certificate identified in the final site design the corridor, subject to the conditions of the site certificate. If the applicant has analyzed more than one corridor in its application for a site certificate, the Council may, subject to the Council's standards, approve more than one corridor.~~



Department Evaluation

Under OAR 345-025-0010(5), the Council must specify an approved corridor for any transmission line approved in a site certificate. The Department disagrees with the certificate holder's proposed changes. The certificate holder only included one proposed corridor for the 600-foot segment of 230 kV transmission line in the Request for Amendment, which was presented in RFA4 Figure 2.2.

In its response to this issue the Department notes that if the certificate holder wishes to change the alignment of the transmission line it must present the alternate corridors so that they can be evaluated for compliance with applicable laws, rules and standards.

In its reply, the certificate holder explained that continued engineering evaluation of site conditions and infrastructure layout identified that the original substation site presented constraints relative to the existing infrastructure. Accordingly, a new location for the proposed substation and battery energy storage system (BESS) was identified to avoid low elevation areas, better align with existing infrastructure, and improve constructability, long-term operability, and overall infrastructure resilience. The certificate holder asserts that this refinement reflects prudent final engineering and results in improved consistency, new and existing infrastructure, rather than a change in project scope. Moving the collector substation location results in a corresponding adjustment to the transmission line corridor, with an updated alignment of a 230-kV transmission line approximately 1,900 feet in length, supported by three 80-foot tall steel monopole structures. The figure below shows the new location of the project substation and gen-tie transmission line, all still located within the Solar Micrositing Area.

Figure 1. Original and Revised Collector Substation Location and Transmission Corridor

The newly proposed substation location is within the proposed Solar Micrositing Area and has been fully surveyed and evaluated for all applicable resources and impacts. In addition, there do not appear to be any residences or linear structures that could be inadvertently energized within the refined corridor. Accordingly, the Department recommends the Proposed Order and draft Amended Site Certificate be amended with the revised substation location. Site certificate conditions will require an updated site plan, acoustic modeling, retirement estimate, and other resource studies to be provided prior to construction. **III.J. Noise Control Regulation (OAR 340-035-0035)**

Issue NC-01 (Certificate Holder) Requests Proposed Order Table 26 be revised to add NSR13 and reference to RFA Exhibit Y Table Y-7.
Comment ID: BCWAMD4Doc24-08 Proposed Order Public Comment Certificate Holder 2026-01-14
Response ID: BCWAMD4Doc26-01 Proposed Order Public Comment ODOE Responses 2026-02-12

Comment Summary
Certificate holder requests for Table 26, *Modeled Operational Noise of the Facility, As Amended*, to be revised to include NSR 13, and requests for Table 26 to include Table Y-7 as a source included in the noise modeling.

Department Evaluation
RFA4 Exhibit Y includes Tables Y-6 and Y-7. Both tables include 6 NSRs, including NSR 13. The data from Tables Y-6 and Y-7 are represented in the Proposed Order Table 26, but NSR is omitted and reference to RFA4 Exhibit Y Table Y-7 is also omitted, as indicated by the certificate holder.

Changes to Proposed Order Table 26 will be incorporated into the draft Final Order to be consistent with RFA4 Exhibit Y, as requested by certificate holder.

Issue NC-02 (Certificate Holder) Requests revisions to recommended Noise Control Condition 2 (PRE-NC-02) allowing for general waiver versus solar specific
Comment ID: BCWAMD4Doc24-22 Proposed Order Public Comment Certificate Holder-2 2026-01-30
Response ID: BCWAMD4Doc26-01 Proposed Order Public Comment ODOE Responses 2026-02-12

Comment Summary
Certificate holder requests that Noise Control Condition 2 (PRE-NC-02) be amended to allow any waivers needed to demonstrate compliance be general, rather than specifically reference the solar facility, consistent with the fact that the noise analysis is based on the facility as a whole.

Department Evaluation
As presented in Section IV.A Noise Control Regulation, the existing, operational wind facility relies on noise waivers to comply with the antiambient degradation standard. The addition of the facility components proposed in RFA4 would not change or increase the predicted exceedances of the existing, operational wind facility; however, the facility, as amended, must demonstrate compliance with the regulation (i.e., obligation to have an executed waiver where exceedances occur).

To ensure that the facility maintains compliance but is not obligated to update waivers solely to refer to a wind and solar facility, the Department agrees to modify recommended Noise Control Condition 2, as provided below in red, underline/strikeout, to be able to accept noise waivers that are applicable to the "facility." The intent of the condition is to receive waivers that align with the NSR ID's and property owners with exceedances identified in RFA4 for compliance verification.

> **Recommended Noise Control Condition 2 (PRE-NC-02)**: Prior to construction of the solar facility, the certificate holder must submit to the Department copies of executed legally effective easement(s) or real covenant(s) for all Noise Sensitive Properties impacted by the ~~solar~~ facility with noise exceedance. ~~The easement or covenant must authorize the solar energy facility to increase the ambient statistical noise levels, L10 or L50, on the sensitive property by more than 10 dBA at the appropriate measurement point.~~

[PRE-NC-01; OAR 340-035-0035(1)(b)(B)(iii)~~(III)~~; Final Order on AMD4]

III.K. Water Rights (OAR Ch. 690)

Issue WR-01 (Certificate Holder); Requests Revisions to recommended Amended Water Rights Condition 1 (PRE-WR-01) to Clarify Well Log Submission Timing
Comment ID: BCWAMD4Doc24-08 Proposed Order Public Comment Certificate Holder 2026-01-14
Response ID: BCWAMD4Doc26-01 Proposed Order Public Comment ODOE Responses 2026-02-12

Comment Summary
Certificate holder requests to modify the language of recommended Water Rights Condition 1 (PRE-WR-01) to clarify that the obligation to submit a well leg to Oregon Water Resources Department (OWRD) applies within 30-days of well construction rather than prior to well construction. Certificate holder describes that the requested changes are consistent with ORS 537.765.

Department Evaluation
The Department agrees with the certificate holder as ORS 537.765(2) states:

> *(2) The business or activity of constructing new wells or altering, abandoning or converting existing wells is declared to be a business or activity affecting the public welfare, health and safety. In order to enable the state to protect the welfare, health and safety of its residents, any licensed or permitted person shall keep a log of each well constructed, altered, abandoned or converted and shall electronically file a certified copy of the log with the Water Resources Department within 30 days after the completion of the construction, alteration, abandonment or conversion.*

Based on the above statutory language, in the draft Final Order the Department will include the condition language changes, as presented in red, underline/strikeout font below, as requested.

> **Recommended Water Rights Condition 1 (~~PRE~~CON-WR-01)**
> No later than 30 days after completing construction ~~prior to construction~~ of any new well, the certificate holder shall provide the Department a copy of the map, well log and all other information it provided to OWRD pursuant to ORS 537.545 and ORS 537.765 to qualify for an exempt ground water use for any onsite exempt wells.
> [Final Order on AMD4]

Issue WR-02 (Certificate Holder); Requests Revisions to recommended Amended Condition 75 (OPR-WR-01) on Applicability of Groundwater Usage Monitoring
Comment ID: BCWAMD4Doc24-08 Proposed Order Public Comment Certificate Holder 2026-01-14

Response ID: BCWAMD4Doc26-01 Proposed Order Public Comment ODOE Responses 2026-02-12

Comment Summary
Certificate holder requests for recommended Amended Condition 75 (OPR-WR-01) to be amended to clarify that onsite well usage monitoring will not be required until a new well is installed, at which point meters would be installed.

Department Evaluation
Recommended Amended Condition 75 (OPR-WR-01) is intended to limit onsite well groundwater usage to 5,000 gallons per day and establishes a requirement for daily monitoring and usage recordkeeping. The recommended amended condition requiring use of flow meters to monitor combined water usage is intended to apply if new well(s) are constructed to support construction and operation of the facility components proposed in RFA4. Therefore, the Department agrees with the certificate holder and recommends that the applicability of the monitoring requirements be clarified. In the draft Final Order, the Department will include the condition language changes, as presented in red, underlined font below.

Recommended Amended Condition 75 (OPR-WR-01)

a. For any onsite exempt wells, ~~Before beginning operation of the facility, the certificate holder shall have in operation a well suitable for delivering water,~~ combined water usage shall not exceed~~ing~~ 5,000 gallons per day~~,~~ for domestic use at the facility's O&M buildings and~~, provided the rate of extraction would not exceed 5,000 gallons per day,~~ solar panel and blade-washing activities.
b. If new exempt well(s) are constructed for the solar facility, certificate holder shall install flow meters on the existing and new well(s); monitor the volume of groundwater used from all onsite wells on a daily basis; maintain a record of such use; and, make the monitoring records available to the Department upon request. ~~The certificate holder shall not change the source of water for the facility's domestic use without prior Council approval.~~

[Final Order on AMD4]

Issue WR-03 (Certificate Holder); Requests Revisions to recommended Amended Condition 75 (OPR-WR-01) on Applicability of 5,000 gallon/day limit
Comment ID: BCWAMD4Doc24-22 Proposed Order Public Comment Certificate Holder-2 2026-01-30
Response ID: BCWAMD4Doc26-01 Proposed Order Public Comment ODOE Responses 2026-02-12

Comment Summary
Certificate holder seeks clarification that the 5,000 gallon per day limitation on groundwater usage only applies to onsite exempt wells.

Department Evaluation

The Department confirms that recommended Amended Condition 74 (OPR-WR-01) is only applicable to exempt wells. In the draft Final Order, the Department will add reference to "exempt wells" to the condition, as presented in the Department Evaluation of Issue WR-02.

Table 1: Council Imposed Requirements

Summary	Timing	Requirement
Prior to Operations - Plan Finalization		
Action Based Plan	This plan shall be finalized based on actions that can be monitored, tracked, and recorded. Detailed narrative or explanation that is not a specific action must be removed. Filter for clarity and remove unnecessary high-level narrative.	
Qualifications and Contact Information	In the Plan: Include the contact information for: 1. The individuals that will manage and oversee vendors and contractors. 2. The individuals that will perform design-phase safety reviews. Evidence to Support Plan Review: Certificate must provide to the Department the names, contact information and qualifications of the individuals that will manage and oversee vendors and contractors; and of the individuals that will perform design-phase safety reviews. The Department may request additional information or justification for any individuals where the experience or qualifications is inadequate.	
Incorporation of requirements/citations from applicable site certificate conditions, protocols and technical plans	In the Plan: Identify all technical and site management plans applicable to operations and compliance for the solar components; incorporate relevant action items into the plan. At a minimum, the plan must reference and incorporate the Emergency Operations Responses Plan, Operational Spill Prevention Control and Countermeasure Plan, Operational Wildlife Mitigation Plan, and Comprehensive Revegetation, Noxious Weed and Soil Reclamation Plan.	
Inspection and maintenance	In the Plan: Identify all inspections and maintenance activities, schedule, protocol and inspection documentation format. Evidence to Support Plan Review: Provide documentation to be used to track maintenance and inspection activities. If information will be tracked via software, explain, demonstrate and provide available data.	
Vendor Performance Scoring System	In the Plan: The final plan shall include details about the certificate holder's vendor performance scoring system. The scoring system must, at a minimum, evaluate vendor response time, corrective maintenance scoring rates and inspection completion.	
Operations and Maintenance Budget	In the Plan: The final plan shall include a section for Operations and Maintenance Budget Tracking, including but not limited to, a summary of the basis for the amount estimated in the initial maintenance reserve, and an	

Tracking and Forecasting	explanation of the 5-year life cycle cost modeling. The plan shall include information about the estimated and available budget. Future plan updates must include 5-year life cycle cost modeling results.
Third-Party O&M Budget Audit	In the Plan: The final plan shall include information about annual third-party condition assessments, and ensure that the scope of the assessment includes annual review of vendor/contractor performance against warranty and reliability benchmarks.
Build Transfer Agreement	Evidence to Support Plan Review: Provide a copy of the executed Build Transfer Agreement (BTA). Confidential terms and conditions, unrelated to the roles, responsibilities, oversight and control of the certificate holder, third-parties, site certificate and facility, may be redacted from the executed BTA provided to the Department.
Community Outreach	In the Plan: The final plan shall include names and addresses of participating landowners, and shall detail the schedule, agenda and outreach efforts for annual coordination meetings, to be conducted by the certificate holder. The final plan shall require that the certificate holder invite Sherman County emergency responders and ODOE to each annual meeting. The plan shall require minutes from each meeting. Any issues will be tracked and evaluated to determine the appropriate response.
Reporting	In the Plan: Require reporting to the Department of the following: 1. Within 72-hours of a change in contractors, vendors or contract terms, report the change, the reasons for the change, and the identification, contact information and qualifications to the Department. 2. Monthly, report to the Department a summary of performance monitoring results (Vendor Performance Scoring System), including identification of any significant performance issues and corrective actions taken by or for the participating entity, contractor(s) and vendor(s). Certificate holder shall identify corrective actions, including stop work or removal from site, required of the vendor(s) for any performance scores less than 95% percent on-time inspection and repair completion rate. 3. Annually, provide to the Department a written report from a third-party contractor evaluating whether the established or forecasted operations and maintenance budget is adequate for site operations. 4. Annually, provide the agenda, attendees list and meeting minutes from the community outreach meetings. Certificate holder shall report any issues identified at the meeting and shall provide their response and/or resolution of the identified issue.

1.0 Introduction

This draft outline of the Operations and Maintenance (O&M) Plan for the amended Biglow Canyon Wind Farm (BCWF) integrates the Solar Components as identified in the BCWF Request for Amendment 4 (RFA 4) into the existing wind facility. It has been jointly developed by Portland General Electric Company (PGE; the Certificate Holder) and BIGL bn, LLC (BIGL), a subsidiary of BrightNight, LLC, to establish the preliminary framework for how the Solar Components of the Amended BCWF will be operated, maintained, and managed in compliance with the Site Certificate and applicable regulatory standards.

This O&M Plan applies exclusively to the Solar Components and associated infrastructure introduced through the BCWF RFA 4. It does not govern the O&M of the existing wind energy infrastructure, which continues to be managed under the previously coordinated PGE Operational Safety Monitoring Program. The O&M Plan reflects lessons learned from legacy wind operations at BCWF and current best practices for utility-scale solar and storage projects.

The O&M Plan framework described in Section 3.0 outlines the structure of operational responsibilities, long-term maintenance protocols, quality assurance processes, environmental compliance measures, and integration with emergency response and monitoring systems. The Certificate Holder will provide an O&M Plan that will use this framework to further detail the specific actions required to operate and maintain the Solar Components. The final O&M plan will be submitted to the Oregon Department of Energy (ODOE) prior to the start of operation of the Solar Components.

The final O&M Plan will reference and incorporate several other technical and site management plans relevant to operations and compliance for the Solar Components at the amended BCWF. These include, but are not limited to, the following plans developed for the BCWF RFA 4:

- The standalone Emergency Operations Response Plan (EOP) specific to solar and battery energy storage system (BESS) components;
- The Construction-phase Wildfire Mitigation Plan (WMP) and the Operations-phase WMP, which outline prevention and response protocols for wildfire risk during all project phases;
- The Comprehensive Solar Revegetation and Soil Management Plan, which details vegetation establishment, monitoring, and long-term maintenance;
- The Dust Abatement Plan, which governs dust control measures during both construction and operations; and
- Other resource-specific plans (e.g., the Decommissioning Plan, Spill Prevention and Control protocols) as required by the Site Certificate.

These documents will be cross-referenced with the final O&M Plan to ensure consistent implementation and clarity of responsibilities. The final O&M Plan will remain a living document, subject to regular review and revision in response to design changes, regulatory updates, and lessons learned during implementation.

2.0 Facility Partnership: Roles and Responsibilities

The Amended BCWF reflects a project delivery model that combines PGE's regulatory responsibility and long-term ownership with development and technical execution support from BIGL. This structure is designed to ensure compliance with Site Certificate conditions while leveraging external technical expertise to deliver the proposed Solar Components efficiently and to current industry standards.

PGE, as the Certificate Holder, retains ultimate oversight and responsibility for the Amended BCWF, including the Solar Components as outlined in RFA 4. BIGL has been engaged to support the initial development and construction of these components under a Build Transfer Agreement and will also provide O&M services for a minimum of the first 5 years of project operation. This approach allows for continuity between construction and early stage operation, while ensuring that all long-term operational accountability remains with PGE.

BrightNight and its subsidiary BIGL will implement a long-term O&M strategy grounded in industry best practices, internal experience, and a robust safety-first culture. While specific vendors have not yet been selected, BrightNight's team draws on a strong national track record in solar and battery storage project delivery and management. The Solar Components of the Amended BCWF will be supported by comprehensive O&M protocols that include scheduled preventive maintenance, real-time monitoring, remote diagnostics, and rapid response to equipment issues. BrightNight's O&M program, which emphasizes cradle-to-grave execution, 24/7 visibility into system performance, and continuous learning, will guide all operational phases. Quality assurance will be embedded through stringent contracting standards, rigorous design-phase safety reviews, and direct oversight by experienced internal personnel. Over the first 5 years of the project, BIGL will manage an experienced third-party O&M provided who will serve as the primary entity responsible for day-to-day maintenance and performance monitoring, while PGE's role will be defined in coordination with project milestones, interconnection requirements, NERC compliance, and long-term asset management planning.

BrightNight is committed to working in partnership with qualified local vendors whenever possible, fostering regional economic benefits and ensuring on-the-ground responsiveness throughout the project's operational life. All third-party vendors, whether local or national, will be selected through a rigorous procurement process that evaluates technical qualifications, safety performance, environmental compliance, and proven experience with utility-scale solar and storage facilities. Selected vendors will be required to adhere to industry best practices, such as:

- Implementing detailed preventive maintenance schedules,
- Providing trained and certified personnel,
- Using real-time monitoring and fault detection systems,
- Following all original equipment manufacturers' maintenance and service guidelines,
- Maintaining transparent documentation and reporting protocols,
- Using digital maintenance management systems,
- Conducting regular quality assurance/quality control (QA/QC) inspections,

- Establishing clear escalation procedures for unplanned outages, and
- Participating in site-specific safety trainings and continuous improvement processes.

BrightNight is also acutely aware of the community concerns stemming from historical O&M challenges at the BCWF. Based on conversations with local stakeholders, a key feature of the O&M strategy, though not highly technical, demonstrates the commitment to maintaining consistent communication with community members over the life of the BCWF Solar Components. The Project Developer and Certificate Holder will provide direct contact information and conduct regular check-ins to ensure residents feel empowered to raise questions or concerns. Any issues brought forward will be relayed promptly to the appropriate O&M teams for timely response and resolution. While BrightNight and PGE do not anticipate concerns of this nature, we believe creating a clear, accessible escalation path is an important part of building lasting community trust.

This structured approach ensures that any vendor engaged in the Amended BCWF will operate with the same high standards of safety, reliability, and performance that define BrightNight's operational philosophy.

This partnership structure does not alter the Certificate Holder's regulatory obligations or diminish its responsibility for compliance with the Energy Facility Siting Council (EFSC) and other applicable state and federal requirements. Rather, it provides a defined and managed pathway for project delivery that integrates third-party expertise into a framework that remains under PGE's control. Any third-party permits associated with construction activities will be secured through BIGL or its contractors but will be limited to standard, project-level requirements (e.g., encroachment, transport, building permits) and do not change the scope or structure of the existing site certificate.

Overall, the division of responsibilities between PGE and BIGL maintains clear regulatory accountability while enabling technically competent execution of the amended facility. This model is consistent with industry practices for utility-owned renewable infrastructure and is expected to support a timely and orderly expansion of the BCWF site in accordance with certificate conditions.

3.0 Integrated Operations and Maintenance Plan Framework

The Certificate Holder will submit a final version of the O&M Plan to ODOE prior to the commencement of operations. This Plan is intended to meet regulatory obligations, and to serve as the foundational framework guiding day-to-day operations of the Solar Components at the Amended BCWF.

To ensure consistency between compliance documentation and real-world implementation, the Plan will be updated as needed to fully incorporate the procedures, protocols, and tools adopted by the selected long-term O&M service provider. This integrated approach is designed to maintain a single, authoritative document that governs both regulatory compliance and operational execution, which eliminates the risk of conflicting or duplicative guidance.

3.1 Purpose and Applicability

The framework described in this section outlines the intended procedures for managing and maintaining the Solar Components of the Amended BCWF. It incorporates requirements from the Site Certificate, applicable codes, and protocols from the EOP, Decommissioning Plan, and supporting exhibits. This Plan applies to the Certificate Holder, BIGL, its contractors, and subcontractors. The final O&M Plan will be a living document. It shall be reviewed annually and revised in coordination with design changes, operational updates, or regulatory amendments.

3.2 Facility Description and Roles

The Amended BCWF includes legacy wind infrastructure and new solar photovoltaic (PV) and BESS systems. These additions are constructed under a Build Transfer Agreement by BIGL, with PGE retaining long-term ownership and regulatory oversight as the Certificate Holder.

- The facility will have three FTE onsite employees, two techs and a BIGL O&M Managemer; operations also rely on remote supervisory control and data acquisition (SCADA) systems.
- Initial O&M management services for solar and BESS components will be performed by BIGL for 5 years.

3.3 Design and Equipment Selection

The Certificate Holder and BIGL are going through the design and equipment selection process. During final design, PGE will consider all solar technologies available to ensure the most efficient and productive solar array layout and BESS equipment. The final O&M plan will incorporate O&M activities specific to the equipment selected, based on the manufacturers' instructions.

3.4 Preventative Maintenance and Asset Monitoring

BIGL or the Certificate Holder will identify preventative maintenance measures and supporting equipment monitoring efforts to ensure safe and reliable operation of the facility.

3.4.1 Substation

- Thermal imaging for termination and buswork
- Visual inspection of structure foundation and conduit
- Lubrication of moving parts (breakers, switches, etc.)
- Cooling system checks
- Control room inspections visual and tests
- Label and nameplate check
- Vegetation management

3.4.2 PV System

- Routine module inspections and annual infrared/aerial thermal imaging: Anomalies detected will generate corrective work orders within 48 hours and will be addressed according to level of severity; otherwise, as soon as reasonably possible and according to the final Operations and Maintenance Plan

- Routine SCADA monitoring and data analysis: Anomalies detected will generate corrective work orders within 48 hours and will be addressed according to level of severity; otherwise, as soon as reasonably possible and according to the final O&M Plan.
- Torque checks per manufacturers recommendations
- Panel washing with water use logs (per Exhibit O limits)
- Visual inspection of inverters, combiner boxes or load break disconnects, trackers, and all major equipment according to manufacturer's recommendation
- Vegetation management

3.4.3 BESS

- Quarterly infrared inspections of power conversion system units,
- Inspections of heating, ventilation, and air conditioning, battery management system (BMS), and fire suppression systems
- SCADA/BMS remote monitoring for anomalies
- Response procedures tied to EOP protocols for thermal runaway (EOP Section 3.2.1)
- Vegetation management

3.5 Compliance, Controls, and Reporting

The Certificate Holder will implement O&M practices that support compliance with applicable regulatory requirements and Site Certificate conditions. This will include operational controls, oversight procedures, and alignment with supporting plans that address vegetation management, spill prevention, wildfire mitigation, air and water quality, and other environmental and safety considerations.

Compliance measures will be scaled to site activities and updated as operations evolve. Documentation of inspections, incidents, and maintenance activities will be maintained. Reporting will follow applicable requirements and timeframes outlined in the Site Certificate and coordinating agency permits.

This section will be updated in the final O&M Plan to reflect specific commitments based on Site Certificate conditions and reporting requirements identified by ODOE and coordinating agencies. The final version will define required reporting content, frequencies, responsible parties, and coordination procedures to demonstrate ongoing compliance.

3.6 Emergency Preparedness Integration

The Certificate Holder will take the following actions to address emergency preparedness:

- Inspect and test all safety equipment.
- Review and update the EOP regularly, and ensure all personnel are fully trained in emergency response.
- Perform all Spill Prevention, Control, and Countermeasure Plan requirements, including maintaining spill kits.

- Develop and maintain a Hazardous Materials Management Plan if required by state or federal regulations.
- If applicable, prepare and maintain an Emergency Planning and Community Right-to-Know Act (EPCRA) Tier I or II form, plus a list and quantities of chemicals that exceed reporting thresholds for EPCRA Tier 2.
- Conduct an audit that includes a review of site compliance with the facility's safety program and onsite observation for proper implementation of safety policies, including Lock Out-Tag Out, and a review of the facility's safety program and any recommended revisions.
- Perform a root cause analysis, corrective actions taken, and recommended corrective work related to injuries or illness requiring medical attention other than first aid, injuries or illness requiring restricted duty or days away from work, or a fatality.
- Notify the operator as soon as possible, not to exceed 1 hour, of any of the following events:
    1) Emergency responders contacted for an emergency or law enforcement response.
    2) Injury on site requiring medical attention more than first aid.
    3) Unplanned outage of one or more medium-voltage (MV) collection or high-voltage circuits.
    4) Onsite fire.
    5) Conditions that necessitate an evacuation of onsite personnel.
    6) Awareness of an impending weather event that has a reasonable probability of causing significant damage or any of the preceding 1) through 5) events.

