# Oregon's EI/ECSE Outcomes Analysis 2015-2016 

Daniel Anderson, PhD Research Associate, University of Oregon Judy Newman, MS Co-Director, Early Childhood CARES<br>LaWanda Potter, MS Program Coordinator, Early Childhood CARES<br>Daniel Smellow, ecWeb Database Administrator

We would like to acknowledge and thank the Review Team for their support and guidance throughout this process. Team members include: Bruce Sheppard from the Oregon Department of Education, Susan Graham from Douglas ESD, Daniel Anderson PhD from the University of Oregon and LaWanda Potter, Dan Smellow and Judy Newman from Early Childhood CARES. A special thank you to Gerald Tindal PhD from the University of Oregon, Behavioral Research and Teaching for his consultation and support to the process.

The state of Oregon uses the Assessment, Evaluation, and Programming System (AEPS) to report to The Office of Special Education Programs (OSEP) on the status of children receiving early intervention and early childhood special education services on three required outcomes: outcome A -positive social- emotional skills (including social relationships); outcome B-acquisition and use of knowledge and skills (including early language development and early literacy); and outcome C - use of appropriate behaviors to meet their own needs. OSEP requires each state calculate and report the following for each of the three outcomes annually:

- The percentage of infants \& toddlers who entered early intervention below age expectations and substantially increased their rate of growth by age 3 or when they exited the program.
- The percentage of infants \& toddlers who were functioning within age expectations by age 3 when they exited the program.
- The percentage of preschool children who entered the preschool program below age expectations and substantially increased their rate of growth by age 6 or when they exited the program.
- The percentage of preschool children who were functioning within age expectations by age 6 when they exited the program.
States have been reporting to OSEP on these outcomes for six years and the results reported by Oregon have been consistently different than other states. A review team was established and charged with examining the potential reasons for Oregon's different performance on the outcomes.

Oregon approaches data collection and outcome reporting differently than other states. A comprehensive curriculum based measure (AEPS) is used as the only data source to calculate outcomes. Oregon chose this method to make the information and process of calculating outcomes as objective as possible. Further, all service providers in Oregon use the AEPS to select goals and objectives and track progress for the majority of children they serve. Eligible children receiving services from the early intervention (EI) and early childhood special education (ECSE) programs in Oregon are administered the AEPS assessment upon entry and exit, provided there are at least six-months between
these dates. The only exception are children eligible for ECSE services because of articulation and are functioning at age level in all developmental areas. Most other states use the Child Outcomes Summary Form (COSF) to calculate outcomes. The COSF involves a team of professionals reviewing more than one assessment on each child and making a determination on the child's progress and then assigning the child to one of the outcomes categories listed above in the bulleted list. This method uses a more subjective determination of progress by the team of professionals. Some states use the AEPS as one of the assessments considered in their COSF process. However, the AEPS data are compiled and calculated differently in the following ways:

- States other than Oregon use either (a) the test item sorts (into outcomes) and calculations developed by the Brookes publisher, or (b) the percentage of items a child can successfully perform by developmental domain. Oregon, by contrast, uses the test item sorts suggested by the Early Childhood Outcomes (ECO) Center, now the Early Childhood Technical Assistance Center (NECTAC), and the calculations developed by researchers and experts in Oregon.
- In Oregon items were compared to the same or similar items on standardized assessments and then reviewed by a panel of developmental experts to assign a chronological age to each assessment item. The Brookes calculation was based on an IRT (Rasch) model with items ordered in terms of difficulty. Average scores for each chronological age were then estimated.
- In the Brookes outcomes (A, B, C), the short term objectives and long term goals of each test item are included in the calculations, while only the long term goals were recommended by the ECO Center and used for the Oregon calculations.
- When Brookes calculates the progress children made on outcomes, they use a $90 \%$ cut off level representing the score that $90 \%$ of typically developing children that age would score. Children are considered delayed when they are unable to successfully perform skills that $90 \%$ of typically developing children would be able to perform. Oregon uses an 80\% threshold, rather than 90\%.

