Continuing medical education activity in *American Journal of Hematology*

CME Editor: Ayalew Tefferi, MD
CME Author: Elihu H. Estey, MD

CME Information: Acute myeloid leukemia: 2013 update on risk-stratification and management

If you wish to receive credit for this activity, please refer to the website: www.wileyhealthlearning.com

Accreditation and Designation Statement:

Blackwell Futura Media Services is accredited by the Accreditation Council for Continuing Medical Education to provide continuing medical education for physicians.

Blackwell Futura Media Services designates this journal-based CME for a maximum of 1 *AMA PRA Category 1 Credit™*. Physicians should only claim credit commensurate with the extent of their participation in the activity

Educational Objectives

Upon completion of this educational activity, participants will be better able to:

1. Assess the relative importance of "treatment related mortality" and "resistance to therapy" as causes of therapeutic failure in AML
2. Be familiar with the need to obtain information about NPM and CEBPA mutations and FLT3 internal tandem duplications
3. Know several means to measure minimal residual disease (MRD) and the prognostic significance of MRD
4. Understand what results of randomized trials using chemotherapy +/− gemtuzumab ozogamicin tell us about the heterogeneity of AML

Activity Disclosures

No commercial support has been accepted related to the development or publication of this activity.

CME Editor - Ayalew Tefferi, MD has no conflicts of interest to disclose.

CME Author - Elihu H. Estey, MD has no conflicts of interest to disclose.

This activity underwent peer review in line with the standards of editorial integrity and publication ethics maintained by *American Journal of Hematology.* The peer reviewers have no conflicts of interest to disclose. The peer review process for *American Journal of Hematology* is single blinded. As such, the identities of the reviewers are not disclosed in line with the standard accepted practices of medical journal peer review.

Conflicts of interest have been identified and resolved in accordance with Blackwell Futura Media Services's Policy on Activity Disclosure and Conflict of Interest. The primary resolution method used was peer review and review by a non-conflicted expert.

Instructions on Receiving Credit

This activity is intended for physicians. For information on applicability and acceptance of continuing medical education credit for this activity, please consult your professional licensing board.

This activity is designed to be completed within one hour; physicians should claim only those credits that reflect the time actually spent in the activity. To successfully earn credit, participants must complete the activity during the valid credit period, which is up to two years from initial publication. Additionally, up to 3 attempts and a score of 70% or better is needed to pass the post test.

Follow these steps to earn credit:

- Log on to www.wileyhealthlearning.com
- Read the target audience, educational objectives, and activity disclosures.
- Read the activity contents in print or online format.
- Reflect on the activity contents.
- Access the CME Exam, and choose the best answer to each question.
- Complete the required evaluation component of the activity.
- Claim your Certificate.

This activity will be available for CME credit for twelve months following its launch date. At that time, it will be reviewed and potentially updated and extended for an additional twelve months.

Annual Clinical Updates in Hematological Malignancies:
A Continuing Medical Education Series

Acute myeloid leukemia: 2013 update on risk-stratification and management

Elihu H. Estey[1,2]*

Disease overview: Acute myeloid leukemia (AML) results from accumulation of abnormal blasts in the marrow. These cells interfere with normal hematopoiesis, can escape into the peripheral blood, and infiltrate CSF and lung. It is likely that many different mutations, epigenetic aberrations, or abnormalities in micro RNA expression can produce the same morphologic disease with these differences responsible for the very variable response to therapy, which is AMLs principal feature.

Diagnosis: This rests on demonstration that the marrow or blood has > 20% blasts of myeloid lineage. Blast lineage is assessed by multiparameter flow cytometry, with CD33 and CD13 being surface markers typically expressed by myeloid blasts. It should be realized that clinical/prognostic considerations, not the blast % per se, should be the main factor determining how a patient is treated.

Risk Stratification: Two features determine risk: the probability of treatment-related mortality (TRM) and, more important, even in patients aged >75 with Zubrod performance status 1, the probability of resistance to standard therapy despite not incurring TRM. The chief predictor of resistance is cytogenetics, with a monosomal karyotype (MK) denoting the disease is essentially incurable with standard therapy even if followed by a standard allogeneic transplant (HCT). The most common cytogentic finding is a normal karyotype(NK) and those of such patients with an NPM1 mutation but no FLT3 internal tandem duplication (ITD), or with a CEBPA mutation, have a prognosis similar to that of patients with the most favorable cytogenetics (inv 16 or t[8;21]) (60–70% cure rate). In contrast, NK patients with a FLT3 ITD have only a 30–40% chance of cure even after HCT. Accordingly analyses of NPM1, FLT3, and CEBPA should be part of routine evaluation, much as is cytogenetics. Risk is best assessed considering several variables simultaneously rather than, for example, only age. Increasing evidence indicates that other mutations and abnormalities in microRNA (miRNA) expression also affect resistance as do post treatment factors, in particular the presence of minimal residual disease. These newer mutations and MRD are discussed in this update.

Risk-adapted therapy: Patients with inv (16) or t(8;21) or who are NPM1+/FLT3ITD—can receive standard therapy (daunorubicin + cytarabine) and should not receive HCT in first CR. It seems likely that use of a daily daunorubicin dose of 90 mg/m^2 will further improve outcome in these patients. There appears no reason to use doses of cytarabine > 1 g/m^2 (for example bid X 6 days), as opposed to the more commonly used 3 g/m^2. Patients with an unfavorable karyotype (particularly MK) are unlikely to benefit from standard therapy (even with dose escalation) and are thus prime candidates for clinical trials of new drugs or new approaches to HCT; the latter should be done in first CR. Patients with intermediate prognoses (for example NK and NPM and FLT3ITD negative) should also receive HCT in first CR and can plausibly receive either investigational or standard induction therapy, with the same prognostic information about standard therapy leading one patient to choose the standard and another an investigational option. This update discusses results with newer agents: quizartinib and crenolanib, gemtuzumab ozogamicin, clofarabine and cladribine, azacitidine and decitabine, volasertib, and means to prevent relapse after allogeneic transplant.

The diagnosis of AML essentially is made as it was in 2012.Thus this review will emphasize new developments in risk stratification and treatment using as references many papers published in 2012. Am. J. Hematol. 88:318–327, 2013. © **2013 Wiley Periodicals, Inc.**

Risk Stratification

TRM vs. resistance

It is important to re-emphasize that the major cause of therapeutic failure in AML is resistance to treatment rather than treatment-related mortality (TRM) [1,2]. Although various criteria for TRM exist, Walter et al.[3] using data from 2,238 MD Anderson Cancer Center (MDA) and 1,127 Southwest Oncology Group (SWOG) patients given 3 days of an anthracycline + either standard doses of ara-C (100 mg/m^2 daily X 7, i.e. "3+7") or higher doses noted a sharp decline in weekly mortality rate once 4 weeks had elapsed from start of induction therapy suggesting that patients who died in these 4 weeks were a distinct group. Using 4-weeks as a criterion they developed (by bootstrapping) a model that predicts TRM. Of note covariates such as performance status, creatinine, albumin, platelet count, WBC and blast count and de novo vs. secondary AML can replace age in

Abstract Diagnosis and classification of acute myeloid leukemia (AML) are based on morphology and genetics. An increasing number of gene mutations have been found, and some are used for risk classification in AML patients with normal karyotype (cytogenetically normal (CN)-AML). In this systematic review and meta-analysis, we examined three frequent mutations in CN-AML: mutations of *fms*-related tyrosine kinase 3 (*FLT3-ITD*), mutated nucleophosmin (*NPM1*), and mutations of the CCAAT enhancer-binding protein alpha (*CEBPA*) gene. A systematic literature search of publications listed in the electronic databases (Embase, Pubmed, Healthstar, BIOSIS, ISI Web of Knowledge and Cochrane) from 2000 up to March 2012 was performed (Fig. 1). Nineteen studies were included and qualitatively analyzed. Two to four studies entered the quantitative meta-analysis incorporating 1,378 to 1,942 patients with CN-AML. Meta-analysis for overall survival (OS) and relapse-free survival (RFS) showed *FLT3*-ITD to predict an unfavorable prognosis, with hazard ratios (HR) of 1.86 and 1.75, respectively. In contrast, meta-analysis of the impact of *NPM1* and *CEBPA* mutations on OS yielded an HR of 0.56 for each mutation, while analysis of impact on RFS produced HRs of 0.37 and 0.42, respectively. This systematic review and meta-analysis aimed to evaluate the prognostic value of mutations in the *NPM1*, *CEBPA*, and *FLT3* genes. *FLT3*-ITD was associated with worse prognosis, whereas mutations in *NPM1* and *CEBPA* genes were associated with a favorable prognosis.

Keywords Acute myeloid leukemia · Normal karyotype · Mutations of fms-related tyrosine kinase 3 · Mutated nucleophosmin · Mutations of the CEBPA gene · Meta-analysis

Introduction

Acute myeloid leukemia (AML) is a clonal disease of hematopoietic progenitor cells that accumulate a variety of mutations and epigenetic events leading to increased proliferation, disruption of differentiation, lack of apoptosis, and suppression of normal hematopoietic progenitor cells [1]. The natural history of disease is thus characterized by the lack of mature blood cells like granulocytes, lymphocytes, erythrocytes, or platelets. Without therapy, the outcome is typically fatal within weeks or months due to severe infection, bleeding, or wasting. Acquired genetic abnormalities determine the pathogenesis and the course of the disease. Until the recent developments in molecular genetics, diagnosis and classification were based on cytological criteria and cytogenetic alterations. The different karyotypes have enabled physicians to classify AML patients as low, intermediate, and high risk. Typically, AML patients are treated with chemotherapy. In adult patients younger than 60 years, therapy includes an induction

Comparative Effectiveness Review: Prostate Cancer Antigen 3 Testing for the Diagnosis and Management of Prostate Cancer

Linda A. Bradley,*,† Glenn E. Palomaki,† Steven Gutman,† David Samson† and Naomi Aronson‡

From the Department of Pathology and Laboratory Medicine, Women & Infants Hospital/Alpert Medical School of Brown University, Providence, Rhode Island (LAB, GEP), and BlueCross BlueShield Association TEC Evidence-based Practice Center, Chicago, Illinois (SG, DS, NA)

Purpose: We compared the effectiveness of PCA3 (prostate cancer antigen 3) and select comparators for improving initial or repeat biopsy decision making in men at risk for prostate cancer, or treatment choices in men with prostate cancer.

Materials and Methods: MEDLINE®, EMBASE®, Cochrane Database and gray literature were searched from January 1990 through May 2012. Included studies were matched, and measured PCA3 and comparator(s) within a cohort. No matched analyses were possible. Differences in independent performance estimates between PCA3 and comparators were computed within studies. Studies were assessed for quality using QUADAS (Quality Assessment of Diagnostic Accuracy Studies) and for strength of evidence using GRADE (Grading of Recommendations Assessment, Development and Evaluation) criteria.

Results: Among 1,556 publications identified, 34 observational studies were analyzed (24 addressed diagnostic accuracy and 13 addressed treatment decisions). Most studies were conducted in opportunistic cohorts of men referred for procedures and were not designed to answer key questions. Two study biases (partial verification and sampling) were addressed by analyses, allowing some conclusions to be drawn. PCA3 was more discriminatory than total prostate specific antigen increases (eg at an observed 50% specificity, summary sensitivities were 77% and 57%, respectively). Analyses indicated that this finding holds for initial and repeat biopsies, and that the markers were independent predictors. For all other biopsy decision making comparisons and associated health outcomes, strength of evidence was insufficient. For treatment decision making, strength of evidence was insufficient for all outcomes and comparators.

Conclusions: PCA3 had a higher diagnostic accuracy than total prostate specific antigen increases, but strength of evidence was low (limited confidence in effect estimates). Strength of evidence was insufficient to conclude that PCA3 testing leads to improved health outcomes. For all other outcomes and comparators, strength of evidence was insufficient.

Key Words: prostatic neoplasms; prostate cancer antigen 3, human; biopsy; predictive value of tests; comparative effectiveness research

Abbreviations and Acronyms

CER = comparative effectiveness review
cPSA = complexed prostate specific antigen
EVN = externally validated nomogram
FPR = false-positive rate
fPSA = free prostate specific antigen
KQ = key question
PCA3 = prostate cancer antigen 3
PSA = prostate specific antigen
PSAD = prostate specific antigen density
SOE = strength of evidence
TEP = Technical Expert Panel
tPSA = total prostate specific antigen

PROSTATE cancer is the second leading cause of cancer death in the United States.[1] The rationale for tPSA screening was to reduce the prevalence of advanced prostate cancer and related mortality through early detection and treatment. While a decrease in prostate cancer related mortality has been observed,[1,2] studies in screened populations have raised concerns about the test's low specificity and the risks of treatment in men with early stage disease that may never progress to symptoms.[3] The balance of

Abstract

Context: Despite widespread screening for prostate cancer (PCa) and major advances in the treatment of metastatic disease, PCa remains the second most common cause of cancer death for men in the Western world. In addition, the use of prostate-specific antigen testing has led to the diagnosis of many potentially indolent cancers, and aggressive treatment of these cancers has caused significant morbidity without clinical benefit in many cases. The recent discoveries of inherited and acquired genetic markers associated with PCa initiation and progression provide an opportunity to apply these findings to guide clinical decision making.

Objective: In this review, we discuss the potential use of genetic markers to better define groups of men at high risk of developing PCa, to improve screening techniques, to discriminate indolent versus aggressive disease, and to improve therapeutic strategies in patients with advanced disease.

Evidence acquisition: PubMed-based literature searches and abstracts through January 2012 provided the basis for this literature review. We also examined secondary sources from reference lists of retrieved articles and data presented at recent congresses. Cited review articles are only from the years 2007–2012, favoring more recent discussions because of the rapidly changing field. Original research articles were curated based on favoring large sample sizes, independent validation, frequent citations, and basic science directly related to potentially clinically relevant prognostic or predictive markers. In addition, all authors on the manuscript evaluated and interpreted the data acquired.

Evidence synthesis: We address the use of inherited genetic variants to assess risk of PCa development, risk of advanced disease, and duration of response to hormonal therapies. The potential for using urine measurements such as prostate cancer antigen 3 (*PCA3*) RNA and the transmembrane protease, serine 2 v-ets erythroblastosis virus E26 oncogene homolog (avian) (*TMPRSS2-ERG*) gene fusion to aid screening is discussed. Multiple groups have developed gene expression signatures from primary prostate tumors correlating with poor prognosis, and attempts to improve and standardize these signatures as diagnostic tests are presented. Massive sequencing efforts are underway to define important somatic genetic alterations (amplifications, deletions, point mutations, translocations) in PCa, and these alterations hold great promise as prognostic markers and for predicting response to therapy. We provide a rationale for assessing genetic markers in metastatic disease for guiding choice of therapy and for stratifying patients in clinical trials, and discuss challenges in clinical trial design incorporating the use of these markers.

PCA3
Prostate biopsy
Prostate cancer detection
Staging
Targeted therapy

Abstract

Context: Newly discovered biomarkers ideally should prove clinical usefulness, provide additional detection, staging, and prognosis information to improve individual risk assessment, and potentially permit targeted cancer therapy.
Objective: To review, display, and evaluate the current evidence regarding the biologic and analytic approach of urinary prostate cancer gene 3 (PCA3) in prostate cancer (PCa) detection, staging, and prognosis, and its therapeutic potential.
Evidence acquisition: A systematic and comprehensive Medline search was performed using the Medical Subject Headings search terms *PCA3, DD3, UPM3, prostate cancer, cell-lines, prostate tissue, prostate biopsy, detection, diagnosis, radical prostatectomy, staging, grading, progression,* and *gene therapy*. Results were restricted to English-language papers published within the period 1999–2011.
Evidence synthesis: The *PCA3* gene is highly overexpressed in specific PCa cell lines and prostatic tumours. In 2006, a simple and robust urine test (Progensa) became commercially available. Despite its costs, prostate cancer antigen 3 (PCA3) is superior to prostate-specific antigen (PSA) and percent free PSA in the early detection of PCa. PCA3 improves the diagnostic accuracy of externally validated nomograms among men with an elevated PSA undergoing biopsy. PCA3 independently predicts low-volume disease and pathologically insignificant PCa but is not associated with locally advanced disease and is limited in the prediction of aggressive cancer. Preliminary data demonstrate that combining PCA3 with other new biomarkers further improves diagnostic and prognostic accuracy. Finally, findings of the first PCA3-Gene-ViroTherapy study suggest therapeutic potential by exploiting PCA3 overexpression.
Conclusions: PCA3, integrated in novel biopsy nomograms or risk stratification tools, can be used to counsel or confirm biopsy indications. If confirmed in further studies, using PCA3 together with established staging risk factors could assist clinicians in specific pretreatment decision making. So far no evidence for the usefulness of PCA3 in active surveillance programs has been presented.

Aetna considers prostate-specific antigen (PSA) screening a medically necessary preventive service for men aged 40 years and older, and for men under 40 years of age who are at high-risk for prostate cancer. Risk groups include African-American men and men with a family history of prostate cancer.

When used for routine screening, annual PSA screening is considered medically necessary, but additional PSA tests may be considered medically necessary in men with previously elevated PSAs or signs or symptoms of disease.

Aetna considers diagnostic PSA testing medically necessary for men of all ages with signs or symptoms of prostate cancer, and for follow-up of men with prostate cancer.

Aetna considers annual digital rectal examination (DRE) a medically necessary preventive service.

Aetna considers alpha-methylacyl coenzyme A racemase (AMACR), early prostate cancer antigen, endoglin, E twenty-six (ETS) gene fusions, human glandular kallikrein 2 (hK2) (also known as kallikrein-related peptidase 2 [KLK2]), interleukin-6, prostate cancer gene 3 (PCA3), TMPRSS2:ERG gene fusion, and transforming growth factor-beta 1 experimental and investigational for prostate cancer screening because they have no proven value for this indication.

Aetna considers measurement of selenium in the blood or in tissues (such as toenail clippings) experimental and investigational to assess the risk of developing prostate cancer because it has no proven value for this indication.

Aetna considers the analysis of prostatic fluid electrolyte composition (e.g., citrate, zinc; not an all inclusive list) experimental and investigational for prostate cancer screening because it has no proven value for this indication.

See also CPB 0352 - Tumor Markers.

Note: Some plans exclude coverage of preventive services. Please check benefit plan descriptions for details. Medically necessary diagnostic PSA testing is covered regardless of whether the member has preventive service benefits.

Background

The decision to perform routine prostate cancer screening with digital rectal examination (DRE) or prostate-specific antigen (PSA) is left to the discretion of the clinician. Patients who request screening should be given objective information about the potential benefits and harms of early detection and treatment.

The American Cancer Society (ACS) recommends PSA screening for all men over age 50 and at age 45 for men at higher risk (e.g., men with a family history of prostate cancer and African-American men). Similar recommendations have been issued by the American Urological Association (AUA) and the American College of Radiology. The ACS, however, acknowledges that currently there is no clinical trial evidence that screening for prostate cancer is associated with a reduction in mortality.

The updated ACS guideline for the early detection of prostate cancer (Wolf et al, 2010) recommends both the PSA blood test and DRE should be offered annually, beginning at age 50, to men who have at least a 10-year life expectancy. Men at high-risk (African-American men and men with a strong family of 1 or more first-degree relatives (father, brothers) diagnosed at an early age) should begin testing at age 45. Men at even higher risk, due to multiple first-degree relatives affected at an early age, could begin testing at age 40. Depending on the results of this initial test, no further testing might be needed until age 45. The ACS states that information should be provided to all men about what is known and what is uncertain about the benefits and limitations of early detection and treatment of prostate cancer so that they can make an informed decision about testing. Men who ask their doctor to make the decision on their behalf should be tested. The ACS states that discouraging testing is inappropriate. Furthermore, not offering testing is also inappropriate.

In a review on prostate cancer screening, Ilic and colleagues (2011) concluded that prostate cancer screening did not significantly decrease all-cause or prostate cancer-specific mortality in a combined meta-analysis of 5 randomized controlled trials. Any benefits from prostate cancer screening may take greater than 10 years to accrue; therefore, men who have a life expectancy of less than 10 to 15 years should be informed that screening for prostate cancer is not beneficial and has harms.

The AUA recommends that prostate cancer screening be offered to men over age 50, and at age 40 for men at high-risk, with the physician explaining the uncertain benefits and risks of such screening.

The National Comprehensive Cancer Network (2005) recommends baseline screening beginning at age 40, especially for men in high-risk groups. Risk groups include African-American men and men with a family history of prostate cancer.

Most professional societies do not recommend routine screening for prostate cancer with DRE or serum tumor markers (e.g., PSA). These include the American Academy of Family Physicians, the U.S. Preventive Services Task Force (USPSTF), the Institute for Clinical Systems Improvement, the Canadian Task Force on the Periodic Health Examination, the American College of Preventive Medicine, the U.S. Office of Technology Assessment, the American Society for Internal Medicine and American College of Physicians, the National Cancer Institute, the Centers for Disease Control and Prevention, and the technology assessment agencies of Canada, England, Sweden, and Australia.

The USPSTF evaluated randomized, controlled trials of the benefits of prostate cancer screening, cohort and cross-sectional studies of the psychological harms of false-positive PSA test results, and evidence on the natural history of PSA-detected prostate cancer and concluded that in men younger than age 75 years, the current evidence is insufficient to determine whether treatment for prostate cancer detected by screening improves health outcomes compared with treatment after clinical detection. In men aged 75 years or older, the USPSTF found no direct evidence of benefits of prostate cancer screening and recommends against screening for prostate cancer in men aged 75 years or older.

If screening is to be performed, the generally accepted approach is to screen with DRE and PSA and to limit screening to men with a life expectancy of greater than 10 years. There is currently insufficient evidence to determine the need and optimal interval for repeat screening or whether PSA thresholds must be adjusted for density, velocity, or age.

Schenk-Braat and Bangma (2006) noted that PSA is currently the most important biochemical marker for the diagnosis of prostate cancer. Because of the limited specificity of PSA, clinically irrelevant tumors and benign abnormalities are also detected that can potentially lead to over-treatment and the associated physical as well as emotional burden for the patient. Furthermore, PSA is used as an indicator of progression or clinical response following prostate cancer therapy, but the prognostic value of this marker is limited. Ongoing research is examining several alternative markers (e.g., osteoprotegerin, human kallikrein 2, and the gene DD3(PCA3)) that may improve the specificity of current PSA-based diagnostics and the prognostic value of PSA.