3.7 Contractor and Staff Oversight

BrightNight, on behalf of PGE, will oversee and facilitate the O&M of the BCWF Solar Components with an O&M service provider experienced in operating and maintaining large-scale PV solar systems and balance-of-plant systems for a large-scale BESS. There will be a long-term service agreement with the Solar Component BESS supplier. The O&M service provider will be responsible for the operation of the Solar Components, maintenance of the PV solar system to the point of interconnection, and maintenance of equipment/circuits from the BESS inverter AC output terminals to the point of interconnection. The O&M service provider's scope will cover equipment, including the PV array, PV system inverters, low-voltage cables, MV transformers (including auxiliary transformers), MV feeders, MV switchgear, site meters, and the O&M building equipment. PGE will perform maintenance on the substation
equipment and gen-tie line.

4.0 Long-term Maintenance and Operational Continuity

To support the proposed 40-year operational life of the Solar Components, the Certificate Holder has developed a long-term maintenance and operations framework that evolves over time and ensures continuous compliance with site certificate conditions.

Years 1–5: BIGL will lead O&M activities under the Build Transfer Agreement. The O&M service provider will have full responsibility for inspections, corrective maintenance, and

warranty compliance. BIGL's scope will also include preventive maintenance scheduling and vendor oversight.

Post-Year 5: PGE will assume full O&M responsibilities, integrating solar and BESS oversight into its internal asset management systems. This transition will be guided by a detailed handover plan including training, document transfer, and performance reviews conducted in Year 4.

Continuity of Practice: Regardless of ownership stage, O&M will be conducted in accordance with procedures established in this document, including vendor management, EOP training, and incident reporting protocols. Performance metrics and component reliability will be tracked in PGE's asset management software and reviewed annually.

4.1 Personnel and Quality Assurance Oversight

The Amended BCWF will be supported by experienced operations personnel through all phases of its operating life.

Operations Roles:

- SCADA/Performance Analyst
- Field Technician Team (PV/BESS certified)
- Asset Manager (PGE)
- QA/QC Lead (during and post-handoff)

Quality Assurance Protocols:

- Annual third-party condition assessments (PV and BESS)
- Annual SCADA data audit for performance anomalies
- Compliance inspections linked to EOP protocols
- Maintenance records retained and reviewed for trends

4.2 Budget Planning and Lifecycle Management

PGE will incorporate the solar and BESS components into its existing capital planning processes. The following measures support financial assurance and long-term reliability:

- Maintenance Budgeting:
  - O&M budgets for the first 5 years are embedded in the Build Transfer Agreement.
  - Post-transfer, expenses are forecasted annually by the Asset Management Team and tracked against site-specific performance.
- Lifecycle Planning:
  - A major maintenance reserve will be included in financial modeling to support inverter replacement, battery module refresh (anticipated at 12–15 years), and other long-term needs.
  - PGE's decommissioning cost estimates (Exhibit X) will be updated every 5 years to reflect equipment aging and market conditions.

5.0 Plan Updates and Reporting

The O&M Plan shall be reviewed and revised annually, if applicable, by the certificate holder based on design changes, operational updates, or regulatory changes; and to incorporate the procedures, protocols, and tools adopted by the selected long-term O&M service provider. All changes are subject to review and approval by the Department.

Comprehensive Plan	Comprehensive Solar Revegetation and Soil Management Plan
County	Sherman County
EFSC	Energy Facility Siting Council
EMC	Environmental Monitoring Contractor
EPC	Engineering, Procurement, and Construction Contractor
NOT	Notice of Termination
NPDES	National Pollutant Discharge Elimination System
ODOE	Oregon Department of Energy
PGE or Certificate Holder	Portland General Electric Company
RC	Revegetation Contractor
RFA	Request for Amendment
WC	Weed Control Contractor

1.0 Introduction

This Comprehensive Solar Revegetation and Soil Management Plan (Comprehensive Plan) has been prepared by Portland General Electric Company (PGE or Certificate Holder) to serve as a primary source of commitments related to revegetation, soil management, dust control, stormwater management, and noxious weed control through the pre-construction, construction, and operations phases for the photovoltaic solar energy generation and battery storage (Solar Components) associated with Request for Amendment (RFA) 4 of the Site Certificate for the Biglow Canyon Wind Farm (BCWF or Facility). PGE will own and operate the Solar Components as a part of the BCWF (together, Amended Facility or Facility), which, to date, have been developed by BIGL bn, LLC (BIGL or Project Developer). BIGL, in its capacity as the project developer, supports PGE in this RFA 4 and may construct and temporarily operate the Solar Components on behalf of PGE under a Build-Transfer Agreement.

For ease of implementation and compliance tracking, this document is structured to identify actionable items by phase and typical sequencing within each phase, with additional details provided as appendices and/or incorporated by reference.

This Comprehensive Plan will be updated, as necessary, in coordination with the Oregon Department of Energy (ODOE) and applicable agencies as specified below prior to construction to reflect the final layout of the Solar Components and additional details only available once an Engineering, Procurement, and Construction Contractor (EPC) has been identified.

1.1 Plan Finalization

Table 1 identifies information that must be incorporated into the Comprehensive Plan before beginning any phase of construction.

Table 1. Action Items for Plan Finalization

Action	Timeframe	Implemented By	Review/ Verification
Notify Department of identity of EMC, EPC, RC, and WC. Provide evidence that each contractor meets the minimum qualifications described in Appendix A.	Plan Finalization	Certificate Holder	ODOE
Update Appendix A, Table A-1 with name and contact information for each contractor.	Plan Finalization	Certificate Holder	ODOE
Update Section 6.0, Table 5 with operations long-term vegetation management details from Public Utility Commission (PUC)-approved vegetation management plan, including monitoring for Wildfire Management Plan vegetation criteria.	Prior to Operations	EMC	ODOE
Update Appendix B, Table B-1 with temporary and permanent disturbance acres by habitat subtype.	Plan Finalization	EMC	ODOE

Action	Timeframe	Implemented By	Review/ Verification
Update Appendix B with a Construction Plan and maps based on final design, expected disturbance levels, and sequencing of construction.	Plan Finalization	EMC	ODOE, ODA, ODFW, County
Update Appendix C with approved National Pollutant Discharge Elimination System (NODES) 1200-C permit and Erosion and Sediment Control Plan (ESCP). Incorporate all stormwater control and treatment best management practices (BMPs) required by the 1200-C permit, and any supplemental BMPs required by this Comprehensive Plan, into ESCP.	Plan Finalization	EPC	ODOE
Update Appendix D with construction dust control measures. Include contact information and procedures for Dust Control Hotline	Plan Finalization	EPC	ODOE
Update Appendix E with proposed baseline soil compaction sample locations.	Plan Finalization	Certificate Holder	ODOE
Update Appendix F with Final Revegetation methods, as needed, for both temporary and permanent disturbance areas in consultation with ODOE	Plan Finalization	EMC	ODOE
Update Appendix G with timing and treatment methods for each identified weed species of concern after consulting with the Sherman County Weed District.	Plan Finalization	WC & EMC	ODOE and County
Update Appendix G with final noxious weed and vegetation monitoring methods.	Plan Finalization	EMC	ODOE
Notes: EMC = Environmental Monitoring Contractor; EPC = Engineering, Procurement, and Construction Contractor; ODOE = Oregon Department of Energy; WC = Weed Control Contractor; County = Sherman County			

2.0 Definitions

Definitions applicable to this Comprehensive Plan are provided in Table 2, below.

Table 2. Definitions for the Biglow Canyon Wind Farm

Term	Definition
BCWF; Facility	Biglow Canyon Wind Farm
Habitat Areas	Any undeveloped, non-agricultural areas, including but not limited to areas mapped as grassland, sagebrush shrub-steppe, or riparian habitat, prior to construction of the Solar Components.
Permanent Disturbance Area	Any area permanently occupied by the Solar Components, including all areas within the fence line of a solar array or substation.
Sensitive Soils	Soils that are highly susceptible to erosion from water, fugitive dust propagation, compaction, or other impacts as described in Appendix E.

Term	Definition
Solar Components	Photovoltaic solar energy generation, battery storage, and other components authorized in RFA 4.
Solar Micrositing Area/ RFA 4 Site Boundary	Maximum area where Solar Components may be built or cause temporary disturbance.
Temporary Disturbance Area	Any area that is disturbed during construction of the Solar Components but will not be permanently occupied during operations.
Weed Management Area	Disturbance area associated with the Solar Components and a 10-foot buffer.

3.0 Plan Goals and Management Objectives

This Comprehensive Plan was developed to demonstrate compliance with the terms and conditions of the Site Certificate and other applicable state and local laws and regulations. Specifically, the actions described in this Comprehensive Plan are intended to increase the probability of revegetation success, reduce erosion and dust pollution, protect topsoil for future agricultural use on agricultural land, prevent and address the establishment and spread of noxious weeds, minimize fire risk, and maintain beneficial vegetation at the site.

The BCWF is located on privately owned agricultural land used primarily for dryland wheat production and, to a lesser extent, cattle grazing. The grazed land is grassland, shrub-steppe rangeland, and/or fallow wheat stubble fields. The Solar Micrositing Area also contains important wildlife habitat and movement corridors, particularly along the John Day River and its tributaries. Sensitive soils are present throughout the Solar Micrositing Area, and erosion hazards from wind and water are severe in areas with steep slopes, including canyons and drainages in the northeast portion. To ensure that the area can be restored adequately to a useful, non-hazardous condition following permanent cessation of construction or operation of the Solar Components, Permanent Disturbance Areas in wildlife habitat will be revegetated for the purposes of soil stabilization to reduce erosion, dust pollution, topsoil depletion, and the potential for invasion by noxious weeds and other invasive plants. Cropland in the Solar Micrositing Area will be returned to landowner control and will not be revegetated by the Certificate Holder.

To minimize impacts to agricultural uses and habitat in Temporary Disturbance Areas, soil disturbance and vegetation removal will be minimized and reasonable efforts will be made to restore vegetation and soils in agricultural and habitat areas to their pre-disturbance condition. Best Management Practices (BMPs) will be implemented to minimize erosion and prevent the introduction or spread of noxious weeds and other invasive plants in both habitat areas and temporarily disturbed developed areas (i.e., existing roads, rock quarries).

4.0 Pre-construction Compliance

Table 3 outlines actions related to revegetation, soil management, dust control, stormwater management, and noxious weed control that must be completed before beginning construction.

Table 3. Pre-construction Compliance Checklist

Action	Timeframe	Implemented By	Review/ Verification
Provide Final Comprehensive Plan to all participating parties.	At least 30 days prior to construction	Certificate Holder	ODOE
Hold a kick-off meeting with the EMC, EPC, County, and ODOE.	At least 14 days prior to construction.	Certificate Holder	ODOE
Collect baseline soil compaction measurements within all anticipated Level 3 and 4 Disturbance Areas described in Appendix B using the protocol described in Appendix E. Submit baseline soil compaction measurement results to ODOE.	Prior to construction	EMC	ODOE
Complete installation of stormwater, erosion, and sediment controls as required by the 1200-C permit. See Appendix C.	Prior to construction	EPC	ODOE
Coordinate the construction schedule and sequence with landowners to maintain land in current production and weed control until the last growing season prior to construction.	Prior to construction	Certificate Holder	ODOE
Conduct on-site Environmental Training with contractors, construction personnel, and environmental inspector(s), inviting specialty contractors, Oregon Department of Agriculture (ODA), Oregon Department of Fish and Wildlife (ODFW), the County, and ODOE. The training must cover all aspects of this Comprehensive Plan and other requirements applicable to construction, including but not limited to: • Roles and responsibilities • Implementation of avoidance buffers for sensitive resources (e.g., flagging) • Methods for identifying and preventing the spread of noxious and invasive weeds • BMPs for soil protection and erosion control under the 1200-C Permit. • Fire prevention practices during construction	Prior to construction	Certificate Holder	ODOE
Provide records demonstrating that all contractor personnel have attended on-site Environmental Training described above.	Prior to construction	Certificate Holder	ODOE
Conduct additional pre-construction noxious weed surveys to identify noxious weeds present within the Solar Components at the time of construction to inform management.	Prior to construction	EMC	ODOE
Provide the Appendix G Weed Control Plan to the Sherman County Weed District for review and concurrence with treatment guidelines.	Prior to construction	Certificate Holder	ODOE
Treat noxious weeds within the Weed Management Area in accordance with methods in Appendix G.	Prior to construction	WC	ODOE

Action	Timeframe	Implemented By	Review/ Verification
Provide evidence that existing noxious weeds have been identified and treated in accordance with methods in Appendix G.	Prior to construction	Certificate Holder	ODOE
Notes: County = Sherman County; EMC = Environmental Monitoring Contractor; EPC = Engineering, Procurement, and Construction Contractor; ODOE = Oregon Department of Energy; RC = Revegetation Contractor; WC = Weed Control Contractor			

5.0 Construction Compliance

Table 4 outlines actions needed for compliance during construction related to revegetation, soil management, dust control, stormwater management, and noxious weed control.

This list includes actions applicable throughout construction as well as actions required as construction nears completion and revegetation commences in preparation for entering the operations phase.

Table 4. Construction Compliance Checklist

Action	Timeframe	Responsible Party	Review/ Verification
During Construction Mobilization			
Provide information about target noxious weed species at the operations and maintenance buildings.	During construction	EPC	EMC & ODOE
Ensure a copy of this Comprehensive Plan and a description of any additional fugitive dust control requirements are available on site.	During construction	EPC	EMC & ODOE
Prominently display Dust Control Hotline signs, providing direct access to the Certificate Holder Site Manager.	During construction	EPC	EMC & ODOE
Flag sensitive environmental resources (e.g., historic, cultural and archaeological resources; active raptor nests; delineated wetlands and waterways) and noxious weed infestations to alert construction personnel of avoidance areas or management requirements.	During construction	EMC	ODOE
During Ground-Disturbing Activities			
On or before April 15 of any year in which construction occurs within Category 2 habitat, all mowing, vegetation removal and/or ground disturbance associated with site preparation must be completed. No mowing, vegetation removal and/or ground disturbance associated with site preparation may occur within Category 2 habitat between April 15 through September 1.	During construction within Category 2 habitat	EPC, Certificate Holder	EMC & ODOE
In Disturbance Level 3, 4, and 5 areas (described in Appendix B), stockpile excavated soils by soil horizon to replace in the same order and prevent mixing of topsoil and subsoils. Put conserved topsoil back in place prior to revegetation activities.	During construction	EPC	EMC & ODOE
Do not move topsoil and other soils from areas with noxious weeds to areas without noxious weeds; instead, return these soils to their previous location during reclamation activities to reduce the transport of weed seeds, roots, or rhizomes.	During construction	EPC	EMC & ODOE
Use appropriate erosion and sediment control practices, as required by the NPDES 1200-C permit (Appendix C).	During construction	EPC	EMC & ODOE
Limit vehicle access to designated routes, whether existing roads or newly constructed roads, and the outer limits of construction disturbances per the final design for the Solar Components; limit vehicle traffic in areas with noxious weeds.	During construction	EPC	EMC & ODOE
Require construction vehicles to pass through a wheel wash station at vehicle ingress/egress points each time they enter or exit the Solar Components.	During construction	EPC	EMC & ODOE

Action	Timeframe	Responsible Party	Review/ Verification
Clean vehicles and equipment associated with ground disturbance and movement of topsoil utilizing a mobile wash station after performing work in areas with noxious weeds and prior to performing work in areas without noxious weeds.	During construction	EPC	EMC & ODOE
Implement appropriate BMPs to control any dust generated by construction activities, such as applying water or stabilizers to roads and disturbed soil areas.	During construction	EPC	EMC & ODOE
Maintain records of U.S. Environmental Protection Agency (EPA) Method 22 (ODEQ 2019) monitoring.	During construction	EPC	EMC & ODOE
After grading is complete but prior to installation of Solar Components, apply temporary or permanent soil stabilization, as described in Appendix F.	During construction	RC	EMC & ODOE
Monitor the Weed Management Area for noxious weeds during and after construction and implement control measures as described in Appendix G.	During and following construction	EMC & Certificate Holder	ODOE
Conduct compliance monitoring to ensure that contractors are complying with noxious weed prevention measures in this Comprehensive Plan. Facilitate coordination meetings with ODOE and Sherman County Weed District, train all personnel to maintain tracking sheets, conduct routine check-in calls with the construction team, and document communication with landowners prior to chemical application. Maintain records and provide ODOE with copies of these records annually during construction. If the Certificate Holder contracts with the Sherman County Weed District to perform weed control at the Solar Components, then monitoring records will include a statement that the county agency performed the work.	During construction	EMC	ODOE
If construction extends into the growing season prior to the commercial date of operations and formal post-construction weed monitoring, conduct informal but comprehensive weed surveys to inform adaptive management. Weed monitoring may be conducted as part of routine environmental monitoring to be completed at least monthly from April to October.	During construction	EMC	ODOE
Soil Stabilization and Reclamation			
Coordinate with the landowner or farm operator to identify the preferred approach for soil stabilization on agricultural land until routine seeding and tillage resumes. Soil stabilization may include applying unseeded hydromulch or crimping in weed-free straw until seeding can occur. Landowner may choose to assume responsibility for soil stabilization. Agricultural lands will be restored to landowner satisfaction.	During and following construction	Certificate Holder	EMC & ODOE

Action	Timeframe	Responsible Party	Review/ Verification
Meet with ODOE in coordination with ODFW and Sherman County Weed District to review the actual extent and conditions of disturbed areas and confirm the revegetation methods to be implemented.	After each phase of construction is complete and before revegetation	Certificate Holder	ODOE
In areas with noxious weeds where soil was removed, return soils to their previous location during reclamation activities to reduce transport of weed seeds, roots, or rhizomes.	During reclamation	EPC	EMC & ODOE
Treat noxious weeds in the Weed Management Area using methods described in Appendix G and in consultation with the Sherman County Weed District as necessary. No weed treatment will occur in agricultural lands without landowner permission.	Before reclamation and revegetation	WC	EMC & ODOE
Decompact soil by mechanical scarification (tilling or ripping the soil) to an appropriate depth as described in Appendix F. Soil amendment, such as addition of organic matter (compost), may also be necessary to alleviate compaction.	Prior to revegetation	EPC	EMC & ODOE
Complete post-construction soil compaction testing in spring or late fall in accordance with Appendix E. Submit results to ODOE for review and approval.	After reclamation and before revegetation	EMC & Certificate Holder	ODOE
Perform soil preparation prior to seeding using methods described in Appendix F.	Before revegetation	EPC	EMC & ODOE
Prevent conditions favorable for noxious weed germination by revegetating as soon as practicable.	After reclamation	RC	ODOE
Revegetation of Permanent Disturbance Areas			
Following completion of construction phases, seed undeveloped permanent disturbance areas in accordance with methods described in Appendix F.	During revegetation	RC	EMC & ODOE
Revegetation of Agricultural Temporary Disturbance Areas			
Coordinate with the landowner or farm operator to identify the preferred approach for revegetating agricultural land. Landowner may choose to assume responsibility for revegetation. Agricultural lands will be restored to landowner satisfaction.	During revegetation, following each construction phase	Certificate Holder, EPC	EMC & ODOE
Report to ODOE on the success of agricultural land restoration efforts; provide evidence that landowner or farm operator is satisfied with restoration.	During & following construction	Certificate Holder	EMC & ODOE
Revegetation of Non-Agricultural Temporary Disturbance Areas			

Action	Timeframe	Responsible Party	Review/ Verification
Reseed areas of temporary disturbance outside of agricultural lands, as described in Appendix F.	During revegetation, following each construction phase	RC	EMC & ODOE
If straw is needed and certified weed-free straw is unavailable, identify a local source of straw and obtain approval for its use by ODOE in consultation with the Sherman County Weed District.	Before revegetation	RC or EPC	ODOE
Consult with ODOE, ODFW, ODA, Sherman County Weed District, and/or the seed supplier to determine the optimal timing for seed application based on climatic conditions of the particular year when construction and revegetation efforts are implemented. Seeding from September to March is typically recommended.	Before revegetation	RC & EMC	ODOE
Stabilize seeded areas to facilitate establishment by applying seedless, certified weed-free hydromulch containing a tackifier or crimped weed-free straw.	During revegetation	RC or EPC	EMC & ODOE
Maintain records of revegetation efforts in all temporary and permanent disturbance areas and update ODOE monthly as revegetation work occurs.	Monthly during revegetation	EMC	ODOE
Notes: EMC = Environmental Monitoring Contractor; EPC = Engineering, Procurement, and Construction Contractor; ODOE = Oregon Department of Energy; RC = Revegetation Contractor; WC = Weed Control Contractor			

6.0 Operations Compliance

Table 5 summarizes actions needed for compliance during operations related to revegetation, stormwater management, and noxious weed control. This list includes actions applicable throughout operations as well as actions required only initially following construction, for example through the Notice of Termination (NOT) for Coverage under a NPDES Permit. Soil management and dust control measures are not included in Table 5 because they are addressed during prior phases.

Table 5. Operations Compliance Checklist

Action	Timeframe	Responsible Party	Review/ Verification
YEAR 1			
Conduct seasonal monitoring of Permanent Disturbance Areas to visually assess the following: a. Establishment of seeded species; b. Inspection of areas of bare soil for erosion; and c. Presence of noxious weeds.	Initiate within 60 days of the completion of revegetation and conduct once per season in the first year following construction	EMC	ODOE
Inspect and maintain stormwater measures as required in the 1200-C permit.	During operations, prior to achieving NOT for the NPDES	Certificate Holder & EMC	ODOE
Inspect and maintain any permanent stormwater management infrastructure. Inspect project facilities (e.g., roads) for erosion issues.	During operations, after achieving NOT for the NPDES	Certificate Holder	ODOE
YEARS 2 to 6			
Conduct annual monitoring of Permanent Disturbance Areas to assess whether vegetation meets success criteria (Appendices B and D).	Annually for 5 years in May or June, beginning the first year after revegetation	EMC	ODOE
Monitor revegetated Temporarily Disturbance Areas, unless the landowner converted the area to land uses that preclude meeting revegetation success criteria. To determine if revegetated temporarily disturbed areas are meeting success criteria, compare vegetation for monitoring and reference transects in each of the non-agricultural habitat subtypes that had more than 0.2 acre of temporary disturbance (Appendix B).	Annually for 5 years in May or June, beginning the first year after revegetation	EMC	ODOE
Determine and report on whether success criteria have been met or are trending towards being met (see Appendix F for report content and success criteria) for Temporary and Permanent Disturbance Areas. Final determination of whether the Certificate Holder is in compliance with revegetation obligations will be made by ODOE. Remedial actions and/or additional monitoring for areas may be required in areas that have been determined by ODOE not to have met the success criteria.	Annually for 5 years in May or June, beginning the first year after revegetation and for the life of the Solar Components on a schedule to be determined in consultation with ODOE	EMC	ODOE
If a revegetated area is damaged by wildfire, develop a plan, subject to ODOE approval, to address the damaged area. Continue to monitor and report on revegetation progress during the remainder of the 5-year period. Report to ODOE within 72 hours of discovery.	During the first 5 years following revegetation if wildfire occurs.	EMC	ODOE

Action	Timeframe	Responsible Party	Review/ Verification
Summarize noxious weed monitoring results in annual reports that describe noxious weeds identified, treatments implemented, treatment efficacy, and recommendations for additional treatments. Submit reports to ODOE, ODA, ODFW, and the County annually. If the Certificate Holder contracts with the Sherman County Weed District to perform weed control at the Solar Components, then no monitoring report needs to be provided except for a statement that the County agency performed the work.	During first 5 years of operations	Certificate Holder & EMC	ODOE
Implement the measures outlined in Appendix F to address vegetation management to reduce wildfire risk	During operation	EMC	ODOE
Consult with ODOE, ODA, and the Sherman County Weed District to design a long-term weed control plan as needed based on the success of control efforts.	After 5th year of annual monitoring	Certificate Holder	ODOE, ODA, County
Provide records demonstrating that all Facility personnel have been trained on noxious weed control.	Annually during operations	Certificate Holder	ODOE
Monitor as outlined in Appendix G within the Weed Management Area for the life of the Solar Components to assess weed growth and inform noxious weed control measures. Assess the success of noxious weed treatments and document any new noxious weed infestations observed.	During operations	Certificate Holder & EMC	ODOE
Control noxious weeds as described in the long-term weed control plan. Maintain ongoing communication with landowners and the Sherman County Weed District regarding noxious weeds at the Solar Components. Control noxious weeds reported by landowners on a case-by-case basis and prepare a summary of measures taken for that landowner.	During operations	Certificate Holder	ODOE
Consult with the Sherman County Weed District on timing, method, and application rates for each identified weed species of concern, to allow for adaptive weed management given changes in weed control effectiveness from noxious weed species tolerance to herbicide treatment over time. Report the results of the consultation to ODOE within 30 days. Any alternative control methods can be proposed by the Certificate Holder or its contractors, subject to approval by the Sherman County Weed District.	Every fall season during operations	Certificate Holder	ODOE

Notes: EMC = Environmental Monitoring Contractor; NOT = Notice of Termination; NPDES = National Pollutant Discharge Elimination System; ODOE = Oregon Department of Energy; ODFW = Oregon Department of Fish and Wildlife

7.0 Plan Amendment

This Comprehensive Plan may be amended from time to time by agreement of the Certificate Holder and the Oregon Energy Facility Siting Council (EFSC). Such amendments may be made without amendment of the site certificate. EFSC authorizes ODOE to agree to amendments to this Comprehensive Plan. ODOE shall notify EFSC of all Comprehensive Plan amendments, and EFSC retains the authority to approve, reject, or modify any amendment agreed to by ODOE.