The review team began their analysis of Oregon's outcome differences by first establishing whether or not children in EI/ECSE programs in Oregon are different than
children in EI/ECSE programs in other states by using item-level data to make the scores more directly comparable, despite the differences listed above. The team then focused on the degree to which differences in the way the AEPS items were sorted into the three outcome categories contributed to the differences in results followed by an analysis to determine the degree to which inclusion of the short term objectives contributed to the differences in results. This phase of the study is referred to as the Comparability Analysis and involves three distinct analyses, which are described in detail below.

## Phase 1: Comparability Analysis

The purpose of this study was to apply common methods (i.e., the same items for each outcome) to an Oregon dataset and a national dataset so the data could be more readily compared. Table 1 below provides the three study research questions, and the corresponding analyses conducted. A separate analysis was conducted for each of the separate research questions listed in Table 1 below. More discussion of each analysis is provided in the Methods section.

Table 1
Research Questions and Analyses for Phase 1: Comparability Analysis

## Research Question Analysis

To what extent do Oregon
children score differently than children nationally?

How much do children's scores differ when Oregon's method of sorting items into outcomes is applied versus the sort used by Brookes?

To what extent do children's scores vary when short-term objectives are included, rather than just long-term objectives?

Oregon's method of sorting items into each outcome ( $\mathrm{A}, \mathrm{B}, \mathrm{C}$ ) was applied to the national dataset. Differences in mean scores between Oregon and the national dataset were then evaluated.

Only the national dataset was used, and two scores on each outcome were computed for each child: one using Oregon's method of sorting items into outcomes, and one using the Brookes method of sorting items into outcomes.

The Brookes method of sorting items into outcomes (A, B, C) was applied with long-term objectives only, and compared to short- and long- term objectives.

## Methods

Sample and Data Cleaning. There are two levels of the AEPS, with one designed for children 0-3 years old (Level 1), and the other designed for children 3-5 years old (Level 2). A portion of ECSE age children (3-5 years old) are given the Level 1 version of the AEPS because developmentally this is a better match for their skill level. There were therefore three distinct samples of children: (1) El age children taking AEPS Level 1, (2) ECSE age children taking AEPS Level 1, and (3) ECSE age children taking AEPS Level 2. For each of these samples, a dataset corresponding to an Oregon sample and national sample was used. The second dataset, ECSE age children taking the AEPS Level 1, was only used in the analysis of the first research question. Across samples, the Oregon data contained only total outcome scores for each of the three outcomes, while the national datasets contained item-level information in addition to total outcome scores. Table 2 below reports the sample size for each sample before and after restricting the data to an analytic sample. For the Oregon sample, the difference between the raw and analytic sample was due to out-of-range records being removed. For the national sample, the difference between the raw and analytic samples were due to restricting the sample to (a) children aged 0-36 months [EI] or 37-60 months [ECSE]; (b) only children coded as "Developmentally Delayed"; and (c) only children who had at least two records, with only the first and last record used in the analysis. These restrictions were needed to have a national sample comparable to the Oregon sample.

Table 2
Sample sizes by dataset

| Sample | Raw $n$ records | Analytic $n$ records |
| :---: | :---: | :---: |
| Oregon EI: AEPS 1 | 14,937 | 14,791 |
| National EI: AEPS 1 | 21,710 | 8,258 |
| Oregon ECSE: AEPS 1 | 713 | 684 |
| National ECSE: AEPS 1 | 10,429 | 9,252 |
| Oregon ECSE: AEPS 2 | 16,023 | 15,884 |
| National ECSE: AEPS 2 | 54,694 | 36,044 |

## Research Question 1 results: To what extent do Oregon children score differently than children nationally?

For the first research question, items from the national dataset were sorted into each of Outcomes A, B and C according to the sorting method used by Oregon. Raw total scores were then computed for each outcome, which were directly comparable between datasets given the common items used and the common sort. (One dataset used the Oregon sample and the other used the national sample.) The difference in means between datasets on each outcome were then compared using a $t$-test. It is worth noting, however, that a priori we expected there to be statistically significant differences in the means because of the large overall sample size (see Table 2). As such, we evaluated the difference between mean scores primarily for practical, rather than statistical, significance. A 95\% confidence interval on the difference between means was computed for each outcome. Large differences between the means would suggest the scores for Oregon children were different (i.e., lower or higher) than average nationally. Small differences were not interpreted as being substantively meaningful (regardless of statistical significance). The analysis was completed for both the first (entrance) and last
(exit) assessments. The distribution of each outcome was also plotted for each dataset to facilitate visual comparisons between the Oregon and National samples.