Prostate-specific antigen velocity, the yearly rate of increase of PSA, has not been proven to improve the test characteristics of PSA, Schroder and colleagues (2006) stated that PSA-driven screening has been applied to a large part of the male population in many countries. An elevated PSA in secondary screens may indicate benign enlargement of the prostate rather than prostate cancer. In such cases the yearly rate of increase of PSA (PSA velocity [PSAV]) may improve the test characteristics of PSA. These investigators examined if PSAV predict prostate cancer in pre-screened populations. Data from the European Randomized Study of Screening for Prostate Cancer Rotterdam were used to study the issue. Relative sensitivity, relative specificity, and positive predictive value (PPV) were calculated. Logistic regression analysis was used to compare odds ratios for positive biopsies. The relationship between PSAV and parameters of tumor aggressiveness was investigated. A total of 588 consecutive participants were identified who presented at their first screening with PSA values less than 4.0 and who progressed to PSA values greater than 4.0 ng/ml 4 years later were included in this study. None was biopsied in round-1, all were biopsied in round-2. Relative sensitivity and specificity depend strongly on PSAV cut-offs of 0.25 to 1.0 ng/ml/year. The use of PSAV cut-offs did not improve the PPV of the PSA cut-off of 4.0 ng/ml, nor did any of the PSAV cut-offs improve the odds ratio (OR) for identifying prostate cancer with respect to the cut-off value of 4.0 ng/ml. The rate of aggressive cancers seems to increase with increasing PSAV. The authors concluded that PSAV did not improve the detection characteristics of a PSA cut-off of 4.0 ng/ml in secondary screening after 4 years.

Wolters et al (2009) evaluated the value of PSAV in screening for prostate cancer. Specifically, the role of PSAV in lowering the number of unnecessary biopsies and reducing the detection rate of indolent prostate cancer was evaluated. All men included in the study cohort were subjects in the European Randomized Study of Screening for Prostate Cancer (ERSPC), Rotterdam section. During the first and second screening round, a PSA test was performed on 2,217 men, and all underwent a biopsy during the second screening round 4 years later. Prostate specific antigen velocity was calculated and biopsy outcome was classified as benign, possibly indolent prostate cancer, or clinically significant prostate cancer. A total of 441 cases of prostate cancer were detected, 333 were classified as clinically significant and 108 as possibly indolent. The use of PSAV cut-offs reduced the number of biopsies but led to important numbers of missed (indolent and significant) prostate cancer; PSAV was predictive for prostate ancer (OR: 1.28, $p < 0.001$) and specifically for significant prostate cancer (OR: 1.46, $p < 0.001$) in uni-variate analyses. However, multi-variate analyses using age, PSA, prostate volume, DRE and transrectal ultrasonography outcome, and previous biopsy (yes/no) showed that PSAV was not an independent predictor of prostate cancer (OR: 1.01, $p = 0.91$) or significant prostate cancer (OR: 0.87, $p = 0.30$). The authors concluded that the use of PSAV as a biopsy indicator would miss a large number of clinically significant cases of prostate cancer with increasing PSAV cut-offs. In this study, PSAV was not an independent predictor of a positive biopsy in general or significant prostate cancer on biopsy. Thus, PSAV does not improve the ERSPC screening algorithm.

The role of selenium in cancer prevention has been the subject of recent study and debate.

Population studies suggest that people with cancer are more likely to have low selenium levels (measured in the blood or in tissues such as toenail clippings) than healthy matched individuals. However, in most cases it is not clear if low selenium levels are a cause or merely a consequence of disease. Initial evidence from the Nutritional Prevention of Cancer (NPC) trial suggests that selenium supplementation reduces the risk of prostate cancer among men with normal baseline PSA levels and low selenium blood levels. The ongoing Selenium and Vitamin E Cancer Prevention Trial (SELECT) aims to definitively address the role of selenium in prostate cancer prevention. The study, which spans from 2001 to 2013, will include 32,400 men. Currently, it is unclear if selenium is beneficial in the treatment of prostate cancer or any type of cancer. Measurement of body selenium (e.g., in serum, toenail clippings) has no proven value in the prevention of prostate cancer.

Costello and Franklin (2009) proposed that changes in prostatic fluid composition could provide accurate and reliable biomarkers for the screening of prostate cancer. Most notable is the consistent and significant decrease in citrate and zinc that is associated with the development and progression of prostate cancer. These researchers provided the clinical and physiological basis and the evidence in support of the utility of prostatic fluid analysis as an effective approach for screening/detection of prostate cancer, especially early stage and "at-risk" subjects. The problem of interference from benign prostatic hypertrophy that hampers PSA testing is eliminated in the potential prostatic fluid biomarkers. The potential development of rapid, simple, direct, accurate clinical tests would provide additional advantageous conditions. The authors stated that further exploration and development of citrate, zinc and other electrolytes as prostatic fluid biomarkers are needed to address this critical prostate cancer issue.

A long-term randomized controlled clinical trial found prostate cancer screening had no effect on mortality (Andriole et al, 2009). From 1993 through 2001, investigators randomly assigned 76,693 men at 10 U.S. study centers to receive either annual screening (38,343 subjects) or usual care as the control (38,350 subjects). Men in the screening group were offered annual PSA testing for 6 years and DRE for 4 years. The subjects and health care providers received the results and decided on the type of follow-up evaluation. Usual care sometimes included screening, as some organizations have recommended. The numbers of all cancers and deaths and causes of death were ascertained. In the screening group, rates of compliance were 85 % for PSA testing and 86 % for DRE. Rates of screening in the control group increased from 40 % in the first year to 52 % in the sixth year for PSA testing and ranged from 41 to 46 % for DRE. After 7 years of follow-up, the incidence of prostate cancer per 10,000 person-years was 116 (2,820 cancers) in the screening group and 95 (2,322 cancers) in the control group (rate ratio, 1.22; 95 % confidence interval [CI]: 1.16 to 1.29). The incidence of death per 10,000 person-years was 2.0 (50 deaths) in the screening group and 1.7 (44 deaths) in the control group (rate ratio, 1.13; 95 % CI: 0.75 to 1.70). The data at 10 years were 67 % complete and consistent with these overall findings. An important limitation of this study is that subjects in the control group underwent considerable screening outside of the clinical trial. An accompanying editorial (Barry, 2009) commented that serial PSA screening has at best a modest effect on prostate cancer mortality during the first decade of follow-up, and that this benefit comes at the cost of substantial over-diagnosis and over-treatment.

Available evidence shows that the majority of men with low-risk prostate tumors receive aggressive treatment, despite the risk of complications. Shao and colleagues (2010) used the Surveillance, Epidemiology and End Results (SEER) database to study the records of 123,934 men over the age of 25 who had newly diagnosed prostate cancer from 2004 to 2006. About 14 % of the men had PSA values lower than 4, generally younger men. In that group, 54 % had low-risk disease that could be safely monitored for progression with little risk. Nonetheless, 75 % of them received aggressive treatment, including a radical prostatectomy and radiation therapy. Among men in that group over the age of 65, in which "watchful waiting" is generally advised for low-risk disease, 66 % had aggressive therapy. In both cases, the percentages were similar to those in the group with PSA levels between 4 and 20.

Mazzola et al (2011) stated that the introduction and widespread adoption of PSA has revolutionized the way prostate cancer is diagnosed and treated. However, the use of PSA has also

led to over-diagnosis and over-treatment of prostate cancer resulting in controversy about its use for screening. Prostate specific antigen also has limited predictive accuracy for predicting outcomes after treatment and for making clinical decisions about adjuvant and salvage therapies. Thus, there is an urgent need for novel biomarkers to supplement PSA for detection and management of prostate cancer. A plethora of promising blood- and urine-based biomarkers have shown promise in early studies and are at various stages of development (human kallikrein 2, early prostate cancer antigen, transforming growth factor-beta 1, interleukin-6, endoglin, prostate cancer gene 3 (PCA3), alpha-methylacyl coenzyme A racemase (AMACR) and E twenty-six (ETS) gene fusions).

Pettersson et al (2012) stated that whether the genomic re-arrangement trans-membrane protease, serine 2 (TMPRSS2):v-ets erythroblastosis virus E26 oncogene homolog (ERG) has prognostic value in prostate cancer is unclear. Among men with prostate cancer in the prospective Physicians' Health and Health Professionals Follow-Up Studies, these researchers identified re-arrangement status by immunohistochemical assessment of ERG protein expression. They used Cox models to examine associations of ERG over-expression with biochemical recurrence and lethal disease (distant metastases or cancer-specific mortality). In a meta-analysis including 47 additional studies, these investigators used random-effects models to estimate associations between re-arrangement status and outcomes. The cohort consisted of 1,180 men treated with radical prostatectomy between 1983 and 2005. During a median follow-up of 12.6 years, 266 men experienced recurrence and 85 men developed lethal disease. These researchers found no significant association between ERG over-expression and biochemical recurrence [hazard ratio (HR), 0.99; 95 % CI: 0.78 to 1.26] or lethal disease (HR, 0.93; 95 % CI: 0.61 to 1.43). The meta-analysis of prostatectomy series included 5,074 men followed for biochemical recurrence (1,623 events), and 2,049 men followed for lethal disease (131 events). TMPRSS2:ERG was associated with stage at diagnosis [risk ratio (RR)(≥T3 vs. T2), 1.23; 95% CI, 1.16-1.30) but not with biochemical recurrence (RR, 1.00; 95 % CI: 0.86 to 1.17) or lethal disease (RR, 0.99; 95 % CI: 0.47 to 2.09). The authors concluded that the findings of this meta-analysis suggested that TMPRSS2:ERG, or ERG over-expression, is associated with tumor stage but does not strongly predict recurrence or mortality among men treated with radical prostatectomy.

Salagierski et al (2012) stated that widespread PSA screening together with the increase in the number of biopsy cores has led to increased prostate cancer incidence. Standard diagnostic tools still cannot unequivocally predict prostate cancer progression, which often results in a significant over-treatment rate. These investigators presented recent findings on PCA3 and TMPRSS:ERG fusion, and described their clinical implications and performance. The PubMed® database was searched for reports on PCA3 (130 articles), TMPRSS:ERG and ETS fusion (180 publications) since 1999. In recent years advances in genetics and biotechnology have stimulated the development of non-invasive tests to detect prostate cancer. Serum and urine molecular biomarkers have been identified, of which PCA3 has already been introduced clinically. The identification of prostate cancer specific genomic aberrations, i.e., TMPRSS2:ERG gene fusion, might improve diagnosis and affect prostate cancer treatment. The authors concluded that although several recently developed markers are promising, often showing increased specificity for prostate cancer detection compared to that of PSA, their clinical application is limited.

Choudhury et al (2012) noted that despite widespread screening for prostate cancer and major advances in the treatment of metastatic disease, prostate cancer remains the second most common cause of cancer death for men in the Western world. In addition, the use of PSA testing has led to the diagnosis of many potentially indolent cancers, and aggressive treatment of these cancers has caused significant morbidity without clinical benefit in many cases. The recent discoveries of inherited and acquired genetic markers associated with prostate cancer initiation and progression provide an opportunity to apply these findings to guide clinical decision-making. In this review, these investigators discussed the potential use of genetic markers to better define groups of men at high risk of developing prostate cancer, to improve screening techniques, to discriminate indolent versus aggressive disease, and to improve therapeutic strategies in patients with advanced disease. PubMed-based literature searches and abstracts through January 2012 provided the basis for this literature review. These researchers also examined secondary sources from reference lists of

retrieved articles and data presented at recent congresses. Cited review articles were only from the years 2007 to 2012, favoring more recent discussions because of the rapidly changing field. Original research articles were curated based on favoring large sample sizes, independent validation, frequent citations, and basic science directly related to potentially clinically relevant prognostic or predictive markers. In addition, all authors on the manuscript evaluated and interpreted the data acquired. These investigators addressed the use of inherited genetic variants to assess risk of prostate cancer development, risk of advanced disease, and duration of response to hormonal therapies. The potential for using urine measurements such as PCA3 RNA and TMPRSS2-ERG gene fusion to aid screening was discussed. Multiple groups have developed gene expression signatures from primary prostate tumors correlating with poor prognosis, and attempts to improve and standardize these signatures as diagnostic tests were presented. Massive sequencing efforts are underway to define important somatic genetic alterations (amplifications, deletions, point mutations, translocations) in prostate cancer, and these alterations hold great promise as prognostic markers and for predicting response to therapy. These researchers provided a rationale for assessing genetic markers in metastatic disease for guiding choice of therapy and for stratifying patients in clinical trials, and discussed challenges in clinical trial design incorporating the use of these markers. The authors concluded that the use of genetic markers has the potential to aid disease screening, improve prognostic discrimination, and prediction of response to treatment. However, most markers have not been prospectively validated for providing useful prognostic or predictive information or improvement upon clinicopathologic parameters already in use. They stated that significant efforts are underway to develop these research findings into clinically useful diagnostic tests in order to improve clinical decision making.

Furthermore, an UpToDate review on "Screening for prostate cancer" (Hoffman, 2013) does not mention the use of human kallikrein 2 and TMPRSS2:ERG gene fusion as screening tools for prostate cancer.

CPT Codes / HCPCS Codes / ICD-9 Codes

CPT codes covered if selection criteria are met:

84152

84153

84154

CPT codes not covered for indications listed in the CPB:

PCA3:

84255 Chemistry, Selenium

TMPRSS2:ERG gene fusion:

No specific code

Other CPT codes related to the CPB:

88271

88272

88273

88274

88275

88291

Modifier 0Z

HCPCS codes covered if selection criteria are met:

G0102	Prostate cancer screening; digital rectal examination
G0103	Prostate cancer screening; prostate specific antigen test (PSA)

HCPCS codes not covered for indications listed in the CPB:

S3721	Prostate cancer antigen 3 (PCA3) testing

ICD-9 codes covered if selection criteria are met:

185	Malignant neoplasm of prostate
222.2	Benign neoplasm of prostate
233.4	Carcinoma in situ of prostate
236.5	Neoplasm of uncertain behavior of prostate
600.00 - 600.91	Hypertrophy of prostate
602.3	Dysplasia of prostate
790.93	Elevated prostate specific antigen (PSA)
V10.46	Personal history of malignant neoplasm of prostate
V16.42	Family history of malignant neoplasm of prostate
V76.44	Special screening for malignant neoplasm of prostate
V84.03	Genetic susceptibility to malignant neoplasm of prostate

Other ICD-9 codes related to the CPB:

788.20 - 788.29	Retention of urine
788.41 - 788.43	Frequency of urination and polyuria
788.61 - 788.65	Other abnormality of urination

Jonas, M.D., M.P.H.

This report is based on research conducted by RTI-UNC EPC under contract to the Agency for Healthcare Research and Quality (AHRQ), Rockville, MD (Contract No. HHSA2902007100561). The findings and conclusions in this document are those of the author(s) who are responsible for its contents; the findings and conclusions do not necessarily represent the views of AHRQ. No statement in this article should be construed as an official position of the Agency for Healthcare Research and Quality or of the U.S. Department of Health and Human Services.

The information in this report is intended to help health care decision-makers; patients and clinicians, health system leaders, and policymakers, make well-informed decisions and thereby improve the quality of health care services. This report is not intended to be a substitute for the application of clinical judgment. Decisions concerning the provision of clinical care should consider this report in the same way as any medical reference and in conjunction with all other pertinent information, i.e., in

the context of available resources and circumstances presented by individual patients.

This report may be used, in whole or in part, as the basis for development of clinical practice guidelines and other quality enhancement tools, or as a basis for reimbursement and coverage policies. AHRQ or U.S. Department of Health and Human Services endorsement of such derivative products may not be stated or implied.

None of the investigators has any affiliations or financial involvement related to the material presented in this report.

Peer Reviewers

We wish to acknowledge individuals listed below for their review of this report. This report has been reviewed in draft form by individuals chosen for their expertise and diverse perspectives. The purpose of the review was to provide candid, objective, and critical comments for consideration by the EPC in preparation of the final report. Synthesis of the scientific literature presented here does not necessarily represent the views of individual reviewers.

Structured Abstract

Structured Abstract

Objectives: To conduct a systematic review and meta-analysis assessing the prognostic value and test performance (analytic validity, clinical validity, clinical utility, and harms) associated with 11 prognostic molecular pathology tests. Many of these tests are indicated for prediction of therapeutic responses, but this review focuses on their potential use as prognostic factors. Our overarching question was whether there is direct evidence that the addition of these molecular pathology tests changed physician decisionmaking and improved outcomes for adult patients.

We evaluated the following tests: microsatellite instability assessment by polymerase chain reaction (PCR) for colorectal cancer (CRC), MLH1 promoter methylation for CRC, *KRAS* mutation testing for CRC, *BRAF* mutation testing for CRC, Oncotype DX Colon mRNA expression for CRC, Oncotype DX Breast mRNA expression for breast cancer, MammaPrint mRNA expression for breast cancer, *ALK* cytogenetics for lung cancer, *EGFR* mutation testing for lung cancer, *KRAS* mutation testing for lung cancer, and UroVysion cytogenetics for urinary bladder cancer.

Data Sources: PubMed®, the Cochrane Library, and EMBASE® (through November 2013); reference lists of pertinent review articles and included studies, test developers' Web sites, ClinicalTrials.gov, the Food and Drug Administration (FDA) Web site, Health Services Research Projects in Progress, the European Union Clinical Trials Register, the College of American Pathologists (CAP), and data submitted by companies that developed the tests.

Review Methods: Two investigators independently selected, extracted data from, and rated risk of bias of each study. For clinical validity, we conducted meta-analyses to estimate weighted summary hazard ratios when three or more studies reported an eligible outcome. For the other review questions, we did not find sufficient data to conduct meta-analyses. Therefore, we synthesized the information qualitatively. We graded strength of evidence based on established guidance.

Results: Evidence from multiple studies supports associations between test results and prognosis, with added value beyond known independent prognostic factors, for MammaPrint, Oncotype DX Breast, *KRAS* mutation testing for lung cancer, *BRAF* and *KRAS* mutation testing for CRC, and microsatellite instability for CRC for at least one of our included outcomes (i.e., risk of recurrence, cancer-specific survival, or overall survival). Although UroVysion is marketed as a diagnostic rather than a prognostic test, limited evidence from two small studies (total N=168) rated as low or medium risk of bias supported associations between test result and prognosis for risk of recurrence. We found no studies that directly assessed the impact of a test of interest on both physician decision-making and downstream health outcomes to establish clinical utility. We attempted to construct an indirect chain of evidence to answer the overarching question, but we were unable to do so. Even in the cases where the tests seemed to add value in determining prognosis (i.e., evidence of clinical validity), we found no evidence that using the test was related to improved outcomes for patients. However, for impact of test use on treatment decisions, we found moderate strength of evidence that Oncotype DX Breast leads to changes in treatment decisions. Although the decision changes were observed in both directions for

individual patients, studies consistently showed an overall shift to less-intensive treatment recommendations as a result of using Oncotype DX Breast, with fewer recommendations for chemotherapy (and less exposure to potential harms of chemotherapy).

Limitations: We were not able to directly address the prognostic value of these tests for the Medicare population. There were several studies that included patients from the Medicare age group and although the impact of these tests were not analyzed with specific reference to this population, we did not come across any evidence that suggested that the prognostic value of these tests would be different for the Medicare population.

Conclusions: Modest evidence supports added prognostic value (i.e., clinical validity) for over half of the tests evaluated, and that Oncotype DX Breast leads to changes in treatment decisions, but we found no evidence to determine whether using the tests to estimate prognosis leads to improved outcomes for patients.

Executive Summary

Background

Molecular pathology tests that identify pathogenic mutations and cytogenetic translocations help us define the molecular subtypes of common cancers. Because several of these acquired mutations/translocations may predict response to specific therapies, screening tests for "targetable" mutations are now commonly available in clinical laboratory improvement amendments (CLIA)-approved clinical labs. It is unclear whether these test results can also serve as independent prognostic factors. This review aims to clarify the value of certain molecular pathology tests for improving our estimates of prognosis for common cancers (breast, lung, colon, urinary bladder) affecting Medicare beneficiaries. The main purpose of this review is to determine whether these tests improve estimation of prognosis (for recurrence), affect physician decision making, and/or improve clinical outcomes when compared with traditional assessment of prognosis of recurrence. These genetic tests are used in two different contexts. In one, the tests are used in a specific context of a diagnostic/therapy combination, where the diagnostic test is being used to predict response to a very specific treatment. In the second context, the genetic tests are used to estimate the patient's prognosis, and physicians use this prognostic information to choose from a variety of different treatment options. CMS requested this report to evaluate the second context. Therefore, studies that evaluate specific diagnostic/therapy combinations are excluded from this report

The following tests are under consideration for this assessment and apply to all Key Questions (KQs): microsatellite instability (MSI) for colorectal cancer (CRC), MLH1 promoter methylation for CRC, *KRAS* mutations for CRC, *BRAF* mutations for CRC, Oncotype DX Colon mRNA expression for CRC, Oncotype DX Breast mRNA expression for breast cancer, MammaPrint mRNA expression for breast cancer, *ALK* cytogenetics for lung cancer, *EGFR* mutations for lung cancer, *KRAS* mutations for lung cancer, and UroVysion cytogenetics for urinary bladder cancer.

Our overarching question was whether there is direct evidence that the addition of the results of these molecular pathology tests to traditional prognostic factors changed physician decisionmaking and improved clinical outcomes for adult patients. We also examined analytic validity, clinical validity and utility, and any harms to patients associated with these tests. In this review, we address the following KQs:

KQ 1. Overarching Question: Is there direct evidence that the addition of the specified molecular pathology tests used alone or in combination with traditional prognostic factors changes physician decisionmaking and improves outcomes for adult patients with CRC, breast, lung, or bladder cancer compared with the use of traditional factors to predict risk of recurrence (RR) for adults with these cancers?

KQ 2. Analytic Validity: Does existing evidence establish the technical accuracy and reliability of these tests for detecting the relevant molecular analytes?

KQ 3. Clinical Validity: Does existing evidence establish the prognostic accuracy of the tests for predicting recurrence?

KQ 4. Clinical Utility: Does existing evidence support clinical utility of the molecular pathology tests?

KQ 4a. What is the evidence that the prognostic information provided by the molecular pathology tests modifies physician decisions regarding use of adjuvant antineoplastic chemo- and/or radiotherapy, enhanced diagnostic testing for recurrence, and/or surgery among adult patients with malignant tumors?