ODEQ (Oregon Department of Environmental Quality). 2019. OAR 340-208-0210 EPA Method 22. https://secure.sos.state.or.us/oard/viewAttachment.action?ruleVrsnRsn=256141

Appendix A. Roles and Qualifications

Roles and Responsibilities

The Certificate Holder is the overall responsible party for construction and operation of the Solar Components and implementation of this Comprehensive Plan. However, the Certificate Holder may use contractors to complete tasks associated with this Comprehensive Plan. Responsible parties and their roles are described in Table A-1. Minimum qualifications for contractors are provided in Table A-2.

Table A-1. Roles and Responsibilities

Responsible Party	Name and Contact Information	Role
Certificate Holder	Portland General Electric Company	Responsible for compliance with all site condition requirements, hiring contractors that meet the minimum qualifications described in Appendix A, and ensuring that all contractors perform work in accordance with the requirements of this Comprehensive Plan.
Engineering, Procurement, and Construction Contractor (EPC)	Name: Contact Person: Address: Phone Email	Responsible for implementing best management practices (BMPs) and other measures specified in the National Pollutant Discharge Elimination System (NPDES) 1200-C permit and this Comprehensive Plan to minimize impacts during construction, as well as for performing restoration and revegetation actions, as identified in this Comprehensive Plan.
Revegetation Contractor (RC)	Name: Contact Person: Address: Phone Email	Responsible for performing revegetation actions during and immediately after construction, as described in this Comprehensive Plan.
Weed Control Contractor (WC)	Name: Contact Person: Address: Phone Email	Responsible for performing weed control actions in the Weed Management Area, as described in this Comprehensive Plan.
Environmental Monitoring Contractor (EMC)	Name: Contact Person: Address: Phone Email	Responsible for conducting environmental monitoring and documenting compliance with aspects of this Comprehensive Plan during and following construction, including conducting revegetation, dust, soil, stormwater, and noxious weed monitoring.

Responsible Party	Name and Contact Information	Role
Oregon Department of Energy (ODOE)	Oregon Department of Energy Compliance Specialist 550 Capitol St. NE Salem, OR 97301 Phone Email	Responsible for providing technical input on proposed BMPs and other measures to minimize impacts and for validating all compliance deliverables described in this Comprehensive Plan. ODOE may utilize contractors to meet its responsibilities under this Comprehensive Plan during some or all phases.
Sherman County (County)	Sherman County Weed Department Nick Weis, Weed District Supervisor 66143 Lone Rock Road Moro, OR 97039 (541) 565-3655 nickw@shermancountyor.gov	Responsible for providing input on weed control and other actions described in this Comprehensive Plan and its implementation as needed. The County will also attend calls with ODOE and other agencies as needed.

Contractor Minimum Qualifications

Table A-2. Contractor Minimum Qualifications

Contractor	Role	Minimum Qualification
Engineering, Procurement, and Construction Contractor (EPC)	Responsible for implementing BMPs and other measures specified in the NPDES 1200-C permit and this Comprehensive Plan to minimize impacts during construction, as well as for performing restoration and revegetation actions.	Minimum qualifications for the EPC include: • Experience implementing measures in the NPDES 1200-C permit; • Demonstration of sufficient resources and staffing for anticipated BMP installations and maintenance; and • Experience in coordination with agencies and private landowners.
Revegetation Contractor (RC)	Responsible for performing revegetation actions during and immediately after construction.	The Certificate Holder will ensure that the RC has the following minimum qualifications: • Demonstrated experience in the Columbia Plateau; • Experience in native plant, non-native and invasive plants, and noxious weed identification and management; • Experience in revegetating natural areas; • Experience with site preparation and applicable seeding methods; • Experience in documenting revegetation actions and providing progress reports; • Experience in coordination with agencies and private landowners; and • No recent (within one year) violations on the contractor's record.
Weed Control Contractor (WC)	Responsible for performing weed control prior to, during, and after construction within the disturbance area and a 10-foot buffer (Weed Management Area).	The Certificate Holder will ensure that noxious weed management actions will be conducted by specialists with the following qualifications: • Experience in native plant, non-native and invasive plants, and noxious weed identification in the Columbia Plateau Ecoregion; • Experience in noxious weed mapping; • If chemical control is used, specialists must possess a Commercial or Public Pesticide Applicator License from the Oregon Department of Agriculture or possess an Immediately Supervised Pesticide Trainee License and be supervised by a licensed applicator;

Contractor	Role	Minimum Qualification
		• Training in noxious weed management or Integrated Pest Management with an emphasis in noxious weeds; • Experience in coordination with agencies and private landowners; and • No recent (within one year) violations on the contractor's record.
Environmental Monitoring Contractor (EMC)	Responsible for conducting environmental monitoring and documenting compliance with aspects of this Comprehensive Plan during and following construction, including conducting revegetation, dust, soil, stormwater, and noxious weed monitoring as described below.	Minimum qualifications for the EMC include: • Have an active certification recognized in the 1200-C permit (e.g., Certified Erosion and Sediment Control); • Experience implementing and monitoring measures in the NPDES 1200-C permit; • Experience and knowledge of U.S. Environmental Protection Agency Method 22 (ODEQ 2019) with respect to the general procedures for determining the presence of visible emissions; • Experience in native plant, non-native and invasive plants, and noxious weed identification and management; • Experience in noxious weed mapping; • Training in noxious weed management or Integrated Pest Management with an emphasis in noxious weeds; and • Experience in coordination with agency and private landowners. The EMC will include a qualified botanist or revegetation specialist who will be responsible for monitoring and reporting on revegetation success.

Appendix B. Construction Plan

Disturbance Acreage

Acres of temporary and permanent disturbance to habitat subtypes associated with Solar Component construction and operation are provided in Table B-1.

Table B-1. Acres of Temporary and Permanent Disturbance

ODFW Habitat Category	Habitat Type	Habitat Subtype	Temporary Disturbance (acres)	Permanent Disturbance (acres)
1	N/A	N/A	-	-
2	Riparian	Riparian Trees	0.0	0.0
	Shrub-steppe	Sagebrush Shrub-Steppe	0.3	20.7
	Category 2 Subtotal		**0.3**	**20.7**
3	N/A	N/A	-	-
4	Grassland-steppe	Grasslands	0.1	3.0
	Surface Water	Ephemeral Streams	0.0	0.0
	Category 4 Subtotal		**0.1**	**3.0**
5	N/A	N/A	-	-
6	Agriculture	Irrigated Cropland	0.1	52.0
	Agriculture	Non-Irrigated Cropland	9.4	1,365.0
	Developed	Developed	1.0	3.9
	Category 6 Subtotal		**10.5**	**1,420.9**
		Total	**10.9**	**1,444.6**

1. There are no disturbances in surface water habitat types. Refer to Exhibit J of RFA 4 for detailed analysis of disturbances to wetlands and waters.

N/A = not applicable; ODFW = Oregon Department of Fish and Wildlife

Disturbance Levels

Revegetation and soil stabilization needs will be determined by a combination of topography, soil type, disturbance level, and existing vegetative cover.

Disturbance levels will primarily be determined by conditions such as slope, gradient, and existing vegetation. As much as is feasible, use of heavy machinery and soil disturbance should be conducted on dry soil. Disturbance of saturated soil has a much greater risk of compaction and requires more effort to revegetate and control weedy species. Disturbance levels are defined as follows and depicted in Figure B-1:

- *Level 1 – Mowing:* Mowing is used to conserve vegetative resources within a facility. Vegetation will be limited to a height of 12 inches and mowed to no less than 6 inches during construction. Mowing to no less than 6 inches protects perennial grass crowns and allows grasses to regenerate. Depending on facility objectives, vegetation can be allowed to reach a normal height

or kept trimmed to a height between 6 inches and the plant's full height potential. Crushing of vegetation will be minimal and this disturbance level is designed to have a minimal impact on existing vegetation. This method is least likely to result in invasions of undesirable plant species.

- *Level 2 – Overland Drive and Crush:* Disturbance caused by accessing a facility without significantly modifying the landscape. Vegetation is crushed to the ground but no surface soil is removed so root structures are left intact. Even though vegetation may be damaged or destroyed, the surface soil and seed bank remain in place. Some crushed vegetation will likely sprout after disturbance ceases. These activities would result in minimal to moderate disturbance. This type of disturbance will result in a faster recovery time for vegetation compared to Levels 3 and 4. Soil seed banks remain largely in place, perennial vegetation can grow back, and minimal external efforts are necessary. This method is less likely to result in invasions of undesirable plant species compared to Levels 3 and 4.
- *Level 3 – Clear and Cut:* Disturbance caused by accessing the facility including having to remove all vegetation to improve or provide suitable access for equipment. All vegetation is removed, soils are compacted, and the root zone or soil A-horizon may be disturbed, but no subsurface soil is removed. Clear and cut activities would result in moderate disturbance. This type of disturbance will result in moderate recovery times for vegetation. This method has a moderate risk for invasion of undesirable plant species. An example is imprinting to crush vegetation down into the soil or incidental grading and smoothing of surface soils.
- *Level 4 – Clear and Cut with Soil Removal*: Disturbance is caused by removing all vegetation in the impact zone, soils are compacted, and surface soil and subsoil are displaced. These activities result in heavy disturbance. This type of disturbance results in an extensive recovery time for vegetation and is most likely to lead to invasions of undesirable plant species, which can result in lengthy and expensive control efforts. Includes disc-and-roll construction and other traditional construction methods where soils are disturbed and no vegetation is left intact. This category includes all work requiring the segregation and replacement of topsoil.
- *Level 5 – Development Footprint*: Disturbance is caused by removing all vegetation and covering the area surface with gravel, concrete, or other vegetation-free surfaces, or where the intended function of a specific area necessitates it remain unvegetated. This disturbance level includes roads, graveled lots, fire breaks, utility pole pads, and the areas underlying any component installed on a foundation. This level does not include vegetated areas under solar arrays. This type of disturbance will result in a complete loss of vegetation and will be required to be monitored and kept free of noxious weeds and other vegetation for the life of the facility.

Maps showing the expected disturbance levels in Temporary and Permanent Disturbance Areas in relation to existing vegetation type, habitat type, and areas with sensitive soils are provided in Figure B-1 below.

<<INSERT DISTURBANCE LEVEL MAPS HERE>>

Figure B-1. Disturbance Levels in Temporary and Permanent Disturbance Areas in Relation to Existing Vegetation Type, Habitat Type, and Areas with Sensitive Soils

Appendix C. 1200-C Permit and Erosion and Sediment Control Plan

Appendix D. Fugitive Dust Control Plan

To manage fugitive dust from construction, the Certificate Holder and its contractors will generally follow the Dust Control Plan Flow Chart (Figure D-1).

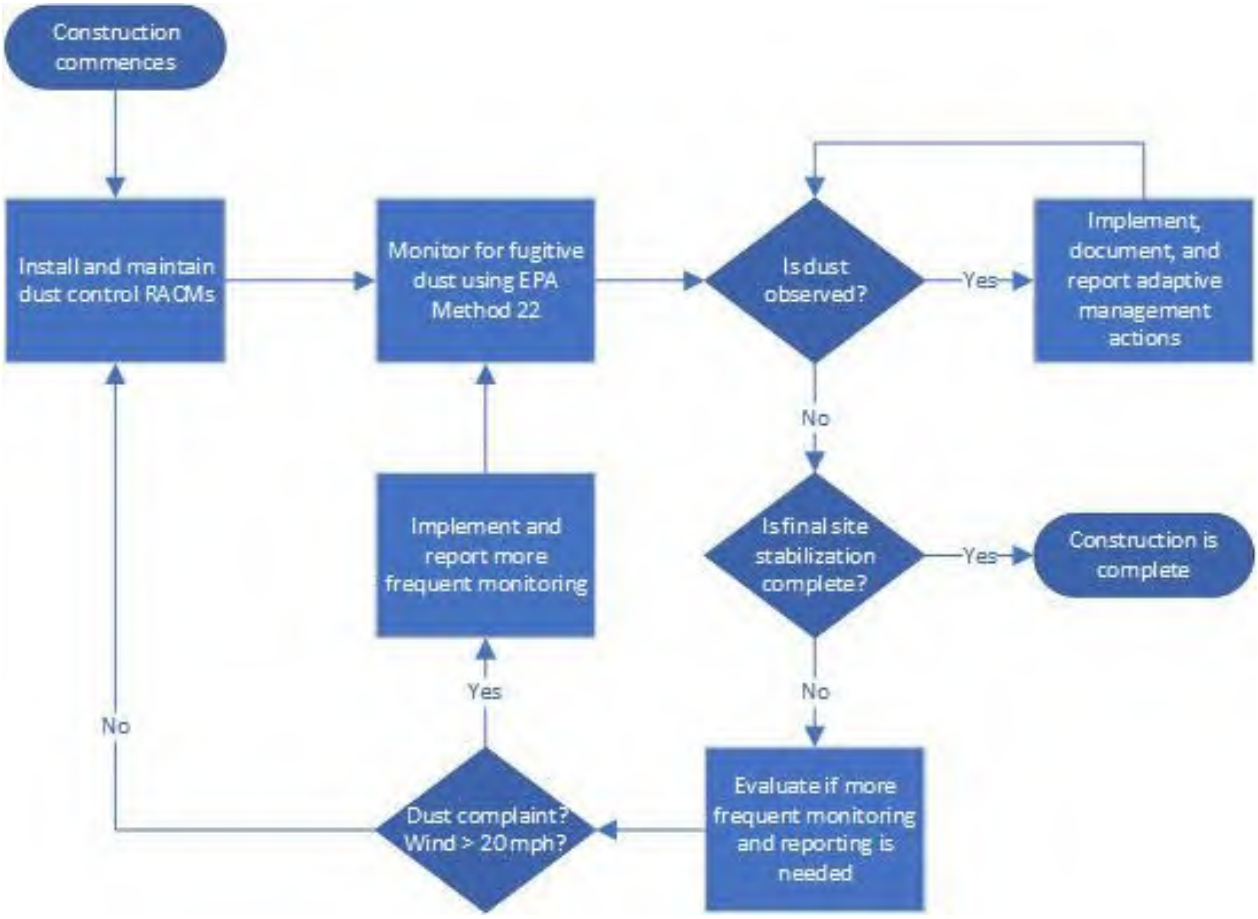

Figure D-1. Dust Control Plan Flow Chart

Fugitive Dust Monitoring and Reasonable Available Control Measures (RACMs)

The visual monitoring required by the 1200-C permit must occur at least once every 14 calendar days. However, because Oregon Administrative Rule (OAR) 340-208-0210 restricts visible fugitive emissions on a continuous standard to a maximum of **18 seconds in any 6-minute period**, and because fugitive dust emissions may provide an immediate public safety concern, this plan requires that fugitive dust be monitored and controlled on an ongoing basis (Table D-1).

Monitoring for fugitive dust emissions shall include:

- Use of U.S. Environmental Protection Agency (EPA) Method 22 (ODEQ 2019), as specified in OAR 340-208-0210, **at least once per day during the dry season, during peak construction activities.**

- The observation shall be performed during times of peak construction activity at the downwind facility boundary.
- Recording of observations in a fugitive dust inspection log that is kept on site and shall be kept digitally, described below.

Triggers for additional, more frequent monitoring will include:

- Observation of visible fugitive dust emissions by the Environmental Inspector, contractor(s), agency, or Certificate Holder staff,
- Wind speeds or gusts greater than 20 miles per hour, or
- Receipt of complaints or concerns through the Project Dust Control Hotline or other means.

Table D-1. Fugitive Dust Sources and Reasonable Available Control Measures (RACMs)

Construction Phase	RACM(s)	Supplemental RACM(s)
All Phases of Construction	Daily fugitive dust monitoring and record keeping.	Increase frequency of monitoring.
	Prominent display of Dust Control Hotline signs, providing direct access to the Environmental Inspector.	If established, proactive engagement with Community Action Council.
	Worker Environmental Awareness Program training for all construction employees.	Additional trainings and refreshers for employees.
	Maintain stockpile of best management practices (BMPs) on site, including sufficient palliatives for a single treatment of all access roads and sufficient palliatives, mulch, and/or hydromulch for a minimum of 25 percent of the total disturbed area, and machinery for application.	Increase stockpile of palliatives, mulch, and/or hydromulch and add additional BMPs.
	Documentation and reporting of adaptive management actions.	Development and submittal of revised Fugitive Dust Control Plan.
Facility Access	Install and maintain stabilized construction entrances at ingress/egress locations and restrict traffic to these locations.	Add additional construction entrance BMPs (e.g., wheel wash).
	Daily sweeping up of sediment from paved surfaces utilizing vacuum sweeper with high efficiency particulate air (HEPA) filtration.	Increase sweeper frequency.
	Access roads shall be graveled.	Road maintenance and reapplication of gravel.
	Access roads will be stabilized with water or palliative sufficient to eliminate visible and sustained dust from vehicular travel and wind erosion. Reapply stabilization as necessary to maintain dust-free condition.	If water is unavailable or ineffective, or if water use is limited by any agency or regulation, access roads will be stabilized with longer-lasting palliatives.
	Restrict construction traffic to established and stabilized access routes.	Install fencing or barricades to prevent traffic outside of established routes.

Construction Phase	RACM(s)	Supplemental RACM(s)
	Limit traffic speeds to 15 miles per hour on stabilized unpaved roads within the facility as long as such speeds do not create significant visible dust emissions. Traffic speed signs shall be displayed prominently at all entrances and exits.	Limit traffic speeds within the facility to 5 or 10 miles per hour.
	Minimize disturbance areas and soil exposure to the maximum extent feasible.	Limit work to a portion of the disturbed area until all disturbed areas receive temporary or final stabilization.
	When wind speeds or gusts exceed 15 miles per hour, minimize new disturbances to the extent possible and/or mobilize additional water trucks or palliatives to minimize fugitive dust from exposed surfaces.	Stop all ground disturbing activities and apply additional dust control measures until measures are effective or wind speeds slow and fugitive emissions stop.
	Separate and cover or otherwise stabilize topsoil to preserve it until it is replaced during revegetation.	Increase maintenance frequency for topsoil cover/stabilization. Combine methods, such as mulch plus tackifier.
	Stabilize exposed soils within the timeframes established in the 1200-C permit. Stabilize exposed soils in stages based on soil conditions and weather.	Stabilize exposed soils more frequently, even if additional work is anticipated within the timeframe established in the 1200-C permit. Reapply stabilization measures following any additional disturbances.
	Temporarily stabilize exposed surfaces to prohibit significant and sustained visible fugitive dust from wind erosion. Utilize BMPs such as mulch, hydromulch with or without seeds, tackifier, spreading stone or gravel, and trackwalking.	Combine stabilization methods, such as mulch plus tackifier, or trackwalking plus hydromulch. Increase frequency of maintenance of stabilization.
	Seed exposed surfaces during the appropriate season with approved temporary or permanent seed mixes.	Reapply seed to newly disturbed areas or areas with poor germination. Use temporary seeding even if additional work is anticipated before final stabilization. Use irrigation to enhance seeding success.
Removing and Hauling Sand, Soil, or Other Loose Materials	Gate seals should be tight on dump trucks. Soil load shall be kept below 6 inches of the freeboard of the truck. Drop heights shall be minimized when loaders dump soil into trucks. Gate seals will be checked and tight on dump trucks. All trucks on highways must be fully covered and secured.	Cover haul trucks with a tarp or other suitable cover.

Fugitive Dust Reporting

A dust inspection log shall be completed after each dust inspection. Log records shall be kept digitally and included in construction monitoring reports as described in Appendix E of this Comprehensive Plan. This log shall include all information required in EPA Method 22. Photos and/or video taken during the observation period to document conditions shall be available

digitally to the Oregon Department of Energy upon request. Any documented exceedance events shall include a detailed explanation of RACMs implemented for corrective action and the results of subsequent monitoring demonstrating fugitive dust has returned to below exceedance thresholds.

Appendix E. Environmental Monitoring Methods

The Environmental Monitoring Contractor (EMC) will be present during construction activities that involve ground disturbance, grading, weed treatments, vegetation removal, and high traffic volumes and is responsible for monitoring and recording construction activity to ensure compliance with this Comprehensive Plan.

In addition, the EMC will:

- Assist contractor(s) for the direction of water trucks, civil activities, and road maintenance to reduce fugitive dust and erosion issues.
- Identify when reasonably available and best available control measures are not adequate, as designated in Appendix D.
- Maintain dust inspection and noxious weed logs and reporting designated in this Comprehensive Plan.

Specific protocols and requirements for testing and monitoring to be performed prior to and during construction and revegetation efforts are described in the sections that follow.

Soil Compaction Testing

Monitoring Protocol

The EMC will conduct pre- and post-construction soil compaction testing in all anticipated Level 3 and 4 Disturbance Areas, and any areas consisting of soils with low soil compaction resistance (e.g., Lickskillet very stony loam (16D) and Lickskillet-Rock outcrop complex [18E] soils). If disturbance level maps are not available at the time of pre-construction sampling, the Certificate Holder may choose to base sample locations on the overall anticipated disturbance area (i.e., regardless of level of disturbance). Soil compaction sample locations will be evenly distributed across the disturbance area at a rate of 1 sample per 50 acres. Sample locations were stratified by soil type to ensure a minimum of three sample locations in each soil type and a representative density of sample locations in major soil types. Additionally, sample locations were selected to avoid infrastructure such as inverters and roads where revegetation will not occur. Sample locations are identified in Figure E-1, below.

Soil compaction measurements will be collected at all sample locations prior to ground disturbing activities and again at the same locations post reclamation but prior to revegetation.

[to be inserted at plan finalization]

Figure E-1. Soil Compaction Sample Locations

Test Methods

Soil Compaction Testing will be conducted using the following standard methods (NRCS 2020; Duiker 2025):

- The surveyor will measure soil resistance using a penetrometer.
- Resistance will be measured at 3-inch intervals to 12 inches or until the meter goes above 300 pounds per square inch (3, 6, 9, and 12 inches if soils allow).
- Measurements will be conducted in conditions favorable to soil testing (e.g., non-saturated or frozen soils).

Results

Testing results will be provided to the Oregon Department of Energy (ODOE) prior to construction and after reclamation but before revegetation.

Baseline Vegetation Conditions

Prior to construction of the Solar Components, the EMC will conduct pre-construction habitat surveys for all temporary disturbance areas. Data collected will include:

- Vascular plant species present;
- Native/non-native species present;
- Percent cover of dominant species; and
- Percent cover of state and county listed noxious weeds.

Revegetation Monitoring

The Certificate Holder will monitor revegetated areas as described below, unless the landowner converted an area to a use that precludes meeting revegetation success criteria such as cropland. The Certificate Holder should coordinate grazing timing and intensity with the landowner so that it does not preclude revegetation success. Revegetated areas will be monitored by a qualified investigator in May or June annually for 5 years, beginning the first year after seeding.

Temporary Disturbance Areas

Reference and Revegetation Transects

Establish 50-meter reference and revegetation transects for each temporarily disturbed wildlife habitat subtype and category with more than 0.5 acres of temporary disturbance as described below. Establish one reference transect for every temporarily disturbed wildlife habitat subtype and category. Reference transects are intended to be representative of baseline conditions for the revegetation effort.

Establish revegetation transects randomly in every wildlife habitat subtype and category that will be temporarily disturbed by construction using existing habitat mapping. Transect locations and/or lengths may need to be adjusted to account for linear features whose disturbance footprint may be too narrow or too short to meaningfully place a transect. Determine the number of transects as follows:

- Less than 0.5 acres of temporary disturbance = 0 transects
- 0.3 to 5 acres of temporary disturbance = 1 transect
- 6 to 10 acres of temporary disturbance = 2 transects
- For each additional 10 acres of disturbance, one additional transect will be added (e.g., 11-20 acres of disturbance = 3 transects, 21-30 acres = 4 transects, etc.)