The distributions of children's scores when applying the Oregon item sorting method to both datasets are displayed for the entrance assessments in Figures 1.1, 1.3, and 1.5, while the distributions of the exit assessment are displayed in Figures 1.2, 1.4, and 1.6. El children given the AEPS 1 are displayed in Figures 1.1-1.2, ECSE children given the AEPS 1 are displayed in Figures 1.3-1.4, and ECSE children given the AEPS 2 are displayed in Figures 1.5-1.6. For each plot, the national distributions are displayed in blue, while the Oregon distributions are displayed in green. The mean of each distribution is displayed with a vertical dashed red line. A 95\% confidence interval on the difference between the National and Oregon means are printed for each outcome.

El children given the AEPS 1 in Oregon entered the program scoring, on average, 3.24, 5.82 , and 6.43 points lower than the national average on Outcomes A, B and C, respectively. These were all statistically significant differences ( $p<.05$ ). However, by the time children were given their exit assessment, children in Oregon were scoring, on average, 0.40 points lower on Outcome X , which was statistically significant ( $p<.05$ ), but not likely substantively meaningful. Children in Oregon did not score statistically significantly different than the national sample on Outcome Y , and scored, on average, 0.69 points higher on Outcome $Z$, which was statistically significant ( $p<.05$ ).

ECSE children given the AEPS 1 in Oregon entered the program scoring, on average, 1.47, 4.55, and 2.76 points lower than the national average on Outcomes $A, B$ and $C$, respectively. These were all statistically significant differences ( $p<.05$ ). However, by the time children were given their exit assessment, children in Oregon were scoring, on average, $1.47,4.55$, and 2.76 points higher on Outcomes A, B and C, respectively, which were all statistically significant ( $p<.05$ ).

ECSE children given the AEPS 2 in Oregon entered the program scoring, on average, $7.45,2.16$, and 0.29 points lower than the national average on Outcomes A, B and C, respectively. These were all statistically significant differences ( $p<.05$ ). However, by the time children were given their exit assessment, children in Oregon were scoring, on
average, $7.57,1.90$, and 0.62 points lower on Outcomes A, B and C respectively, which were all statistically significant ( $p<.05$ ).

In sum, these results suggest that when children in Oregon are compared to a national sample using common items, they appear to generally enter the program with lower scores, but exit with scores comparable or higher than their peers nationally. While some children appear to exit with lower scores than the national sample, these differences are not generally substantively meaningful. The exception were ECSE children in the AEPS 2, who began much lower, and generally maintained this gap upon exit. For many outcomes, however, despite the $t$-test being significant, their levels of achievement on exit were, for all intents and purposes, indistinguishable. The conclusion, then, is that there are no substantively meaningful differences between children served in EI/ECSE programs in Oregon and those served in other states. And for the purpose of this study, the two data sets can be considered comparable for further analysis.

Figure 1.2. Distribution of each outcome for the Oregon and National Samples: EI AEPS 1 Exit Test. Note that the mean of each distribution is displayed with a red dotted vertical line. The mean difference between each distribution is displayed in text for each Oregon distribution. Confidence intervals crossing zero are not statistically significant.

Figure 1.3. Distribution of each outcome for the Oregon and National Samples: ECSE AEPS 1 Entrance Test. Note that the mean of each distribution is displayed with a red dotted vertical line. The mean difference between each distribution is displayed in text for each Oregon distribution. Confidence intervals crossing zero are not statistically significant.

Figure 1.4. Distribution of each outcome for the Oregon and National Samples: ECSE AEPS 1 Exit Test. Note that the mean of each distribution is displayed with a red dotted vertical line. The mean difference between each distribution is displayed in text for each Oregon distribution. Confidence intervals crossing zero are not statistically significant.

Figure 1.5. Distribution of each outcome for the Oregon and National Samples: ECSE AEPS 2 Entrance Test. Note that the mean of each distribution is displayed with a red dotted vertical line. The mean difference between each distribution is displayed in text for each Oregon distribution. Confidence intervals crossing zero are not statistically significant.