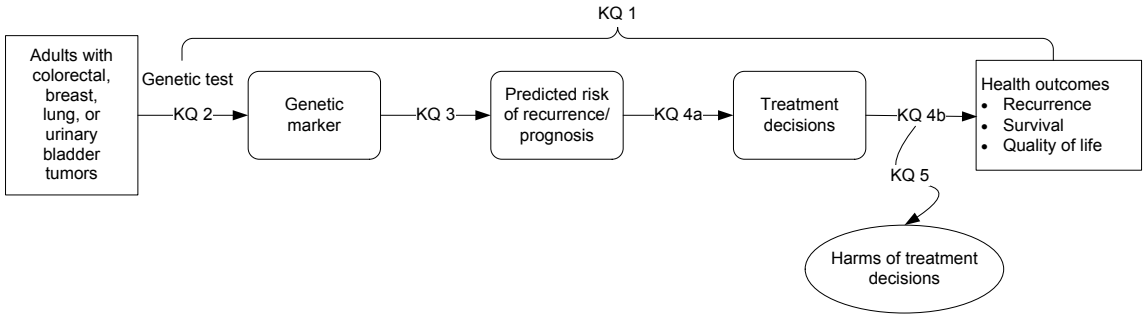
KQ 4b. What is the evidence that modified decisions lead to improved outcomes, including patient-centered outcomes such as improved quality of life, reduced disease recurrence, increased overall survival (OS) or disease-free survival (DFS), or reduced therapeutic side effects?

KQ 5. What are the harms associated with treatment decisions that are informed by the molecular pathology tests?

Analytic Framework

We developed an analytic framework to guide the systematic review process (Figure A).

Figure A. Analytic framework



Abbreviation: KQ = Key Question.

Methods

Literature Search Strategy

We searched PubMed®, the Cochrane Library, and EMBASE® for English-language, adult, and human-only studies published from inception through November 2013. Searches were run by an experienced Evidence-based Practice Center (EPC) librarian and were peer reviewed by another EPC librarian. We manually searched reference lists of pertinent review articles and studies meeting our inclusion criteria to look for any relevant citations that our searches might have missed. We searched for unpublished studies relevant to this review using test developers' Web sites, ClinicalTrials.gov, the Food and Drug Administration Web site, Health Services Research Projects in Progress, and the European Union Clinical Trials Register. In addition, we requested information from the College of American Pathologists (CAP) and from relevant companies, asking for data that they believe should be considered for the review.

Eligibility Criteria

We developed eligibility criteria for Populations, Interventions (i.e., tests for this report), Comparators, Outcomes, Timing, Settings (PICOTS), and study designs. Briefly, we included studies of adult patients with one of the cancer types of interest that evaluated an eligible molecular pathology test (listed in the Background). For KQs 1, 4, and 5, we included studies that compare at least 1 of the 11 molecular pathology tests plus standard prognostic factors with the standard prognostic factors alone to determine whether the molecular pathology test adds independent prognostic value (benefit) or introduces additional harms (KQ 5). Studies that compare an eligible molecular pathology test alone with standard prognostic factors were also eligible for inclusion. For KQ 2 (analytic validity), we included studies of test performance, including intra/interlab reproducibility. For KQ 3 (clinical validity), we included studies comparing patients with different test results (e.g., those with a mutation versus those who are wild-type) to establish prognostic value, with a multivariate analysis to adjust for known factors. To inform whether these molecular pathology tests *add value* above standard prognostic factors, we required that results were either adjusted for known prognostic factors or were specifically addressed in other ways, such as through inclusion/exclusion criteria of the study or stratification.

We required studies to report one of the following outcomes: for KQ 1, direct evidence of the impact of the test on physician decisionmaking and also on health outcomes (OS, DFS, time to recurrence, or quality of life); for KQ 2, tissue sample acceptance/rejection criteria, test performance, intra- and interlab reproducibility for the same specimen, lower limit of detection in admixtures of carcinoma and normal cells, and quality controls; for KQ 3, assessment of added prognostic value (i.e., by assessing discrimination, calibration, or association of test results with recurrence) beyond known independent prognostic factors for recurrence, cancer-specific survival (CSS), and overall survival (OS); for KQ 4a, modification of physician decisions about treatment; for KQ 4b, health outcomes (OS, DFS, time to recurrence, quality of life); and for KQ 5, adverse effects of tests, adverse effects of adjuvant therapy, and decreased quality of life.

We did not include studies focused on patients with advanced/metastatic cancer or studies focused on predicting response to treatments (e.g., studies focused on response to gefitinib for people with *EGFR*-mutant advanced lung adenocarcinomas). Progression-free survival was not an eligible outcome. Additional details of the eligibility criteria, including eligible study designs, are provided in the full technical report.

Study Selection

Two members of the research team independently reviewed each title and abstract identified through searches for eligibility. Studies marked for possible inclusion by either reviewer and those that lacked adequate information to determine eligibility underwent a full-text review. Two members of the research team independently reviewed each full-text article to determine eligibility. If the reviewers disagreed, they resolved conflicts by discussion and consensus or by consulting a third member of the review team.

Data Extraction

We designed and used structured data extraction forms to gather pertinent information from each article; this included characteristics of study populations, settings, interventions, comparators, study designs, methods, and results. Trained reviewers extracted the relevant data

from each included article. All data extractions were reviewed for completeness and accuracy by a second member of the team.

Risk-of-Bias Assessment of Individual Studies

We assessed the risk of bias (RoB) (internal validity) using an approach supported by the *Methods Guide for Medical Test Reviews*.[1] For studies of analytic validity, we considered the potential for bias due to flaws in the sample selection, testing protocol, reference standards, verification procedures, interpretation, and analysis. We used the questions relevant for prognostic tests from the QUADAS-2[2,3] (which was developed for diagnostic tests) for assessing risk of relevant biases. For studies of clinical validity and clinical utility, we assessed the potential for selection bias, confounding, performance bias, attrition bias, and detection bias. We assessed these biases using relevant questions and predefined criteria based on guidance from the AHRQ *Methods Guide for Effectiveness and Comparative Effectiveness Reviews* and the RTI Question Bank.[4] We rated RoB for each study as low, medium, high, or unclear. Two independent reviewers assessed the RoB for each study. Disagreements between the two reviewers were resolved by discussion and consensus or by a third member of the team.

Data Synthesis

For clinical validity (KQ 3), we conducted meta-analyses using techniques described in Hedges and Vevea.[4] We estimated summary hazard ratios (HRs) for outcomes (for any given test-cancer pair) with three or more independent adjusted HR estimates. We tested the null hypothesis of homogeneity of effect sizes across the studies[4,5] for each of the outcomes. If the null hypothesis was rejected at a significance level of 0.05, the summary HR was estimated using a random effects model; if not, it was estimated using a fixed effects model. In both cases, the inverse of the variance was used to estimate a weighted summary HR.

For the other KQs, we did not find sufficient data to conduct meta-analyses. Therefore, we synthesized the information qualitatively, in tabular and narrative format.

We did not include studies with a high or unclear RoB in our main analyses/main data syntheses.

Strength of the Body of Evidence

We graded the strength of evidence (SOE) as high, moderate, low, or insufficient based on the guidance established for the EPC Program.[6,7] Developed to grade the overall strength of a body of evidence, this approach incorporates four key domains: RoB (includes study design and aggregate quality), consistency, directness, and precision of the evidence. It also considers other optional domains. For each test being evaluated in this review, two reviewers assessed each domain for each key outcome and determined an overall SOE grade based on domain ratings. In the event of disagreements on the domain or overall grade, they resolved differences by consensus discussion or by consulting with a third investigator.

We attempted to find studies that directly address the overarching question (KQ 1). If we did not find adequate direct evidence addressing the overarching question, we attempted to construct an indirect chain of evidence (using studies identified for the other KQs). We graded the SOE separately for analytic validity and for evidence on our overarching KQ. For analytic validity, we graded the SOE for the following: sensitivity and specificity, positive and negative predictive

value, and intra/interlab reproducibility. For evidence on the overarching KQ, we graded the SOE for the following outcomes: RR, CSS, OS, and decisions about treatment.

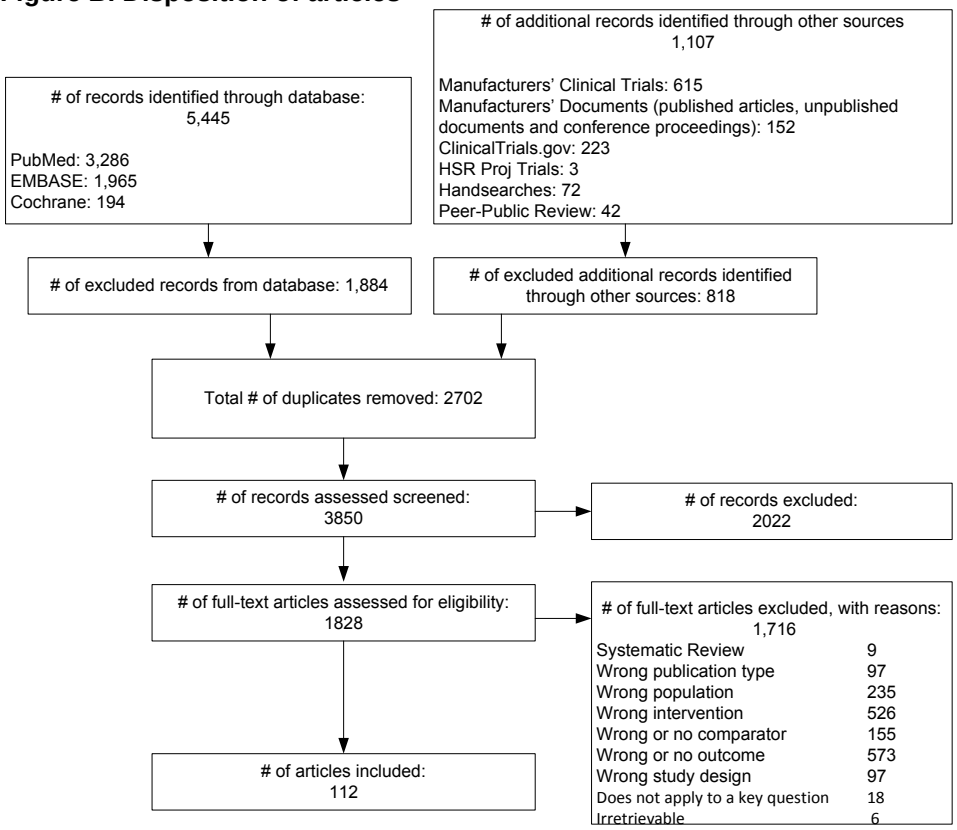
Applicability

We assessed applicability of the evidence following guidance from the *Methods Guide for Comparative Effectiveness Reviews*.[5,8] We used the PICOTS framework to explore factors that affect applicability.

Results

We included 112 publications reporting on tests of interest for the 4 cancers (Figure B).

Figure B. Disposition of articles



We found no studies that directly addressed our overarching questions (KQ 1) (i.e., no study directly assessed the impact of a molecular pathology test result of interest on both physician decisionmaking and downstream health outcomes). We attempted to construct an indirect chain of evidence to answer the overarching question, but no studies addressed whether modified decisions lead to improved health outcomes (KQ 4b, clinical utility), so we were unable to do so. The furthest downstream evidence that we found addressed whether prognostic information provided by the molecular pathology tests modifies treatment decisions (KQ 4a).

The majority of studies meeting inclusion criteria for our review focused on clinical validity (KQ 3), and they evaluated associations between prognostic tests and outcomes. For two tests, MammaPrint and Oncotype DX Breast, we found studies rated as low or medium RoB

addressing whether prognostic information provided by their mRNA abundance risk stratification tests modified treatment decisions (KQ 4a).

Analytic Validity

Included studies provide some evidence regarding analytic validity (KQ 2) for all of the included tests. Data from included studies was supplemented with proficiency tests results provided by the College of American Pathologists (CAP) for five tests for which this data was available.

Data on intra- and interlab reproducibility is available in the primary literature and through national organization proficiency testing programs. Beau-Faller[9] found high interlab reproducibility for EGFR and KRAS mutation testing. Cronin's[10] group at Genomic Health (Clin Chem 2007) found high intralab reproducibility for Oncotype quantitative RT-PCR mRNA abundance measurements relevant to the Oncotype DX tests for breast and colon carcinoma. The College of American Pathologists sends proficiency test unknowns to CLIA-approved US clinical laboratories or International clinical laboratories, an excellent mechanism for assessing nationwide interlab reproducibility. The three most recent surveys for each of these analytes showed average accuracy rates of 95 percent for EGFR (413/438), 98 percent for *KRAS* (602/612), 99 percent for *BRAF* (528/533), 99 percent for MSI (288/291), and 99 percent for UroVysion (552/555) (data presented are percentage of labs with correct results; and number with correct results/total number of labs that tested in parentheses).[11-15]

Clinical Validity

Included studies provided some evidence on clinical validity for 9 of the included tests, adjusted for known prognostic factors (Table A). Evidence from multiple studies supports clinical validity, with added value beyond traditional prognostic factors, for MammaPrint, Oncotype DX Breast, *KRAS* mutation testing for lung cancer, *BRAF* mutation testing for CRC, *KRAS* mutation testing for CRC, and MSI for CRC for at least one of our included outcomes (i.e., RR, CSS, or OS). For UroVysion, limited evidence from 2 small studies (total N=168) rated as low or medium RoB supported prognostic value for RR. *EGFR* lung cancer did not add prognostic value to the traditional factors used to determine prognosis. For CRC, evidence did not adequately support added prognostic value for Oncotype DX Colon. The metric used to assess the clinical validity of the test for recurrence, CSS, or OS in all of these studies was the HR. HRs in this report range from 0.57 to 3.93. If the test is noninformative, we expect that the probability of experiencing the end point would be the same for either group, with an HR of 1. If the HR is greater than 1, the probability of the endpoint is higher in the group with the higher hazard. If the HR is lower than 1, the probability of experiencing the endpoint is lower in the group with the lower hazard. For example, an HR of 2 for CSS indicates that one group (e.g., those with high risk results for Oncotype DX Breast) has twice the rate per unit of time as the comparison group (e.g., those with low-risk test results).

Table A. Summary of findings on clinical validity

Test: Cancer	Outcome	N studies; N subjects	Results Effect Size (95% CI)	Evidence from Multiple Studies Supports Association between Test Result and Prognosis?
MammaPrint: Breast	RR	6; 1,913	HR: 2.84 (2.11 to 3.89) for poor prognosis vs. good prognosis	Yes
	CSS	5; 1,615	HR: 3.3 (2.22 to 4.9) for poor prognosis vs. good prognosis	Yes
	OS	1; 144	HR: 1.67 (0.73 to 3.82) for poor prognosis vs. good prognosis	No
Oncotype DX Breast	RR	6; 3,222	HR: 2.97 (2.19 to 4.02) for high risk vs. low risk	Yes
	CSS	2; 1,234	HR: 2.02 (1.35 to 3.00) for high risk vs. low risk	Yes
	OS	1; 668	HR: 1.65 (1.24 to 2.19) for high risk vs. low risk	No, single study
EGFR: Lung	RR	6; 1,870	HR: 0.87 (0.65 to 1.15); No association	No
	CSS	0; 0	NA	No
	OS	6; 1,820	HR: 0.76 (0.50 to 1.19); No association	No
KRAS: Lung	RR	4; 611	2.84 (1.14 to 7.1) *KRAS* mutation associated with greater RR	Yes
	CSS	0; 0	NA	No
	OS	2; 253	2.69 (1.91 to 3.8); 3.33 (1.03 to 10.82)	Yes[a]
BRAF: CRC	RR	5; 4,106	HR 1.07 (0.76 to 1.52) for wild-type vs. mutation	No
	CSS	7; 5,409	HR 1.50 (1.26 to 1.77) for wild-type vs. mutation	Yes
	OS	11; 7,610	HR 1.45 (1.29 to 1.62) for wild-type vs. mutation	Yes
KRAS: CRC	RR	5; 4,085	HR 1.02 (0.91 to 1.14) for wild-type vs. mutation	No
	CSS	2; 1,174	HR 1.30 (1.02 to 1.66) for wild-type vs. mutation	Yes
	OS	10; 5,328	HR 1.22 (0.93 to 1.60) for wild-type vs. mutation	No
MSI: CRC	RR	10; 7,130	HR 0.60 (0.50 to 0.72) for MSI-H vs. MSS	Yes
	CSS	6; 3,439	HR 0.65 (0.51 to 0.82) for MSI-H vs. MSS	Yes
	OS	12; 8,839	HR 0.57 (0.43 to 0.77) for MSI-H vs. MSS	Yes
Oncotype DX: CRC	RR	1; 690	HR 1.68 (1.18 to 2.38)	No, single study
	CSS	0; 0	NA	No
	OS	0; 0	NA	No
UroVysion: Bladder	RR	2; 168	Association between mutation and RR in 2 small studies	Yes, but limited to 168 subjects
	CSS	0; 0	NA	No
	OS	0; 0	NA	No

[a] Meta-analyses were conducted only when we had 3 or more HRs to combine

Notes: Table includes results of our main analyses that were based on studies rated as low or medium RoB. HRs reported are results of our meta-analyses of studies rated as low or medium RoB reporting adjusted associations for clinical validity (KQ 3).

Abbreviations: *BRAF* = gene name; CI = confidence interval; CRC = colorectal cancer; CSS = cancer-specific survival; *EGFR* = gene name; HR = hazard ratio; *KRAS* = gene name; MSI = microsatellite instability; MSI-H = microsatellite instability high; MSS = microsatellite stability: N = number; NA = not applicable; OS = overall survival; RR = risk of recurrence; vs. = versus.

Clinical Utility and the Overarching Question

Table B summarizes the evidence on the overarching question, clinical utility, and the impact of test use on treatment decisions. Ultimately, we found insufficient SOE to answer the overarching question for most tests. Even in the cases where the tests seemed to add value in determining prognosis (i.e., evidence of clinical validity), we found no evidence that using the test was related to improved outcomes for patients. For a few tests, we found low SOE, suggesting that using the test would not improve outcomes for patients—for these tests we found

evidence that did not support clinical validity (because with evidence suggesting lack of clinical validity, it is unlikely that the tests will be found to have clinical utility).

For impact on treatment decisions, we found moderate SOE that one test, Oncotype DX Breast, leads to changes in decisions. Although the decision changes were observed in both directions for individual patients, studies consistently showed an overall shift to less-intensive treatment recommendations as a result of using Oncotype DX Breast, with fewer recommendations for chemotherapy (and therefore less exposure to potential harms of chemotherapy; but studies did not follow patients to actually report on harms or to assess the overall balance of clinical benefits and harms). We found just one study of low or medium RoB for the impact of MammaPrint on treatment decisions, and we concluded that evidence was insufficient to determine the impact of MammaPrint on treatment decisions, primarily because of unknown consistency and imprecision.

Table B. Summary of findings and strength of evidence for impact on treatment decisions, clinical utility, and our overarching question

Test: Cancer	Outcome	N studies; N subjects	Conclusions	Strength of Evidence
MammaPrint: Breast	RR	6; 1,913	All studies assessed clinical validity; no evidence that test use leads to improved outcomes	Insufficient
	CSS	5; 1,615	All studies assessed clinical validity; no evidence that test use leads to improved CSS	Insufficient
	OS	1; 144	Study assessed clinical validity; no evidence that test use leads to improved mortality	Insufficient
	Decisions about Rx	1; 427	Adjuvant therapy was used less if the prognosis signature is used	Insufficient
Oncotype DX Breast	RR	6; 3,222	All studies assessed clinical validity; no evidence that test use leads to improved outcomes	Insufficient
	CSS	2; 1,234	All studies assessed clinical validity; no evidence that test use leads to improved CSS	Insufficient
	OS	1; 668	All studies assessed clinical validity; no evidence that test use leads to improved mortality	Insufficient
	Decisions about Rx	16; 2,251	~30% of treatment decisions changed by the test	Moderate
EGFR: Lung	RR	6; 1,870	All studies assessed clinical validity and found no prognostic value; test is unlikely to improve outcomes	Low
	CSS	0; 0	NA	Insufficient
	OS	6;1,820	No prognostic value; none of the reported HRs were statistically significant; test unlikely to improve mortality	Low
	Decisions about Rx	0; 0	NA	Insufficient
KRAS: Lung	RR	4; 611	All studies assessed clinical validity; no evidence that test use leads to improved outcomes	Insufficient
	CSS	0; 0	NA	Insufficient
	OS	2; 253	Studies assessed clinical validity; no prognostic value; no evidence that test use leads to improved mortality	Insufficient
	Decisions about Rx	0; 0	NA	Insufficient

Table B. Summary of findings and strength of evidence for impact on treatment decisions, clinical utility, and our overarching question (continued)

Test: Cancer	Outcome	N studies; N subjects	Conclusions	Strength of Evidence
BRAF: CRC	RR	5; 4,106	All studies assessed clinical validity; no prognostic value; test is unlikely to improve outcomes	Low
	CSS	7; 5,409	All studies assessed clinical validity; no evidence that test use leads to improved CSS	Insufficient
	OS	10; 7,610	All studies assessed clinical validity; no evidence that test use leads to improved mortality	Insufficient
	Decisions about Rx	0; 0	NA	Insufficient
KRAS: CRC	RR	5; 4,085	All studies assessed clinical validity; no prognostic value; test is unlikely to improve outcomes	Low
	CSS	2; 1,174	All studies assessed clinical validity; no evidence that test use leads to improved outcomes	Insufficient
	OS	10; 5,328	All studies assessed clinical validity; no prognostic value; test is unlikely to improve mortality	Low
	Decisions about Rx	0; 0	NA	Insufficient
MSI: CRC	RR	10; 7,130	All studies assessed clinical validity; no evidence that test use leads to improved outcomes	Insufficient
	CSS	6; 3,439	All studies assessed clinical validity; no evidence that test use leads to improved CSS	Insufficient
	OS	12; 8,839	All studies assessed clinical validity; no evidence that test use leads to improved mortality	Insufficient
	Decisions about Rx	0; 0	NA	Insufficient
Oncotype DX: CRC	RR	1; 690	Study assessed clinical validity; no evidence that test use leads to improved outcomes	Insufficient
	CSS	0; 0	NA	Insufficient
	OS	0; 0	NA	Insufficient
	Decisions about Rx	0; 0	NA	Insufficient
UroVysion: Bladder	RR	2; 168	Both studies assessed clinical validity; no evidence that test use leads to improved outcomes	Insufficient
	CSS	0; 0	NA	Insufficient
	OS	0; 0	NA	Insufficient
	Decisions about Rx	0; 0	NA	Insufficient

Abbreviations: *BRAF* = gene name; CRC = colorectal cancer; CSS = cancer-specific survival; *EGFR* = gene name; HR = hazard ratio; *KRAS* = gene name; MSI = microsatellite instability; N = number; NA = not applicable; OS = overall survival; RR = risk of recurrence; Rx = treatment.