Temporary Disturbance Area Monitoring Methods

Vegetation will be measured quantitatively using the line-point intercept (LPI) method combined with a belt transect to document species richness and sagebrush density, where necessary (Elzinga et al. 1998; MacKinnon et al. 2011). The LPI method is described in detail in the *Monitoring Manual for Grassland, Shrubland, and Savanna Ecosystems, Volume I* (Herrick et al. 2021). The surveyor will drop a narrow pin perpendicular to the ground at 1-meter intervals along a 50-meter transect and record up to four plant species that intercept the pin in order of interception as well as the soil surface type (bare ground, litter, rock, moss, or biotic crust) where the pin touches the ground. Once all 50 points have been collected, the surveyor will walk back along the transect and record any species within 1 meter on either side of the transect that were not documented at a point. The surveyor will take a photo from the transect start point, looking down the length of the transect. For transects in sagebrush shrub-steppe habitat, the surveyor will record the number of sagebrush individuals by size class (i.e., less than 1 foot tall, between 1 and 2 feet tall, greater than 2 feet tall) occurring within 1 meter on either side of the 50-meter transect.

Following field surveys, foliar cover will be determined by multiplying the number of top hits for each species by two. Cover of bare ground will be determined by counting every point in which bare ground was recorded as a surface type and no plants were intercepted and multiply this number by two. Species richness will be determined by counting all the unique species that were recorded at a point or along the belt transect.

Permanent Disturbance Areas

Following implementation of revegetation efforts, the Certificate Holder will monitor revegetated permanent disturbance areas as described below. Revegetated areas will be monitored by a qualified investigator annually for 5 years, beginning the first year after seeding. If success criteria are met in the first 5 years, then long-term vegetation monitoring to document and manage vegetation to reduce wildfire risk will be determined in consultation with ODOE.

The Certificate Holder will monitor Permanent Disturbance Areas to assess the following:

- Dominant species composition;
- Relative cover of desirable and undesirable forbs and grasses;
- Percent cover of bare soil;
- Degree of erosion;
- Presence of noxious weeds; and

- Qualitative assessment of overall vigor of vegetation within revegetated areas.

The EMC will monitor revegetated Permanent Disturbance Areas with a meander survey beginning within 60 days of the completion of initial revegetation. During the meander survey, the EMC will walk in revegetated Permanent Disturbance Areas and document the assessment items listed above using photos and spatial data collection. Areas of erosion and significant patches of bare soil will be mapped and photographed. The EMC will record dominant species, overall percent cover of forbs and grasses, and general notes about plant vigor.

Monitoring will be conducted at least once per season during the first year following construction. After the first complete year of monitoring, the Certificate Holder will consult with ODOE to determine if the monitoring cycle can be reduced based on revegetation progress. After five years of monitoring, the Certificate Holder will design a long-term monitoring plan in consultation with ODOE.

Revegetation Monitoring Reports

Revegetation monitoring reports will be prepared and submitted to ODOE annually for five years following revegetation. The first monitoring report will include a detailed description and timeline of revegetation methods that were implemented including species, amounts, and locations of seed applications and dates revegetation work was performed. Annual monitoring reports will include:

a. Geographic information system (GIS) maps of revegetated areas and disturbance levels;
b. Monitoring methods;
c. Local climatic data (i.e., precipitation, temperature) for the monitoring month and year and percent deviation from the historical average;
d. Results of monitoring efforts;
e. Photos of transects and representative overview photos of revegetated areas;
f. Assessment of whether revegetated areas are trending toward meeting success criteria;
g. Assessment of factors impacting the ability of revegetated areas to trend towards meeting the success criteria; and
h. Recommendations for remedial actions, if any. If applicable, provide recommendations for reseeding, weed control, or other remedial measures for areas (either permanently or temporarily disturbed) that are not showing progress toward meeting success criteria. Include adaptive management measures taken in the next monitoring report.

Appendix F. Revegetation and Soil Stabilization Methods

Soil Stabilization

- The Engineering, Procurement, and Construction Contractor (EPC) will use appropriate erosion and sediment control practices (i.e., seeded or unseeded hydromulch, tackifier, weed-free erosion control blankets, weed-free or locally sourced straw mulch) to maintain topsoil during construction in Temporary and Permanent Disturbance Areas.
- After grading is complete but prior to installation of Solar Components, apply temporary or permanent soil stabilization.
- If seeding is used for temporary soil stabilization, seed areas with less than 70 percent vegetative cover with a non-invasive, non-persistent cover crop such as winter wheat or sterile triticale.
- Select cover crop based on the time of year; for example, winter wheat or sterile triticale can be seeded from fall to early spring while peas should be seeded in spring. Tillage radish and sunflowers can be seeded in spring to reduce compaction but are not suitable options for soil stability.

Soil Reclamation

In areas where soil is removed during construction, the following measures will be taken where appropriate:

- During construction, excavated topsoil will be stockpiled separately from subsoil and replaced in proper order with topsoil on the surface to maintain soil productivity. Stockpiled soil will be put back in place prior to revegetation activities.
- Topsoil and other soils from noxious weed infested areas will not be moved outside infested areas and will be returned to their previous location during reclamation activities to eliminate the transport of weed seeds, roots, or rhizomes. Noxious weed occurrences will be flagged and monitored for compliance.

Site Preparation

- Ensure that soils from weed infested areas are treated with a pre- or post-emergent herbicide as needed prior to initiation of revegetation efforts, depending on site-specific conditions.
- Prior to final regrade and revegetation efforts, any weeds that have grown during periods of construction dormancy should be treated as described in Appendix G.
- Perform site preparation using methods described below. Consider site-specific factors including slope, soil type, size of area, and erosion potential when determining methods.
    - Soil Roughening: Also known as imprinting, tracking, or track walking, soil roughening is a temporary erosion control practice and seedbed preparation technique implemented when grading a slope (EPA 2021). This technique involves creating grooved soil surface with depressions running parallel to the hill contour to promote seed germination and provide moderate erosion control while vegetation is established.

Tracking with heavy equipment may compact the soil and inhibit root penetration; this can be mitigated by using lighter-weight equipment and not tracking saturated soil. Soil roughening should be done prior to applying hydromulch, straw mulch, or installing erosion BMPs. Seed and mulch roughened areas as soon as possible to obtain optimum seed germination and growth (ODOT 2023).

- Deep Tilling: Reduce soil compaction by fracturing restrictive soil layers in areas where compaction levels inhibit plant growth (NRCS 2022). Deep tillage s only suitable in areas outside of solar arrays and where solar infrastructure is not present (i.e., temporary roads) and should be conducted after construction and prior to revegetation when soil moisture is at 30-50 percent of field capacity.
- Decompaction: Where soil compaction testing demonstrates that soils are compacted greater than 300 pounds per square inch (psi), then remediation activities may be completed in those areas prior to the construction contractor moving to a new location or offsite as described in Table F-1. Areas with intact vegetation (typically in areas with Level 1 or 2 disturbance) will not be decompacted to avoid additional soil disturbance and erosion risk. Locations where baseline monitoring indicated that soils were compacted more than 300 psi prior to construction will only be decompacted as needed based on field assessment of likely vegetation success (see Table F-1). Remediation activities may include mechanical scarification (e.g., tilling or ripping the soil) to an appropriate depth to reduce the potential effects of compaction, to maintain soil productivity, and reduce the potential for erosion on compacted soils. Dry soils should be decompacted using an agricultural disc, soil ripper, or similar equipment

- Prepare salvaged topsoil into a firm, fine-textured seedbed before seeding or planting (ODOT 2023). Loosen the top 1 to 2 inches of the soil surface by shallow tilling with a disc, followed by harrow or drag if necessary and where feasible with construction equipment. If soil is assessed as too soft by the Revegetation Contractor or the Environmental Monitoring Contractor (EMC), firm with a roller or cultipacker.

Table F-1. Decompaction Action by Disturbance Lavel

Disturbance Lavel	Baseline Soil Compaction under 300 psi	Baseline Soil Compaction over 300 psi
1 – Mowing	If intact, living vegetation present, then no action; confirm vegetation success in next growing season.	If intact, living vegetation present, then no action; confirm vegetation success in next growing season.
	If bare soil, revegetate as described in the following section	If bare soil, decompact prior to revegetation

2 – Overland Drive and Crush	If intact, living vegetation present, then no action; confirm vegetation success in next growing season.	If intact, living vegetation present, then no action; confirm vegetation success in next growing season.
	If bare soil, revegetate as described in the following section	If bare soil, decompact prior to revegetation
3 – Clear and Cut	Revegetate as described in the following section.	Decompact prior to revegetation
4 – Clear and Cut with Soil Removal	Revegetate as described in the following section.	Decompact prior to revegetation

Revegetation Methods

- The Certificate Holder will restore temporarily disturbed areas by re-establishing slope, surface stability, and drainage features, as needed, followed by soil preparation and seeding as described below.
- Revegetation will begin as soon as feasible after completion of each construction phase. Seeding and planting will be done in a timely manner and in the appropriate season to facilitate germination and establishment of seeded species.
- Following seeding, stabilize seeded areas to facilitate establishment by applying seedless, certified weed-free hydromulch containing a tackifier or crimped weed-free straw.
- Cropland outside the Solar Components fenceline will be returned to landowner control and will not be revegetated by the Certificate Holder.
- Revegetation methods for each disturbance level were developed to tailor revegetation to specific conditions (Table F-2).

Table F-2. Revegetation Methods by Disturbance Level

Disturbance Level	Soil Reclamation	Site Preparation	Seeding
1 – Mowing	No soil disturbance. Retain existing vegetation to prevent erosion.	Weed control.	Seed if necessary to achieve success criteria.
2 – Overland Drive andCrush	No soil disturbance. Retain existing vegetation and	Weed control.	Seed if necessary to achieve success criteria.

	implement erosion control practices.		
3 – Clear and Cut	Track or decompact soil as necessary. Implement erosion control practices.	Weed control. Seed cover crop if necessary to stabilize soil. Prepare firm, fine-textured seedbed prior to seeding.	Required
4 – Clear and Cut with SoilRemoval	Stockpile topsoil separately from subsoil and stabilize during construction. Regrade and replace subsoil then topsoil prior to seeding. Track or decompact soil as necessary. Implement erosion control practices.	Weed control. Regrade and add soil amendments if necessary. Seed cover crop if necessary to stabilize soil. Prepare firm, finetextured seedbed prior to seeding.	Required

•

Seed Mix and Shrub Planting

A low-growing seed mix was developed for revegetation of Temporary Disturbance Areas and Permanent Disturbance Areas within the Solar Micrositing Area (Table F-3).

Table F-3. Seed Mix for Revegetation of Disturbed Areas

Growth Habit	Common Name	Scientific Name	Pounds of pure live seed/acre[1]
Grasses			
	Squirreltail	*Elymus elymoides*	3.5
	Thurber's needlegrass	*Eriocoma thurberiana*	4.4
	Idaho fescue	*Festuca idahoensis*	2.1
	Sandberg bluegrass	*Poa secunda* ssp. *secunda*	2.1
Forbs (choose 3 or 4 depending on seed availability)			
	Common yarrow	*Achillea millefolium*	0.1
	Oregon sunshine	*Eriophyllum lanatum*	0.1
	Fleabane	*Erigeron filifolius* or *E. pumilus*	0.1
	Wooly plantain	*Plantago patagonica*	0.2
	Clover	*Trifolium macrocephalum*	0.1
Total			**12**

Note: The species and seeding rates included in this table are a recommendation. Substitutions can be made through consultation with ODOE.

1. Pounds of pure live seed per acre listed for drill seeding and imprint seeding. Double drill seeding rate for broadcast seeding and multiply by 2.5 for hydroseeding.

Seeding Methods

Four common seed application methods that may be used for revegetation include broadcast seeding, drill seeding, imprint seeding, and hydroseeding; each of these are discussed further below. Other seeding methods may be proposed for review and approval prior to revegetation efforts.

Broadcast Seeding

Broadcast seeding is the application of seed directly to the ground surface. This method may be chosen for areas with shallow and rocky soils, and the type of broadcast spreader would depend on the size of the area to be seeded and the terrain.

In this method, the seed mix would be broadcast at 24 pounds of pure live seed per acre, or twice the recommended rate for drill seeding. When feasible, due to the seasonality of when planting can occur, the entire area will be seeded after grading is complete but before placement of solar components, providing more flexibility in seed application. In those instances where seeding occurs prior to installation of components, follow-up seeding will occur in areas temporarily disturbed by installation and any areas that are deficient in vegetation from the first round of seeding. Immediately following seed application, hydromulch or certified weed-free straw would be applied. Broadcast seeding will not be employed if winds exceed 5 miles per hour. If certified weed-free straw is unavailable, the Certificate Holder or EPC will identify a local source of straw. The local

source of the straw will be approved by the Sherman County Weed District and the Oregon Department of Fish and Wildlife (ODFW) prior to purchase. This straw will either be crimped into the ground or applied with a tackifier.

Drill Seeding

Drill seeding can be used for large areas with deep soils and moderate to gentle terrain to accommodate mechanical equipment. This method provides the advantage of planting the seed at a uniform depth and may provide better soil to seed contact. Using a range seed drill, seeds will be sown at 12 pounds pure live seed per acre or according to application rates recommended by the seed supplier. Drill seeding will be difficult after solar components have been installed, so it will primarily be used if seeding occurs after grading is complete but before components are installed, or in areas that were temporarily disturbed during construction that do not have any permanent infrastructure (e.g., temporary access roads, laydown areas).

Imprint Seeding

Imprint seeding is a no-till drill seeding method used to restore grasslands in areas with low annual precipitation. Seeds will be sown at 12 pounds pure live seed per acre or according to application rates recommended by the seed supplier. The seeder consists of a heavy metal drum roller with V-shaped, angled teeth and a seed agitator box. The teeth create V-shaped troughs with a depth of 4-7 inches to collect rainwater. The rolling drum presses the seed into the soil, insuring good seed-to-soil contact. The troughs collect rainwater for seed germination and seedling growth. Imprint seeders can be used on steep slopes and do not require seed bed preparation before seeding. Seeding can occur on soils with light to moderate vegetative cover, with the vegetation acting as a mulch, preventing soil erosion until seedlings are established. Imprint seeders do not work well in areas with shrubs or heavy vegetation cover. Heavily compacted soils may need to be ripped or de-compacted before seeding. The seeding rate for this method should be the same as for broadcast seeding.

Hydroseeding

Hydroseeding is most applicable for areas where drill or broadcast seeding machinery cannot access; this usually includes steep slopes or narrow terrain but can be used in all terrains. Soil bed preparation is also crucial for growth success and frequently includes tracking perpendicular to the slope to create micro conditions for seed. Flat grading and compaction are not recommended. Seeding rates increase by 30 to 50 percent of broadcast seeding rates (i.e., 30 pounds pure live seed per acre) per consultation with the seed supplier and ODFW. Prior to hydroseeding, the tackifier will be reviewed and approved in consultation with the Oregon Department of Energy (ODOE). Fertilizer should not be used when hydroseeding wildlife habitat.

Revegetation Records

The EMC will maintain records of revegetation efforts in all temporary and permanent disturbance areas and update ODOE monthly as revegetation work occurs. Revegetation records will include:

a. Date construction phase was completed;

b. Acreage of each disturbance level;

c. Description and photos of the affected area;

d. Date revegetation was initiated;

e. Description of the revegetation effort, including methods and timing;

f. Supporting figures representing the location, acres affected, and pre-disturbance condition of the revegetation area; and

g. Confirmation from the landowner that temporary disturbances in cropland have been satisfactorily restored.

Success Criteria for Temporary Disturbance Areas

Reclamation of Temporary Disturbance Areas on agricultural lands will be considered complete after the land is returned to farm operations and landowners provide written confirmation that they are satisfied that any impacts to soil productivity have been addressed. The Certificate Holder will provide evidence that landowners are satisfied after one crop cycle.

In non-agricultural areas, the Certificate Holder will make reasonable efforts to restore vegetation and soils in habitat areas to their pre-disturbance condition.

a. **Native Shrubs**: Average density of sagebrush on revegetation transects in areas planted with sagebrush should be at least 50 percent of the reference transect within 5 years.

b. **Native and Desirable Forbs**: Cover of native and desirable (i.e., non-native species included in the seed mix) forbs, averaged across revegetation transects by habitat subtype and category, will be at least 75 percent of reference transects for the corresponding habitat subtype within 5 years.

c. **Native and Desirable Grasses**: Cover and richness of native and desirable (i.e., non-native species included in the seed mix) grass species, averaged across revegetation transects by habitat subtype and category, will be at least 85 percent of reference transects for the corresponding habitat subtype within 5 years.

d. **Noxious Weeds**: Presence and cover of noxious weeds on revegetation transects is 75 percent or less than that of the reference transect for the corresponding habitat subtype.

Vegetation Management for Permanent Disturbance Areas

During operation of the Solar Components, vegetation under the solar panels will be managed to minimize fire risk and erosion by maintaining low growing vegetation.

Prohibition on Use of Domestic Sheep and Goats for Vegetation Management

The certificate holder may not keep or use domestic sheep, goats, or other livestock at the solar facility for vegetation control or other purposes without written approval from the Department. Any request to use domestic sheep, goats, or other livestock at the solar facility must be accompanied by a description of practices and controls that will be implemented to prevent

zoonotic disease transmission to wild sheep populations. The Department may impose additional requirements to prevent zoonotic disease transmission based on consultation with ODFW.

Success Criteria for Permanent Disturbance Areas

The Certificate Holder will establish uniform (i.e., evenly distributed, without large bare areas) perennial, non-invasive vegetation that provides 70 percent or more cover on all exposed areas in compliance with the soil protection standard (Oregon Administrative Rule 345-022-0022); National Pollutant Discharge Elimination System 1200-C permit requirements; and Sherman County requirements.

Integrated Vegetation Management

To support reclamation success and reduce wildfire risk throughout all phases (i.e., both construction and operations) of the Solar Components, vegetation management will be implemented consistent with the draft Construction Wildfire Mitigation Plan and anticipated Operations Wildfire Management Plan. In the interim, while those plans are being finalized, this section establishes the minimum vegetation management and fire prevention requirements that will apply during construction and operation of the Solar Components. Vegetation will be managed in accordance with the applicable provisions of the 2025 Oregon Fire Code:

Oregon Fire Code, Section 1205.5.1 Provides:

> *"A clear brush free area of 10 feet shall be required around the perimeter of the ground-mounted photovoltaic arrays or as determined by the fire code official. A maintained vegetative surface or noncombustible base, approved by the fire code official, shall be installed and maintained under the photovoltaic arrays and associated electrical equipment installations.".*

These measures are intended to minimize ignition potential, maintain defensible space, support consistent vegetation control, and outline inspection practices that will contribute to long-term fire resiliency. At a minimum, the following criteria will be met:

a. **Vegetation Height and Clearance**

- Vegetation within and adjacent to the Solar Components will be maintained as follows:
    - During the dry season (June to October), vegetation height will be limited to 4 to 8 inches. Vegetation will be mowed to a height of 4 inches prior to June of each year.
    - Outside of the dry season (November to May), vegetation will be maintained at a maximum height of less than 12 inches,
    - A minimum vertical clearance of 12 inches from all electrical and mechanical equipment will be maintained at all times.
- Vegetation exceeding the heights listed above will be mowed or removed in accordance with any Oregon Department of Forestry or County-issued fire restrictions.
- At no time shall vegetation come into contact with electrical infrastructure, inverters, or cable runs.

- A minimum 20-foot, clear, brush free area will be maintained around perimeter of fenced solar array areas (10-feet inside the fence and 10-feet outside the fence). Activities necessary to maintain the area as clear, brush free shall be based on consultation with the local fire code official; and
- Gravel or compacted soil surfaces will be maintained beneath and around all inverter skids, the collector substation, O&M building, and meteorological towers.

b. **Fuel and Debris Management**

- Vegetation and debris removed from the Facility will be disposed of off-site and will not be stored or burned on-site.
- The Certificate Holder and contractors will prevent accumulation of combustible materials or "burn piles."
- Inspections will ensure that fence lines, service roads, and work areas remain clear of dry vegetation, woody debris, or stored materials that could create fuel continuity during fire season.
- All newly constructed or maintained service roads within the Solar Micrositing Area will maintain a minimum 16-foot width of graveled, all-weather surface to facilitate emergency response access.

c. **Designated Noncombustible Areas**

- All-weather service roads will be compacted soil or gravel and maintained in good condition.
- A 20-foot non-vegetated perimeter buffer will be maintained around substations and Operations and Maintenance buildings.
- Parking and laydown areas will consist of compacted soil, gravel, or other non-combustible material to reduce ignition potential from vehicles and equipment.
- Areas immediately surrounding electrical equipment, transformers, and battery energy storage system (BESS) enclosures will remain vegetation-free and will be maintained as graveled or earthen surfaces.

d. **Standards and Continuous Improvement:** Vegetation management and fire prevention measures will be reviewed annually to ensure continued compliance with applicable codes and evolving best practices, including:

- North American Electric Reliability Corporation (NERC) FAC-003-0 – Vegetation Management Standard for Transmission Lines
- Oregon Fire Code and National Fire Protection Association (NFPA) Standards relevant to energy facilities
- OAR Chapter 477 and 629-043 – ODF Fire Prevention Standards
- OAR 860-024 – Public Utility Commission (PUC) Electrical Safety Standards
- American Clean Power (ACP) and Avian Power Line Interaction Committee (APLIC) industry best practices

The Certificate Holder will evaluate new technologies, standards, and operational lessons learned each year to incorporate applicable improvements into this Comprehensive Plan or the future Operations Wildfire Management Plan.

Appendix G. Weed Control Plan

Regulatory Framework

The Oregon Department of Agriculture (ODA) and Sherman County Weed District maintain lists and classifications of noxious weeds. Although not all listed noxious weeds occur in the vicinity of the Solar Micrositing Area, the Certificate Holder and its contractors should be aware of the entire list while monitoring and controlling weeds.

State of Oregon

In Oregon, a noxious weed is defined under Oregon Revised Statutes (ORS) 569.175 as "a terrestrial, aquatic, or marine plant designated by the State Weed Board under ORS 569.615 as among those representing the greatest public menace and as a top priority for action by weed control programs." Noxious weeds have been declared by ORS 569.350 as a menace to public welfare, and control of these plants is the responsibility of private landowners and operators, as well as county, state, and federal governments.

The Oregon State Weed Board (OSWB) was created by ODA under ORS 569.600. OSWB provides recommendations for noxious weed control at the state level and is responsible for updating the State Noxious Weed List. The OSWB and the ODA classify noxious weeds in Oregon in accordance with the ODA Noxious Weed Classification System; there are three designations under the State's system:

- **A-Listed Weed:** A weed of known economic importance which occurs in the state in small enough infestations to make eradication or containment possible; or is not known to occur, but its presence in neighboring states makes future occurrence in Oregon seem imminent.
    - **Recommended Action:** Focus on prevention of new infestations through vector control, certification programs, education, outreach and surveys. New and existing infestations are prioritized for eradication or intensive control when and where found. Regionally focused, species-specific Statewide Management Strategies for A-listed weeds may be developed as necessary.
- **B-Listed Weed:** A weed of economic importance that is regionally abundant but may have limited distribution in some counties.
    - **Recommended Action:** Limited to intensive control at the state, county, or regional level as determined on a site-specific, case-by-case basis. Where implementation of a fully integrated statewide management plan is not feasible, biological control (when available) shall be the primary control method.
- **T-Designated Weed:** A designated group of weed species selected from the B list as a focus for prevention and control by the Noxious Weed Control Program. T-designated noxious weeds are determined by the Oregon State Weed Board and management actions are prioritized and informed by species-specific T-List Statewide Management Strategies created and maintained by the ODA. Action against these weeds will receive priority in accordance with the recommendations of the Statewide Management Strategy.

Sherman County

The Sherman County noxious weed list and protocol were developed by the Sherman County Weed District. Sherman County defines weeds of significance with six classes:

- **A Class:** High priority. Any noxious weed which greatly endangers the overall economic well-being of the County and has a small enough distribution where eradication is possible.
- **B Class:** Moderate priority. A noxious weed which is well established in the County and has known negative impacts, but due to its distribution, eradication is not feasible.
- **C Class:** Low priority. A noxious weed which is widespread throughout the County and has known economic impacts.
- **Q Class**: Questionable list. A newly detected weed which may have some importance, but more information is needed to determine its impact on agriculture. There is only one Q Class weed currently: hairy willow herb (*Epilobium hirsutum*).
- **T Class:** Targeted list. A noxious weed from any Class that the Sherman County Weed Control Board wishes to focus efforts and resources on. This list is reviewed annually.
- **W Class:** Watch list. Any noxious weed that may occur in neighboring counties, the State or similar environments as the County, and could potentially endanger the overall economic well-being of the County. Once detected, these weeds shall be moved to the appropriate list.

Noxious Weeds Identified at the Solar Components

Noxious weeds identified within the Solar Micrositing Area on July 9 and 10, 2024, are listed in Table G-1. Twelve listed noxious weeds were documented, including 8 ODA-listed noxious weeds and 12 Sherman County listed noxious weeds. Eight of the noxious weeds observed were state and/or County "B" listed weeds. One species, rush skeletonweed (*Chondrilla juncea*), is an "A" Class Weed in Sherman County and a state "T"-designated weed, meaning that ODA targeted this species for prevention and control.

In addition to noxious weeds, cheatgrass (*Bromus tectorum*), an invasive annual grass, was identified in grassland habitats within the Solar Micrositing Area. While cheatgrass is not a listed noxious weed, it and other invasive annual grasses can adversely impact habitat and increase fire risk.