Figure 1.6. Distribution of each outcome for the Oregon and National Samples: ECSE AEPS 2 Exit Test. Note that the mean of each distribution is displayed with a red dotted vertical line. The mean difference between each distribution is displayed in text for each Oregon distribution. Confidence intervals crossing zero are not statistically significant.

Research Question 2 results: How much do children's scores differ when Oregon's method of sorting items into outcomes is applied versus the sort used by Brookes?

For the second research question, only the national dataset was used. Children's scores on each outcome were then computed using both sorting methods (Oregon's and Brooke's). Given that the two sorts included a different number of items in each outcome, mean scores could not be compared. However, scores were correlated to examine the extent to which children's scores computed by one sort corresponded to the score when the alternative sort was used.

Figures 2.1 to 2.4, below, display scatterplots of children's scores calculated by both the Oregon and the Brookes item sorting method. Scatterplots for the El age children are displayed in Figures 2.1 and 2.2, while ECSE age children scores are displayed in Figures 2.3 and 2.4. Pearson's correlation coefficient, $r$, is also displayed in each plot. The correlations were all quite strong, indicating that the two sorts were both getting at the same underlying construct. However, meaningful differences were apparent when viewing the data on a bychild basis.

Score Comparisons By Method

Figure 2.1. AEPS 1: El Children, First Assessment

Score Comparisons By Method

Outcome Y

Outcome Z

Figure 2.2. AEPS 1: El Children, Last Assessment

Figure 2.3. AEPS 2: ECSE Children, First Assessment

Score Comparisons By Method

Figure 2.4. AEPS 2: ECSE Children, Last Assessment

In summary these results indicate that the two sorting methods are comparable and highly correlated. There were no statistical differences between groups when using the Oregon method to sort AEPS test items into the three outcome categories $(A, B, C)$, rather than when using the Brookes method.

## Research Question 3 results: To what extent do children's scores vary when shortterm objectives are included, rather than just long-term objectives?

Only the national dataset was used with the Brookes item sort. Children's scores were computed using long-term goals only, versus with long-term goals and short term objectives. Again, mean score differences between these methods would not be meaningful, given that including short-term objectives resulted in substantially more items. However, children's scores computed with each method were correlated for each outcome. This provided an indication as to whether the inclusion of short-term objectives resulted in the measurement of a different construct.

Overall, we found that the ability estimates correlated very high, implying that the overall "picture" of children's performance would not change when only long term goals are used as compared to when long term goals and short term objectives are used. Figures 3.1 to 3.4 plot these relations. Figures 3.1 and 3.2 show the comparison for each outcome for El age children and Figures 3.3 and 3.4 show the same comparison for the ECSE age children.

Figure 3.1. AEPS 1: El Children, First Assessment

Figure 3.2. AEPS 1: El Children, Last Assessment

Figure 3.3. AEPS 2: ECSE Children, First Assessment

Figure 3.4. AEPS 2: ECSE Children, Last Assessment

## Conclusions of Phase 1 Comparability Analysis

The results of these three analyses suggest that (a) when common methods are used, children in Oregon do not appear to be performing substantially different upon exit from the El or ECSE programs, although Oregon children do enter performing substantially lower; (b) inferences of children's ability, overall, are invariant to both the method used for sorting items into outcomes and the inclusion of short-term objectives versus long term goals only, while (c) inferences about a single child may depend on these factors.

Following this analysis, Oregon made a decision to set new developmental standards for each age using the method for sorting items into outcomes used by Paul Brookes publisher, and to include short-term objectives into the outcome calculation. These decisions were made, in part, to better align with data collected and analyzed nationally, as well as to obtain more nuanced information about children that could potentially be used to inform individual decisions.

## Phase 2: Setting New Cut-Off Points

Phase 2 of the project involved setting new cutoff scores (developmental standards) for the Brookes item sort using the long term goals and short term objectives. This was accomplished using a four-step process. Step 1 consisted of setting initial cut-scores guided by an empirical process with a large extant dataset (the national dataset used in the analyses in Phase 1). Step 2 consisted of gathering judgments by experts in the field to confirm or modify the initial cut-score placement. Step 3 consisted of reviewing the recommendations from the experts and determining final cut-score placement, based on balancing recommendations from the field with empirical evidence from a small pilot sample of children. Finally step 4 of the project compared and considered the data results using $90 \%$, $85 \%$ and $80 \%$ percentile cutoffs and the national data results to decide what cutoff level best reflected Oregon's children in EI/ECSE programs.