Discussion

Our review demonstrated that the weight of published research to date in the area of molecular pathology tests for improving estimates of prognosis has focused on the clinical validity of the tests of interest in giving information about prognosis and little emphasis on how these tests can be integrated into the overall care of cancer patients in terms of measuring changes in management decisions or the effect of those altered decisions on downstream outcomes of value to patients. Such changes in management may be occurring and may be of benefit, or possibly of harm, to patients, but they have not been measured and studied, with the notable exception of the Oncotype DX assay in breast cancer, which does have a sizeable body of evidence to suggest an effect on treatment decisions (resulting in fewer recommendations for chemotherapy), though not yet a clear effect on downstream outcomes.

At this point, physicians can, in many cases, rely on the prognostic value of molecular pathology tests, share test results with patients, and discuss whether the test result indicates a better- or worse-than-average prognosis. However, in most cases, physicians cannot be sure whether using this information will improve any clinical outcomes. Although having accurate information about prognosis may be valued by patients independent of its effects on survival and recurrence outcomes, this has yet to be demonstrated for the tests of interest.

Limitations

Many of the included studies had methodological limitations, introducing some RoB. For example, most of them were observational studies assessing associations between test results and outcomes, and are susceptible to potential confounding. To limit such bias, we only included studies for KQ 3 that adjusted for most or all standard prognostic factors. Also, we assessed potential selection bias and confounding in our RoB assessments—limiting our main data syntheses to studies with low or medium RoB.

We were also not able to address the prognostic value of the tests for the Medicare population due to a lack of data that was specific to that age group. However, several studies included subjects from the Medicare agegroup and although there wre no analyses done specific to the agegroup, there was no evidence that suggested that the prognostic value of the tests would be different for this group.

Future Research

We found no direct evidence of the impact of the information provided by these tests on downstream health outcomes such as patients' quality of life or survival. Thus, future research should focus on quality of life, survival, and other health outcomes.

There is no information on the differential effects of the test by race or cancer subtype (e.g., ductal versus lobular in breast cancer) or location (e.g., proximal versus distal in CRC). As described in the results, the subpopulations that were represented in the studies varied in terms of stage, tumor type, and location in the case of CRC. Race and location have both been shown to be important predictors of the prognostic value of genetic markers in CRC.[16,17] Similar differences in prognostic value by subpopulations could be a factor in terms of *EGFR* and *KRAS* in the lung. There is thus a need to create an evidence base that replicates results in the same subpopulations, particularly in CRC and lung cancer.

As in many studies in the oncology field, the published literature uses a variety of specific definitions for outcomes such as recurrence, distant recurrence, DFS, CSS, and OS, making comparison of effects across studies more difficult. Future research should take into account careful selection of the most appropriate endpoints, both in the context of the existing body of literature and the endpoints of most clinical relevance to doctors and patients.

Conclusions

We found modest evidence supporting added prognostic value (i.e., clinical validity), beyond traditional prognostic factors, for MammaPrint; Oncotype DX Breast; *KRAS* mutation testing for lung; *BRAF* mutation testing for CRC; *KRAS* mutation testing for CRC; and MSI for CRC for RR, CSS, and/or OS. For UroVysion, which is marketed as a diagnostic (not prognostic) test, limited evidence supported an association between test result and prognosis for RR. For impact

of test use on treatment decisions, we found moderate SOE that Oncotype DX Breast leads to changes in treatment decisions, resulting in fewer recommendations for chemotherapy.

We found no studies that directly assessed the impact of test use on downstream health outcomes to establish clinical utility. Even for the tests with good evidence supporting clinical validity, we found no evidence that using the test was related to improved outcomes for patients.

Many of the included tests are currently used to predict response to specific treatments, an aspect that was not evaluated in this report. Determining whether the tests have clinical utility for predicting therapeutic response is beyond the scope of this review.

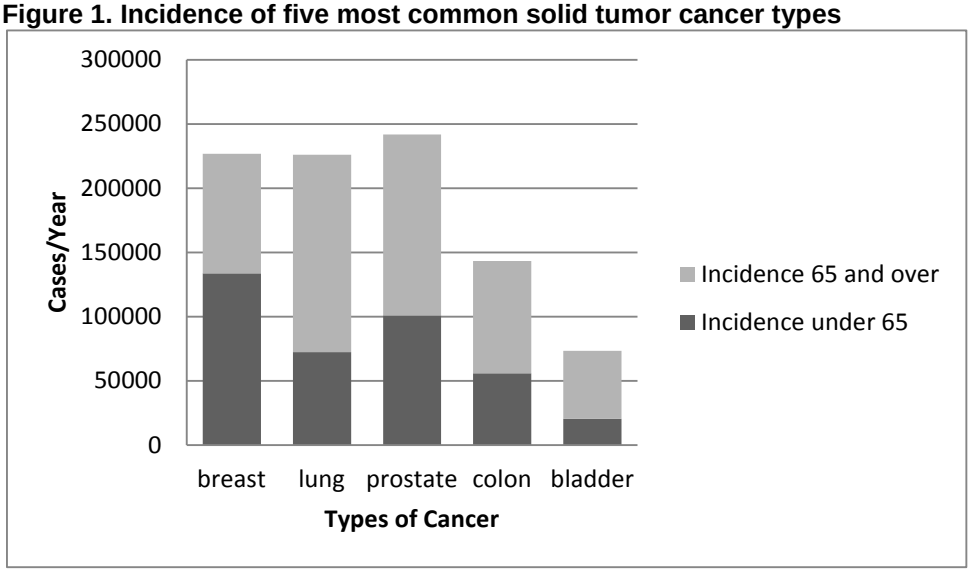
Background and Objectives

Burden of Cancer in the Medicare Population

Cancer is a leading cause of death in the United States. More than 1.6 million new cases of cancer are expected to be diagnosed in the United States in 2012.[1] Because rates of cancer incidence increase with age, almost half of these new cases will occur in the Medicare beneficiary population. As illustrated in Figure 1, adults ages 65 or older carry a disproportionate burden of new cancer diagnoses for the five most common solid tumor cancer types. For newly diagnosed Medicare beneficiaries with cancer and their care providers, estimating the prognosis of their cancer is a key step in understanding their diagnosis and forming a treatment plan. As our understanding of cancer has evolved to include the DNA mutational diversity and mRNA expression differences in the neoplastic clones, molecular pathology tests are playing an increasingly important role in determining cancer prognosis. This review aims to clarify the value of certain molecular pathology tests in determining prognosis for common cancers (breast, lung, colon, bladder) affecting Medicare beneficiaries.

Figure 1. Incidence of five most common solid tumor cancer types



Source: Data drawn from National Cancer Institute, Surveillance, Epidemiology, and End Results (SEER) Program, http://seer.cancer.gov/.[1] This figure represents an estimate of new cancer cases in the 65 or older population for the year 2012 based on overall incidence estimates for 2012 and historical distribution of new cases by age between 2005 and 2009 provided in the SEER Cancer Statistics Review.

What Is a Prognostic Test?

Prognosis is "a forecasting of the probable course and termination of an illness."[2] A prognostic test is used to predict a patient's probability of developing a disease or experiencing a medical event.[3] Determining prognosis is one of the most important steps for a newly diagnosed cancer patient and his or her health care providers. For people with cancer, a prognostic test is used to provide estimates for the likelihood of recurrence after curative-intent treatment, death from cancer, or death due to any cause after a diagnosis of cancer. In cancer research studies, these estimates are frequently referred to as recurrence-free survival, cancer-specific survival,

and overall survival. Recurrence of the cancer, cancer-specific deaths, and all-cause death are outcomes of great interest for the physician and patient as well as for researchers.

Prognostic estimates are important to cancer patients for several reasons. First, the patients and caregivers are naturally interested in finding out what to expect after the cancer is diagnosed and treated, for emotional and psychological reasons as well as for planning purposes. Second, prognostic information is often used to assist in treatment decisions, and to weigh the potential harms of treatment against the risk of disease recurrence. For example, if a patient were told that his cancer has a 10 percent chance of recurrence after initial surgical treatment, he might decide not to undergo additional chemotherapy with the potential for significant harms, whereas a patient given a 60 percent chance of recurrence might be more likely to decide to have chemotherapy. Pieces of information that distinguish patients who have different likelihoods of specific cancer outcomes are often referred to as *prognostic factors*.

Standard Prognostic Factors in Solid Tumor Cancer

The stage of a patient's cancer is one of the most powerful factors used to assess a patient's prognosis. The TNM staging system is based on the local extent of invasion by the tumor (T), whether cancer cells have spread to nearby (regional) lymph nodes (N), and whether distant (to other parts of the body) metastasis (M) has occurred.[4,5]

In addition, the grade of the tumor; other pathologic features; and other patient characteristics such as age, sex, and race are all factors that can affect prognosis depending on the primary site of the cancer. Table 1 lists the most widely accepted and validated prognostic factors for the cancer types of interest for this review.

Molecular Pathology Tests and Cancer Prognosis

As the science of cancer pathology has evolved over the past several decades, scientists have increasingly appreciated that there is biological diversity within cancers occurring in the same anatomic location and that patients with anatomically similar cancers may, in fact, have a variety of outcomes driven by molecular subtypes. The search for biomarkers to identify patients with better or worse prognoses within similar stage cancers began with the identification of distinct histologic cell types (e.g., squamous cell versus adenocarcinoma as two kinds of nonsmall cell lung cancer). These distinctions have been enriched by immunohistochemical assays, which can identify altered expression of cellular proteins. Such markers may or may not be associated with differences in prognosis. A key example includes the expression of the human epidermal growth factor 2 (HER2) receptor in breast cancer in which HER overexpression is associated with poor prognosis[6], but also serves as a predictor of response to anti-HER2 therapy. Such biomarkers have become a part of routine clinical care, and help clinicians offer more personalized prognoses and therapies to patients.

Table 1. Key standard prognostic factors in nonmetastatic solid tumors

Cancer Type	Prognostic Factor	Relationship
Colorectal	• Depth of invasion of bowel wall[a] • Invasion of adjacent structures[a] • Lymph node involvement[a] • Grade • Special cellular subtypes (e.g., mucinous, signet ring) • Lymphovascular invasion • Elevated carcinoembryonic antigen (CEA) level • Location (rectum vs. colon) • Sex • Age	Compton et al., 2000[7] Sun et al., 2009[8]
Breast	• Tumor size[a] • Tumor grade • Lymph node involvement[a] • Hormone (estrogen and progesterone) receptor status • HER2 receptor status • Inflammatory disease[a] • Age • Special cellular subtypes (e.g., mucinous, tubular)	Fitzgibbons et al., 2000[9] Rakha et al., 2008[10]
Lung	• Tumor size[a] • Invasion of adjacent tissues[a] • Spread to more than one lobe[a] • Lymph node involvement[a] • Cell type • Performance status • Weight loss • Sex	Groome et al., 2007[11] Sculier et al., 2008[12]
Bladder	• Depth of invasion of bladder wall[a] • Invasion of adjacent structures[a] • Lymph node involvement[a] • Lymphatic or vascular invasion	International Bladder Cancer Nomogram Consortium et al., 2006[13] Shariat et al., 2006[14]

[a] Factor included in American Joint Committee on Cancer staging criteria.

Abbreviations: CEA = carcinoembryonic antigen; HER2 = Human Epidermal Growth Factor Receptor 2, also known as Neu..

The search for better markers to estimate prognosis has been further enhanced with the advances in our understanding of the human genome. Genetic diversity between tumors of the same cancer type may or may not be associated with differences in prognosis. In some cases, tests for DNA mutations, DNA translocations, or mRNA expression differences (hereafter referred to as "molecular pathology tests") may offer a more accurate estimate of prognosis as an alternative or complement to traditional prognostic factors. To the extent that the results of a molecular pathology test add distinct information about a patient's likelihood of a certain outcome, such as recurrence, they can be valuable in patient education and decisionmaking.

Although molecular pathology tests are potentially valuable new tools, all such tests for common cancers are not created equal. Molecular pathology tests may vary in the extent to which they have been validated in groups of patients for whom long-term outcome data are available, and in the extent to which the patient population used in validation represents the average patient with the cancer of interest. Molecular pathology tests may also vary in their performance characteristics, including reproducibility, sensitivity and specificity, and lower limit of detection. In addition, some molecular pathology tests may change prognostic estimates by large increments when used in addition to traditional predictors, whereas others refine prognostic

estimates only slightly or not at all. All of these characteristics influence the degree to which a molecular pathology test is useful in clinical oncology practice.

How Is Prognosis Estimated?

Researchers developing prognostic models generally start with information about patient and cancer characteristics for a group of patients whose cancer outcomes (such as survival or cancer recurrence) are already known. These data are used to figure out mathematical relationships between the potential prognostic factors and the outcome of interest. Researchers must consider which outcome they wish to predict, identify the population for which they wish to make an estimate, and consider all the potential prognostic factors to include in their model based on prior literature and clinical observation.[15] Multivariable prognostic models are statistical tools that enable physicians and patients to estimate prognosis based on a combination of clinical and laboratory factors. For most cancers, the following outcomes are of greatest interest: all-cause survival (measured as time from diagnosis to death due to any cause), disease-specific survival (time from diagnosis to death due to cancer), and recurrence (time from initial surgical resection and treatment to recurrence). Thus, the mathematical models that estimate prognosis will assess the ability of the prognostic markers to predict one of these three outcomes. After comparing potential models to determine which one works best, the model's performance should be tested by using statistical methods and applying the model to different groups of patients to see if it performs as well as it did in the initial patient group. In many cases, these models can be simplified into nomograms or risk calculators that can be used in the office setting to estimate prognosis for individual patients. The usefulness of these tools depends on the validity of the predictive model that underlies them.

All prognostic estimates contain an element of uncertainty. A physician seeing a new patient may have an educated guess as to how the patient's cancer course will proceed based on the physician's experience. Although this guess may often be correct, there is still a significant degree of uncertainty. Similarly, a statistical model that estimates the likelihood of recurrence in a group of patients has some degree of uncertainty. By incorporating as many strong prognostic factors into the estimate as possible, we can reduce this uncertainty. As new candidate prognostic factors are discovered, they can be tested in combination with the known prognostic factors to investigate whether the new combination provides more accurate estimates of prognosis than the old combination (i.e., the known prognostic factors).

In evaluating prognostic tests, researchers consider *prognostic accuracy*, defined as the extent to which the test is able to predict which individuals have a higher or lower likelihood of getting the outcome (discrimination) and the extent to which the probability of a certain outcome in the population predicted by the test matches the actual probability (calibration).[16] In a disease with multiple prognostic factors, it is important to know whether a prognostic estimate incorporating a molecular pathology test of interest has improved calibration and discrimination compared with a model using only previously known prognostic factors such as those in Table 1. Further, it may be even more informative to assess net reclassification[17-19] (i.e., how much more frequently appropriate reclassification occurs than inappropriate reclassification when using a new model [incorporating a molecular pathology test] than with a model only using previously known prognostic factors). Unfortunately, not all newly discovered molecular pathology prognostic tests are evaluated in this manner. Thus, when a novel prognostic marker is reported in the scientific literature, physicians and patients may not know whether to place more value in estimates of prognosis based on older information, or on estimates based on the novel marker.

This review evaluates the value of 11 tests that are potentially useful for assessing prognosis for patients with colorectal (CRC), breast, lung, or bladder cancers. The outcome of interest in this review is recurrence of the cancer after the initial resection and treatment.

In a preliminary literature search and discussion with clinical experts for this systematic review, no commercially available molecular prognostic tests were identified for prostate cancer; therefore, prostate cancer is excluded from further consideration for this review. The molecular pathology tests of interest for the remaining four most common solid tumors among Medicare beneficiaries (Table 2) were selected based on preliminary literature searches, consultation with clinical experts, and consultation with the funding agency.

Table 2. Descriptions of genomic tests evaluated in this report

Cancer Type	Vendor	Vendor Test, Kit, or LDT	FDA-Approved	Sample Requirements	Type of Analyte	Panel Size	Neoplasms to be Tested	Results Reported from Which Lab?
Colorectal ACa

Table 2. Descriptions of genomic tests evaluated in this report (continued)

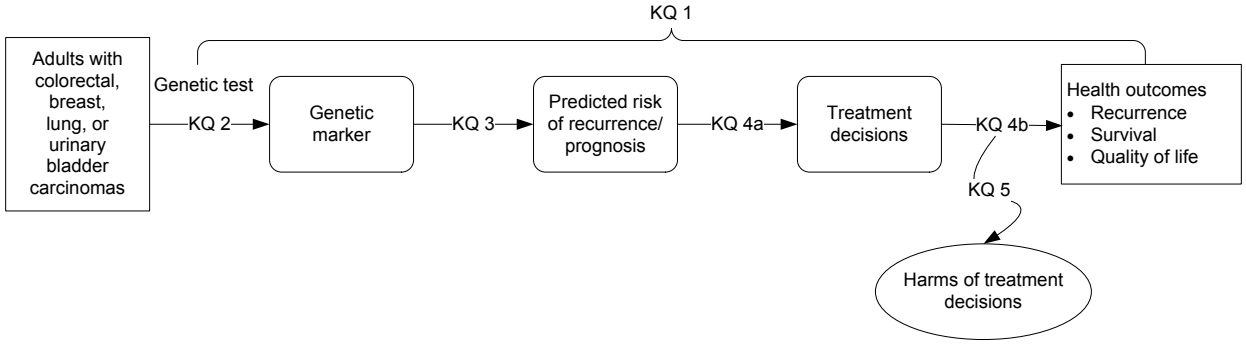
Cancer Type	Vendor	Vendor Test, Kit, or LDT	FDA-Approved	Sample Require-ments	Type of Analyte	Panel Size	Neo-plasms to be Tested	Results Reported from Which Lab?
Bladder (Urothe-lial) Ca								
UroVysion	Vysis	Kit	Yes	Alcohol-fixed	Cells	DNA (4 inter-phase chromo-somes)	Urothelial	Vendor

Abbreviations: ACa = adenocarcinoma; *ALK* = gene name; *BRAF* = gene name; Ca = cancer; BrCa = breast cancer; CRC = colorectal cancer; DNA = deoxyribonucleic acid; DX = diagnosis; *EGFR* = gene name; ER+ = estrogen receptor positive; FDA = Food and Drug Administration; FFPE = formalin-fixed paraffin-embedded tissue; IVDMIA = in vitro diagnostic multivariate index assays; *KRAS* = gene name; LDT = lab-developed test; LN- = lymph node; MGP = molecular genetic pathology; MLH-1 PHM = MLH-1 gene name promoter hypermethylation; mRNA = messenger ribonucleic acid; MSI = microsatellite instability; NL = normal; NSCLC = nonsmall cell lung carcinoma; PCR = polymerase chain reaction; seq = sequence; Stg = stage.

Scope and Objectives of the Review

These genetic tests are used in two different contexts. In one, the tests are used in a specific context of a diagnostic/therapy combination, where the diagnostic test is being used to predict response to a very specific treatment. In the second context, the genetic tests are used to estimate the patient's prognosis, and physicians use this prognostic information to choose from a variety of different treatment options. CMS requested this report to evaluate the second context. Therefore, studies that evaluate specific diagnostic/therapy combinations are excluded from this reporte thus did not include studies that were assessing tests for that purpose.The main purpose of this review is to determine whether the tests improve estimation of prognosis (for recurrence); affect physician decision-making; and thereby improve outcomes for patients with colorectal, breast, lung, or bladder cancer compared with traditional assessment of prognosis of recurrence. This technology assessment will use the analytic framework illustrated in Figure 2 and the associated Key Questions (KQs) to systematically review the evidence on 11 molecular pathology tests. In this review, we address the KQs listed below.

Figure 2. Analytic framework



Abbreviation: KQ = Key Question.

The following tests are under consideration for this assessment and apply to all KQs: microsatellite instability for CRC, MLH1 promoter methylation for CRC, *KRAS* mutation testing for CRC, *BRAF* mutation testing for CRC, Oncotype DX Colon for CRC, Oncotype DX Breast

for breast cancer, MammaPrint for breast cancer, *ALK* translocations for non-small cell lung carcinoma (NSCLC), *EGFR* for NSCLC, *KRAS* for NSCLC, and UroVysion for urinary bladder cancer.

KQ 1. Overarching Question: Is there direct evidence that the addition of the specified molecular pathology tests used alone or in combination with traditional prognostic factors changes physician decisionmaking and improves outcomes for adult patients with CRC, breast, lung, or bladder cancer compared with the use of traditional factors to predict risk of recurrence (RR) for adults with these cancers?

KQ 2. Analytic Validity: Does existing evidence establish the technical accuracy and reliability of these tests for detecting the relevant molecular analytes?

KQ 3. Clinical Validity: Does existing evidence establish the prognostic accuracy of the tests for predicting recurrence?

KQ 4. Clinical Utility: Does existing evidence support clinical utility of the molecular pathology tests?

KQ 4a. What is the evidence that the prognostic information provided by the molecular pathology tests modifies physician decisions regarding use of adjuvant antineoplastic chemo- and/or radiotherapy, enhanced diagnostic testing for recurrence, and/or surgery among adult patients with malignant tumors?

KQ 4b. What is the evidence that modified decisions lead to improved outcomes, including patient-centered outcomes such as improved quality of life, reduced disease recurrence, increased overall survival (OS) or disease-free survival (DFS), or reduced therapeutic side effects?

KQ 5. What are the harms associated with treatment decisions that are informed by the molecular pathology tests?

Methods

The methods for this systematic review follow the methods suggested in the Agency for Healthcare Research and Quality (AHRQ) *Methods Guide for Medical Test Reviews*.[3,20-23]

Literature Search Strategy

Search Strategy

To identify articles relevant to each Key Question (KQ), we searched PubMed®, the Cochrane Library, and EMBASE®. The full search strategy is presented in Appendix A. We used either Medical Subject Headings (MeSH) or major headings as search terms when available or key words when appropriate, focusing on terms to describe the relevant cancers and tests of interest. Searches were run by an experienced information scientist serving as the Evidence-based Practice Center (EPC) librarian and were peer reviewed by another information scientist.