Table G-1. Noxious Weeds Observed During Surveys in 2024

Scientific Name	Common Name	ODA Status[1]	Sherman County Status[1]	Frequency[2]
Aegilops cylindrica	jointed goatgrass	B	C	Infrequently observed.
Centaurea diffusa	diffuse knapweed	B*	B	Several small to medium-sized populations observed.
Chondrilla juncea	rush skeletonweed	B (T)*	A (T)	Frequently observed in non-cultivated areas.

Scientific Name	Common Name	ODA Status[1]	Sherman County Status[1]	Frequency[2]
Cirsium arvense	Canada thistle	B*	B (T)	One observation made.
Cirsium vulgare	bull thistle	B*	C	Observed in two locations.
Convolvulus arvensis	field bindweed	B	B	Many small to large populations observed.
Conyza canadensis	horseweed	Not listed	C	Commonly observed.
Lactuca serriola	prickly lettuce	Not listed	C	Frequently observed.
Onopordum acanthium	Scotch thistle	B	B (T)	Several observations made.
Rhaponticum (Acroptilon) repens	Russian knapweed	B*	B	One observation made.
Salsola tragus	Russian thistle	Not listed	C	Frequently observed.
Secale cereale	cereal rye	Not listed	C	Frequently observed.

1. Species marked with a (*) are targeted for biocontrol.
2. Patch/observation sizes are as follows: small = less than 0.1 acre, medium = 0.1 to 1.0 acre, large = greater than 1 acre.

Management Objectives

Management objectives shall be based on the classification status of a species and frequency of observations (Tables G-1 and G-2). Classification status will be determined based on the higher-status identified by the State or County Weed List unless recommended otherwise by the County. Management objectives for unlisted species will be determined on a case-by-case basis based on need for control (e.g., fire control, etc.)

Table G-2. Management Objectives

Weed Classifications	Years		
	0	1-6	6+
A, A(T) or B(T)	Begin control prior to construction; continue throughout consttruction	Intensive control with goal of eradication within first 5 years of operations. Prevent new infestations	Intensive control and eradication for life of facility. Prevent new infestations
B	Begin control prior to construction and continue throughout construction.	Intensive control with the goal to eradicate within first 5 years of operations. Prevent new infestations.	Monitor and manage to prevent new populations/spread of existing populations.
C	Monitor and manage to prevent new populations/spread of existing populations.	Monitor and manage to prevent new populations/spread of existing populations.	Monitor and manage to prevent new populations/ spread of existing populations.
Invasive Annual Grasses	Monitor and manage to minimize wildfire risk.	Monitor and manage to minimize wildfire risk.	Monitor and manage to minimize wildfire risk.

Weed Control Methods

Noxious weed control methods for the Weed Management Area (i.e., the disturbance area associated with the Solar Components plus a 10-foot buffer) described in this Comprehensive Plan were developed utilizing information from the ODA Noxious Weed Control Program and the Sherman County Weed District. Management of noxious weeds will be considered throughout all stages of construction and operation of the Solar Components and will include:

- **Prevention:** Implementing measures to prevent the spread of noxious weeds during construction, operation, and maintenance activities.
- **Treatment:** Treating noxious weed populations with their appropriate control methods, at appropriate time intervals.
- **Monitoring:** Assessing noxious weed changes within the Weed Management Area over time and ensuring that legacy as well as new weed populations are not increasing their distribution.

Portland General Electric Company's (the Certificate Holder) objective is to prevent the introduction of new noxious weed populations and spread of existing noxious weed populations. The methods described above in this Comprehensive Plan and supplemented below will be implemented to minimize the spread of noxious weeds during construction activities. New noxious weeds detected within the Weed Management Area during post-construction revegetation will be considered a result of construction activities and will be controlled accordingly.

Biological Control

Biological control involves the use of prescribed insects, fungi, and livestock to control noxious weeds to achieve management objectives. Biological control methods are typically targeted to a specific species or plant to control its persistence. They are also used for maintenance in targeted areas for vegetation management control in height and density that includes mitigating fire risk and erosion. Biological control is environmentally friendly and should be the first consideration when applicable.

Mechanical Treatment

Mechanical treatment will be the preferred method of treatment for existing noxious weed populations where appropriate within the Weed Management Area. Mechanical control methods rely on removal of plants, seed heads, and/or cutting roots with a shovel or other hand tools or equipment that can be used to remove, mow, or disc noxious weed populations. Hand removal of plants is also included under this treatment method. Mechanical methods are useful for smaller, isolated populations of noxious weeds in areas of sensitive habitats. Additionally, hand removal of small infestations can minimize soil disturbance, allowing desirable species to remain and limiting conditions favorable for noxious weeds.

Some rhizomatous plants can spread by discing or tillage. For example, rush skeletonweed, which has been identified within the Solar Micrositing Area (Appendix E), can reproduce vegetatively from small segments of root, and discing or tilling can facilitate the spread of this species. As such,

implementation of discing will be species-specific and avoided in areas where it will be counter-productive.

If discing is employed in areas that will be revegetated following construction, subsequent seeding will be conducted to re-establish desirable vegetative cover that will stabilize the soils and slow the potential re-invasion of noxious weeds. Discing, tilling, or other mechanical treatments that disturb the soil surface within native habitats will also be avoided in favor of herbicide application, which is an effective means of reducing the size of noxious weed populations as well as preventing the establishment of new infestations.

Chemical Treatment

Chemical control can effectively remove noxious weeds through use of selective herbicides. The specific herbicide used, and the timing of application will be chosen based on the specific noxious weed being treated, as appropriate herbicides differ between species and types of plants (i.e., dicots such as rush skeletonweed versus monocots such as jointed goatgrass).

Herbicides will be applied to identified, treatable, noxious weed infestations. The Certificate Holder or their contractors will coordinate with the Sherman County Weed District to determine which populations are treatable and will notify landowners of proposed herbicide use on their lands prior to application. If a noxious weed population is deemed to be untreatable (e.g., too widespread and established in an area to successfully control), the Certificate Holder will implement the applicable prevention measures discussed in this Comprehensive Plan, subject to approval by the Oregon Department of Energy (ODOE) and the Sherman County Weed District.

Apply only herbicides approved by the U.S. Environmental Protection Agency (EPA) and ODA; annually check the status of herbicide approval (e.g., confirming herbicides are approved for use by the EPA and ODA).

Herbicide application will be performed within the appropriate season to achieve desired results, as approved by ODOE and the Sherman County Weed District. No weed treatment will occur in agricultural lands without landowner permission.

Herbicide Application and Handling

Hand application methods (e.g., backpack spraying) may be used in roadless areas or in rough terrain. Vehicle-mounted sprayers (e.g., handgun, boom, and injector) will be used mainly in open areas that are readily accessible by vehicle. Calibration checks of equipment will be conducted prior to spraying activities, as well as periodically throughout use, to ensure that appropriate application rates are achieved.

Herbicides will be transported with the following stipulations:

- Only the quantity needed for that day's work will be transported.
- Concentrate will be transported in approved containers only, and in a manner that will prevent spilling, stored separately from food, clothing, and safety equipment.

- Mixing will be done at a distance greater than 200 feet from open or flowing water, wetlands, or other sensitive species' habitat. No herbicides will be applied at these areas unless authorized by the appropriate regulatory agencies.
- All herbicide equipment and containers will be inspected daily for leaks.
- Herbicide use will be in accordance with all manufacturers' label recommendations and warnings.
- Apply herbicide under appropriate conditions (i.e., not when wind velocity exceeds 15 miles per hour for granular application or exceeds 10 miles per hour for liquid applications; snow or ice covers the foliage of target species; or adverse weather conditions are forecasted within the next few days).

Herbicide Spills and Cleanups

All appropriate precautions will be taken to avoid herbicide spills. In the event of a spill, cleanup will be immediate. Contractors will keep spill kits in their vehicles to allow for quick and effective response to spills. Items included in the spill kit will be:

- Protective clothing and gloves;
- Adsorptive clay, "kitty litter," or other commercial adsorbent;
- Plastic bags and a bucket;
- A shovel;
- A fiber brush and screw-in handle;
- A dustpan;
- Caution tape;
- Highway flares (use on existing hard-top roads only); and
- Detergent.

Response to an herbicide spill will vary with the size and location of the spill, but general procedures include:

- Stopping the leak;
- Containing the spilled material;
- Traffic control;
- Dressing the clean-up team in protective clothing;
- Cleaning up and removing the spilled herbicide, as well as the contaminated adsorptive material and soil; and
- Transporting spilled herbicide and contaminated material to an authorized disposal site.

Herbicide Spill Reporting

All herbicide contractors will have readily available copies of the appropriate material safety data sheets for the herbicides used at their disposal and will keep copies of the safety data sheets in the application vehicle. If an herbicide spill of any size occurs, the appropriate agency and spill coordinators will be notified promptly. In case of a spill into wetlands and waterbodies, the appropriate federal, state, and county agencies will be notified immediately. All herbicide spills equal to or greater than 200 pounds or 25 gallons of pesticide residue will be reported to the Oregon Emergency Response System in accordance with applicable laws and requirements (Oregon Administrative Rules 340-142-0050). The Certificate Holder, BIGL bn, LLC (BIGL or Project Developer), or the Environmental Monitoring Contractor (EMC) will report all herbicide spills to ODOE by phone or email within 72 hours with follow-up reporting as appropriate.

Special Considerations

Special consideration will be provided to perennial, intermittent, and ephemeral streams/draws during treatment activities. No herbicide will be sprayed where the drift can enter standing water or saturated soil. It will be the herbicide applicators' responsibility to ensure that no herbicide or drift enters standing water, regardless of the season when the herbicide is applied. Similar considerations will be made when in proximity to agricultural fields.

Weed Monitoring and Reporting

Weed inspections will occur within the Weed Management Area through visual inspection of the site while driving or walking. During the construction phase, the EMC will conduct periodic monitoring of noxious weeds. Noxious weeds observed during construction will be treated with mechanical or chemical treatments or other best management practices, as applicable. If construction extends into the growing season prior to the commercial date of operations and formal post-construction weed monitoring, the EMC will conduct informal but comprehensive weed surveys to inform adaptive management. In addition, weed monitoring may be conducted by the EMC as part of routine construction environmental monitoring monthly from April to October.

The EMC will conduct annual post-construction noxious weed monitoring within the Weed Management Area starting the first growing season after construction to map the extent of all noxious weed occurrences and identify areas for treatment. Results will be summarized in annual monitoring reports that describe treatments performed, treatment efficacy, recommendations to improve efficacy (if necessary), and any new noxious weed occurrences. Reports will be submitted to ODOE, ODFW, and the County annually. The Certificate Holder will be responsible for treating all noxious weeds observed within the Weed Management Area.

Based on the success of control efforts after the second year of monitoring, the Certificate Holder will consult with ODOE and the Sherman County Weed District to determine if the monitoring cycle can be reduced for Year 3 through Year 5. After 5 years of monitoring, the Certificate Holder will design a long-term weed control plan in consultation with ODOE and the Sherman County Weed District . The Certificate Holder will maintain ongoing communication with individual landowners, the Sherman County Weed District, and ODOE regarding noxious weeds within the Weed

Management Area. Landowners may also contact the Certificate Holder directly to report the presence of noxious weeds related to Solar Component activity. The Certificate Holder will control reported noxious weeds on a case-by-case basis and prepare a summary of measures taken for that landowner. During the operational period of the Solar Components, the Certificate Holder will control noxious weeds as described in the long-term weed control plan. The Certificate Holder will report the investigator's findings and recommendations regarding weed control in the Solar Component's annual report required by Oregon Administrative Rule 345-026-0080.

Treatment Plan

Table G-3, below, provides a treatment plan for noxious and invasive weeds (listed by ODA and Sherman County) in the Weed Management Area, including management objectives and treatment guidelines. This table will be updated in each year's annual monitoring report. Specific herbicide application rates will be determined in consultation with the Sherman County Weed District and the Weed Control Contractor.

Table G-3. Treatment Plan for Noxious and Invasive Weeds

Scientific Name	Common Name	State/County Status	Frequency	Management Objective	Treatment Guidelines[1]
Aegilops cylindrica	jointed goatgrass	B/C	Infrequently observed.	Monitor and manage to prevent new populations/spread of existing populations	Mechanical: Timing is critical, mow after flowering but before seeds reach soft boot stage. Early mowing will result in new tiller growth. Requires multiple mowings throughout the growing season over several years. **Chemical:** Apply to actively growing plants in late winter or spring before flowering or pre-emergent herbicide in fall. Biocontrol: None
Centaurea diffusa	diffuse knapweed	B/B	Several small to medium-sized populations observed.	Monitor and manage to prevent new populations/spread of existing populations	Mechanical: Manually remove entire plant, including taproot, prior to flowering. Chemical: Apply to actively growing plants in fall or spring from rosette to bolting stage. **Biocontrol:** Agents include several seed feeding flies and weevils and a root-boring beetle.
Chondrilla juncea	rush skeletonweed	B (T)/A(T)	Frequently observed in non-cultivated areas.	Intensive control, eradication within first 5 years of operations. Prevent new populations.	Mechanical: Regenerates from root fragments. Manually remove entire plant, including taproot, prior to flowering. Will require multiple efforts during the growing season for more than one year. **Chemical:** Apply to rosettes in the spring immediately before or during bolting. Biocontrol: Agents include a gall midge, gall mite, rust fungus, and root-mining moth
Cirsium arvense	Canada thistle	B/B(T)	One observation made.	Eradication of observation prior to construction. Monitor and manage to prevent new populations.	Mechanical: Not recommended, rhizomatous. **Chemical:** Apply from rosette to bud stage to actively growing thistle in spring or in fall with select chemicals only. Biocontrol: Four approved agents; stem weevil, seed head weevil, crown weevil, and stem gall fly.

Scientific Name	Common Name	State/County Status	Frequency	Management Objective	Treatment Guidelines[1]
Cirsium vulgare	bull thistle	B/C	Observed in two locations.	Begin control prior to construction. Eradication within 5 years of operations of. Prevent new populations.	**Mechanical:** Till or pull prior to flowering. Cut off root below soil surface. Chemical: Treat rosettes in fall or spring. Biocontrol: Seed head gall fly, not effective for individuals but can reduce overall population.
Convolvulus arvensis	field bindweed	B/B	Many small to large populations observed.	Monitor and manage to prevent new populations/spread of existing populations.	Mechanical: Not recommended, bindweed has extensive root systems and can spread by seed and root fragments. **Chemical**: Apply to rapidly growing plants in spring or summer, prior to flowering. Plants should not be under drought stress at time of application. Biocontrol: Two approved agents; a moth and mite.
Conyza canadensis	horseweed	Not listed/C	Commonly observed.	Monitor and manage to prevent new populations/spread of existing populations.	**Mechanical**: Mow or pull prior to flowering. Chemical: Apply to rapidly growing plants prior to flowering. Biocontrol: Unknown
Lactuca serriola	prickly lettuce	Not listed/C	Frequently observed.	Monitor and manage to prevent new populations/spread of existing populations.	Mechanical: Graze, till, or pull prior to flowering. Mowing not considered effective due to robust regrowth. **Chemical:** Apply to rapidly growing plants in spring prior to flowering. Biocontrol: None
Onopordum acanthium	Scotch thistle	B/B(T)	Several observations made.	Intensive control, eradication within first 5 years of operations	**Mechanical:** Pull prior to flowering, cut off root below soil surface. Tilling will control emerged plants but stimulate germination. Follow up tilling with herbicide application to treat seedlings. Sheep and goats will eat young plants and flower heads. Chemical: Treat from rosette to bolting stage in fall or spring. Most effective on small rosettes. Biocontrol: None

Scientific Name	Common Name	State/County Status	Frequency	Management Objective	Treatment Guidelines[1]
Rhaponticum (Acroptilon) repens	Russian knapweed	B/B	One observation made.	Eradication of observation prior to construction. Monitor and manage to prevent spread/new populations.	**Mechanical:** Manually remove entire plant, including taproot, prior to flowering. Chemical: Apply to actively growing plants in fall or in spring from rosette to bolting stage. Biocontrol: Gall nematode available.
Salsola tragus	Russian thistle	Not listed/C	Frequently observed.	Monitor and manage to prevent new populations/spread of existing populations.	Mechanical: Hand pulling effective for small populations. Mow just before flower maturation or repeatedly mow younger plants. **Chemical:** Treat young, rapidly growing plants from seedling to mid-rosette stage in spring or fall. Most effective on smaller plants. Preemergence also effective. Many populations are herbicide resistant in the inland northwest, consult with local herbicide applicator or county weed manager. Biocontrol: Leaf mining and stem boring moths have provided poor control.
Secale cereale	cereal rye	Not listed/C	Frequently observed.	Monitor and manage to prevent new populations/spread of existing populations.	**Mechanical**: Repeated mowing in spring prior to seed set or tillage combined with herbicide application in fallow fields. Hand pull prior to seed set. Chemical: Treat prior to seed set. Herbicide more effective if applied one year after mowing to reduce thatch buildup. Biocontrol: None
Bromus tectorum (and others)	Cheatgrass; other annual invasive grasses	Not Listed	Common in grassland habitat	Monitor and manage to minimize wildfire risk.	**Mechanical:** Repeated mowing (every 3 weeks) to 2 inches in spring can eliminate seed production in areas where herbicide application is unacceptable. Chemical: Apply pre-emergent herbicide prior to germination. Post emergent in fall or early spring/summer to rapidly growing plants prior to seed set.

Scientific Name	Common Name	State/County Status	Frequency	Management Objective	Treatment Guidelines[1]
					Biocontrol: None

1.0 Introduction

The Portland General Electric Company (PGE or Certificate Holder) owns and operates the Biglow Canyon Wind Farm (BCWF or Existing Facility) under Site Certificate on Amendment 3, issued October 31, 2008 (Site Certificate). PGE has filed a Request for Amendment 4 (RFA 4) to add photovoltaic (PV) solar energy generation and battery storage (Solar Components[1]) to the Existing Facility.

BCWF currently consists of 217 wind turbines, with a peak generating capacity of 450 megawatts (MW). RFA 4 adds up to 125 MW alternating current (AC) generating capacity from PV solar arrays and 125 MW in battery storage capacity (Solar Components) in approximately 1,445 acres (Solar Area) sited within the existing BCWF site boundary Solar Micrositing Area (RFA 4 Site Boundary). The Solar Micrositing Area is approximately 1,924 acres and provides a conservative estimate of the maximum acreage needed for development, micrositing, and temporary disturbances from the Solar Components during construction, rather than the anticipated disturbance footprint. The permanent disturbance[2] area impacted by the Solar Components within the Solar Micrositing Area is up to 1,455 acres (Solar Area) and the final footprint will be confirmed during pre-construction compliance.

The Solar Micrositing Area is zoned entirely Exclusive Farm Use (EFU) by Sherman County and is currently cultivated for dryland wheat. Because the permanent disturbance area from the Solar Components will exceed 12 acres and 20 acres of high-value and arable farmland, respectively, RFA 4 requires an exception to Oregon Statewide Planning Goal 3 (Agricultural Lands).

This Community Investment Plan (CIP) supports PGE's Goal 3 exception request and helps justify why a Goal 3 exception is warranted for the BCWF, as amended. The CIP is a mitigation plan that, once implemented, will ensure that any potential adverse impacts to the local agricultural economy from the removal of cultivated wheat land are offset to a level acceptable to Sherman County and the community.

PGE will own and operate the Solar Components as a part of the BCWF, which, to date, have been developed by BIGL bn, LLC (BIGL, or Project Developer). BIGL, in its capacity as the project developer, is supporting PGE in the RFA 4 and may construct and temporarily operate the Solar

[1] Solar Components will include solar arrays, inverters, and inverter step-up transformers. Related or supporting facilities include underground medium voltage collector lines, a collector substation, battery energy storage system (BESS) facilities and their subcomponents (i.e., inverters), approximately 600 feet of a new 230-kV generation tie transmission line, operations and maintenance structures, site access roads, internal roads, perimeter fencing, facility entry gates, and temporary laydown areas. The maximum generating capacity from the Solar Components will be 125 MW AC, and the infrastructure will be fenced within the Solar Micrositing Area creating a permanent impact area of up to 1,445 acres (i.e., Solar Area).
[2] Permanent disturbance includes areas and infrastructure (trackers, inverters, internal roads, buildings, stormwater basins, and parking) inside the perimeter fence for the Solar Micrositing Area.

Components on behalf of PGE under a Build-Transfer Agreement and may implement components of the CIP including providing mitigation fund payments on behalf of PGE.

1.1 Project Layout and Construction Schedule

The proposed layout for the Solar Components includes a primary area of infrastructure improvements within the Solar Micrositing Area. The Solar Area will connect to the electrical grid through the existing point of interconnection (POI) at the Biglow Canyon Substation, which is situated within the Solar Micrositing Area.

Solar Micrositing Area: The Solar Micrositing Area is a continuous area of land that covers approximately 1,924 acres, fully within the approved BCWF site boundary, within which construction of the Solar Components may occur, subject to site certificate conditions. This area includes the Existing Facility's current POI and may be expanded to add a new 230-kilovolt (kV) line terminal, all Solar Components, and the fenced area for where such components will be located (1,445 acres; Solar Area).

Solar Area: This area falls within both the approved BCWF site boundary and the Solar Micrositing Area. It will host new solar arrays using tracking systems, a new BESS, a new collector substation, a new operations and maintenance building, a temporary laydown yard for construction, new access roads, perimeter fencing, the Existing Facility's current POI, approximately 600 feet of new 230-kV generation tie line, and other associated project components.

The Solar Components located within this area will add approximately 125 MW AC generating capacity on a total of up to 1,445 acres that would be fenced within the approved BCWF site boundary. All Solar Components will be set back at least 520 feet from the existing wind turbines per PGE requirements.

Construction is expected to begin in Q2 of 2026 and continue through Q4 of 2027 for a duration of approximately 17 to 19 months from mobilization to final completion.

1.2 Goal 3 Exception and Need for Mitigation Plan

Oregon Statewide Planning Goal 3 (Agricultural Lands) (Goal 3) requires counties to identify farmland on its comprehensive plan map, and zone those lands as EFU. An EFU zone places certain restrictions on developments to minimize uses that conflict with farming (DLCD 2023). Oregon Administrative Rule (OAR) Chapter 660, Division 33 and similar provisions under Sherman County Zoning Ordinance (SCZO) Article 3 regulate EFU lands and permitted uses on these lands. The SCZO has not been amended since 2003 and does not reflect the current list of uses and standards provided by OAR 660-033-0130. As a result, PGE directly applied OAR 660-033-0130(38)(g), which states that a PV solar power generation facility shall not use, occupy, or cover more than 12 acres of high-value farmland unless certain criteria under OAR 660-033-0130(38)(h) are met or an exception is taken pursuant to Oregon Revised Statutes (ORS) 194.732. Similarly, per OAR 660-033-0130(38)(i), a PV solar power generation facility shall not use, occupy, or cover more than 20 acres of arable lands unless certain criteria under OAR 660-033-0130(38)(i) are met or an exception is taken pursuant to ORS 194.732.

As the Solar Components will occupy more than 12 acres of high-value farmland and more than 20 acres of arable land, it does not meet the acreage standards under OAR 660-033-0130(38)(g) and (i) and requires a Goal 3 exception. The Energy Facility Siting Council (Council or EFSC) may approve an exception to Goal 3 for an energy facility that meets the criteria listed under ORS 469.504(2)(c) and OAR 345-022-0030(4)(c). These criteria include the following:

- Reasons justify why the state policy embodied in the applicable goal should not apply;
- The significant environmental, economic, social and energy (EESE) consequences anticipated as a result of the proposed facility have been identified and adverse impacts will be mitigated in accordance with rules of the Council applicable to the siting of the proposed facility (EESE consequences); and
- The proposed facility is compatible with other adjacent uses or will be made compatible through measures designed to reduce adverse impacts.

This CIP supports the approval of PGE's Goal 3 exception request by supporting the "reasons" to justify the Goal 3 exception and ensuring that potential adverse impacts under the EESE consequences are properly mitigated. Measures to address the Amended Facility's compatibility are outlined in RFA 4 Exhibit K, Sections 6.2 and 8.3.

PGE justifies a Goal 3 exception by demonstrating that reasons justify removing up to 1,445 acres of dryland wheat from agricultural production for 40 years. One of the reasons is that the Amended Facility will result in rural local economic development benefits. This CIP ensures that the rural local economic benefits will offset potential adverse impacts the Solar Components may have on Sherman County's agricultural economy. In addition, participating landowners—many of whom represent multigenerational farm families—have emphasized that solar development provides an opportunity to diversify income and strengthen long-term financial stability. This landowner perspective reinforces the rationale for a Goal 3 exception, as the Amended Facility not only contributes to rural economic development but also supports the continuity of agricultural operations across generations.