## Step 1

A large national dataset was used to set initial developmental cut scores for each outcome. The dataset was the same that was used in Phase1, but was restricted to include only children who were typically developing. Raw-total scores were then computed for each child for each outcome. The normative $10^{\text {th }}, 15^{\text {th }}, 20^{\text {th }}$ and $50^{\text {th }}$ percentiles were then calculated for each outcome by child's age, in months, rounded to the nearest whole month. These represented the points at which $90 \%, 85 \%, 80 \%$ and $50 \%$ of children who were typically developing would perform at or above, respectively, for the corresponding age. The raw-total score corresponding to a particular percentile (i.e., $10^{\text {th }}$ ) generally increased as age increased. However, there was some variability due to measurement and sampling error, necessitating a smoothing function be applied (e.g., so the cut score did not bounce around as age level increased). Three smoothing functions were explored: linear, quadratic, and a locally weighted scatterplot smoothing (LOESS).

Figure 4.1-4.3 below shows the plots evaluated to set initial cut scores. The plots shown represent Outcome A, B and C for the AEPS level 1 (for birth to 3 year old children). Similar plots are presented for Outcome A, B and C for the AEPS level 2 (for 3 to 5 year old children) in Figure 4.4-6.6. At the top of the figures, a histogram of the number of children represented within each age, in months, is presented. The histogram helped evaluate how many children's scores were represented within each normative data point. A child's age, in months, is plotted along the x -axis of the figures below the histogram, while their score is plotted along the y axis. Among children within each age month, the scores corresponding to the normative $10^{\text {th }}$ percentile are plotted with red circles, while the scores corresponding to the normative $50^{\text {th }}$ percentile are plotted with blue triangles. The $50^{\text {th }}$ percentile data points were plotted as a point of reference relative to the $10^{\text {th }}$ percentile data points. Three smoothing functions were then fit, with the LOESS displayed by the thin line of the corresponding color, linear function displayed with a thick dashed line, and quadratic function displayed with a thick dotted line in a slightly lighter color. Smoothing functions were chosen based on the fit of the function to the data, and the consistency of fit across outcomes. That is, there was a desire to have the same smoothing function applied across outcomes, within and across the AEPS level 1 and the AEPS level 2.

## Typical Children Birth through 3 years - Outcome A

Figure 4.1. Normative $10^{\text {th }}$ (red) and $50^{\text {th }}$ (blue) national percentiles for AEPS 1 , with three smoothing functions fit to the data (linear, quadratic, and LOESS).

## Typical Children Birth through 3 years - Outcome B

Figure 4.2. Normative $10^{\text {th }}$ (red) and $50^{\text {th }}$ (blue) national percentiles for AEPS 1 , with three smoothing functions fit to the data (linear, quadratic, and LOESS).

## Typical Children Birth through 3 years - Outcome C

Figure 4.3. Normative $10^{\text {th }}$ (red) and $50^{\text {th }}$ (blue) national percentiles for AEPS 1, with three smoothing functions fit to the data (linear, quadratic, and LOESS).

## Typical Children 3-5 years Old - Outcome A

Figure 4.4. Normative $10^{\text {th }}$ (red) and $50^{\text {th }}$ (blue) national percentiles for AEPS 2, with three smoothing functions fit to the data (linear, quadratic, and LOESS).

## Typical Children 3-5 years Old - Outcome B

Figure 4.5. Normative $10^{\text {th }}$ (red) and $50^{\text {th }}$ (blue) national percentiles for AEPS 2, with three smoothing functions fit to the data (linear, quadratic, and LOESS).

## Typical Children 3-5 years Old - Outcome C

Figure 4.6. Normative $10^{\text {th }}$ (red) and $50^{\text {th }}$ (blue) national percentiles for AEPS 2, with three smoothing functions fit to the data (linear, quadratic, and LOESS).