We limited the electronic searches to English-language, adult, and human-only studies. Sources were searched from inception through November 2013. We manually searched reference lists of pertinent review articles and studies meeting our inclusion criteria to look for any relevant citations that our searches might have missed. We imported all citations into an EndNote® X5 (Thomson Reuters, New York, NY) electronic database.

We also searched for unpublished studies relevant to this review using test developers' Web sites, ClinicalTrials.gov, the Food and Drug Administration (FDA) Web site, Health Services Research Projects in Progress, and the European Union Clinical Trials Register. In addition, we requested unpublished information from the College of American Pathologists (CAP) and from the relevant companies, asking for data that they believe should be considered for the review. In cases in which relevant information was unclear or not reported, we contacted authors to get additional or unpublished information.

Any literature suggested by reviewers was investigated and, if appropriate, incorporated into the final review. We determined appropriateness for inclusion in the review by the same methods described in this chapter.

Eligibility Criteria

We developed eligibility (inclusion and exclusion) criteria for Populations, Interventions (i.e., tests for this report), Comparators, Outcomes, Timing, Settings (PICOTS), and study designs (Table 3). We included studies meeting the criteria described in Table 3 that were relevant to at least one of the KQs.

Table 3. Inclusion/exclusion criteria

Category	Inclusion	Exclusion
Population	Adult patients (19 years of age or older) with cancer of the colon/rectum, breast, lung, or urinary bladder (cancer types known to be of higher incidence in the core Medicare beneficiary population [people 65 years of age or older])	People 18 years of age or younger; all other tumor types and sites. Studies focused on a population with advanced/metastatic cancer.
Interventions (i.e., tests)	The following molecular pathology tests when used alone or in combination with "traditional" prognostic factors to measure the likelihood of malignant tumor recurrence (e.g., tumor size, tumor grade, estrogen receptor status; see Table 1): Lung cancer: *ALK*, *EGFR*, *KRAS* CRC: Microsatellite instability (MSI), MLH1 promoter methylation, *KRAS*, *BRAF*, Oncotype DX Colon Breast cancer: Oncotype DX Breast, MammaPrint Urinary bladder cancer: UroVysion	Molecular pathology tests used to measure the likelihood of malignant tumor recurrence that are not commercially available in the United States. Studies focused on predicting response to treatments (e.g., studies focused on response to gefitinib for people with advanced lung cancer).
Comparators	We will compare the molecular pathology tests listed above with standard tests or markers (see Introduction) used to measure the likelihood of malignant tumor recurrence. We will collect information about comparators as they are defined and reported in each study. For KQs 1, 4, and 5, we are looking for studies that compare an eligible molecular pathology test plus all known prognostic factors with all known prognostic factors alone to isolate whether the test adds any value (benefit) or introduces additional harms (KQ 5). Alternatively, studies that compare an eligible molecular pathology test alone with known prognostic factors are also eligible for inclusion. If a study uses most of the known prognostic factors but not all of them, it could also meet our inclusion criteria, and the comparison would be considered in the risk of bias (RoB) assessment (related mainly to confounding and approach to statistical adjustment). For KQ 2 (analytic validity), comparators also include intra- and interlaboratory repeat testing of samples. For KQ 3 (clinical validity), cohort studies that do the test on everyone, follow them over some period of time to capture relevant outcomes, and then do a multivariate analysis to adjust for known factors and to determine whether the tests have prognostic value for predicting recurrence are eligible. Such studies must compare those with different test results (e.g., those with a mutation versus those who are wild-type) to establish prognostic value, adjusted for known factors. To inform whether molecular pathology tests add value above standard prognostic factors, results must be adjusted for known prognostic factors (or they must be addressed in other ways, such as through inclusion/exclusion criteria of the study or stratification). Relevant case-control studies for KQ 3 could compare cases (people with recurrence) and controls (without recurrence) by rates of exposure (e.g., test positive vs. test negative), adjusting for known prognostic factors.	Unadjusted studies demonstrating associations between test results (e.g., those with a mutation versus those who are wild-type) and outcomes.

0

Table 3. Inclusion/exclusion criteria (continued)

Category	Inclusion	Exclusion
Outcomes	KQ 1. Overarching question. Studies must provide direct evidence of the impact of a test of interest on physician decision-making (regarding the use of adjuvant anti-neoplastic chemo- and/or radiotherapy, enhanced diagnostic testing for recurrence, or preventive surgery) and also on health outcomes (overall survival, disease-free survival, time to recurrence, or quality of life). KQ 2. Analytic validity Tissue sample acceptance/rejection criteria. Sensitivity/specificity of testing for each marker at assay conditions. Degree of variation in the results if the same tumor is tested in multiple laboratories. Uniqueness of the markers used in the panel and their robustness to contamination. Quality control standards for considering the validity of the overall assay (for multiplex tests). Proportion of probes or antibodies that must return a valid result (for multiplex tests). KQ 3. Clinical validity Prognostic value for recurrence (e.g., time to recurrence and disease-free survival) and overall survival. Differences in prognostic value associated with patient characteristics. Differences in prognostic value between non-Medicare and Medicare population. KQ 4. Clinical utility 4a. Decision-making Modification of physician decisions regarding the use of the following: adjuvant anti-neoplastic chemo- and/or radiotherapy enhanced diagnostic testing for recurrence preventive surgery 4b. Health outcomes Overall survival, disease-free survival, time to recurrence, quality of life (must be assessed using a valid and reliable quality-of-life measurement tool) KQ 5. Harms Adverse effects of tests, adverse effects of adjuvant therapy, decreased quality of life	Prediction of response to treatment. Progression-free survival is not an eligible outcome.
Time Frame/ Duration	We will include studies of any duration that otherwise meet inclusion criteria.	

Table 3. Inclusion/exclusion criteria (continued)

Category	Inclusion	Exclusion
Study Designs	Include/eligible study designs, by KQ: KQ 1a. Randomized controlled trials (RCTs), non-RCTs, prospective cohort studies with eligible comparison groups, and case-control studies that directly assess the impact of a test of interest on physician decision-making (regarding the use of adjuvant antineoplastic chemo- and/or radiotherapy, enhanced diagnostic testing for recurrence, or preventive surgery) and also on health outcomes (overall survival, disease-free survival, time to recurrence, or quality of life). KQ 2. Collaborative studies using panels (ideally large panels) of well-characterized samples, data from external proficiency testing schemes, data from inter-laboratory comparison programs, test and retest of samples, or validation studies (including those from manufacturers). KQ 3. Prospective and retrospective cohort studies and case-control studies with eligible comparison groups. This could also include publications of validated clinical decision algorithms that were developed using cohort data to quantify the contributions of different variables (e.g., molecular pathology test result, tumor size, tumor grade) in order to determine classification/interpretation of a molecular pathology test result for prognosis. KQ 4a. RCTs, non-RCTs, prospective and retrospective cohort studies with eligible comparison groups, and case-control studies. Case series will be considered for KQ 4a for decision-making outcomes only if other eligible study designs are not available. KQ 4b.[a] RCTs, non-RCTs, prospective and retrospective cohort studies with eligible comparison groups, and case-control studies. KQ 5. RCTs, non-RCTs, prospective and retrospective cohort studies with eligible comparison groups, and case-control studies.	Non-English publications, systematic and nonsystematic reviews, case series (except as noted for KQ 4a; we determined that the RoB in case series is too high to provide valid and reliable information for the other KQs), letters, editorials, abstracts, and observational studies without comparison groups.
Settings	Any country (no limits)	

[a] An RCT that randomized subjects to use a molecular pathology testmolecular pathology test alone or in combination with standard prognostic factors compared with standard prognostic factors alone to inform decisions and that reported health outcomes would address the overarching question (KQ 1), whereas KQ 4b would include studies that evaluated the link between decisions and health outcomes.

Abbreviations: *ALK* = gene name; *BRAF* = gene name; DX = diagnosis; *EGFR* = gene name; KQ = Key Question; *KRAS* = gene name; MLH-1 = gene name promoter hypermethylation; MSI = microsatellite instability; RCT = randomized controlled trial; RoB = risk of bias.

Study Selection

We developed and pilot tested review forms for review of titles/abstracts and full texts. All references were tracked in a Microsoft Excel® Version 14.0 (Microsoft Corporation, Redmond, WA) database. Two trained members of the research team independently reviewed each title and abstract identified through searches for eligibility. Studies marked for possible inclusion by either reviewer underwent a full-text review. For studies that lacked adequate information to determine inclusion or exclusion, we retrieved the full text and then made the determination. If the necessary information in full-text articles was unclear or missing, we contacted authors of the publications.

Two trained members of the research team independently reviewed each full-text article for inclusion or exclusion based on the eligibility criteria described above. If both reviewers agreed that a study did not meet the eligibility criteria, we excluded it. If the reviewers disagreed, they resolved conflicts by discussion and consensus or by consulting a third member of the review

team. We recorded the principal reason that each excluded full-text publication did not satisfy the eligibility criteria (Appendix B).

Data Extraction

For studies that met our inclusion criteria, we extracted study characteristics and results into evidence tables. We designed, pilot tested, and used structured data extraction forms to gather pertinent information from each article; this included characteristics of study populations, settings, interventions, comparators, study designs, methods, and results. Trained reviewers extracted the relevant data from each included article into the data extraction forms. All data extractions were reviewed for completeness and accuracy by a second member of the team. All data extraction was performed using Microsoft Excel® software.

Risk-of-Bias Assessment of Individual Studies

We assessed the RoB (internal validity) in the reviewed studies using an approach supported by the *Methods Guide for Medical Test Reviews*.[3] For studies of analytic validity, we considered the potential for bias due to flaws in the sample selection, testing protocol, reference standards, verification procedures, interpretation, and/or analysis. We used the questions relevant for prognostic tests from the QUADAS-2[24,25] (which was developed for diagnostic tests) for assessing risk of relevant biases. For studies of clinical validity and clinical utility, we assessed the potential for selection bias, confounding, performance bias, attrition bias, and detection bias. We assessed these biases using relevant questions and predefined criteria based on guidance from the AHRQ *Methods Guide for Effectiveness and Comparative Effectiveness Reviews* and the RTI Question Bank.[26]

We summarized RoB for each study as low, medium, high, or unclear. In general, studies with a low RoB are those that have a low risk of selection bias, use valid and reliable outcome measures, use appropriate statistical and analytical methods, have low attrition, and report methods and outcomes clearly and precisely. Studies with a medium RoB are those that do not meet all criteria required for low RoB but do not have flaws that are likely to cause major bias. Missing information often led to ratings of medium as opposed to low RoB. Studies with inadequate reporting to allow assessment of RoB were described as having unclear RoB—this was often the case for abstracts from conference proceedings. Studies with a high RoB are those with at least one substantial flaw in the study's design, conduct, or analysis that could invalidate the results. Two independent reviewers assessed the RoB for each study. Disagreements were resolved by discussion and consensus or by consulting a third member of the team. Appendix C details the criteria used for evaluating the RoB of all included studies and explains the rationale for high RoB ratings.

Data Synthesis

For clinical validity, data were synthesized for each test by cancer type using meta-analytic techniques described in Hedges & Vevea.[27] The measure of the effect size in most studies was a hazard ratio (HR). A few studies had odds ratios. A summary HR was estimated for any outcome that had three or more independent HR estimates. In cases where subpopulations from one study were included in the sample for another study, we used the study with the largest included population in our meta-analyses (to avoid double-counting any data). If studies provided separate estimates for different subsamples (e.g., node negative and node positive), both estimates were

included if no overall HR was provided. If an overall HR for the entire sample and the separate HRs for subsamples were provided, then only the overall measure was used.

If the test is non-informative, we expect that the probability of experiencing the end point would be the same for either group, with an HR of 1. If the HR is greater than 1, the probability of the endpoint is higher in the group with the higher hazard. If the HR is lower than 1, the probability of experiencing the endpoint is lower in the group with the lower hazard. For example, an HR of 2 for CSS indicates that one group (e.g., those with high risk results for Oncotype DX Breast) has twice the rate per unit of time as the comparison group (e.g., those with low-risk test results).

The standard error (SE) of the HR was used to estimate the variance of the effect size. In most cases, the SE was estimated from the 95% confidence interval (CI). We tested the null hypothesis of homogeneity of effect sizes across the studies[27,28] for each of the outcomes. If the null hypothesis was rejected at a significance level of 0.05, the summary HR was estimated using a random effects model; if not, it was estimated using a fixed effects model. In both cases, the inverse of the variance was used to estimate a weighted summary HR. Forest plots with indicators of the weight assigned to each study were used to help visualize the contributions of each study and to show the summary HR.

We did not include studies with a high or unclear RoB in our main analyses/main data syntheses.

Strength of the Body of Evidence

We graded the strength of evidence (SOE) based on the guidance established for the Evidence-based Practice Center program Program.[29,30] Developed to grade the overall strength of a body of evidence, this approach incorporates four key domains: RoB (includes study design and aggregate quality), consistency, directness, and precision of the evidence. It also considers other optional domains that may be relevant for some scenarios, such as a dose-response association, plausible confounding that would decrease the observed effect, strength of association (magnitude of effect), and publication bias. Table 4 defines the grades of evidence that we assigned.

Table 4. Definitions of the grades of overall strength of evidence

Grade	Definition
High	High confidence that the evidence reflects the true effect. Further research is very unlikely to change our confidence in the estimate of effect.
Moderate	Moderate confidence that the evidence reflects the true effect. Further research may change our confidence in the estimate of the effect and may change the estimate.
Low	Low confidence that the evidence reflects the true effect. Further research is likely to change our confidence in the estimate of the effect and is likely to change the estimate.
Insufficient	Evidence either is unavailable or does not permit estimation of an effect.

Source: Owens et al., 2010[29]

For each test being evaluated in this review, two reviewers assessed each domain for each key outcome and determined an overall SOE grade based on domain ratings. In the event of disagreements on the domain or overall grade, they resolved differences by consensus discussion or by consulting with a third investigator.

We attempted to find studies that directly address the overarching question (KQ 1). If we did not find adequate direct evidence addressing the overarching question, we attempted to construct an indirect chain of evidence (using studies identified for the other KQs).

Appendix D includes tables showing our assessments for each domain and resulting SOE grades for each outcome, organized by type of cancer and test. We graded the SOE separately for analytic validity and for evidence on our overarching KQ. For analytic validity, we graded the SOE for the following: sensitivity and specificity, positive and negative predictive value, and cross-lab validity. For evidence on the overarching KQ, we graded the SOE for the following outcomes: risk of recurrence, cancer-specific survival, overall survival, and decisions about treatment.

Applicability

We assessed applicability of the evidence following guidance from the *Methods Guide for Comparative Effectiveness Reviews*.[28,31] We used the PICOTS framework to explore factors that affect applicability. Some factors identified that may limit the applicability of evidence include age, sex, and race or ethnicity of enrolled populations.

Peer Review and Public Commentary

Peer Review

The comments were generally favorable from the peer reviewers. Two main areas were identified as needing revisions.

1. Emphasizing that this report focused on the prognostic value of the tests and did not examine the predictive value of the tests (i.e., in predicting response to treatment).
2. Incorporating CAP's information into the description of the analytic validity for the tests and general comments on improving the description of analytic validity of the tests.

We have incorporated these suggestions in the document.

Public Comments

A lot of the public comments were from the manufacturers of the tests examined. Besides disputing some of the SOE grades and conclusions or suggesting revisions to KQs, one salient issue raised by a manufacturer was about including UroVysion in the report. Abbott Molecular pointed out that UroVysion was not designed or marketed as a test to assess prognosis and requested that the test be excluded from the report.

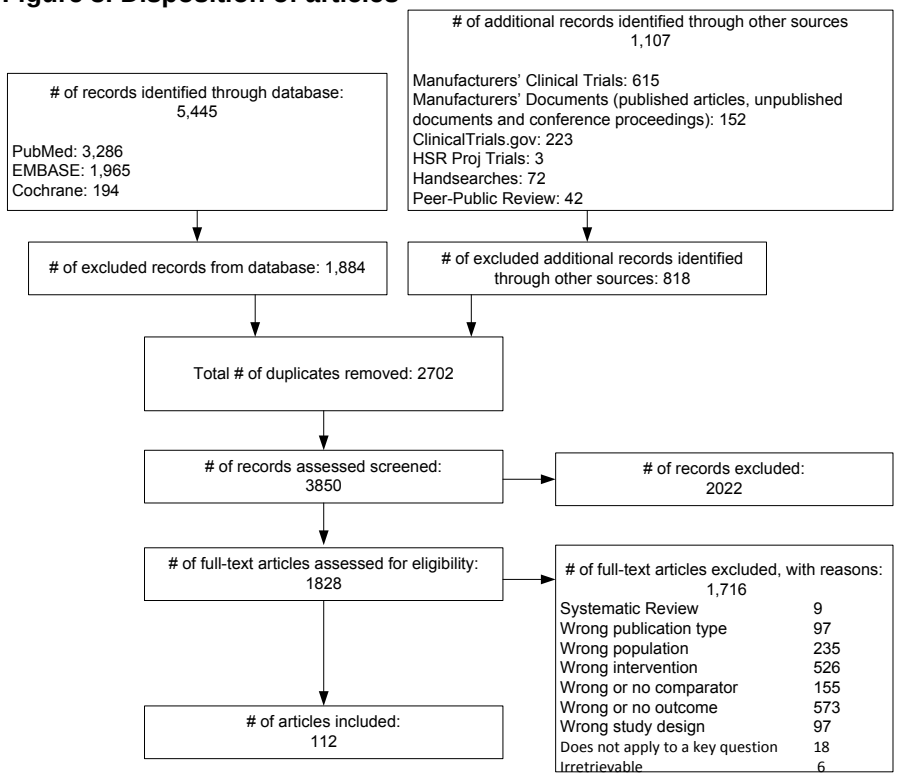
We have decided to keep UroVysion in the report but have added clear statements in various sections to clarify the intended use of the test.

Results

Literature Search

We included 112 publications reporting on the tests of interest (Figure 3). We included 21 publications for Key Question (KQ) 2, 70 for KQ 3, and 22 for KQ 4a. We found no eligible studies for KQ 1, KQ 4b, or KQ 5. Of the included studies, we rated 31 as low, 57 as medium, 12 as high, and 12 as unclear risk of bias (RoB).

Figure 3. Disposition of articles



Results of Included Studies

Key Question 1. Direct Evidence That Using the Tests Changes Physician Decisionmaking and Improves Outcomes

We found no eligible studies that addressed this overarching question.

Key Question 2. Analytic Validity

We included 21 studies, using a total of 23 different tests (Table 5) as well as data from the College of American Pathologists. We analyzed marker test performance and intra/interlab reproducibility.

Abbreviations: ARMS = Amplification Refractory Mutation System; ARMS/S = Amplification Refractory Mutation System and a Scorpion fluorescent primer/probe system; BML = Bio Medical Laboratories (Tokyo, Japan); *BRAF* = v-Raf murine sarcoma viral oncogene homolog B1; DNA = deoxyribonucleic acid; *EGFR* = epidermal growth factor receptor gene; FFPE = formalin-fixed, paraffin-embedded; HRM = high-resolution melting; *KRAS* = V-Ki-ras2 Kirsten rat sarcoma viral oncogene homolog; ME = mutant enriched; NA = not applicable; NOS = not otherwise specified; NR = not reported; PCR = polymerase chain reaction; PNA = peptide nucleic acid; RH = reverse hybridization.

Of the 11 potentially considered molecular pathology tests of interest, we found published studies rated as low or medium RoB for 6 tests: MammaPrint mRNA expression for breast cancer, *EGFR* mutations and *KRAS* mutations for lung cancer, *KRAS* mutations and *BRAF* mutations for colorectal cancer (CRC), and Oncotype DX Colon mRNA expression for CRC. The published studies that we identified reporting on *ALK* cytogenetics for lung cancer, Oncotype DX Breast mRNA expression for breast cancer, and MLH1 promoter methylation for CRC were rated as high or unclear RoB. Results of the included studies are provided in Table 6.

Abbreviations: ARMS = Amplification Refractory Mutation System; AS = Allele-Specific; BML = Bio Medical Laboratories (Tokyo, Japan); *BRAF* = gene name; DNA = deoxyribonucleic acid; *EGFR* = gene name; ER = estrogen receptor; FFPE = formalin-fixed, paraffin-embedded; HER2 = Human Epidermal Growth Factor Receptor 2, also known as (Neu); HRM=high-resolution melting; *KRAS* = gene name; ME = mutant enriched; N = number of samples; NA = not applicable; NOS = not otherwise specified; NPA = negative percent agreement; NR = not reported; PCR = polymerase chain reaction; PNA= peptide nucleic acid; PPA = positive percent agreement; RH = reverse hybridization; SGn = SpectrumGreen; SO = SpectrumOrange.

Data from the College of American Pathologists' for *EGFR* mutations, *KRAS* mutations, *BRAF* mutations, microsatellite instability for colorectal cancer, and UroVysion cytogenetics for urinary bladder cancer support the analytic validity of these tests (see data in relevant sections below).

Breast Cancer: MammaPrint

Characteristics of Included Studies Assessing Analytic Validity of MammaPrint

MammaPrint uses a 70-gene signature to classify breast carcinoma patients into those with a good or poor prognosis, based on risk of distant metastasis.

One study by Poulet[52] was rated unclear in terms of RoB and is excluded from the description of results below.

Two MammaPrint studies were rated as low or medium RoB (Table 5).[39,49] van't Veer[49] developed the 70-gene signature prognostic assay (now known as MammaPrint) for risk of recurrence in early-stage breast cancer, and tested prediction to metastases in 97 patients. Delahaye,[39] affiliated with Agendia NV, studied the analytical performance of MammaPrint, including reproducibility, precision, repeatability, tumor heterogeneity, and inter-lab reproducibility.

MammaPrint: Analytic Validity

Both MammaPrint studies indicated that the MammaPrint test is precise, repeatable (98.5 to 99 percent), and reproducible for prediction of metastasis in breast cancer (Table 6). The largest contributor to assay variation was intratumor heterogeneity, which is significantly greater than the technical variation in the MammaPrint test.

Nonsmall Cell Lung Carcinoma: *EGFR* and *KRAS* Mutations

Characteristics of Included Studies Assessing Analytic Validity of *EGFR* Mutation

We reviewed the analytic validity of tests that detected mutations in the *EGFR* gene. All studies looked at mutations in the gene within exons 18, 19, and/or 21.