2.0 Development of the Plan

To help inform the development of the CIP and to identify example projects that could be funded through the mitigation fund (see Section 4.0), PGE and the Project Developer spent considerable time and effort coordinating with the local agricultural community to understand what potential projects/investments would be most beneficial to support the local agricultural economy. Meetings were held with local wheat farmers, the Oregon Watershed Enhancement Board (OWEB), Oregon State University (OSU) including its extension service in Sherman County and the College of Agricultural Sciences, the Oregon Wheat Commission, the Sherman County Fire District, Sherman County Emergency Services, the Rural Sherman County Fire Board, the Weed Master, the Road Master, the County Planning office, and County Judge

Engagement also included targeted discussions with project landowners and surrounding landowners, who underscored the importance of financial resilience in maintaining viable farm operations. While coordination with the Sherman County Soil and Water Conservation District (SWCD) has not yet occurred in person, the Project Developer remains committed to continued outreach.

Fire safety emerged consistently as the most pressing community concern—not only in relation to the Solar Components, but as a broader and growing threat to Sherman County's agricultural economy. In response, the Project Developer has prioritized coordination with local fire districts, including a presentation to the North Sherman Fire Board on August 12, 2025, and a follow-up meeting with Chief Burbank of the North Sherman County Fire District on September 9. These meetings provided an opportunity to review site layout and engineering plans, incorporate feedback, and identify opportunities to strengthen local fire response capacity.

Several key themes for possible agricultural mitigation investments emerged from this coordination:

1. Investments in minimizing wildland fire risk to agricultural crops, properties, and infrastructure and minimizing risk of liability to farmers from farm activities igniting fires and impacting non-farm uses in the agricultural district;
2. Research into agrivoltaics techniques in the context of dryland farming in central and eastern Oregon;
3. Research into long-term effects to soils that have been removed from cultivation and placed in long-term vegetation management programs within solar array areas;
4. Maintaining and/or improving weed control county-wide on agricultural lands and minimizing costs for weed control;
5. Technical assistance training for heavy equipment operation and repairs for farmers and laborers in the County to provide uplift in firefighting support, construction, and farming;
6. Providing funding for 4H, National Future Farmers of America Organization, or other youth programs; and
7. Providing additional funds to supplement Natural Resources Conservation Service and SWCD cost share programs for technical assistance programs such as improving haul routes, weed control, establishing fire breaks, etc.

As described further in Section 4.0, the final decision on what projects would be funded and/or what organizations would be awarded mitigation funds will be determined by the Sherman County Court. The mitigation projects identified in Section 5.0 and the selection criteria identified in Section 4.2.4 are unique to the Sherman County agricultural community and its specific needs. The projects identified in this plan are in direct response to community feedback and will bring economic benefit to the County's agricultural community, which is primarily composed of dryland wheat farmland.

3.0 Overview of Project Impacts on Agricultural Economy

PGE evaluated the potential adverse impacts to Sherman County's agricultural economy from removing up to 1,445 acres of dryland wheat from production for the life of the project. For details of this evaluation, see RFA 4 Exhibit K, Attachment K-1. The removal of 1,445 acres of winter wheat would have an estimated reduction in annual output of $281,300 in the grain sector. Putting this into context, $281,300 is equivalent to 0.8 percent of the Sherman County's average value of production of winter wheat and 0.1 percent of the State's average value of production of winter wheat. This highlights the small percent of the county and state's winter wheat production value impacted by the Solar Micrositing Area.

Using a worst-case scenario impact analysis of a full build out of the Solar Components resulting in the loss of 1,445 acres of dryland wheat over 40 years, PGE estimates that the Amended Facility may result in a loss of annual indirect economic output of $100,000 over the life of the Facility, as amended. This loss of indirect economic output represents decreases in spending on wheat farming inputs like seeds, fertilizer, and fuel and contract services.

Calculated over a period of 40 years of operation, and adjusting for inflation, the estimated indirect output would be $2,315,218 or $1,600 per acre of farmland taken out of production. The final mitigation payments will be based on the actual acres identified in the final design of the Solar Components, which may be less than the full 1,445 acres identified in the Goal 3 exception request.

4.0 Mitigation Fund

PGE and the Project Developer have partnered with Sherman County and the Mid-Columbia Economic Development District (MCEDD) to establish an agricultural mitigation fund that will administer and distribute dollars for projects having a benefit to the Sherman County agricultural economy. The fund will ensure that any potential adverse impacts from the Solar Components are offset to levels acceptable to Sherman County and the community. Maintaining local control over investment decisions was identified as an essential element of trust-building during stakeholder engagement. For this reason, all mitigation fund allocations will ultimately be directed by the Sherman County Court to ensure alignment with community priorities and accountability to local stakeholders.

4.1 Establishing the Biglow Community Investment Fund

MCEDD will administer the Biglow Community Investment Fund under an Administrative Agreement (as described in the Memorandum of Understanding among Sherman County, MCEDD, and PGE, dated [add]). Prior to construction, $1,600 per acre for each acre the Solar Components remove from agricultural production will be placed into the Biglow Solar Account that will then be used to fund mitigation projects under the CIP. The total number of acres removed will be determined based on the final layout confirmed during the Oregon Department of Energy pre-

construction compliance review. The mitigation payment may be provided by PGE or the Project Developer (or other entity) on behalf of PGE.

4.2 Administration of the Biglow Community Investment Fund

MCEDD will administer the Biglow Community Investment Fund, which will be funded prior to construction of each phase of the Solar Components. MCEDD will also oversee the following administrative steps.

4.2.1 Selection Committee

MCEDD will form and oversee a six-person advisory committee (Selection Committee) to review applications for funding and make recommendations to Sherman County BOC on funding projects. The Selection Committee will comprise the following individuals:

- One representative from Sherman County government;
- One representative from an academic institution engaged in agriculture research in Sherman County or an agricultural-related nonprofit entity located in Sherman County;
- One dryland farm producer in the County;
- One representative selected by the Oregon Wheat Grower's League;
- One community member; and
- One representative with expertise in wildfire as it relates to agricultural lands.

Sherman County will have the ability to propose candidates for the Selection Committee in accordance with the aforementioned criteria, provided that the County proposes candidates within 30 calendar days of the formation of the committee. If the County elects not to propose candidates to the Selection Committee, MCEDD shall make any remaining necessary appointments.

In addition to the members above, the Selection committee shall include one non-voting member with subject matter expertise over statewide or regional agriculture issues selected by the Energy Facility Siting Council.

4.2.2 Applications for Funding

MCEDD shall issue a notice of available funding for mitigation projects as provided by the administrative agreement and contemplated in the Memorandum of Understanding. The notice will identify the selection criteria for qualifying projects and include an application form. All applications for funding would need to be filed with MCEDD at a time determined by the parties, ahead of the Start of Construction (Application Deadline).

4.2.3 Awarding Funds

The Selection Committee will review applications, rank the projects against the selection criteria, and make recommendations to the Sherman County BOC within 3 months of the Application Deadline. The BOC will aim to make a decision on funding within 60 days of receipt of the Selection Committee's recommendation. MCEDD will award funds within 30 days of the County's decision.

4.2.4 Selection Criteria

The selection criteria for a qualified mitigation project are to ensure that projects provide uplift of the Sherman County agricultural economy and are responsive to community needs as described in Section 2.0 and as may be identified by the community in the future. These selection criteria were identified after significant community engagement and listening sessions.

Except as provided in Section 4.2.5 below, the Selection Committee will apply and balance the selection criteria when recommending projects for funding. The five selection criteria are as follows:

1. Improving resiliency and efficiency of Sherman County's agricultural economy;
2. Improving agricultural wildfire protection and risk management capacity;
3. Investing in research to further agrivoltaics for dryland wheat lands;
4. Investing in agricultural education for next-generation farmers; and
5. Subsidizing the price of wheat produced in Sherman County

4.2.5 Pre-Screened Projects

A preliminary list of pre-screened projects is included in Section 5.0. These projects have been identified by Sherman County and the community as having a direct benefit to the rural agricultural economy of Sherman County and are deemed to meet, on balance, the selection criteria. A project proponent of a pre-screened project must still apply for funding through MCEDD and provide a project plan to identify the project's fiscal contribution to the rural agricultural economy and confirm that the selection criteria will be satisfied. A pre-screened project application goes directly to the BOC for consideration and bypasses review by the Selection Committee.

4.3 Reporting Obligations

Award recipients shall provide an annual report to the County, MCEDD, and PGE, as further described in the MOU.

5.0 Pre-Screened Projects

The five pre-screened projects were developed based on extensive outreach and coordination with key stakeholders from the Sherman County agricultural community, as well as state-wide

agricultural-related organizations (see Section 2.0). These projects have the support of both the County and the community, who agree they will provide meaningful benefits to Sherman County's agricultural economy. In particular, they include initiatives that support essential services such as wildfire mitigation. For Sherman County, wildfire mitigation is especially critical, as it helps protect wheat farms—the primary land use in the county—and their supporting infrastructure, including roads, equipment, grain elevators and storage facilities, as well as urban areas tied to farm operations.

5.1 Project 1: Agricultural Wildfire Risk Minimization and Capacity Building

Project Sponsors: North Sherman County Rural Fire Department

Project Description: Sherman County has experienced large-scale wildfires that have burned thousands of acres and have destroyed more than 1 million bushels of wheat in a single fire resulting in more than $5 million in damage (Sherman County 2024). In response to increased community support for fire mitigation and prevention efforts, Sherman County developed and adopted a Community Wildfire Protection Plan (CWPP) in 2024 to identify and mitigate wildfire risk and to develop a strategy to reduce those risks. The CWPP is also meant to assist the county, its communities, and fire districts by making them eligible for certain grants or other funding sources. Grants and funding sources may include National Fire Plan grants, U.S. Forest Service Community Wildfire Defense Grants, and other funding sources to treat hazard fuel situations and to better prepare residents for wildfires that may occur.

The CWPP[3] identifies several projects such as:

1. Upgrading, maintaining, or adding firefighting equipment for Sherman County's Rural Fire Protection Districts.
    a. See Project #7 in CWPP Section XIII.
    b. See Project #31 in CWPP Section XIII.
2. Upgrading and developing new facilities at Rufus Fire Hall, North Sherman Rural Fire Protection District Station, and/or South Sherman Rural Fire Protection District Station
    a. See Project #6 in CWPP Section XIII.
3. Training for volunteers
    a. See Project #13 in CWPP Section XIII.
4. Funding for additional staff
    a. See Project #2 in CWPP Section XIII – develop paid seasonal county firefighting positions.
    b. Fund administrative staff to support all projects identified in CWPP Section XIII.
5. Fund projects to develop fuel breaks, reduce wildfire hazards, provide firefighting water.
    a. See Projects #14, #15, #22 through #30 in CWPP Section XIII.

[3] See Section XII of the CWPP (Sherman County 2024) for a list of identified wildfire mitigation projects.

The County could allocate mitigation funding to support either partial or full implementation of the projects identified in the CWPP, as well as other initiatives aimed at supporting the County's agricultural community in wildfire mitigation and response.

Project Benefit: Section V.E. of the County's CWPP identifies the probability of wildfire in Sherman County as high, with significant vulnerability to grain fields, pastures, and utility infrastructure. As noted in the CWPP, previous fires in the county have burned one million bushels of wheat and caused over $5 million in damages. Any project that reduces the risk or extent of wildfire damage to dryland wheat crops and their supporting infrastructure would provide a direct economic benefit to the County's agricultural community. Stakeholder feedback reinforced that agricultural mitigation and wildfire mitigation are deeply interconnected in Sherman County. Farmers repeatedly emphasized that their livelihoods depend on the resilience of their land and crops, and that wildfire protection must be addressed alongside agricultural investments. Accordingly, the coordination on behalf of RFA4 with the North Sherman Fire District demonstrates a proactive approach to integrating agricultural and fire mitigation needs.

Proposed Budget: To be provided by project sponsor. Project budget is anticipated to range from $100,000 to $500,000.

5.2 Project 2: Funding matching for SWCD programs for wheat farmers

Project Sponsors: Sherman County SWCD

Project Description: Provide funding to supplement funding of SWCD County Cost Share (CCS) program. The Sherman County SWCD CCS program is funded from county tax dollars and includes projects such as improving farming haul roads with gravel, solar well developments, border fencing, terrace and water and sediment control basin reshaping, weed control, pasture/range planting, and creation and maintenance of fire breaks (Sherman County SWCD 2025). As funding for this program is limited, mitigation funds could be directed to SWCD to supplement this program's funding and provide additional opportunities for Sherman County farmers to participate in this program.

Project Benefit: Benefits to farmers participating in the SWCD CCS program would depend on the project but would result in offsetting costs to farmers for soil conservation, weed control, fire mitigation, etc.

Proposed Budget: To be provided by project sponsor. The current annual budget for this program is $100,000 allocated at $25,000 quarterly. For conservation projects, landowners provide 25 percent of the cost while SWCD provides 75 percent of the cost share rate with projects up to $20,000.[4] Mitigation funds allocated to this program could increase the annual budget to provide capacity to fund more projects in the county depending on demand by Sherman County farmers.

[4] See CCS grant application:
https://www.shermancountyswcd.com/files/a1235c3b6/CCS_Application_2024.pdf

5.3 Project 3: Next-Generation Farming Innovation and Technology Training Program

Project Sponsors: To be determined. Sponsors could be individual wheat farmers seeking funding for precision agricultural technology investments, school district seeking funding for heavy equipment training programs, or other community programs such as 4H or National Future Farmers of America Organization seeking funding for youth programs focused on wheat farming.

Project Description: A variety of projects could be included, such as:

- Grant program for county wheat farmers to invest in precision agricultural technology such as weed management equipment, remote sensing technology to assist with weed mapping or soil mapping, variable rate technology to collect data on soil variability to inform application of fertilizers, and other technologies.
    - The precision agricultural technology grant program is intended to increase Sherman County wheat farmer's access to this technology through a cost-sharing agreement between farmers and MCEDD.
    - The cost-share agreement would be determined by the County BOC but is assumed to be 50 percent of the total cost of the precision tech equipment and installation. A cost-share program ensures prospective recipients of the program are fully invested in the use and maintenance of the precision agricultural technology.
- Grant program to offset tuition costs for Sherman County residents to participate in heavy equipment training and receive large equipment operator certification.

Project Benefit:

- The cost-share grant program for precision agricultural technology is assumed to increase the number of farmers who otherwise would not have access to precision management technology due to the significant upfront cost barrier. Investments in this technology could help county wheat farmers decrease costs to expensive farming inputs such as chemicals, fertilizers, and fuel resulting in economic benefits to these farmers.
- The grant program for heavy equipment operation training would directly relate to increasing local capacity to operate farm equipment, firefighting equipment, and construction equipment. This increased capacity would economically benefit farmers in the County by providing additional labor capacity.

Proposed Budget: To be provided by project sponsor. Project budget is anticipated to range from $200,000 to $1,000,000 depending on the number of grants allocated.

5.4 Project 4: Capacity Building for Wheat Growers

Project Sponsor: Sherman County, individual wheat farmers.

Project Description: This project proposes a per-bushel support mechanism to strengthen the financial resilience of Sherman County's wheat growers. For every bushel of wheat produced in the

County, an additional $0.05 would be paid directly to farmers on top of the prevailing market price. This payment is intended to help offset the rising costs of inputs such as seed, fertilizer, fuel, machinery, and labor.

Project Benefits: The benefit of this project is that it directly places funds into the hands of Sherman County wheat farmers at a time when input costs are rising and market prices remain unpredictable. More specifically, the project would:

- Support farm income by providing an additional payment linked to production levels.
- Help offset rising input costs such as seed, fertilizer, and fuel.
- Provide flexibility for reinvestment in farm operations, equipment, or practices that improve efficiency.
- Contribute to the local agricultural economy by supplementing the revenue available to wheat growers.
- Offer modest support for community stability, as additional farm income can help sustain agricultural operations in the County.

Proposed Budget: To be provided by project sponsor. At a rate of $0.05 per bushel, the project could cost up to approximately $282,550 in a single harvest season, assuming an annual production of 5.65 million bushels. The actual budget would vary depending on annual yield volumes and prevailing market conditions.

1.0 Introduction

This draft Habitat Mitigation Plan (HMP) was submitted by the Portland General Electric Company (PGE or Certificate Holder) for the photovoltaic solar energy generation and battery storage (Solar Components) at the Biglow Canyon Wind Farm (BCWF or Existing Facility). Located approximately 4.5 miles northeast of Wasco in Sherman County, Oregon, BCWF currently consists of 217 wind turbines, with a peak generating capacity of 450 megawatts (MW).

The Solar Micrositing Area identified as part of Request for Amendment 4 of the Site Certificate (RFA 4) is approximately 1,924 acres and provides an estimate of the maximum area needed for development, micrositing, and temporary disturbances from the Solar Components during construction, rather than the anticipated disturbance footprint. The permanent disturbance area impacted by the Solar Components is approximately 1,445 acres.

PGE will own and operate the Solar Components as a part of the BCWF (together, Facility), which, to date, have been developed by BIGL bn, LLC (BIGL). BIGL, in its capacity as the project developer, supports PGE in this RFA 4 and may construct and temporarily operate the Solar Components on behalf of PGE under a Build-Transfer Agreement.

The Certificate Holder's goal is to preserve and maintain in-kind habitat in the Columbia Plateau Ecoregion to achieve a net benefit to Category 2 habitat, and no net loss of Category 4 habitat through the measures described in this HMP.

2.0 Finalization of the HMP (PRE-FW-01)

Fish and Wildlife Habitat Condition 1 requires finalization of the draft HMP, stating the following:

> *Prior to construction of a phase or component of the solar facility, as applicable, the certificate holder shall submit a final Habitat Mitigation Plan substantially similar to Final Order on RFA4 Attachment F, base don the finalization requirements included in Section 2.0 of the plan. The final plan must be submitted for review and approval by the Department, in consultation with ODFW.*

The HMP must be finalized prior to construction, based on the estimated permanent habitat impacts associated with the facility, component or phase, as applicable. Final review and approval of the HMP has been delegated by the Council under ORS 469.402 to the Department. The Department, in consultation with the Oregon Department of Fish and Wildlife (ODFW), will review the final HMP based on the following scope:

1. **Final habitat and impact assessment.** Based on final design/layout, update tabular summaries of temporary and permanent disturbance estimates (acres).
    a. Table 2. Temporary and Permanent Impacts by Habitat Category and Habitat Subtype,
    b. Table 3. Calculating Mitigation for Permanent Impacts, and

   c. Table 4. Calculating Mitigation for Temporary Impacts
2. **Execute legal instrument.** Obtain and submit to ODOE a copy of the conservation easement or legal instrument securing the Habitat Mitigation Area (HMA) for conservation purposes as outlined in this HMP:
   a. The term of the conservation easement or legal instrument will be for the life of the Solar Components;
   b. The terms of the conservation easement or legal instrument will be binding upon the landowner, heirs, or successors and would run with the land if property is sold;
   c. The conservation easement or legal instrument will identify restricted uses that have the potential to diminish wildlife habitat functions and value, including but not limited to grazing; grading, mowing, blading or expansion of impervious surfaces or access road networks; division of the Property.
3. **Identify/map baseline condition/monitoring sites and enhancement action areas.** Map baseline habitat conditions of the HMA. Propose number and location of monitoring sites for noxious weeds and shrub-planting. Submit habitat mapping and monitoring site locations to ODOE and ODFW for review and approval.
   a. Provide baseline habitat maps, photographs and maps/GIS data for proposed monitoring:reference sites at the HMA with a description of the weed and vegetative cover.
      i. Baseline monitoring plot photo points within the HMA, include 1) a minimum of five permanent photo points distributed to show general vegetation status throughout the HMA, and 2) additional photo points as needed to monitor success of noxious weed control and shrub-planting;
4. **Finalize enhancement actions and success criteria in Section 6.2.1, 6.2.2 and 6.2.3.** Based on the baseline assessment completed under Sub(3) above:
   a. Provide maps/GIS data of weed treatment and shrub-planting areas.
   b. Determine sagebrush planting density.
   c. Finalize the success criteria for weed treatment and shrub planting.
      i. Success criteria for weed treatment must represent a percent increase in native vegetation cover and percent decrease in invasive cover at monitoring sites compared to baseline.
      ii. Shrub planting will be considered successful when sagebrush density in enhancement areas is 50 percent of planting density at 5 years.
   d. Propose restoration methods in the event of fire which at a minimum include post-burn seeding and noxious weed control.
   e. The ODOE and ODFW must evaluate whether the combined enhancement actions satisfy the Category 2 mitigation goal of a net benefit in habitat quality. If the HMA has minimal need or opportunity for the enhancement actions as currently proposed, additional actions may be identified/required.
5. **Finalize Implementation Schedule.** Provide an implementation schedule for habitat enhancement actions and monitoring.

6. **Finalize Monitoring Protocols and Survey Methods.** Submit final proposed monitoring protocol and survey methods to monitor and evaluate the success of enhancement actions.

Approval of the final HMP will be based on review by the ODOE, in consultation with ODFW, based on the adequacy of the information provided to address the steps/requirements listed above.

3.0 Habitat Categories and Habitat Types

A habitat survey was conducted as part of RFA4 to verify habitat subtypes and habitat categories of all areas to be affected by the Facility. The ODFW Fish and Wildlife Habitat Mitigation Policy (OAR 635-415-0025) provides a framework to categorize habitats based on type, quality, availability, and usefulness/importance to wildlife, and establishes mitigation goals and implementation standards for each. Table 1 defines each of the six habitat category types as presented in the ODFW Habitat Mitigation Policy.

Table 1. Habitat Categorization Types

Category Type	Definition[1]	Mitigation Goal
1	Irreplaceable, essential habitat for a fish or wildlife species, population, or a unique assemblage of species and is limited on either a physiographic province or site-specific basis, depending on the individual species, population or unique assemblage.	The mitigation goal for Category 1 habitat is no loss of either habitat quantity or quality.
2	Essential habitat for a fish or wildlife species, population, or unique assemblage of species and is limited either on a physiographic province or site-specific basis depending on the individual species, population or unique assemblage.	The mitigation goal if impacts are unavoidable is no net loss of either habitat quantity or quality and to provide a net benefit of habitat quantity or quality.
3	Essential habitat for fish and wildlife, or important habitat for fish and wildlife that is limited either on a physiographic province or site-specific basis, depending on the individual species or population.	The mitigation goal is no net loss of either habitat quantity or quality.
4	Important habitat for fish and wildlife species.	The mitigation goal is no net loss of either habitat quantity or quality.
5	Habitat for fish and wildlife having high potential to become either essential or important habitat.	The mitigation goal, if impacts are unavoidable, is to provide a net benefit in habitat quantity or quality.
6	Habitat that has low potential to become essential or important habitat for fish and wildlife.	The mitigation goal is to minimize impacts.
1. Source: OAR 635-415-0025.		

4.0 Temporary and Permanent Impacts

Impacts may be permanent or temporary. Permanent impacts are defined as those impacts that will exist for the life of the Solar Components. Temporary impacts are those impacts that will last for a time less than the life of the Solar Components. The duration of temporary impacts to habitat will vary by habitat subtype. For example, the recovery period for agricultural areas that were temporarily disturbed could be as short as 1 to 3 years, grasslands generally recover within 3 to 7 years, and shrublands may require 10 to 50 years to recover (with the longer recovery periods associated with disturbances in mature sagebrush [*Artemisia* sp.] habitats). The Certificate Holder will restore temporary impacts consistent with the Comprehensive Solar Revegetation and Soil Management Plan (Final Order on RFA4, Attachment D).

As described in Exhibit P, there are no impacts to Category 1 habitat within the Solar Micrositing Area. Category 2 habitat occurs in the Solar Micrositing Area and will be impacted by the Solar Components (Table 2). Category 2 habitat within the Solar Micrositing Area is associated with Shrub-steppe; Sagebrush Shrub-steppe habitat along Biglow Canyon and to a lesser extent, Riparian: Riparian Tree habitat. Category 4 and 6 habitat will also be impacted by the Solar Components, while Category 3 and 5 habitat were not identified in the affected area.

Table 2 shows the acres of permanent and temporary impacts in each habitat category by habitat subtype for the Solar Components.

Table 2. Temporary and Permanent Impacts by Habitat Category and Habitat Subtype

Habitat Category	Habitat Subtype	Impact (acres)	
		Temporary	Permanent
2	Riparian Trees	<0.1	<0.1
	Sagebrush Shrub-Steppe	0.3	20.7
Category 2 Subtotal		**0.3**	**20.7**
4	Grassland-steppe	0.1	3.0
	Ephemeral Streams	<0.1	<0.1
Category 4 Subtotal		**0.1**	**3.0**
6	Irrigated Cropland	0.1	52.0
	Non-Irrigated Cropland	9.4	1,365.0
	Developed	1.0	3.9
Category 6 Subtotal		**10.5**	**1,420.9**
Grand Total		**10.9**	**1,444.6**

Note: Totals in this table may not sum correctly due to rounding; "--" = no impact; <0.1 = greater than zero but less than 0.05 acre.