Based on the analysis of the plots in Figures 4.1-4.3, the decision was made for the AEPS level 1 to set a cut score corresponding to a quadratic function because the loess line was too erratic and likely represented overfitting to the data, while the quadratic curve followed the data progression most closely. The initial standards for each of the birth to 3 outcomes were set according to the normative $10^{\text {th }}, 15^{\text {th }}$, and $20^{\text {th }}$ percentiles following the quadratic lines with minor smoothing functions at the oldest month(s).

The AEPS level 2 assessment had more children represented in each age category, which generally led to less variability in the same percentile across age groups (see Figures 4.4-4.6 above). The LOESS function was again deemed too erratic, and likely represented overfitting to the data. The linear and quadratic functions were nearly indistinguishable, so the decision was made to use the quadratic curve to be consistent with the birth to 3 year old outcomes from the AEPS level 1 calculations. The initial standards for each outcome were set according to the normative $10^{\text {th }}, 15^{\text {th }}$, and $20^{\text {th }}$ percentiles, and similar to the birth to 3 outcomes, at the very end of each curve, the line was smoothed so it did not decline because for practical and theoretical purposes, a cut score should not decline as age increases.

The initial cutoffs for each outcome, set according to the normative $10^{\text {th }}, 15^{\text {th }}$, and $20^{\text {th }}$ percentiles, and following the quadratic lines with minor smoothing functions at the oldest month(s), described above, are displayed for both the AEPS level 1 (El ages birth to 3 years) and AEPS level 2 (ECSE ages 3 through 5 years) in Appendix $A$.

## Step 2

Following the initial setting of standards, derived from a normative, empirically driven process, expert recommendations were sought to confirm or disconfirm the initial placement of cut scores. The process mirrored a bookmark standard setting methodology. First, a partial-credit Rasch model was fit to obtain item difficulty estimates for all items across outcomes. Rasch modeling represents a special case of item response theory, and has considerable benefits over classical test theory methods. For example, item parameters are not necessarily reliant on representative samples. All item difficulties were estimated concurrently, leading to all estimates being calibrated to a common scale and being directly comparable (for more information on Rasch modeling see: http://testolog.narod.ru/Rasch5.pdf).

All items were assembled by outcome into an EXCEL spreadsheet and ordered according to the calibrated item difficulty. Items within the spreadsheet, theoretically, represented a
developmental progression. In other words, as children became older and their skills increased, they would be able to correctly perform more items for each outcome. A cumulative score was then computed, which would correspond to a child having previously responded to all previous items correctly. The corresponding cut scores representing the raw score that $90 \%$ of children at that monthly age would score for each age were then mapped to the cumulative score, and the experts were asked whether $90 \%$ of typically developing children could reasonably be expected to have the skills up to that item. In some cases, it was deemed that more than $90 \%$ of typically developing children at that age would have those skills, and the cut score was moved up to include more difficult items (and a higher cumulative score). In other cases, it was deemed that fewer than $90 \%$ of typically developing children at that age would have those skills, and the cut score was moved down to easier items (corresponding to a lower cumulative score). The $80 \%$ and $50 \%$ cut off scores were also calculated and added to the spreadsheet to provide a developmental perspective to the cumulative score to assist the experts in their review. Appendix B contains the EXCEL spreadsheets for each of the three outcomes for the El birth to 3 year olds using the AEPS 1 level items and each of the three outcomes for the ECSE 3 to 5 year olds using the AEPS level 2 items in the outcomes.

Experts were recruited from the University Oregon Early Intervention Masters and PhD Program faculty and experienced staff from the Early Childhood CARES Program who conduct assessments and provide services to children enrolled in early intervention and early childhood special education. The individuals selected had expertise in both typical and atypical development as well as a minimum of 20 years experience.