We rated 5 studies reporting analytic validity of *EGFR* testing for lung cancer as having low RoB (Table 5). Angulo[50] compared *therascreen EGFR* mutation screening to direct sequencing of *EGFR* in FFPE lung tumor tissue. Lopez-Rios[46] compared the Cobas *EGFR* Mutation Test and *therascreen EGFR* Mutation Test with direct sequencing of *EGFR* in FFPE lung carcinoma tissue. Sriram[53] compared mutant-enriched-PCR and high-resolution melting methods in frozen lung tissue, a subset (97 of 522 samples) of which were previously DNA sequenced in the *EGFR* gene. Naoki[51] compared the PCR-invader method with direct DNA sequencing in FFPE lung tissue and pleural and pericardial effusions. Beau-Faller[35] compared several PCR-based methods to direct DNA sequencing of *EGFR* in FFPE lung tissue across 15 centers.

Also, we received results of proficiency testing from The College of American Pathologists (CAP) to address intralab reproducibility of *EGFR* mutation testing.

EGFR Mutation: Analytic Validity

In general, all five *EGFR* testing studies for lung cancer compared various PCR-based methods against one another or against DNA sequencing in FFPE tissue (Table 6). All of these studies found that, compared with DNA sequencing, PCR-based methods of screening for *EGFR* mutations had a lower limit of detection and thus were more sensitive in samples with <20% carcinoma. However, because PCR-based methods are based on known mutations found between exons 18 and 21 of the *EGFR* gene, DNA sequencing is a better method for identifying novel mutations and mutations elsewhere in the gene.

The CAP sends proficiency test *EGFR* unknowns to CLIA-approved US clinical laboratories or International clinical laboratories for assessing nationwide interlab reproducibility. The three most recent surveys[54] found accuracy rates of 93 percent (122/131; EGFR-B, 2012), 96 percent (157/164; EGFR-A, 2013), and 96 percent (195/204; EGFR-B, 2013), for an average diagnostic accuracy of 94 percent (474/499).

Characteristics of Included Studies Assessing Analytic Validity of *KRAS* Mutation in Nonsmall Cell Lung Carcinoma

We reviewed the analytic value of tests that detected mutations in the *KRAS* gene. The studies looked at mutations at codons 12 and 13 or on exon 2 in the *KRAS* gene but not at codon 61.

One study by Jancik[44] was rated as having a high RoB and is excluded from the description of results below.

We rated two *KRAS* mutant lung cancer studies as having low RoB (Table 5). Beau-Faller (2009)[36] compared peptide-nucleic-acid-mediated PCR clamping to direct DNA sequencing in frozen lung tissue. Beau-Faller (2011)[35] compared several PCR-based methods to direct DNA sequencing of *KRAS* in FFPE lung tissue across 15 centers.

Also, we received results of proficiency testing from CAP to address intralab reproducibility of *KRAS* mutation testing.

KRAS Mutation for Lung Cancer: Analytic Validity

Both of the *KRAS* mutant lung cancer studies (Table 6) found that, compared with DNA sequencing, PCR-based methods of screening for *KRAS* mutations had a lower limit of detection, and thus were more sensitive when the samples contained <20% carcinoma.

CAP sends proficiency test *KRAS* unknowns to CLIA-approved US clinical laboratories or International clinical laboratories for assessing nationwide interlab reproducibility. The three most recent surveys[55] found accuracy rates of 98 percent (194/197; KRAS-B, 2012), 98 percent (206/209; KRAS-A, 2013), and 98 percent (211/215; KRAS-B, 2013), for an average diagnostic accuracy of 98 percent (611/621).

Characteristics of Included Studies Assessing Analytic Validity of *ALK* Translocation

There were no published studies that provided any information about the analytic validity of the ALK Translocation test. Abbot Labs, 2011[32] has information provided with their Vysis ALK Break Apart FISH Probe Kit literature on specific performance characteristics, including analytical sensitivity and specificity, tissue reproducibility, and external reproducibility (Tables 5 and 6). This work was rated unclear in terms of RoB and is excluded from the description of results.

Colorectal Carcinoma:

Characteristics of Included Studies Assessing Analytic Validity of *BRAF* Mutation

The *BRAF* mutation tests being examined in this report screen for the V600E mutation in the *BRAF* gene.

One study by Pang (2011)[48] was rated as having a high RoB and is excluded from the description of results below.

A single *BRAF* CRC study had a rating of medium RoB (Table 5). Mancini[47] compared a novel lower denaturation temperature PCR (COLD-PCR) with the more traditional high-resolution melting (HRM) PCR method in screening for *BRAF* c.1799 T>A (p.V600E) mutation.

Also, we received results of proficiency testing from CAP to address intralab reproducibility of *BRAF* mutation testing.

BRAF Mutation: Analytic Validity

Mancini[47] found that COLD-PCR was more sensitive than HRM-PCR for detecting the *BRAF* mutation (Table 6).

The College of American Pathologists sends proficiency test *BRAF* unknowns to CLIA-approved U.S. clinical laboratories or International clinical laboratories, an excellent mechanism for assessing inter-lab reproducibility. The three most recent surveys[56] found accuracy rates of 100% (140/140; BRAF-B, 2012), 98% (192/195; BRAF-A, 2013), and 98% (196/200; BRAF-B, 2013), for an average diagnostic accuracy of 99% (528/535).

Characteristics of Included Studies Assessing Analytic Validity of *KRAS* Mutation in Colorectal Carcinoma

The genetic test for *KRAS* mutations described here checks for mutations in codons 12 and 13 in the *KRAS* gene but not in codon 61.

One study by Pang[48] was rated as having a high RoB, and two studies—Gao[41] and Hancer[43]—were rated as having unclear RoB and are excluded from the description below.

We rated five *KRAS* mutant CRC studies as having low to medium RoB (Table 5). Mancini[47] compared COLD-PCR with the HRM PCR method in screening for *KRAS* mutations in frozen colorectal tissue. Kobunai[45] compared peptide nucleic acid-clamp PCR with direct sequencing in frozen colorectal tissue. Gonzalez de Castro[42] compared the cobas *KRAS* Mutation Test and the Qiagen *therascreen KRAS* Kit methods to direct *KRAS* sequencing in FFPE colorectal tissue. Bando[34] compared the *KRAS* StripAssay and *therascreen KRAS* Mutation kit with direct *KRAS* sequencing. Feigelson[40] compared five different *KRAS* mutation testing regimens for comparability and consistency across five laboratories.

Also, we received results of proficiency testing from CAP to address intralab reproducibility of *KRAS* mutation testing.

KRAS Mutation for Colorectal Carcinoma: Analytic Validity

All of these studies found that, compared with DNA sequencing, PCR-based methods of screening for *KRAS* mutations had a lower limit of detection, and thus were more sensitive in samples with <20% carcinoma (Table 6).

CAP sends proficiency test *KRAS* unknowns to CLIA-approved US clinical laboratories or International clinical laboratories for assessing nationwide interlab reproducibility. The three

most recent surveys[55] found accuracy rates of 98 percent (194/197; KRAS-B, 2012), 98 percent (206/209; KRAS-A, 2013), and 98 percent (211/215; KRAS-B, 2013), for an average diagnostic accuracy of 98 percent (611/621).

Characteristics of Included Studies Assessing Analytic Validity of MSI

We found no individual published studies meeting our inclusion criteria that reported eligible information on analytic validity of the microsatellite instability (MSI) test for CRC.

We received results of proficiency testing from CAP to address intralab reproducibility of MSI testing.

MSI for Colorectal Carcinoma: Analytic Validity

CAP sends proficiency test MSI unknowns to CLIA-approved US clinical laboratories or International clinical laboratories for assessing nationwide interlab reproducibility. The three most recent surveys[57] found accuracy rates of 100 percent (89/89; MSI-B, 2012), 99 percent (96/97; MSI-A, 2013), and 98 percent (103/105; MSI-B, 2013), for an average diagnostic accuracy of 99 percent (288/291).

Characteristics of Included Studies Assessing Analytic Validity of Oncotype DX (for Breast and Colon)

Oncotype DX Breast and Oncotype DX Colon are mRNA abundance assays performed on formalin-fixed paraffin-embedded tissue. They are not intended to act as surrogate tests for identifying underlying gene mutations. Selected mRNA abundance differences have been correlated with known clinical outcomes and are now used to predict risk of recurrence and to guide adjuvant therapy use in new patients who have undergone resection of their primary carcinomas for cure. Oncotype DX Breast uses a 21-gene mRNA expression signature and assigns a recurrence risk score (RS) ranging from 0 to 100 for each patient. Oncotype DX Colon uses a 12-gene mRNA expression signature and assigns an RS ranging from 0 to 100 for each patient.

The Cronin lab at Genomic Health measured intralaboratory detectability, dynamic range, and reproducibility for assays on this set of 21 mRNAs for Oncotype DX Breast.[38] This study was rated as having unclear RoB (Table 5). Published data on Oncotype DX Colon by Clark-Langone,[37] affiliated with the Cronin lab and referencing the above paper, provided similar analytical validity data for the 12-gene Oncotype DX Colon assay.

Oncotype DX: Analytic Validity

The data from Cronin's group at Genomic Health[38] found high intralab reproducibility for Oncotype quantitative RT-PCR mRNA abundance measurements relevant to the Oncotype DX tests for breast and colon carcinoma. Clark-Langone[37] reported high analytic validity and precision for the Oncotype DX Colon assay (Table 6). No references were found to estimate interlaboratory reproducibility, because this assay is not performed outside of Genomic Health.

Bladder Cancer: UroVysion

Characteristics of Included Studies Assessing UroVysion

UroVysion is a fluorescence in situ hybridization (FISH) test of exfoliated urothelial cells that has been shown to be sensitive in terms of diagnosing urothelial cancer.

We found no individual published studies meeting our inclusion criteria that reported eligible information on analytic validity of the UroVysion test for bladder cancer.

We received results of proficiency testing from CAP to address intralab reproducibility of UroVysion testing.

UroVysion: Analytic Validity

CAP sends proficiency test UroVysion unknowns to CLIA-approved US clinical laboratories or International clinical laboratories for assessing nationwide interlab reproducibility. The four most recent surveys[58] found accuracy rates of 99 percent (168/170; UroVysion-A, 2013), 99 percent (168/170; UroVysion-B, 2013), 99 percent (191/192; UroVysion-C, 2013), and 100 percent (193/193; UroVysion-D, 2013), for an average diagnostic accuracy of 100 percent (552/555).

Clinical Validity: Breast Cancer: MammaPrint and Oncotype DX

Characteristics of Included Studies Assessing Clinical Validity of MammaPrint

We found 11 studies[49,59-68] that reported on the prognostic value of the RS from MammaPrint for RR, CSS, or OS in patients with breast cancer (Table 7). All were cohort studies. Sample sizes ranged from 89 to 964. Median followup was 3 to 10 years. Eight out of 10 studies were conducted in the Netherlands either exclusively by the group that developed the signature or in collaboration with other European countries. One study was conducted in the United States,[61] and one was conducted in France, Sweden, and the United Kingdom.[60]

All studies compared outcomes of patients who had a good prognosis signature with those who had a poor prognosis signature. Age of the women in the studies for which age is reported was approximately 50 years, although a couple of studies included women who were in their twenties. Race or ethnicity was not reported in any of the studies.

There were some differences in the populations enrolled in the included studies. Differences were in stage and ER, node positivity, and age. Three studies restricted the sample to node-negative cancers,[59,60,65] a couple included cases with one to three positive nodes,[63,67] one looked at patients with four to nine positive nodes[68]and two included stages I through III,[62,63] whereas the others restricted the study to stage I or II.

Table 7. Characteristics of included studies: MammaPrint for breast cancer

Author, Year Study Type Risk of Bias	N Length of Followup	Country(ies)	Disease Stage(s) Other Tumor/ Disease Characteristics	Study Groups	Race Ethnicity	Overall Age (years) % Female
Bueno-de-Mesquita 2009[59] Cohort Low	151 Median 10.2 years (0.7–21.3)	The Netherlands	Early stage Node-negative breast cancer, tumor diameter pT1–2.	Good prognosis signature Poor prognosis signature	NR NR	Mean (range): 47 (27–55)

Nuyten, 2008[66] Cohort Medium	144 Median (range): 10.2 (0.05 to 21.7) years	The Netherlands	II Node positive	Good prognosis Poor prognosis	NR NR	NR NR

Table 7. Characteristics of included studies: MammaPrint for breast cancer (continued)

Author, Year Study Type Risk of Bias	N Length of Followup	Country(ies)	Disease Stage(s) Other Tumor/ Disease Characteristics	Study Groups	Race Ethnicity	Overall Age (years) % Female
Saghatchian, in press[68] Cohort Medium	173 Median, 7.9 years	The Netherlands, Italy	Primary invasive breast cancer with 4 – 9 positive nodes, T1-3, estrogen receptor +/-, progesterone receptor +/-, HER2 +/-	Genomic high risk Genomic low risk		Age for each group, mean (SD): GHR = 49.1 (9.7); GLR = 51.4 (9.5 100%
Van't Veer, 2002[49] Cohort Medium	98	The Netherlands	Sporadic breast cancer 55 years or younger, 18 cases of BRCA1 and 2 BRCA2	Good prognosis Poor prognosis	NR NR	All patients were younger than 55 years at diagnosis 100%
Van de Vijver, 2002[67] Cohort Low	295 Median (range): 7.8 years (0.05 to 18.3) years (207 patients without metastasis as the first event) Median (range): 2.7 (0.3 to 14.0) years (88 patients with metastasis as the first event). Median (range): 6.7 (0.05 to 18.3) years (all 295 patients)	The Netherlands	I-II	Good prognosis Poor prognosis	NR NR	All patients were younger than 53 years 100%

Abbreviations: HER2 = Human Epidermal Growth Factor Receptor 2, also known as Neu; MUT = mutation; N = number; NR = not reported; SD = standard deviation.

MammaPrint: Risk of Recurrence

Six cohort studies rated as low or medium RoB reported RR (total N=1,913).[59,62-64,67,68] All studies used distant metastasis-free survival (DMFS) instead of recurrence-free survival (local and distant recurrence) as their outcome. All six reported on the prognostic value of MammaPrint after controlling for traditional prognostic factors such as stage, size, and differentiation, for example. One study used the composite score from Adjuvant! Online—an online program that combines traditional prognostic factors to calculate an RS.[69] All studies concluded that patients with a poor prognosis signature had a higher risk of distant metastasis compared with patients with a good prognosis signature. The hazard ratios (HRs) in these studies ranged from 2.43 to 5.8, and all the studies had overlapping 95% confidence intervals (Table 8).

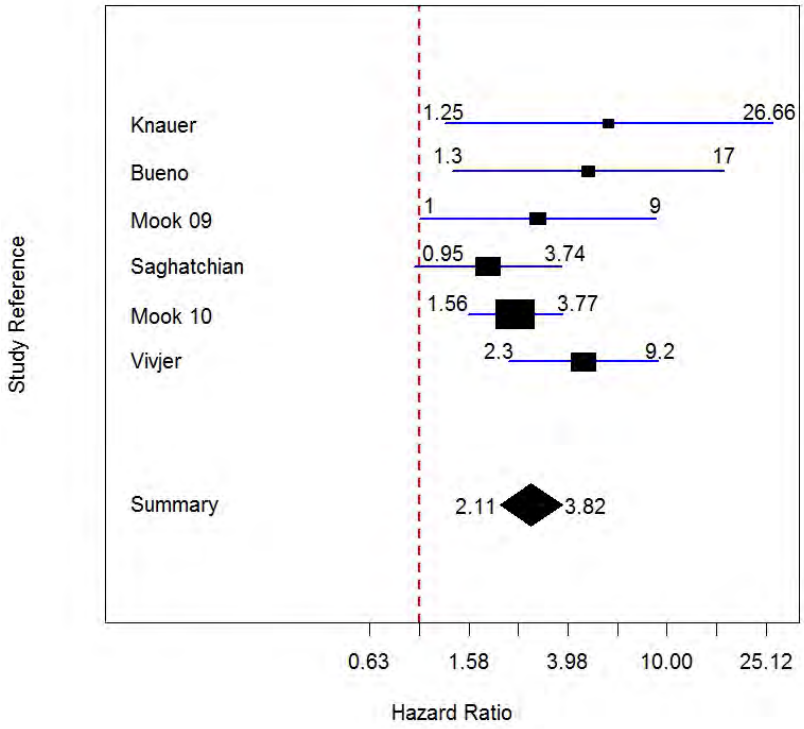
Table 8. Breast Cancer: MammaPrint risk of distant metastasis-free survival

Author, Year, Design, N, Risk of Bias	Adjusted HR (95% CI), p-value	Variables Used in Multivariate Model
Knauer, 2010[62] Cohort 89 Low	DMFS HR: 5.8 (1.25 to 26.66) p=0.025	Age at diagnosis, tumor size, number of positive lymph nodes, histological grade (1/2 vs. 3), ER status, progesterone receptor (PR) status, adjuvant hormonal therapy
Bueno-de-Mesquita 2009[59] Cohort 151 Low	DMFS RS in NKI-RdGG series HR: 4.8 (1.3 to 17) RS in updated validation series HR: 5.3 (95% CI: 2.4 to 12)	Performance of 70-gene prognosis signature vs. performance of predictor with results for 4 different models; results from Adjuvant! Online
Mook, 2009[63] Cohort 241 Low	DMFS HR: 3.0 (1.0 to 9.0) p=0.05	Age (years); number of positive nodes: 2 vs. 1 and 3 vs. 1; tumor size (20 mm vs. ≤20 mm); histological grade: moderate vs. good, poor vs. good; ER status; HER2 receptor status; surgery (mastectomy vs. breast conservation therapy [BCT]) chemotherapy; endocrine therapy; prognosis signature (poor vs. good signature)
Mook, 2010[64] Pooled analysis of several cohorts 964 Medium	DMFS HR: 2.43 (1.56 to 3.77) p<0.001	Age, histology, tumor size, nodal status, grade, ER status, HER2 status, type of surgery, hormonal therapy (yes/no), chemotherapy (yes/no), 70-gene signature
Saghatchian, in press[68] Cohort 173 Medium	DMFS MammaPrint, low risk vs. high risk, main analysis HR: 1.888 (0.953 to 3.739) p=0.068 DMFS MammaPrint, low risk vs. high risk, subgroup analysis (N=129 women with 4 to 9 positive nodes) 2.698 (1.267 to 5.748) p=0.010	Main analysis: Age, invasive ductal carcinoma, number of positive nodes, grade, ER status, PR status, and HER2 status Subgroup analysis: Age, invasive ductal carcinoma, number of positive nodes, grade
Van de Vijver, 2002[67] Cohort 295 Low	DMFS HR: 4.6 (2.3 to 9.2) p<0.001	Age, lymph node status, diameter of tumor, tumor grade, vascular invasion, estrogen receptor status, mastectomy, chemotherapy, hormonal treatment

Abbreviations: BCT = breast conservation therapy; CI = confidence interval; ER =estrogen receptor; HER2 = Human Epidermal Growth Factor Receptor 2, also known as Neu; HR = hazard ratio; mm = millimeter; N = number; N+ = number positive; NKI-RdGG = the name of a clinical trial; p = probability; PR = progesterone receptor; RS = risk score.

Using a fixed effects model, our meta-analysis found a greater risk of recurrence for the poor prognosis group than for the good prognosis group (HR, 2.84; 95% CI, 2.11 to 3.82; Figure 4).

Figure 4. Prognostic value of MammaPrint for risk of recurrence, meta-analysis of adjusted hazard ratios



MammaPrint: Cancer-Specific Mortality

Five studies (N=1,615) rated as medium RoB reported on CSS for MammaPrint.[62-65,68]

The reported HRs are from models that controlled for traditional prognostic factors such as histology, size, and nodal status. Mook (2010)[65] used Adjuvant! Online that combines various clinic pathological factors to create an RS; the remaining studies included the clinic pathological factors in the model. All studies reported that patients with a poor prognosis signature had a higher cancer-specific mortality rate than those with a good prognosis signature (Table 9).

Table 9. Breast cancer: MammaPrint cancer-specific survival

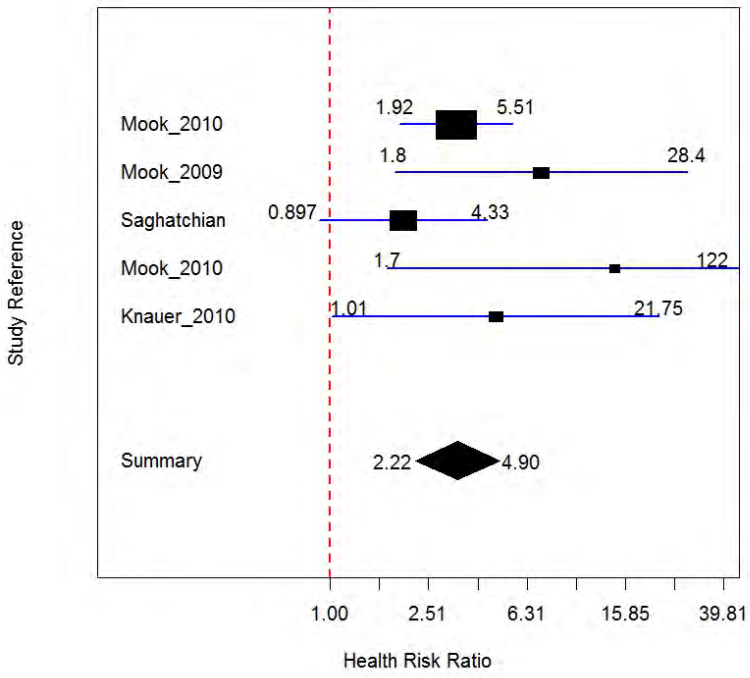
Author, Year, Design, Number of Patients, Risk of Bias	HR (95% CI),	p-value	Variables Used in the Multivariate Model
Knauer, 2010[62] Cohort 89 Medium	4.7 (1.01 to 21.75)	p=0.048	Age at diagnosis, tumor size, number of positive lymph nodes, histological grade (1/2 vs. 3), ER status, PR status, adjuvant hormonal therapy
Mook, 2010[65] Cohort 148 Moderate	14.4 (1.7 to 122) at 5 years	p=0.01	Adjuvant! Online score, which incorporates age, tumor size and grade, lymph node status, health status, hormone receptors
Mook, 2010[64] Pooled analysis of several cohorts 964 Moderate	3.25 (1.92 to 5.51)	p<0.001	Age, histology, tumor size, nodal status, grade, ER status, HER2 status, type of surgery, hormonal therapy (yes/no), chemotherapy (yes/no), 70-gene signature
Mook, 2009[63] Cohort 241 Low	7.2 (1.8 to 28.4)	p=0.005	Age (years), number of positive nodes: 2 vs. 1 and 3 vs. 1, tumor size (20 mm vs. ≤20 mm) Histological grade: moderate vs. good, poor vs. good, ER status, HER2 receptor status, surgery (mastectomy vs. BCT) chemotherapy, endocrine therapy, prognosis signature (poor vs. good signature)
Saghatchian, in press[68] Cohort 173 Medium	MammaPrint, low risk vs. high risk, main analysis 1.971 (0.897 to 4.330)	p=0.091	Main analysis: Age, invasive ductal carcinoma, number of positive nodes, grade, ER status, PR status, and HER2 status
	MammaPrint, low risk vs. high risk, subgroup analysis (N = 129 women with 4 to 9 positive nodes 2.674 (1.069 to 6.685)	p=0.035	Subgroup analysis: Age, invasive ductal carcinoma, number of positive nodes, grade

[a] calculated from years by abstractor

Abbreviations: BCT = breast conservation therapy; CI = confidence interval; ER = estrogen receptor; HER2 = Human Epidermal Growth Factor Receptor 2, also known as Neu; HR = hazard ratio; p = probability; PR = progesterone receptor.