5.0 Methods for Calculating Mitigation

Solar Component impacts, as determined based on the Solar Micrositing Area, would result in a mitigation need of 45 acres, including 44.4 acres of mitigation for permanent impacts (41.4 acres of Category 2 and 3.0 acres of Category 4 habitat) and 0.6 acres of mitigation for temporary impacts (0.6 acres of Category 2 and <0.1 acres of Category 4; Table 3 and Table 4).[1] The actual acres of temporary and permanent impacts and the associated mitigation requirements will be confirmed following construction. The Certificate Holder is not proposing compensatory mitigation under the ODFW Fish and Wildlife Habitat Mitigation Policy for impacts to Category 6 habitat.

Table 3. Calculating Mitigation for Permanent Impacts

Habitat Category	Impact Acres	Mitigation Ratio[1]	Mitigation Need	Mitigation Description
Category 2	20.7	2:1	41.4	The mitigation goal for Category 2 habitat is "no net loss" and "net benefit." Accordingly, mitigation for permanent impacts on Category 2 habitat needs to demonstrate a net benefit in quality or quantity.
Category 4	3.0	1:1	3.0	The mitigation goal for Category 4 habitat is "no net loss" in quantity or quality. During a site visit on January 10, 2025, ODFW recommended that impacts on Upland Tree habitat types should be mitigated within grassland or shrubland habitat types.
Category 6	1,420.9	0:1	--	The mitigation goal for impacts on Category 6 habitat is minimization; no compensatory mitigation proposed.
Grand Total	**1,444.6**	**--**	**44.4**	--

1. Acres mitigation per acres impacted.

Note: Totals in this table may not sum correctly due to rounding.

Table 4. Calculating Mitigation for Temporary Impacts

Habitat Category	Habitat Subtype	Impact Acres	Mitigation Ratio[1]	Mitigation Need	Mitigation Description
Category 2	Riparian Trees	<0.1	2:1	<0.1	The mitigation goal for Category 2 habitat is "no net loss" and "net benefit." Accordingly, mitigation for permanent impacts on Category 2 habitat needs to demonstrate a net benefit in quality or quantity.
	Sagebrush Shrub-steppe	0.3	2:1	0.6	

[1] Temporary impacts result in temporal loss of habitat function and values from the time an impact occurs to the time when the restored habitat provides a pre-impact level of habitat function. Sagebrush steppe and riparian tree habitat subtypes are reasonably expected to require a longer restoration timeframe (5+ years) and therefore would be expected to result in temporal loss requiring compensatory mitigation beyond the Certificate Holder's revegetation obligation.

Habitat Category	Habitat Subtype	Impact Acres	Mitigation Ratio[1]	Mitigation Need	Mitigation Description
Category 4	Grassland-steppe	0.1	0:1	--	The mitigation goal for Category 4 habitat is "no net loss" in quantity or quality. The proposed mitigation ratio would result in a lesser amount of acreage of mitigation than what is impacted by the Solar Components. Combined with restoration of temporary disturbances, the proposed mitigation ratio is intended to account for the temporary loss of habitat functionality and meet the "no net loss" goal. Temporary disturbances to Category 4 Grassland-steppe are not mitigated beyond restoration.
	Ephemeral Streams	<0.1	1:1	<0.1	
Category 6	Agriculture, Developed	10.5	0:1	--	The mitigation goal for impacts on Category 6 habitat is minimization; no compensatory mitigation proposed.
Grand Total		**10.9**	**--**	**0.6**	--

1. Acres mitigation per acres impacted.

Note: Totals in this table may not sum correctly due to rounding. "--" = no impact; <0.1 = greater than zero but less than 0.05 acres.

6.0 Biglow Canyon Wind Farm Habitat Mitigation Area

The HMA is the area where the Certificate Holder is proposing to perform enhancement and preservation actions that are in addition to the revegetation of areas of temporary disturbance associated with the Biglow Solar Project. The HMA must be large enough and have the characteristics to meet the standards set in OAR 635-415-0025.

According to ODFW standards, areas appropriate for mitigation of Category 2 habitat impacts must provide "in-kind" mitigation that creates similar structure and function to that being disturbed, be "in-proximity" to the Solar Components, and have potential for habitat enhancement. The Certificate Holder identified 78 acres for the HMA located within 880 acres of land owned by the Certificate Holder adjacent to the Carty Generating Facility in Morrow County (Figure 1). The Certificate Holder identified an area larger than its mitigation need to allow for flexibility in management of the HMA. The Certificate Holder discussed the location of the HMA with ODFW and received assurance that the mitigation goals of "in-kind" and "in-proximity" can be met.

6.1 Habitat Assessment and Mitigation Accounting

The Certificate Holder identified 78 acres of suitable in-kind and in-proximity habitat within an 880-acre parcel. The HMA is adjacent to the existing PGE-owned Conservation Area and a conservation area maintained by The Nature Conservancy (South Farm Conservation Area; Figure 1). The habitat mapped within the HMA includes rabbitbrush shrubland and broom

snakeweed shrubland (Figure 1). The HMA is dominated by Sandberg's bluegrass (*Poa secunda*), bluebunch wheatgrass (*Pseudoroegneria spicata*), and intermittent areas of needle-and-thread grass (*Hesperostipa comata*), as well as cheatgrass (*Bromus tectorum*). There are also occasional occurrences of green rabbitbrush (*Chrysothamnus viscidiflorus*), gray rabbitbrush (*Ericameria nauseosa*), big sagebrush (*Artemisia tridentata*), fiddleneck (*Amsinckia menziesii*), and yarrow (*Achillea millefolium*).

The HMA is within a PWCA connector (ODFW 2023).[2] The HMA also contains Category 1 and Category 2 habitat associated with Washington ground squirrel (*Urocitellus washingtoni*) colonies that are immediately adjacent to the HMA.

The Certificate Holder plans to mitigate for the habitats impacted by placing a conservation easement on the appropriate acreage and by providing habitat uplift through the habitat enhancement and monitoring activities described below.

6.2 Habitat Enhancement Actions

Based on the acres of impact and mitigation need identified in Tables 2, 3, and 4, the Certificate Holder identified 78 acres available to fulfill the mitigation need for Solar Component impacts, subject to confirmation of impacts following construction. The objectives of habitat enhancement and restoration are to protect habitat within the mitigation area from degradation and improve the habitat quality of the mitigation area. The Certificate Holder shall initiate the habitat enhancement actions for the Facility before beginning operation of the Solar Components. The Certificate Holder shall restrict uses of the mitigation area that are inconsistent with the goal of no net loss and net benefit of Category 2 habitat and no net loss of Category 4 habitat as designated in the conservation easement. The Certificate Holder shall implement habitat enhancement actions as described in this HMP and as specified in the Site Certificate Enhancement actions and monitoring procedures are detailed below and will be finalized in this HMP prior to construction. Besides legal protection to ensure no development, enhancement actions for the HMA include those detailed in the following subsections.

6.2.1 Restoration and Enhancement Actions in the Event of Fire

The final HMP must include a description of enhancement actions to be implemented at the HMA if the site is damaged from fire or fire suppression efforts (e.g., vehicular disturbance or chemical

[2] The Oregon Conservation Strategy (ODFW 2025) defines PWCA "regions" as the combined top one percent of connectivity priorities across all 54 Oregon Connectivity Assessment and Mapping Project (OCAMP) species' connectivity models. Regions are large, contiguous areas and represent the highest-value habitat for facilitating species movement throughout the state. PWCA "connectors" are then described as pathways that provide the best available habitat for facilitating movement between regions. Connectors may pass through high-quality habitat in intact, relatively undisturbed parts of the landscape, as well as the best remaining marginal habitat in developed or degraded areas. The Solar Components impact a PWCA region along Biglow Canyon.

application). At a minimum, the enhancement actions must include a plan for seeding and noxious weed treatment, and coordination of the final measures to be implemented after the fire or fire suppression activities.

6.2.2 Noxious Weed Prevention, Inventory, and Control

Weeds will be controlled as needed to maintain and enhance habitat quality within the mitigation area, with the goal of working toward eradication of targeted noxious weeds or, if eradication is not practical, decreasing their abundance to minimize impacts on native plant communities. Weeds known to occur within the HMA include rush skeletonweed (*Chondrilla juncea*), knapweed (*Centaurea* spp.), and yellow starthistle (*Centaurea solstitialis*).

The final HMP will identify the weed management practices including schedule and treatment, consistent with an integrated weed management approach, using an appropriate combination of inventory, prevention (such as best management practices to prevent weed establishment), and control methods (such as hand pulling, mowing, biological control, and/or herbicides). The Certificate Holder shall obtain ODFW's approval prior to the use of pesticides. Controlling weeds in the HMA should promote growth of native vegetation.

6.2.3 Access Control

The Certificate Holder will monitor and control access to the HMA and will post informative signs depicting the area(s) as "protected" and including natural resources information as appropriate for the life of the Facility. Primary access to the PGE property is controlled by a gate off Tower Road north of the Carty Generating Station (currently used by PGE and The Nature Conservancy), the gated entrance to the Boardman Plant, and a gated road from Ione to the south. The Nature Conservancy and Three Mile Canyon Farms may occasionally use the two-track access crossing PGE's property to access the Farm's conservation area. Approved access to the site is currently limited to such occasional approved use of access roads and PGE's general operational needs. No livestock grazing is currently occurring on the site, and grazing would be a restricted use identified in the conservation easement, as established in Section 2.0 of this HMP. Periodic monitoring will be conducted to evaluate the effectiveness of access control measures and signage maintenance needs.

6.2.4 Sagebrush Plantings

To mitigate for temporal and permanent impacts to Category 2 sagebrush habitat, the Certificate Holder will plant sagebrush in the HMA, focusing on enhancing and expanding remnant stands of shrubs that were impacted by past wildfires. Planting density will be determined in this HMP prior to construction.

6.3 HMA Enhancement Monitoring

The Certificate Holder will use a qualified investigator (botanist, wildlife biologist, or revegetation specialist) to conduct monitoring at the HMA. The purpose of this monitoring is to evaluate on an ongoing basis the protection of habitat quality and the results of enhancement actions.

The investigator will visit the HMA each growing season for the first five years post planting/weed treatment. If success is achieved at year five, monitoring may be reduced to every fifth year thereafter (in years divisible by five, unless otherwise specified for specific measures) for the life of the Facility.

Monitoring methods and frequency will be established in the final HMP, as established in Section 2.0 of this Plan. Monitoring activity shall include an assessment of the following:

1. General quality of vegetation cover (dominant species, structural age, etc.), as determined by ocular estimates, measurements, and photo points;
2. Success of weed control efforts:
    a. Weed control efforts at the HMA will be considered successful when native plant cover within monitoring sites is greater than baseline, and invasive cover within monitoring sites is less than baseline. The final success criteria should be a percent increase and percent decrease value, following evaluation of baseline conditions at the monitoring sites.
    b. Annual inventories will be conducted on the HMA to identify new weed infestations, the status of existing infestations, and the progress of weed control efforts in eradicating or reducing infestations.
    c. Weed inventories will be conducted on foot. Detailed information on weed infestations will be collected, including, but not limited to, data on species, location, growth form, infestation size, and weed cover class (an ocular estimate of the percentage of the ground covered or concealed by weeds in a specific infestation area). In addition, the surveyor will identify potential weed control strategies for each infestation, as well as constraints that could limit the effectiveness of weed control efforts.
    d. Results from the surveys will be incorporated into a GIS database and provided to the Department with the Monitoring Report. Weed infestations will also be photographed over time to document progress of weed control efforts.
3. Sagebrush planting will be considered successful when sagebrush density in enhancement areas is 50 percent of planting density at 5 years of planting. Density (plant counts) will be measured within macroplots, quadrats, and/or belt transects randomly located within the enhancement area.
4. Success of remedial actions to restore habitat quality in damaged areas (such as managed weed infestations, fire damage, and any necessary seeding/planting areas), as determined by vegetation cover (ocular estimate) and photo points (see below);

5. Photos taken from established monitoring positions (photo points) within the HMA, including 1) a minimum of five permanent photo points distributed to show general vegetation status throughout the HMA, and 2) additional photo points as needed to monitor success of significant enhancement activities, such as managed weed infestations and/or any necessary seeding/planting areas;
6. Incidental wildlife occurring within the HMA (counts concurrent with all other monitoring work);
7. Environmental factors found on site during monitoring activities and annual summary records (such as precipitation); and
8. Surveys of resident special status wildlife species (Washington ground squirrel) that have been documented during previous monitoring or survey efforts within the HMA, using existing protocols approved by ODFW.

7.0 Data Reporting

The Certificate Holder will submit a report including wildlife and habitat monitoring data and analysis to ODOE and ODFW during each monitoring year according to the schedule in Table 5. The Certificate Holder will notify the U.S. Fish and Wildlife Service and ODFW within one business day if any federal or state endangered or threatened species are killed or injured on the facility site or within the HMA. The Certificate Holder may include the reporting of wildlife monitoring data and analysis in the report required under OAR 345-026-0080 or submit this information as a separate document concurrently with the submittal of the report. In addition, the Certificate Holder will provide ODOE with any data or record generated by the investigators in carrying out this Plan upon request by ODOE.

Table 5. Schedule of Monitoring

Task	Schedule
General HMA Monitoring	During the first, third, and fifth years after Solar Component construction, and otherwise every fifth year thereafter for the life of the Facility.
Washington Ground Squirrel Monitoring	
General Weed Inventory, Control and Monitoring Activity for HMA	Every year for the first 5 years following implementation of initial enhancement; long-term monitoring frequency to be determined after year 5.
HMA Sagebrush Habitat Monitoring	Every year for the first 5 years following implementation of initial enhancement; long-term monitoring frequency to be determined after year 5.

8.0 Amendment of the HMP

This HMP may be amended from time to time by agreement of the Certificate Holder and the Energy Facility Siting Council (EFSC), or ODOE, acting within its delegated authority of EFSC under ORS 469.402. Such amendments may be made without amendment of the site certificate. EFSC authorizes ODOE to agree to amendments to this HMP. ODOE shall notify EFSC of all amendments, and EFSC retains the authority to approve, reject, or modify any amendment of this plan agreed to by ODOE.

Attachment 1. Residence/Landowner Outreach Letter

1.0 Introduction

The Energy Facility Siting Council (EFSC) approved Portland General Electric Company's (PGE or Certificate Holder) Draft Construction Wildfire Mitigation Plan (WMP) as part of the Request for Amendment (RFA) 4 to the Site Certificate for the Biglow Canyon Wind Farm (BCWF or Existing Facility) which added photovoltaic solar energy generation and battery storage (Solar Components) to the operating BCWF in Sherman County, Oregon.

This plan is intended to satisfy the approval standards under OAR 345- 022-0115(1)(b), which requires the Plan to:

(A) Identify areas within the site boundary that are subject to a heightened risk of wildfire, using current data from reputable sources, and discuss data and methods used in the analysis;

(B) Describe the procedures, standards, and time frames that the applicant will use to inspect facility components and manage vegetation in the areas identified under subsection (a) of this section;

(C) Identify preventative actions and programs that the applicant will carry out to minimize the risk of facility components causing wildfire, including procedures that will be used to adjust operations during periods of heightened wildfire risk;

(D) Identify procedures to minimize risks to public health and safety, the health and safety of responders, and damages to resources protected by Council standards in the event that a wildfire occurs at the facility site, regardless of ignition source; and

(E) Describe methods the applicant will use to ensure that updates of the plan incorporate best practices and emerging technologies to minimize and mitigate wildfire risk.

This plan is submitted in adherence to the following Site Certificate Conditions relating to RFA 4:

Wildfire Prevention and Risk Mitigation Condition 1 (PRE-WF-01)
Prior to construction of any component or phase of the solar facility, the certificate holder shall finalize and submit to the Department, for review and approval, a Construction Wildfire Mitigation Plan (WMP), consistent with Attachment G to the Final Order on AMD4.

Wildfire Prevention and Risk Mitigation Condition 2 (CON-WF-01)
During construction of the solar facility, the certificate holder shall require onsite contractors and employees to adhere to the Construction Wildfire Mitigation Plan (WMP) approved under Condition PRE-WF-01.

2.0 Final Wildlife Mitigation Plan Checklist (Prior to Construction)

2.1 Update Applicable Sections of Construction WMP

To finalize this Construction WMP prior to construction of the Solar Components, the following sections will be updated:

- Update Section 4.0 based on final Solar Component design including a brief description of areas within the site that are subject to high wildfire risk, fire prevention features at the site, such as road dimensions, setbacks, fire breaks, entry/exit locations, location of water trucks and fire protection equipment locations.
- Update Section 4.1 and include in this WMP the facility site maps described in Section 4.1.6.
- Update Section 4.3 with contact information and emergency response procedures for the fire department, Certificate Holder, and operational manager. Update Section 4.3 with analysis area residence contact information and confirm analysis area residence contact letter sent to residences within site boundary and 0.5 miles from the facility.
- Update Section 4.6 to describe vegetation management and areas that will be managed to be vegetation-free, noncombustible space, or gravel surface.

3.0 Prior to Construction Task List (PRE)

Prior to construction of the facility, the activities in Sections 3.1 and 3.2 will be completed.

3.1 Training

The Certificate Holder will organize and hold an on-site training with Certificate Holder, contractors and construction personnel, inviting specialty contractors, local fire departments, participating and adjacent landowners, emergency management office personnel, ODOE, and any other emergency management agency that covers:

- Description of construction phasing;
- The type, location, and proper use of fire protection equipment;
- Fire protection equipment usage and maintenance requirements;
- The locations of water sources and proper usage, storing and maintenance for the pump, hose nozzle; and water hose;
- Overview of smoking policy and locations;
- Overview of procedures and restrictions of construction maintenance activities during Fire Season and Red Flag Warnings designated in this Plan;
    - Rescue, Alarm, Contain and Extinguish RACE procedures including:

  - Rescue anyone in danger (if safe to do so);
  - Alarm – call the control room, who will then determine if 911 should be alerted;
  - Contain the fire (if safe to do so); and
  - Extinguish the incipient fire stage (if safe to do so).
- Provide information and encourage attendees to sign up for the County's emergency management notification system.

The training attendee list and training materials will be provided to ODOE to demonstrate compliance. The Certificate Holder will fill out and submit to ODOE the template residence outreach letter provided as Attachment 1 of this WMP. Once ODOE confirms the letter to be sufficient, the letter will be mailed to each residence within the 0.5-mile analysis area. The mailing will be confirmed and submitted to ODOE.

3.2 Solar Micrositing Area Site Maps Submission

The Certificate Holder will update site maps from Section 4.1.6 concurrently to local fire departments and ODOE.

4.0 Construction Wildfire Mitigation Plan (CON)

The information in Section 4.0 will be updated in the finalized WMP.

4.1 Summary of Solar Component Design Features and Fire Protection Equipment

4.1.1 Construction Phasing

The Certificate Holder and contractors will maintain vegetation within the Solar Micrositing Area and will also maintain a defensible space clearance along Facility features. Defensible space will be free of combustible vegetation or other materials. Roads and parking areas will be maintained to be free of vegetation tall enough to contact the undercarriage of the vehicle.

During construction clearing, grubbing, and grading, the contractor will establish create a clear, brush free area extending a minimum of 10 feet inside the fence line and another minimum 10-foot limits of disturbance buffer outside the fence line. Vegetation within the area will be managed in accordance with the recommendations of the local fire official.

While hot work permits are not generally anticipated for the construction of the Solar Components, such permits or formal approval will be required during fire season if any hot work is to be conducted.

Fuel storage and handling protocols include the following:

- Any equipment or vehicles carrying fuel must remain parked at a designated location along a county-right-of way.
- Vehicles leaving the right-of-way must not carry fuel containers, with the exception of a single five-gallon container used to operate the water truck pump.

- Smoking will be restricted to designated areas within the Facility only.

4.1.2 Wildfire Risk

The data sources used in this Plan to identify areas within the Solar Micrositing Area subject to heightened risk of wildfire include the Oregon CWPP Planning Tool (ODF and USFS 2024) and the Sherman County Multiple-Jurisdictional Natural Hazards Mitigation Plan (Sherman County 2024).

This Section will be updated in the finalized WMP.

The Sherman County Multiple-Jurisdictional Natural Hazards Mitigation Plan describes a county-wide risk assessment of wildfire as "high" probability and identifies many areas in the county as "conducive for large and fast-moving wildfires" due to high winds typical for regional dry conditions and terrain. The plan identifies risk factors for starting wildfires in the county as highways, railroads, lighting, power lines, debris burning, and equipment.

4.1.3 Fire Prevention

The greatest risk of fire is during construction, when welding and metal cutting will take place, and vehicles and construction equipment may be used in areas of tall, dry grass. To prevent fires from occurring, the construction contractor will implement a number of systems and procedures. These will include requirements to conduct welding or metal cutting only in areas cleared of vegetation, and to keep firefighting equipment on-site as discussed in Section 4.4. Construction workers will keep vehicles on roads during the dry months of the year, unless offroad activities are required for emergency purposes, in which case fire precautions will be observed. Construction workers will be prohibited from parking vehicles in areas of tall, dry vegetation to prevent fires caused by contact with hot mufflers or catalytic converters. In the event of a large fire, emergency responders will be dispatched.

Fire prevention specific to solar arrays is dependent on proper installation and maintenance of electrical equipment to prevent short-circuits and consequent sparking, and reduction in fuel to reduce the chance of fire spreading. Qualified staff will be employed to install and maintain electrical equipment. The solar array will have shielded electrical cabling, as required by applicable code, to prevent electrical fires. All electrical equipment will meet National Electrical Code and Institute of Electrical and Electronics Engineers standards. With proper maintenance and safety checks, the electrical collection system and gen-tie lines are unlikely to cause a fire. The substrate on the ground inside the solar array fence line will be gravel where needed for maintenance and access roads or where gravel already exists, and vegetation where gravel isn't needed or already present. Weeds will be managed in accordance with the weed management procedures described in the Comprehensive Solar Revegetation and Soil Management Plan.

New needed for emergency access shall be sufficiently sized and designed for emergency vehicles in accordance with 2022 Oregon Fire Code requirements, including Section 503 and Appendix D - Fire Apparatus Access Roads. The areas immediately around the O&M buildings, proposed substation, and BESS will be graveled, with no vegetation present.

Additionally, the RFA 4 solar arrays, BESS, and associated project components will be setback at

least 50 feet from all property lines of non-participating landowners.

4.1.4 Battery Energy Storage System Fire Prevention

The Certificate Holder will implement the following fire prevention and control methods to minimize fire and safety risks for the Li-ion batteries proposed for the BESS:

- The batteries will be stored in completely contained, leak-proof modules.
- The Li-ion battery system will be kept in a temperature-controlled facility with individual battery modules isolated to prevent the spread of fire if it were to occur.
- The batteries will be based on Lithium Iron Phosphate chemistry, which has a lower risk of fire.
- The Li-ion battery system will be comprised of multiple temperature-controlled battery enclosures, each with its own fire detection, monitoring and fire protection systems. The battery enclosures will be spaced at a minimum recommended distance from each other as required by the battery supplier, AHJ requirements and applicable codes and standards. Minimum spacing isolates each battery enclosure and reduces the risk of fire propagation between battery enclosures in the unlikely event of a fire.
- Ample working space will be provided around the BESS for maintenance and safety purposes.
- Twenty-four-hour monitoring of the BESS will be implemented and will include shutdown capabilities.
- Transportation of Li-ion batteries is subject to 49 CFR 173.185 – Department of Transportation Pipeline and Hazardous Material Administration. This regulation contains requirements for prevention of a dangerous evolution of heat, prevention of short circuits, prevention of damage to the terminals, and prevention of batteries coming into contact with other batteries or conductive materials. Adherence to the requirements and regulations, personnel training, safe interim storage, and segregation from other potential waste streams will minimize any public hazard related to transport, use, or disposal of batteries.
- Design of the BESS will be in accordance with applicable Underwriters Laboratories (UL 2023; specifically 1642, 1741, 1973, 9540A), National Electric Code, and National Fire Protection Association (specifically 855) standards, which require rigorous industry testing and certification related to fire safety and/or other regulatory requirements applicable to battery storage at the time of construction.
- Additionally, the Certificate Holder will employ the following design practices, as applicable to the available technology and design at time of construction:
    - Employment of an advanced and proven battery management system;
    - Qualification testing of battery systems in accordance with UL 9540A (Revision 4) at the batter cell, module, and unit level;

- Installation of fire sensors, smoke and hydrogen and/or carbon monoxide detectors, alarms, emergency ventilation systems, cooling systems within each battery enclosure;
- Employment of fire control panels with 24-hour battery backup;
- Installation of doors that lock with restricted access to authorized personnel only;
- Implementation of locks and fencing to prevent entry of unauthorized personnel;
- Installation of remote power disconnect switches; and
- Clear and visible signs to identify remote power disconnect switches.

4.1.5 Facility Access

The locations of specific access points and gates will depend on the final configuration of the solar areas and related infrastructure. The perimeter fencing will have lockable vehicle access gates. As currently designed, five gates are. Additional gates may be included for emergency exits or for removal of wildlife. Each solar array would be enclosed by wire mesh, chain link, or similar perimeter fencing, up to 7-8 feet in height.