- Misti Waddell - a Senior Research Assistant in the Early Intervention Program at the University of Oregon working the development and standardization of the AEPS and the SEAM. She is an author on the AEPS and is a national trainer.
- Jantina Clifford - a Lecturer and Research Associate in the Early Intervention masters and doctoral program at the University of Oregon. She has been involved with research on the AEPS and ASQ and is currently working on the research of the ASQ Inventory.
- LaWanda Potter - A Program Coordinator and supervisor for early Childhood CARES with experience serving and assessing children from 3 to 5 years of age. She is an author and trainer of the Ages and Stages Questionnaire (ASQ3).
- Val Taylor Close - Co-director of Early Childhood CARES with extensive experience in serving children birth to three years of age and doing standardized, criterion referenced and observational developmental assessments.
- Judy Newman - Co-director of Early Childhood CARES with extensive experience in serving children birth to three years of age and doing standardized, criterion referenced and observational developmental assessments.
- Natalya McComas - a service provider for birth to 5 year old children with extensive experience working with three through 5 year olds. Natalya has been involved with gathering data on the AEPS for revisions over the years.
- Jane Farrell - a service provider of birth to 5 year olds with extensive experience working with birth to three year olds Jane is a national trainer of the ASQ3 and ASQSE with over 30 years of experience in the field.
- Vicki Swanson - a service provider of for birth to 5 year olds with over 30 years of experience in all settings and with all disabilities.

The experts found it was very difficult to look at a cumulative score and make a determination about whether or not this was a score that $90 \%$ or even $80 \%$ of children at that age would receive on the AEPS. However, the group was able to determine if items were in a developmental sequence based on the Rasch analysis and look at individual items and assess why they may have been out of place. A few items (3-4) stood out to all experts as being divergent from an appropriate developmental age and these items were adjusted in the analysis. In addition, some items were found to be out of the expected developmental sequence. Upon further analysis of those test items, it was discovered that these items were exclusively "additive" AEPS items that are scored differently than the "developmental" AEPS test items, which comprise the majority of the test items. The scoring of these items was adjusted for the cumulative score analysis by using only a 0 or a 2 for the score of a long term additive goal and not allowing the use of a 1 score. So if the additive long-term goal had been scored 1 , it was calculated as a 0 in the cumulative score to be consistent with the developmental process. Once the scoring of these items was adjusted for the analysis, the developmental sequences appeared to be correct.

## Step 3

Since the developmental experts had difficulty confirming the cutoff cumulative scores, an additional cross check was added. The cumulative scores associated with the cut off levels were compared to a small sample ( $n=15$ ) of AEPS scores of typically developing children at various ages to help verify whether or not the cumulative scores suggested for the cutoffs for each chronological age were accurate. This analysis provided reassurance that the cutoff scores were accurate and reflected the scores that a typically developing child would have at the ages sampled.

## Step 4

Finally, the outcome scores were calculated for each outcome using an $80 \%, 85 \%$ and $90 \%$ cut off level with the current Oregon dataset, as they are prepared for the annual federal report. The results from all three were displayed along with national outcome results from the previous year. (Figure 5.1 below shows the figures used in the comparison.) The original review team, the Oregon Department of Education staff, the EI/ECSE Contractors and the EI/ECSE stakeholder group who sets statewide outcome targets were all asked to study and analyze them and determine which cut off level Oregon should use for reporting to the federal government. The consensus was to use the $80 \%$ cut off level for reporting the El and the ECSE outcomes. It was believed that this most closely represents the children who are eligible for EI/ECSE programs and receive services in Oregon.

Figure 5.1 Outcome comparison table.

## Conclusion

Oregon's EI/ECSE program is unique in the way it collects and calculates it's annual outcomes to report to the federal government. Because Oregon's outcome results to date have differed significantly from national results, the authors of this paper undertook a study to examine whether the unique aspects of Oregon's system were causing results to differ. The first task was to demonstrate that Oregon's population was similar to a national EI/ECSE sample and if the methods and applications used were significantly influencing Oregon's results. Authors concluded that while some differences existed, Oregon's methods and sample were comparable to national data and outcome results. Ultimately the authors recommended Oregon adopt procedures more closely aligned with the procedures used by other states who use the AEPS assessment tool in order to achieve greater consistency over time. Specifically Oregon's new methodology uses the same sorting of items into outcome categories as Brookes Publishing Company uses and includes both short term objectives and long term goals in the scores. The second task of this group was to develop new standards that would inform cutoff points for determining progress and status using the results from the new methodology. These results were analyzed and shared with the Oregon Department of Education who recommended that Oregon adopt the $80 \%$ cutoff point because the results appear to most accurately represent Oregon's EI/ECSE population and more closely align with national averages.