Using a fixed effects model, our meta-analysis found a greater RR for the poor prognosis group than for the good prognosis group (HR, 3.3; 95% CI, 2.22 to 4.9) (Figure 5).

Figure 5. Prognostic value of MammaPrint for cancer-specific survival, meta-analysis of adjusted hazard ratios



MammaPrint: Overall Survival

Only one study[66] with a moderate RoB rating was available to assess the prognostic value of MammaPrint for overall survival (Table 10). The study included 144 patients and did not find a statistically significant association between test result and survival.

Table 10. Breast cancer: MammaPrint overall survival

Author, Year, Design, N, Risk of Bias	Adjusted Ratios (95% CI), p-value	Variables Used in Multivariate Model
Nuyten, 2008[66] Cohort N=144 Moderate	Death: HR:1.67 (0.73 to 3.82) p=0.23	Diameter, grade age; ER status; angio invasion; chemotherapy; hormonal therapy hypoxia-wound signature combination

Abbreviations: CI = confidence interval; ER = estrogen receptor; HR = hazard ratio; p = probability; N = number.

Characteristics of Included Studies Assessing the Clinical Validity of Oncotype DX

We included eight studies[70-77] that reported on the prognostic value of Oncotype DX Breast for RR, CSS, and OS in patients with breast cancer. Six were cohort studies with sample sizes that ranged from 338 to 1,231. Median followup was between 8 and 10 years. Two studies were case-control studies. Five studies were conducted in the United States, one in Japan, and one in

the United Kingdom. Race and ethnicity were not reported for most studies; one study reported enrolling 80 percent non-Hispanic White subjects,[71,72] and one reported enrolling 92 percent White subjects.[76]

All of the cohort studies used tissue collected during large randomized clinical trials. Dowsett[70] used tissue from the ATAC trial; Habel sampled cases and controls from the Kaiser Permanente Tumor registry. Paik (2004)[74] and Tang[76] report on the same 668 patients from the NSABP-14 trial. Mamounas[72] includes the 668 patients used in Paik (2004)[74] and Tang[76] in the 895 patients they report on in their paper. Solin[75] used tissue from the E2197 trial. One of the case-control studies identified 165 cases as those who died from breast cancer, and 401 controls matched by age, race, and calendar year[71]; the other case-control study used 10 cases who had distant metastases and age-matched controls who did not have metastases during the observation period.

Most of the studies included only ER+ patients.[72-74,77] Half of the included studies also restricted enrollment to node-negative subjects[72-74,76] (Table 11).

Table 11. Characteristics of included studies: Oncotype DX for breast cancer

Yorozuya, 2010[77] Case-control Medium	40 (10 cases), 30 controls Median: 232.3 weeks (cases)	Japan	Stage I or IIa, ER+ primary breast cancer	Low (RS<18) Intermediate (RS 18–30) High (RS≥31) (within 2 years)	NR NR	Cases mean (range): 49.1 (37 to 76) Controls mean (range): 50.9 (37 to 78) 100%

[a] Risk score was a continuous variable, with the HR for distant recurrence calculated relative to an increment of 50 units (e.g., the HR for Risk Score=55 vs. Risk Score=5), chosen to be consistent with prior clinical validation studies.

[b] RI-PCT had a range from 0 to 100; it was by 50 and rescaled to a range from 0 to 2 in regression analyses so that the associated HRs were comparable to those HRs associated with clinicopathologic factors.

Abbreviations: cm = centimeter; ER = estrogen receptor; MUT = mutation; N = number; NR = not reported; RS = risk score.

Oncotype DX: Risk of Recurrence

Six cohort studies[70,72,74-77] with low or medium RoB rating (total N=3,222 patients) and a case-control study with 40 patients (10 cases with recurrence and 30 controls) reported on the prognostic value of Oncotype for RR in breast cancer.

Dowsett,[70] Paik (2004),[74] Tang,[76] and Yorozuya[77] all used distant recurrence as the primary endpoint. Solin[75] and Mamounas[72] used loco or loco-regional recurrence (LRR) as the primary end point. All of the included studies reported on the prognostic value of Oncotype DX after controlling for traditional prognostic factors such as stage, size, and differentiation, for example. The number of variables in the models varied across the studies, and a couple looked at the effect of controlling for several combinations of prognostic factors (Table 12). A high RS was consistently shown to be a predictor of distant recurrence but not for LRR.

Table 12. Breast cancer: Oncotype DX risk of cancer recurrence (disease-free survival, recurrence-free survival, distant metastasis-free survival)

Author, Year, Design, Number of Patients, Risk of Bias	Adjusted Ratios(95% CI), p-values	Variables Used in Multivariate Model
Dowsett, 2010[70] Cohort 1,231 Moderate	Distant recurrence N0 patients: HR: 5.25 (2.84 to 9.73) p<0.001 N+ patients: HR: 3.47 (1.64 to 7.38) p=0.002	Tumor size (>2 vs. ≤2 cm); central grade (moderate vs. well, and poor vs. well); age (<65 vs. ≥65); positive nodes (≥4 vs. 1–3 nodes); positive nodes variable only included in analyses for N+ patients
Mamounas, 2010[72] Cohort 895 qwModerate	RS as a continuous variable calculated relative to an increment of 50 units: LRR HR: 2.16 (1.26 to 3.68) p=0.005 Intermediate vs. low risk: HR: 2.16 (0.98 to 4.75) p=0.143 High vs. low risk: HR: 1.67 (0.78 to 3.58) p=NR	Age (≥50 vs. <50); mastectomy vs. lumpectomy and radiation therapy; clinical tumor size (>2 vs. ≤2 cm); tumor grade (moderate vs. well); tumor grade (poor vs. well)

Table 12. Breast cancer: Oncotype DX risk of cancer recurrence (disease-free survival, recurrence-free survival, distant metastasis-free survival) (continued)

Author, Year, Design, Number of Patients, Risk of Bias	Adjusted Ratios(95% CI), p-values	Variables Used in Multivariate Model
Paik 2004[74] Cohort 668 Medium	RS Distant recurrence HR:3.21 (2.23 to 4.61) p<0.001	Age, tumor size, RS
Solin 2012[75] Cohort 388 Medium	NR NS for local or LRR	Chemotherapy arm, patient age, HR status, pathologic axillary lymph node status, histologic grade, pathologic T stage, biologic subtype, and 21-gene RS
Tang, 2011[76] Cohort 668 Low	Distant recurrence RS-PCT/50 Model 4: HR: 2.83 (95% CI: 1.91 to 4.18) p<0.001 Model 5: HR: 2.37 (95% CI, 1.58 to 3.55) p<0.001 Model 6: HR: 2.34 (95% CI, 1.56 to 3.5) p<0.001	Model 4: Adjuvant! Online score (RI) as a composite covariate representing common prognostic factors Model 5: included Adjuvant! Online score (RI); also included common prognostic factors as individual covariates including: age (>50 vs. ≤50); tumor size (cm); grade (moderate vs. well); grade (poor vs. well); RI-PCT/50 Model 6: included only individual prognostic factors as covariates including age (>50 vs. ≤50); tumor size (cm); grade (moderate vs. well); grade (poor vs. well); RI-PCT/50
Yorozuya, 2010[77] Case-control 40 (10 cases), 30 controls) Moderate	OR: 2.85 (95% CI: 0.07 to 115.5) p=0.579	Age at diagnosis; ER score; PgR score; RS 50 or more vs. RS<50; histological grade lymphatic invasion

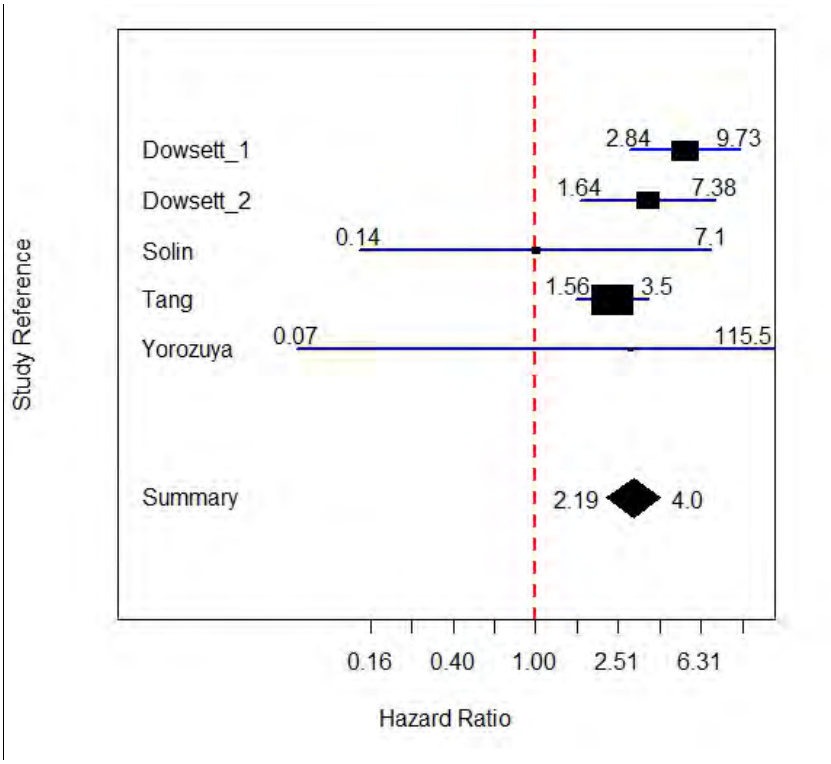
[a] Calculated from years by abstractor

Abbreviations: CI = confidence interval; cm = centimeter; ER = estrogen receptor; HR = hazard ratio; LRR = loco-regional recurrence; N+ = number positive; N0 = node negative; NR = not reported; OR = odds ratio; p = probability; PgR =progesterone receptor; RI = risk index; RI-PCT = risk index percentile; RS = risk score; RS-PCT = risk score percentile; vs. = versus.

Mamounas[72] and Solin[75] reported that the RS was not a significant predictor of the risk of LRR. Paik and Tang used the same set of patients but fitted different models to assess the prognostic value of the Oncotype DX RS in predicting distant recurrence. Models reported in Paik[74] and Tang[76] found statistically significant HRs between 2.3 and 3.1. Dowsett[70] reported a significant HR for both node-negative (5.25) and node-positive patients (3.47). The case-control study reported that cases having a distant recurrence had a higher RS than age-matched controls with no distant metastasis.

In a fixed effects model, our meta-analysis found an overall HR for RR for the high RS group compared with the intermediate/low RS group of 2.97 (95% CI, 2.19 to 4.0) (Figure 6).

Figure 6. Prognostic value of Oncotype DX Breast for risk of recurrence, meta-analysis of adjusted hazard ratios



Oncotype DX: Cancer-Specific Survival

We found two included studies rated as low RoB that reported on the prognostic value for CSS. One was a cohort study, Tang,[76] that included 668 patients, and one was a case-control study, Habel,[71] that included 566 patients. Tang[76] fit several models to the data and reported HRs ranging from 2 to 2.45, depending on the prognostic variables controlled for. Habel[71] reported that both tamoxifen-treated and tamoxifen-untreated breast cancer patients who died had higher RSs than matched patients who survived (Table 13).

Table 13. Breast cancer: Oncotype DX cancer-specific survival

Author, Year, Design, Number of Patients, Risk of Bias	Adjusted Risk (95% CI), p-value	p-value	What Variables Were Used in the Multivariate Model?
Habel, 2006[71] Case-control 566 Low	RS: Tamoxifen treated RR: 5.3 (1.6 to 17.2) p=0.003 Tamoxifen untreated RR: 2.4 (1.1 to 5.2) p=0.03	NR	Tumor size continuous (cm); grade (well, moderate, poor); RS (continuous)
Tang, 2011[76] Cohort 668 Low	RS-PCT/50 Model 4: HR: 2.45 (1.66 to 3.61) p<0.001 Model 5: HR: 2.02 (1.35 to 3.00) p<0001 Model 6: HR: 2.01 (1.35 to 2.98) p<0.001	NR	Model 4: Adjuvant! Online score (RI) as a composite covariate representing common prognostic factors but did not also include those factors individually Model 5: included Adjuvant! Online score (RI); also included common prognostic factors as individual covariates including age (>50 vs. ≤50); tumor size (cm); grade (moderate vs. well); grade (poor vs. well); RI-PCT/50 Model 6: included only individual prognostic factors as covariates including age (>50 vs. ≤50), tumor size (cm), grade (moderate vs. well), grade (poor vs. well), RI-PCT/50

[a] calculated from years by abstractor

Abbreviations: cm = centimeter; HR = hazard ratio; p = probability; RI = risk index; RI-PCT = risk index percentile; RR = relative risk; RS = risk score; RS-PCT = risk score percentile.

One cohort study, Tang,[76] rated as low RoB, was available. Tang fitted models with different combinations of adjustments for traditional prognostic factors. The HRs were of a similar magnitude in all three models, and the association between high RS and earlier death from all causes was positive and significant (Table 14).

Table 14. Breast cancer: Oncotype DX—overall survival

Author, Year, Design, N, Risk of Bias	Median Length of Followup to Determine Recurrence/Survival	Adjusted Ratio (95% CI), p-values	Variables Used in Multivariate Model
Tang, 2011[76] Cohort N=688 Low	14.3 years (range: NR)	RS-PCT/50 Model 4: HR: 1.77 (1.35 to 2.33) p<0.001 Model 5: HR: 1.65 (1.24 to 2.19) p<0.001 Model 6: HR: 1.65 (1.24 to 2.19) p<0.001	Model 4: Adjuvant! Online score (RI) as a composite covariate representing common prognostic factors but did not also include those factors individually Model 5: included Adjuvant! Online score (RI); also included common prognostic factors as individual covariates including age (>50 vs.≤50), tumor size (cm), grade (moderate vs. well), grade (poor vs. well), RI-PCT/50 Model 6: included only individual prognostic factors as covariates including: age (>50 vs.≤50), tumor size (cm), grade (moderate vs. well), grade (poor vs. well), RI-PCT/50

Abbreviations: CI = confidence interval; HR = hazard ratio; p = probability; NR = not reported; RI = risk index; RI-PCT = risk index percentile; RS = risk score; RS-PCT = risk score percentile.

Lung Cancer: *EGFR* and *KRAS* Mutations

Characteristics of Included Studies Assessing the Clinical Validity of *EGFR* Mutation Testing

We found 12 studies[78-89] that examined the added prognostic value of *EGFR* mutations in patients with nonsmall cell lung carcinoma (NSCLC). All were cohort studies. Sample sizes ranged from 50 to 524 patients. Median followup was not reported in all studies. Followup varied from 4 to 14 years. Studies were conducted in Japan, South Korea, Taiwan, China, various European countries, and the United States.

All studies primarily compared outcomes of patients with *EGFR* wild-type to those with *EGFR* mutations. A few looked at specific mutations such as the exon 19 deletion or the exon 21 L858R. The representation of female patients in the studies ranged from a low of 16 percent to a high of 65 percent. Race or ethnicity was reported only in two studies[84,89] conducted in the United States and Canada; Mak[84] and Tsao[89] had samples with 93 percent and 44 percent white patients, respectively.

Populations represented in the studies varied somewhat. The differences were both in cancer stage and cancer type. Four studies included all four stages,[78-80,88] three included stages I to III,[82,83,86] two included only stage I,[81,85] and the remaining included stages I and II. Not all studies specify the type of tumors included (Table 15).

Table 15. Characteristics of included studies: *EGFR mutation testing for lung* cancer

Abbreviations: *EGFR* = gene name; IQR = interquartile range; mm = millimeter; MUT = mutation; N = number; NR = not reported; SD = standard deviation; WT = wild-type.

EGFR Mutation: Risk of Recurrence

Six cohort studies[80,81,84,87-89] (total N=1,870) assessed the prognostic value of this test for RR. Kobayashi[81] used recurrence as the outcome; Mak[84] looked at LRR and distant recurrence but provided adjusted results only for LRR. Scoccianti[87] used time to disease progression as the outcome. Tsao[89] used relapse-free survival as the outcome. Kim[80] used freedom from recurrence as the outcome. Three[80,81,89] of the five studies did not specify whether the outcome was loco–regional or distant or both.

Although the HRs for *EGFR* mutation suggest a protective effect (i.e., were all <1), none of the findings were statistically significant. Thus, the test for *EGFR* mutations does not appear to have prognostic value in predicting recurrence in NSCLC (Table 16).

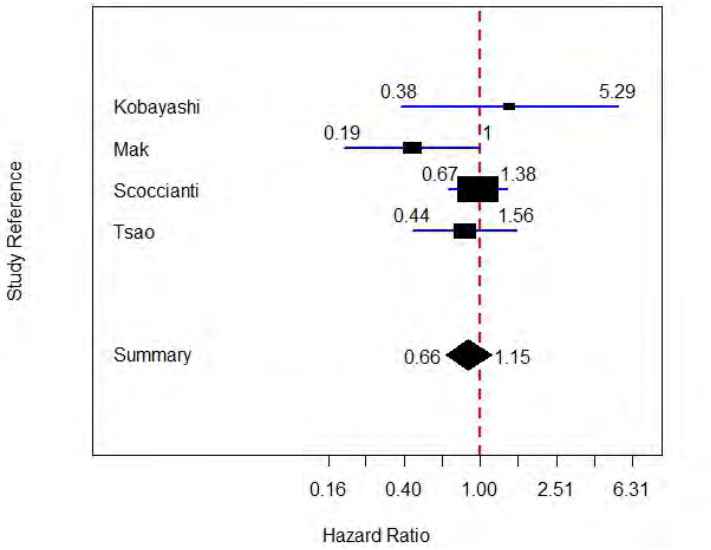
Table 16. Lung cancer: Risk of cancer recurrence/disease-free survival/recurrence-free survival for *EGFR*

Author, Year, Design, N, Risk of Bias	Adjusted Ratios, (95% CI) p-value Test Positive, Test Negative	Variables Used in Multivariate Model
Kim, 2008[80] Cohort 71 Medium	Freedom from Recurrence HR: NR, p=NS	Male, age >60 years, smoking+, BAC feature+, ≥Stage IIIA, *KRAS*+, EFGR−
Kim,2013[88] Cohort863 Medium	Freedom from recurrence EGFR NS	BAC, age, smoking, pathologic stage, cell type
Kobayashi, 2008[81] Cohort 127 Medium	Risk of cancer recurrence: HR: 1.42 (0.38 to 5.29) p=0.60 DFS: HR: 1.55 (0.54 to 4.49) p=0.42	Age (≥64 vs. <64); sex; smoking status (ever vs. never); CEA level (≥5.0 vs. <5.0); tumor size ≥15 vs. <15); non-BAC component (>50% v. ≤50%); *EGFR* mutation (yes or no)
Mak, 2011[84] Cohort 123 Medium	LRR HR: 0.44 (0.19 to 1.00) p=0.05	*EGFR* mutation status, stage, use of surgery, chemotherapy use, RT dose, primary tumor size
Soccianti, 2012[87] Cohort 250 Medium	Time to Disease Progression HR: 0.97 (0.67 to 1.38) p=0.68	Pathological tumor score, pathological node score
Tsao, 2011[89] Cohort 436 Low	RFS: HR: 0.83 (0.44 to 1.56) p=0.56	Sex, age, performance status, stage, histology, smoking status, baseline anemia, resection, serum LDH, p53 mutation status, and immunohistochemistry

Abbreviations: BAC = bronchioloalveolar cancer; CEA = carcinoembryonic antigen; CI = confidence interval; CISH = cytokine-inducible SH2-continaing protein; DFS = disease-free survival; *EGFR* = gene name; HR = hazard ratio; *KRAS* = gene name; LDH = lactate dehydrogenase; LRR = loco-regional recurrence; NR = not reported; NS = not statistically significant; p = probability; RFS = recurrence-free survival; RT = radiation therapy.

Using a fixed effects model, our meta-analysis, which included the four studies that reported HRs, found no added prognostic value for the *EGFR* mutation in predicting risk of recurrence HR: 0.87 95% CI (0.65 to 1.15) (Figure 7).

Figure 7. Prognostic value of *EGFR* mutation testing for risk of recurrence in lung cancer, meta-analysis of adjusted hazard ratios



EGFR Mutation: Cancer-Specific Survival

We found no studies meeting our inclusion criteria.

EGFR Mutation: Overall Survival

Six studies[81,83-85,88,89] representing 1,820 patients reported on the prognostic value of *EGFR* mutation for this outcome. One of the studies did not report any quantitative measures and therefore did not contribute to our strength of evidence determination. All studies looked at the prognostic value of the test in patients with NSCLC.

None of the included studies found a statistically significant HR for overall survival. The magnitude ranged from 0.6 to 1.6 in studies that reported quantitative measures. The other studies only reported that the result was not statistically significant (Table 17).