4.1.6 Facility Site Maps

This Construction WMP includes facility site maps that identify:

- The phasing for construction of facility features and components:
- During construction clearing, grubbing, and grading, the contractor will establish a clear, brush free area extending a minimum of 10 feet inside the fence line and another minimum 10-foot limits of disturbance buffer outside the fence line for a total of a minimum of 20 feet of clear, brush free area around the perimeter of the site.;
- Location and dimensions of facility roads;
- Solar arrays, BESS, and associated project components will be setback at least 50 feet from all property lines of non-participating landowners;
- Location of vegetation free, noncombustible, defensible spaces;
- Wildfire risk at the site;
- High-fire consequence areas/resources (includes existing infrastructure, residences, sensitive habitat, or cultural resources)
- The location of facility access points;
- A description and the location of emergency access procedures, including how emergency responders and/or adjacent landowners may access site for fire protection equipment or to extinguish an on-site fire when personnel will not be onsite;
- The type and location of fire protection equipment on site;
- The locations of water sources that will be on-site during construction.

Facility site maps will be included in the final WMP..

The final Construction WMP will include a site map detailing specific access points, location of fire protection equipment, and location of water sources.

4.2 Specifications for Fire Protection Equipment

The following fire suppression equipment will be carried in vehicles conducting maintenance activities and stored on-site at the O&M building at all times:

- Fire Extinguisher: Dry chemical. 2A:10BC (5 pound), properly mounted or secured;
- Pulaski;
- Hand Shovel: Round point. 26 to 28 in "D" Handle, blade - 12 inches long and 10 inches wide; and
- Collapsible Pail or Backpack Pump: 5-gallon capacity.

During fire season (designated Fire Season or June to October each year) water trucks/water source, water buffalo, or tank with minimum 500-gallon capacity must be on site. The water truck or water supply shall include the following, unless approved by ODOE:

- Pump should be maintained ready to operate and capable to provide a discharge of not less than 20 gallons per minute at 115 psi at pump level. Note: Volume pumps will not produce the necessary pressure to effectively attack a fire start. Pressure pumps are recommended.
- Provide enough hose (500 feet minimum) not less than 3/4" inside diameter to reach areas where power driven machinery has worked.
- Water supply, pump, and at least 250 feet of hose with nozzle must be maintained as a connected, operating unit ready for immediate use.

All internal combustion engines must be equipped with exhaust systems, mufflers and screens, or include an appropriate spark arrestor; and must be kept in good operating condition. All combustion engines (including but not limited to off road vehicles, chainsaws, and generators) will be equipped with a spark arrester that meets U.S. Forest Service Standard 5100-1.

All power-driven machinery will be kept free of excess flammable material which may create a risk of fire.

4.3 Solar Component Contact Information and Emergency Response Procedures

Local fire department and county emergency management contact information:

- North Sherman County Rural Fire Protection District: (541) 442-5252 or 911
- Sherman County Emergency Services: (541) 565-3100 or 911

Fire department response times to the site:

- The Project Developer and Certificate Holder will work with North Sherman County RFPD to determine response times and procedures for the site and these will be included in the final

Construction
WMP.

Certificate holder primary contact and contact of construction contractor managers:

Certificate Holder Primary Contact Information	
Name	Dan Wilson
Company	Portland General Electric Company
Street Address	121 SW Salmon Street, 3WTC0403
City/State/Zip	Portland, OR 97204
Phone	503-630-8138
Email	Dan.Wilson@pgn.com
Construction Contractor Manager Contact Information	
Name	Construction contractor managers contact information will be provided in the final Construction WMP.
Title	
Street Address	
City/State/Zip	
Phone	
Email	

Residence addresses within the site boundary and 0.5 miles from the site boundary:

- Attachment 2 of the finalized WMP will include a list of property owners within the RFA 4 Site Boundary and a 0.5-mile radius.
- Residence/landowner outreach letter is provided as Attachment 1 of this WMP. Use this letter to provide to new or updated residences with the analysis area as designated in Section 5.0, Plan Updates and Reporting Requirements.

Contact 911 in the event of:

- A fire or emergency on-site that cannot be addressed by personnel on-site and requires the assistance of fire or emergency medical personnel;
- A fire ignition on-site that spreads out of the fence line;
- Any fire off-site that does not have emergency responders on site.
    - To the extent that construction personnel can safely assist and/or provide equipment to help extinguish off-site fires until emergency responders are on site, it is encouraged to do so to assist in the spread of the fire, loss of life, property and damage to the environment.

4.4 Use of Vehicles and Power Driven Machinery at Site

The following best management practices (BMPs) to minimize fire risk from vehicle travel, equipment use, and fueling activities will be implemented at the site during construction:

- The movement of vehicles will be planned and managed to minimize fire risk.
- The contractors will be responsible for identifying and marking paths for all off-road vehicle travel. All off-road vehicle travel will be required to stay on the identified paths. No off-road vehicle travel will be permitted while working alone. Travel off road or parking in vegetated areas will be restricted during fire season as designated in this Plan.
- Areas with grass that are as tall or taller than the exhaust system of a vehicle must be wetted or mowed before vehicles travel through it.
- Workers will be instructed to shut off the engine of any vehicle that gets stuck, and periodically inspect the area adjacent to the exhaust system for evidence of ignition of vegetation. Stuck vehicles will be pulled out rather than "rocked" free and the area will be inspected again after the vehicle has been moved.
- The contractors will designate a location for field fueling operations at the temporary construction yards. Any fueling of generators, pumps, etc. shall take place at this location only.
- Fuel containers, if used, shall remain in a vehicle or equipment trailer, parked at a designated location alongside a county right-of-way. No fuel containers shall be in the vehicles that exit the right-of-way except the five-gallon container that is required for the water truck pump.
- All power-driven machinery will be kept free of excess flammable material which may create a risk of fire.

4.5 Fire Weather Monitoring and Restrictions during Fire Season

4.5.1 Definitions

- **Non-Fire Season –** Approximately October - May
- **Fire Season –** Approximately June-September, formally designated by the Oregon Department of Forestry (ODF). Under ORS 478.960 (4), a Fire Chief can establish Fire Season within a Fire District when ODF, under ORS 477.505, declares Fire Season. Begins seasonal restrictions for public and industry.
- **Fire Weather Watch –** A fire weather watch is issued when there is a high potential for the development of a red flag event. A watch is issued 18 to 96 hours in advance of the expected onset of criteria. Intent of a fire weather watch is to alert forecast users at least a day in advance for the purposes of resource allocation and fire fighter safety. A watch means critical fire weather conditions are possible but not imminent or occurring.
- **Red Flag Weather Warning –** A red flag warning is used to warn of impending or occurring

red flag conditions. Its issuance denotes a high degree of confidence that weather and fuel conditions consistent with local red flag event criteria will occur in 48 hours or less. Specific Red Flag criteria differ for each situation and district in Oregon. Be extremely careful with open flames and other activities that emit sparks.

- **Hot Work –** Any cutting, grinding, welding, or other activity that creates spark or open flame

4.5.2 Fire Watch Service

Fire watch shall:

- Be physically capable and experienced to operate firefighting equipment.
- Have facilities for transportation and communications to summon assistance.
- Observe portions of the facility where equipment activity occurred during the day.

Upon discovery of a fire, fire watch personnel must: First report the fire, summon any necessary firefighting assistance, describe intended fire suppression activities; then, after determining a safety zone and an escape route that will not be cut off if the fire increases or changes direction, immediately proceed to control and extinguish the fire, consistent with firefighting training and safety.

4.5.3 Fire-Prevention Measures and Restrictions

Certificate holder shall maintain a log when construction activities are impacted by Fire Restrictions during Fire Season as designed in this Section. The log will include:

- The date;
- Fire Precaution Level;
- Description of actions taken, including if any measures were taken to reduce wildfire risk that are not identified in this Plan.

4.5.3.1 Non-Fire Season

- All hot work (must be conducted on roads or on non-combustible surfaces.
- Smoking in designated areas only.

4.5.3.2 Fire Season

- All hot work (any cutting, welding, or other activity that creates spark or open flame) must be conducted on roads or on non-combustible surfaces.
- Water source meeting specifications in this Plan will be on site during fire season.
- Following the completion of hot work, the Certificate Holder or contractors must maintain a fire watch for 60 minutes to monitor for potential ignition.

- Fire watch shall be on duty during any breaks and for one hour after all power driven machinery used by the operator has been shut down for the day.
- Smoking in designated areas only.

4.5.3.3 Fire Weather Watch

- No hot work permitted.
- Driving and parking only permitted on graveled or paved surfaces.
- Fire watch shall be on duty during any breaks and for one hour after all power driven machinery used by the operator has been shut down for the day.
- No smoking on site.

4.5.3.4 Red Flag Weather Warning

- No hot work permitted.
- On-site personnel must be aware of Red Flag Warning.
- Driving and parking only permitted on graveled or paved surfaces.
- Fire watch shall be on duty during any breaks and for one hour after all power driven machinery used by the operator has been shut down for the day.
- No smoking on site.

Table 1. Fire Prevention Measures during Fire Season

Requirement	Non-Fire Season	Fire Season	Fire Weather Watch	Red Flag Warning
Fire weather advisory	Not required	Not required	Not required	On-site personnel must be aware of Red Flag Warning.
On-site water source	N/A	As specified in Section 4.2	As specified in Section 4.2 and 4.3.	As specified in Section 4.2 and 4.3.
Hot work	Only permitted on roads or on non-combustible surfaces.	Only permitted on roads or on non-combustible surfaces; fire watch required for 60 minutes after completion	Not Permitted	Not Permitted
Fire Watch Service	Not required	During breaks and for 60 minutes after all power-driven machinery has been shut down for the day.	During breaks and for 60 minutes after all power-driven machinery has been shut down for the day.	During breaks and for 60 minutes after all power-driven machinery has been shut down for the day.

Requirement	Non-Fire Season	Fire Season	Fire Weather Watch	Red Flag Warning
Driving and Parking	As described in Section 4.4.	As described in Section 4.4.	Only permitted on roads or on non-combustible surfaces and Section 4.4.	Only permitted on roads or on non-combustible surfaces and Section 4.4.
Smoking	Designated areas only	Designated areas only	Not permitted	Not permitted

4.6 Vegetation Management

4.6.1 Vegetation-free, Noncombustible Space, and Vegetation Standards

Vegetation within the fence line and below the solar arrays will be maintained in accordance with the approved Comprehensive Solar Revegetation and Soil Management Plan for the facility.

- Vegetation within and adjacent to the Solar Components will be maintained as follows:
    - During the dry season (June to October), vegetation height will be limited to 4 to 8 inches. Vegetation will be mowed to a height of 4 inches prior to June of each year.
    - Outside of the dry season (November to May), vegetation will be maintained at a maximum height of less than 12 inches,
- A minimum vertical clearance of 12 inches from electrical and mechanical equipment will be maintained at all times.
- Vegetation exceeding the heights listed above shall be removed or mowed. Mowing must be done in advance of fire season or in accordance to any fire restrictions.
- A minimum 20-foot clear, brush free area will be maintained around the perimeter of fenced solar array areas (10-feet inside the fence and 10-feet outside the fence). Activities necessary to maintain the area as clear, brush free shall be based on consultation with the local fire code official;
- Vegetation along service roads will be managed by mowing or other vegetation removal
- At no point shall vegetation come in contact with electrical equipment.
- Any vegetation removed from the site will be disposed of and not stored onsite.
- The Certificate Holder and contractors will prevent the accumulation of combustible "burn piles" on site.

The following areas will be managed to be vegetation-free, noncombustible space, or gravel surface:

- Fenced areas around the collector substation, operations and maintenance structure, and meteorological stations will be graveled, with no vegetation present
- All newly constructed roads will be graded and graveled to meet load requirements for all equipment

- Vegetation in these areas will be managed by the following techniques:
- Mechanical Clearing: mowing, brushing, chipping, tree trimming/felling
- Manual Clearing: hand tools (chainsaws, machetes, handsaws)
- Chemical Treatment: use of approved herbicides by licensed applicators to control or suppress vegetation growth (broadcast spray, spot treatment, cut-stump/basal bark)

4.7 Construction Trainings

4.7.1 Safety Training

Once per year after construction begins, organize and hold an on-site training with Certificate Holder and construction personnel, inviting equipment manufacturers, specialty contractors, local fire departments, participating and adjacent landowners, emergency management office personnel, ODOE, and any other emergency management agency that covers:

- The location of electrical facility components and the fire safety measures associated with each component that have been constructed;
- Description of remaining construction phasing;
- The type, location, and proper use of fire protection equipment;
- Fire protection equipment usage and maintenance requirements;
- The locations of water sources and proper usage, storing and maintenance for the pump, hose nozzle; and water hose;
- Overview of smoking policy and locations;
- Overview of procedures and restrictions of construction activities during Fire Season, Fire Weather Watches, and Red Flag Warnings designated in this Plan;
- Rescue, Alarm, Contain and Extinguish (RACE) procedures including:
    - Rescue anyone in danger (if safe to do so);
    - Alarm – call the control room, who will then determine if 911 should be alerted;
    - Contain the fire (if safe to do so); and
    - Extinguish the incipient fire stage (if safe to do so).
- Provide information and encourage attendees County's emergency management notification system.

5.0 Plan Updates: Amendments and Reporting Requirements:

The following will be provided to ODOE in the semi-annual construction report required per OAR 345-026-0080:

- Sections 4.1 and 4.2, any changes in wildfire risk at the site or changes in facility components or preventative features.
- Section 4.3, any changes in local fire protection agency personnel and operational managers.
- Section 4.3, any changes in analysis area residence/landowner addresses or contact information.
- A copy of the Fire Season Restriction Log identified in Section 4.5.3.
- Changes in wildfire risk if different from the Site Plan provided prior to construction. Evaluation of wildfire risk will be consistent with the requirements of OAR 345-022--0115(1) using current data from reputable sources.

This information may be used to establish the performance of the Construction WMP. If determined by certificate holder or ODOE, adjustments or improvements must be proposed to ensure the Construction WMP provides wildfire mitigation. Any ODOE required updates shall be implemented within 14 days, unless otherwise agreed to by ODOE based on a good faith effort to address wildfire hazard.

This Plan may be amended from time to time by agreement of the certificate holder and the Oregon Energy Facility Siting Council (EFSC) or ODOE, acting within its delegated authority of EFSC. Such amendments may be made without amendment of the site certificate. EFSC authorizes ODOE to agree to amendments to this Plan. ODOE will notify EFSC of all amendments, and EFSC retains the authority to approve, reject, or modify any amendment of this Plan agreed to by ODOE.

Re: Community Outreach Letter for Big low Canyon Wind Energy Facility

My name is XXX and I'm the XXX for XX LLC. We are the certificate holder of the Big low Canyon Wind Farm Energy Facility, approved by the Oregon Energy Facility Siting Council (EFSC). Construction of the facility will start/was completed in XX. The facility is a XX megawatt solar facility located XX. You are receiving this letter because your address is within 0.5 miles from the facility site boundary and we want to make sure you are aware of the following information:

- Safety at the facility is our highest priority. We have emergency procedures in place in the event of an emergency on site or off site that may impact the facility and adjacent areas. This includes an EFSC Wildfire Mitigation Plan (WMP) that addresses vegetation management, facility inspections, and maintenance protocols to ensure that the facility minimizes fire risk. The WMP also requires fire protection equipment to be on site and allows for emergency access for fire departments in the event of a fire on site or off site.

- In the event of an emergency on site or off site that cannot be addressed by facility personnel, local emergency and law enforcement will be contacted and procedures designated by the Sherman County's Office of emergency management will be followed, if necessary.

- If you have not already done so, we recommend you sign up for Sherman County emergency notification system. You may sign up via the County's webpage or directly via this link: Link: https://www.co.sherman.or.us/question/get-notified-county-emergency-alerts/#/city/answers/public-information/get-notified-county-emergency-alerts

Please contact me if you have any questions about the facility, XX company, or any other concerns regarding construction and operation of the facility. Further, the Oregon Department of Energy (ODOE) is staff to EFSC and can be contacted if you have questions. Follow the link below for contact information:

Attachment H: Draft Inadvertent Discovery Plan

1. Purpose

This procedure provides a protection and mitigation protocol for an inadvertent **cultural resource's** discovery, until the discovery has reached an appropriate resolution. Most inadvertently discovered **cultural resources** occur during ground-disturbing activities associated with facilities development, maintenance, or improvement.

Cultural resources consist of the physical remains of the activities of people in the past. This Inadvertent Discovery Procedure (IDP) should be followed should any archaeological sites, objects, or human remains are found. These are protected under Federal and State laws and their disturbance can result in criminal penalties.

1.1. Scope

1.1.1. The scope of this procedure is to minimize impacts to **cultural resources**.

1.1.2. This procedure is applicable to all PGE Personnel and PGE contractors.

1.1.3. The procedure outlines appropriate steps for PGE Personnel and Contractors when **cultural resources** are inadvertently or unanticipatedly discovered during work.

1.1.4. **Inadvertent discoveries** are categorized as either "definitely human remains" or "not definitely human remains" and the steps after each type of discovery are distinct.

1.1.5. **Cultural resources** can be found during any ground-disturbing activity. If encountered all excavation and work in the area MUST STOP. Archaeological objects vary and can include evidence or remnants of historic-era and precontact activities by humans. Archaeological objects can include but are not limited to:

A. Stone flakes, arrowheads, stone tools, bone or wooden tools, baskets, beads

B. Historic building materials such as nails, glass, metal such as cans, barrel rings, farm implements, ceramics, bottles, marbles

C. Layers of discolored earth resulting from hearth fire

D. Structural remains such as foundations

E. Shell Middens

F. Culturally Modified Trees

G. Human skeletal remains and/or bone fragments which may be whole or fragmented

1.1.6. If there is an **inadvertent discovery** of any **cultural resources**, follow this procedure. If in doubt, call it in.

1.2. Precautions

1.2.1. Determine that the area of the **inadvertent find** is safe to work in before implementing protection measures.

1.2.2. The **inadvertent find** should not be photographed, handled or removed until a professional archaeologist is contacted or on site.

1.2.3. Any communication with media should be routed through PGE's Corporate Communication department and must be avoided until adequate assessment of the discovery is made.

1.2.4. If the **inadvertent find** is clearly human, it must be treated with respect and not further disturbed.

1.2.5. PGE shall make its best efforts, in accordance with federal and state law to ensure that its personnel and contractors keep any discovery confidential. PGE will not contact the media, or any third-party member or members of the public regarding a discovery. Prior to any release of information by PGE, PGE shall concur with the responsible agencies and Tribes on the amount of information, if any, to be released to the public.

1.2.6. If applicable, review the sites HPMP (Historical Properties Management Plan) which is included in the FERC license.

1.2.7. For known environmentally sensitive areas, notify EHS prior to any ground disturbance.

1.3. Limitations

1.3.1. This procedure is limited to the treatment of unanticipated identification of **cultural resources** in the course of a PGE action/operation.

2. Responsibilities

2.1. PGE Personnel and Contractors

2.1.1. Stops work when an **inadvertent discovery** of a cultural resource is made.

2.1.2. Contacts appropriate personnel and protects the area, per the procedure.

2.2. PGE Security

2.2.1. Acts as point of contact for calls about **inadvertent discoveries**.

2.2.2. Notifies law enforcement when probable human remains are involved.

2.3. Cultural Resources Specialist

2.3.1. Conducts preliminary in-field assessment of the discovery.

2.3.2. Coordinates with PGE security as required.

2.3.3. Notifies appropriate agencies and/or appropriate Tribes within 24 hours of the discovery.

2.3.4. Provides direction and support services to affected personnel.

2.3.5. Engages an external consultant if required.

2.4. PGE Management

2.4.1. Ensures all site/facility Personnel have received the **cultural resources** sensitivity training.

2.4.2. Contacts PGE's Cultural Resources Specialist to discuss adequate protection for the discovery until a professional in-field assessment of the discovery is made.

2.4.3. Follows any additional management plan guidance specific to PGE project facilities.

3. Procedure

3.1. Prerequisite Actions

3.1.1. Field personnel and supervisors must complete the required Environmental Compliance Training provided by Environmental and Licensing Services that includes cultural awareness training.

3.2. Procedure

3.2.1. Initial Response

A. If an **inadvertent discovery** of a cultural resource is made, all work within the area of discovery shall cease immediately.

1. If the **inadvertent discovery** is believed to be human remains stop ALL work immediately and follow these steps.
    a. Contact PGE Security and Environmental Health & Safety (EHS) immediately within two hours or as soon as reasonably practical.
    b. Cover the remains in a manner that will avoid directly touching them and will protect them from damage, exposure, and obscure their view. Restrict access to the area and leave the cover in place until directed otherwise. Do not take photographs. Do not speak to the media.
    c. PGE Security: Contact Oregon State Police (OSP) to determine whether the find is forensic, i.e., a recent death requiring a criminal investigation.
    d. Contact the PGE's Cultural Resources Specialist (EHS): See the "Cultural Resources Discovery Contact List" (A01).
2. If the discovery is not definitively human remains, PGE's personnel who uncovered the find or their supervisor will contact PGE's Cultural Resources Specialist (EHS) within two hours of discovery or as soon as practical.
    a. PGE's Security does not need to be contacted.

B. PGE Personnel will flag off a buffered area about 200 feet around the discovery if possible.
    1. The area of work stoppage must be large enough to provide for the security, protection, and integrity of the discovery.

C. PGE Personnel must promptly protect the discovery from continued exposure to the weather and from public view.
    1. This may be accomplished using a clean tarp or other fabric.

3.2.2. Assessment

A. After being contacted by PGE Security, OSP, in consultation with the State Medical Examiner and the State Physical Anthropologist, will conduct an assessment to determine if it is a crime scene.

B. If the site is determined not to be a crime scene by OSP, or that the find is definitely not modern, do not move anything! The remains will continue to be secured in place along with any associated funerary objects, and protected from weather, water runoff, and shielded from view. PGE's Cultural Resources Specialist will conduct an on-site assessment of the **inadvertent discovery**.

1. PGE's Cultural Resources Specialist will ensure that all work has halted near the find, that the protection buffer has been created and is adequate, and that the **inadvertent discovery** continues to be treated with respect and secured from harm.

2. If the discovery has been determined non-modern human remains by law enforcement, PGE's Cultural Resources Specialist will contact the State Historic Preservation Office (SHPO), the State Physical Anthropologist, and the Legislative Commission on Indian Services (LCIS) for further guidance as soon as possible, along with the notifying the appropriate Tribes as designated by LCIS.

3. If the discovery is not human remains but a cultural resource, PGE's Cultural Resources Specialist will contact the State Historic Preservation Officer and appropriate Tribes as designated by LCIS within 24 hours of the discovery.

4. PGE's Cultural Resources Specialist will inform PGE Management or Project Manager of a reasonable time frame within which construction or maintenance activity can resume at the location of discovery.

5. PGE's Cultural Resources Specialist will inform appropriate PGE management of the **inadvertent discovery** within 24 hours of the find.

C. Do not resume any work in the buffered area until a plan is developed and carried out between the State Police, SHPO, LCIS, and appropriate Native American Tribes and you are directed that work may proceed.

3.3. Acceptance Criteria

3.3.1. None.

3.4. Post-Performance Activity

3.4.1. PGE's Cultural Resources Specialist will coordinate further archaeological fieldwork and reporting required to complete documentation of the **inadvertent find**.

3.4.2. If Tribes require repatriation of any **cultural resources**, PGE's Cultural Resources Specialist will coordinate the effort with stakeholders jointly identified by the SHPO, Tribes designated by LCIS, and PGE within a reasonable time frame.

3.4.3. PGE will follow appropriate laws and management procedures to assure the proper treatment and care of the discovery.

3.4.4. PGE's Cultural Resources Specialist will confirm with PGE Management when the area is cleared for work to resume.

5. Definitions and Acronyms

5.1. Definitions

5.1.1. **Cultural Resources:** Physical evidence of past human activity (site, object, structure, natural feature or landscape) considered significant by a group of people traditionally associated with it. **Cultural resources** are defined as being fifty years or older. These resources may include artifacts (lithic or stone tools or fragments of tools, ceramic vessels, animal remains, can scatters, farm

equipment), or features (remnants of walls, petroglyphs, cooking hearths or trash middens). **Cultural resources** may be the location of a significant event, prehistoric or historic occupation or activity, whether standing, ruined, or vanished, and possessing historical, cultural, or archaeological value.

5.1.2. **Inadvertent Discoveries/Finds: Cultural resources** found unexpectedly during construction or maintenance activities.

5.2. Acronyms

5.2.1. EHS: Environmental Health and Safety

5.2.2. HPMP: Historical Properties Management Plan

5.2.3. IDP: Inadvertent Discovery Procedure

5.2.4. LCIS: Legislative Commission on Indian Services

5.2.5. NAGPRA: Native American Graves Protection and Repatriation Act

5.2.6. SHPO: State Historic Preservation Office

6. Forms and Appendices

6.1. Forms

6.1.1. None.