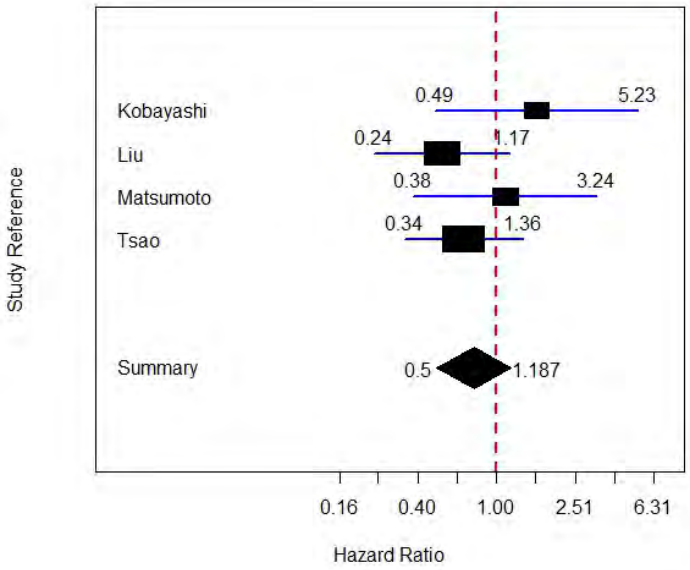
Table 17. Lung Cancer: *EGFR* mutation testing overall survival

Author, Year, Design, Risk of Bias	Adjusted Ratios, (95% CI) p-value Test Positive, Test Negative	Variables Used in Multivariate Model
Kim, 2013[88] Cohort 863 Medium	EGFR NR p=NS	BAC, Gender, age, pathologic stage, and smoking status
Kobayashi, 2008[81] Cohort 127 Medium	HR: 1.60 (0.49 to 5.23) p=0.44	Age (≥64 v. <64); sex; smoking status (ever vs. never); CEA level (≥5.0 vs. <5.0); tumor size (≥15 vs. <15); non-BAC component (>50% vs. ≤50%); *EGFR* mutation (yes or no)
Liu, 2010[83] Cohort 164 Medium	HR: 0.53 (95% CI, 0.24 to 1.17), p=NR	Year group, gender, age, pathology, stage, smoking status, CISH, *KRAS* mutation status, *EGFR* mutation expression
Mak, 2011[84] Cohort 123 Medium	HR: NR p=NS	*EGFR* mutation status, age, stage, PS score, smoking status, use of surgery, chemotherapy use, RT dose, primary tumor size (i.e., all outcomes that were significantly different between groups)
Matsumoto, 2006[85] Cohort 107 Medium	HR: 1.11 (0.38 to 3.24) p=0.85	Adjusted by all potential prognostic factors including gender, age, smoking status, tumor stage, tumor size, differentiation, *KRAS* status
Tsao, 2011[89] Cohort 436 Low	HR: 0.68 (0.34 to 1.36) p=0.28	Sex, age, performance status, stage, histology, smoking status, baseline anemia, type of resection, serum lactate dehydrogenase, p53 mutation status, and p53 immunohistochemistry

Abbreviations: BAC = bronchioloalveolar cancer; CI = confidence interval; CISH = cytokine-inducible SH2-continaing protein; *EGFR* = gene name; HR = hazard ratio; *KRAS* = gene name; NR = not reported; NS = not statistically significant; OS = overall survival; p = probability; PS = performance status; RT = radiation therapy.

Using a fixed effects model, our meta-analysis, which included the four studies that reported HRs, found no added prognostic value for the *EGFR* mutation in predicting overall survival HR, 0.77; 95% CI (0.50 to 1.19) (Figure 8).

Figure 8. Prognostic value of *EGFR* mutation testing for overall survival in lung cancer, meta-analysis of adjusted hazard ratios



Characteristics of Included Studies Assessing the Clinical Validity of *KRAS* Mutation testing

We found six studies[79,80,83,86,87,90] that examined the added prognostic value of *KRAS* mutations on the RR, CSS, and OS in patients with NSCLC. All were cohort studies with sample sizes that ranged from 100 to 250 patients. Studies were conducted in Japan, South Korea, Taiwan, and various European countries. Race/ethnicity was not reported in any of the studies. All studies compared outcomes of patients with *KRAS* wild-type with those with *KRAS* mutations. The representation of female patients in the studies ranged from a low of 16 percent to a high of 59 percent. Median length of follow-up was not available in all studies. Length of follow-up ranged from 4 to 14 years.

Populations represented in the studies varied somewhat. The differences were both in cancer stage and cancer type. Three studies included all stages.[79,80,87] Two included stages I to III,[83,86] and one[90] included only stage I (Table 18).

Table 18. Characteristics of included studies: *KRAS* mutation testing for nonsmall cell lung cancer

Abbreviations: IQR = interquartile range; *KRAS* = gene name; MUT = mutation; N = number; NR = not reported; SD = standard deviation; WT = wild-type.

KRAS Mutation: Risk of Recurrence

Four studies[80,86,87,90] examining five cohorts(total N=611) rated as low or medium RoB assessed the prognostic value for RR (Table 19). Kim[80] and Scoccianti[87] studied

NSCLC, whereas Woo[90] studied the effect of the mutation specifically on stage I adenocarcinomas.

Table 19. Lung cancer: *KRAS* risk of cancer recurrence/disease-free survival/recurrence-free survival

Author, Year, Design, N, Risk of Bias	Adjusted Ratios, (95% CI) p-value Test Positive, Test Negative	Variables Used in Multivariate Model

Woo, 2009[90] Cohort 1A N = 131 Cohort 1B N = 59 Medium	DFS For stage IA: HR: 4.55, (1.61 to 12.82) p=0.004 For Stage IB: HR: 14.99 (1.55–145.21) p=0.019	Age, tumor size, vessel invasion, Ki-67 expression

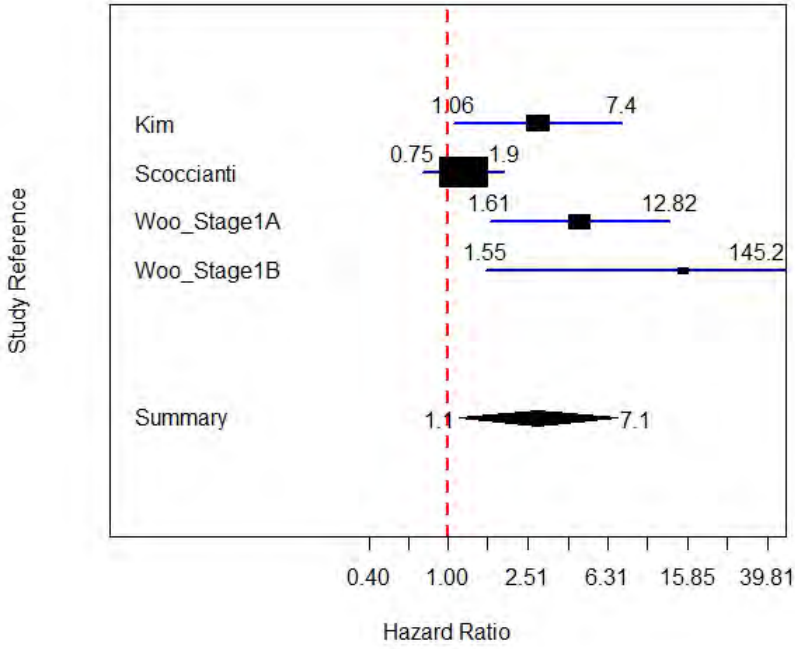
Abbreviations: BAC = bronchioloalveolar cancer; CI = confidence interval; CISH = cytokine-inducible SH2-containing protein; *EGFR* = gene name; HER2 = Human Epidermal Growth Factor Receptor 2, also known as Neu; HR = hazard ratio; *KRAS* = gene name; NR = not reported; OR = odds ratio; p = probability.

Kim[80] used freedom from recurrence as the outcome; the publication did not specify whether the recurrence was restricted to loco-regional or distant recurrence. Scoccianti[87] used time to disease progression as the outcome. Woo[90] also used disease-free recurrence as the outcome and did not specify if this was restricted to loco-regional or distant recurrence. Rouquette[86] used disease-free survival as the outcome and defined it as relapse, metastases, or death by any cause, whichever occurred first.

Rouquette[86] and Scoccianti[87] reported that *KRAS* mutation did not have added prognostic value. However, Kim[80] and Woo[90] reported that *KRAS* is a significant predictor for RR after controlling for other prognostic factors; the HRs range between 2.8 and 4.55.

Using a random effects model, our meta-analysis found added prognostic value of *KRAS* for risk of recurrence (HR, 2.84; 95% CI, 1.14 to 7.10) (Figure 9).

Figure 9. Prognostic value of *KRAS* mutation testing for risk of recurrence in lung cancer, meta-analysis of adjusted hazard ratios



KRAS Mutation: Cancer-Specific Survival

We found no studies meeting our inclusion criteria.

KRAS Mutation: Overall Survival

Two studies[80,91] with 253 patients reported that *KRAS* testing had added prognostic value for OS (Table 20).

Table 20. Lung cancer: *KRAS* overall survival

Colorectal Cancer—*BRAF* Mutation

Characteristics of Included Studies Assessing the Clinical Validity of *BRAF* Mutation Testing

We included 17 studies[92-108] that examined the added prognostic value of *BRAF* mutations for RR, CSS, and OS in patients with CRC. All were cohort studies. Sample sizes ranged from 69 to 1,680. Median followup ranged from 3 to 8 years. Studies were conducted in Australia, China, various European countries, and the United States.

All studies compared outcomes of patients with *BRAF* wild-type to those with *BRAF* V600 mutations. The representation of female patients in the studies ranged from 2 percent to 53.6 percent. Race or ethnicity was not reported in most studies; one reported enrolling 98 percent white patients.[102]

Populations represented in the studies varied somewhat. The differences were both in cancer stage and the inclusion or exclusion of rectal cancers. Two studies[92,109] examined a sample of stage I and stage III colon cancers. Nine[93,94,99,102-106,108] included all stages and colon and rectal cancers. Two[95,102] included all stages of colon (not rectal) cancers. In the rest, one study[96] included both colon and rectal cancers stages I through III, another[97] had only stage III colon cancer patients, one study[98] included patients with only proximal colon cancer stages I through IV, and two[100,107] included stages II and III colon cancer (Table 21).

BRAF: Risk of Recurrence

Five cohort studies[92,97,100,103,107] rated as low or medium RoB (total N=4,106) examined the prognostic significance of the *BRAF* mutation for RR (Table 22). The definitions for the outcomes differed a little between the studies. Farina[92] defined disease-free survival (DFS) as time to recurrence of disease or distant metastasis; Ogino[97] defined DFS as time to disease recurrence or distant metastasis or death from any cause; Roth (2010),[100] Roth (2012)[107] and Tie[103] defined their outcome as recurrence of CRC and did not specify if recurrence includes local and distant.

Table 22. Colorectal cancer: *BRAF* risk of cancer recurrence/disease-free survival/recurrence-free survival

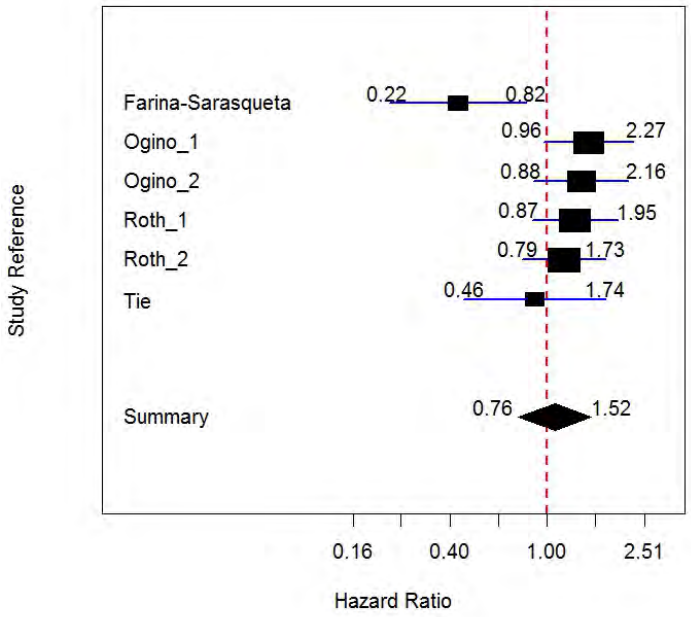
Author, Year, Design, N Test (Cancer), Risk of Bias	Adjusted Ratios, (95% CI) p-value	Variables Used in Multivariate Model
Farina-Sarasqueta, 2010[92] Cohort 364 Low	DFS HR=0.43 (0.22 to 0.82) p=NR	Differentiation grade, age, sex, tumor location, tumor stage, node stage, *KRAS* status, *BRAF* status, and MSI status
Ogino, 2012[97] Cohort 506 Medium	DFS HR: 1.48 (0.96 to 2.27) p=NR RFS HR: 1.38 (0.88 to 2.16) p=NR	Age, sex, baseline body mass index (BMI), family history of CRC in first-degree relatives, performance status, presence or absence of perforation and/or obstruction at surgery, treatment arm, tumor location, tumor and node stage, *KRAS* status, MSI status
Roth, 2010[100] Cohort 1307 Medium	RFS, All subjects HR: 1.30 (0.87 to 1.95) p=0.21 Stage II subjects HR: 1.93 (0.67 to 5.60) p=0.23 Stage III subjects HR: 1.23 (0.79 to 1.92) p=0.35	Treatment arm, age, sex, grade, tumor site, nodal stage, MSI, *KRAS*, *BRAF* mutation status
Roth, 2012[107] Cohort 1404 Medium	RFS, HR: 1.17 (0.79 to 1.73) p=0.44	Age, sex, grade, stage, number of examined lymph nodes, site, treatment group, MSI status, SMAD4 expression, 18qLOH status, and KRAS
Tie, 2011[103] Cohort 525 Medium	RR HR: 0.89 (0.46 to 1.74) p=0.74	Age, gender, stage, tumor site, use of adjuvant therapy

Abbreviations: BMI = body mass index; *BRAF* = gene name; CI = confidence interval; CRC = colorectal cancer; DFS = disease-free survival; HR = hazard ratio; *KRAS* = gene name; MSI = microsatellite instability; N = number; NR = not reported; p = probability; RFS = recurrence-free survival; RR = risk of recurrence.

The included studies reported on the prognostic value of testing for *BRAF* after controlling for certain traditional prognostic factors such as stage, sex, and age. Three of the four studies found no association between *BRAF* and prognosis in adjusted analyses. Farina[92] reported a significant association (HR, 2.32; 95% CI, 1.21 to 4.54) between RR and the *BRAF* mutation.

Using a random effects model, our meta-analysis found no added prognostic value of *BRAF* for risk of recurrence (HR, 1.07; 95% CI, 0.76 to 1.52) (Figure 10).

Figure 10. Prognostic value of *BRAF* mutation testing for risk of recurrence in colorectal cancer, meta-analysis of adjusted hazard ratios



BRAF for Colorectal Cancer: Cancer-Specific Mortality

Seven studies reporting on eight different cohorts with low or medium RoB (total N=5,409) reported on *BRAF* mutation and CSS.[92,95,96,99,105,106,108] Five out of seven cohorts had statistically significant HRs, suggesting a positive association between mutation and greater risk of cancer-specific death (Table 23). A summary measure was estimated using a fixed effects model. The overall HR for CSS for the patients with wild-type compared with mutated was 1.50, 95% CI (1.26 to 1.77) (Figure 11).

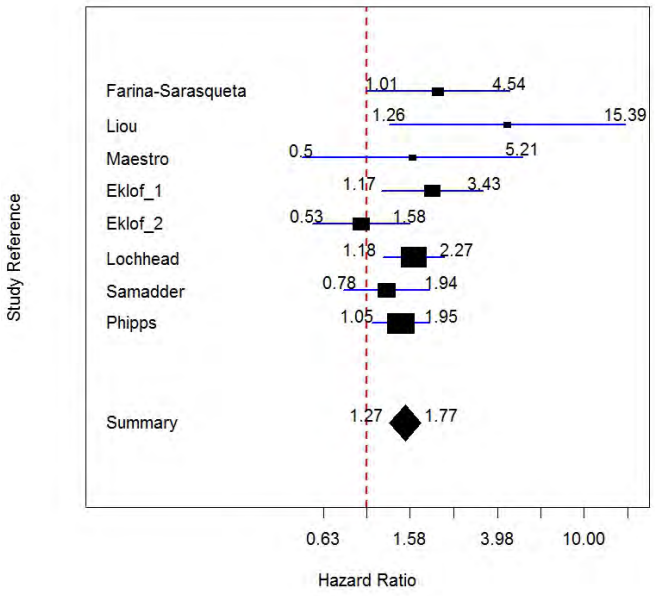
Figure 11. Prognostic value of *BRAF* mutation testing for cancer-specific survival in colorectal cancer, meta-analysis of adjusted hazard ratios



BRAF for Colorectal Cancer: Overall Survival

Eleven studies with twelve cohorts rated as low or medium RoB reported on prognostic value of *BRAF* for OS in patients with CRC[92,94,95,97,99,100,102,103,105-107] (total N=7,610) (Table 24).

Nine out of twelve cohorts reported significant associations between *BRAF* mutation status and survival. The summary HR for overall survival used a fixed effects model for patients with wild-type compared with those with *BRAF* mutations of 1.45 (1.3 to 1.62) (Figure 12).

Table 24. Colorectal cancer: *BRAF* overall survival

Author, Year, Design, Risk of Bias	Adjusted Ratios, (95% CI) p-value	Variables Used in Multivariate Model
Farina-Sarasqueta, 2010[92] Cohort 364 Low	*BRAF* HR: 2.22 (1.25 to 4) p<0.05	Differentiation grade, age, sex, tumor location, tumor stage, node stage, *KRAS* status, *BRAF* status, and MSI status

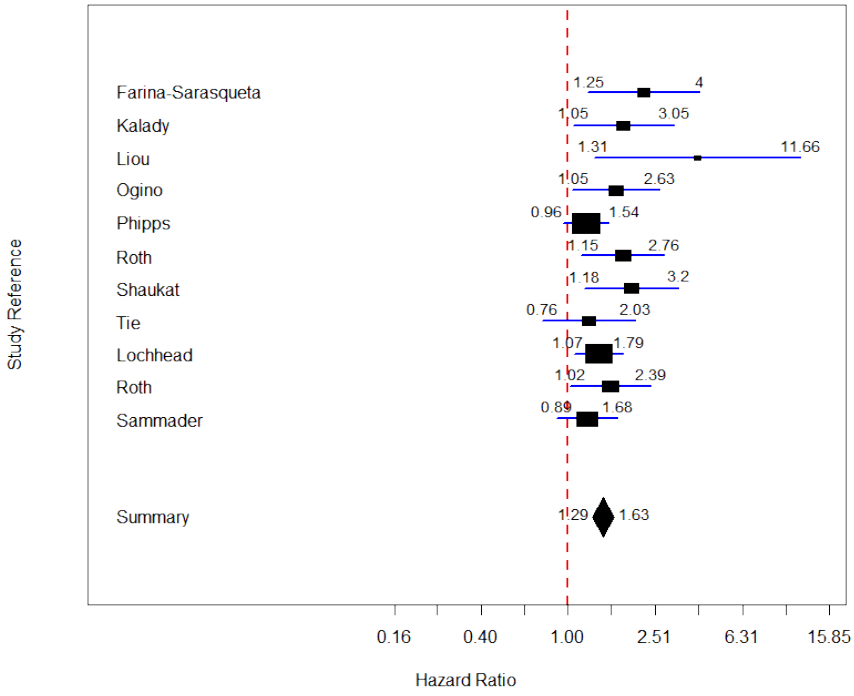
Figure 12. Prognostic value of *BRAF* mutation testing for overall survival in colorectal cancer, meta-analysis of adjusted hazard ratios



Colorectal Cancer: *KRAS* Mutation

Characteristics of Included Studies Assessing the Clinical Validity of *KRAS* Mutation Testing

The genetic test for *KRAS* mutations described here checks for mutations in codons 12 and 13 in the *KRAS* gene. We included 14 cohort studies[92,95,98,100,103,106-114] that examined the effect of *KRAS* mutations on the RR, CSS, or OS in patients with CRC (Table 25). Sample sizes ranged from 135 to 1,404. Median followup was between 3 to 12 years. Studies were conducted in Australia, China, various European countries, and the United States.

Table 25. Characteristics of included studies: *KRAS* mutation testing for colorectal cancer (continued)

Author, Year Study Type Risk of Bias	N Length of Followup	Country(ies)	Disease Stage(s) Other Tumor/ Disease Characteristics	Study Groups	Race Ethnicity	Overall Age (years) % Female
Tie, 2011[103] Cohort Medium	510 Median 38.5 months (recurrence) Median 12.9 months (overall survival)	Australia	I–IV	*KRAS*-WT *KRAS*-MUT	NR	*KRAS*-WT median: 70.7 *KRAS*-MUT median: 70.4 *KRAS*-WT: 68% *KRAS*-MUT: 32%

Abbreviations: IQR = interquartile range; *KRAS* = gene name; MUT = mutation; N = number; NR = not reported; SD = standard deviation; WT = wild-type.

All studies compared outcomes of patients with *KRAS* wild-type with those who had *KRAS* mutations. Some also looked at mutations in codon 13 and the mutation from G to C/t and G to A. The representation of female patients in the studies ranged from 42 percent to 55 percent. Race or ethnicity was not reported in any of the studies.

Populations represented in the studies varied somewhat. The differences were both in cancer stage and the inclusion or exclusion of rectal cancers. Five studies[103,107-112,114] included all stages and colon and rectal cancers. Among the rest, one[95] included all stages of colon (not rectal) cancers, another[92] examined a sample of stage II and stage III colon cancers, and Maestro[96] included stages I to III and both colon and rectal cancers. Ogino[97] had only stage three colon cancer patients, Pai[98] studied proximal colon stages I through IV, and Roth[100] included stage II and III colon cancer.

KRAS for Colorectal Cancer: Risk of Recurrence

Five cohort studies (total N=4,085) rated as low or medium RoB[92,100,103,107,113] examined RR as an outcome (Table 26). Farina[92] defined DFS as time to recurrence of disease or distant metastasis; Ogino[113] defined DFS as time to disease recurrence or distant metastasis or death from any cause; Roth[100] did not define their outcome of relapse-free survival but presumably included loco-regional and distant recurrence; and Tie[103] defined their outcome as recurrence of CRC, which presumably means loco-regional and distant recurrence.

Table 26. Colorectal cancer: *KRAS* risk of cancer recurrence/disease-free survival/recurrence-free survival

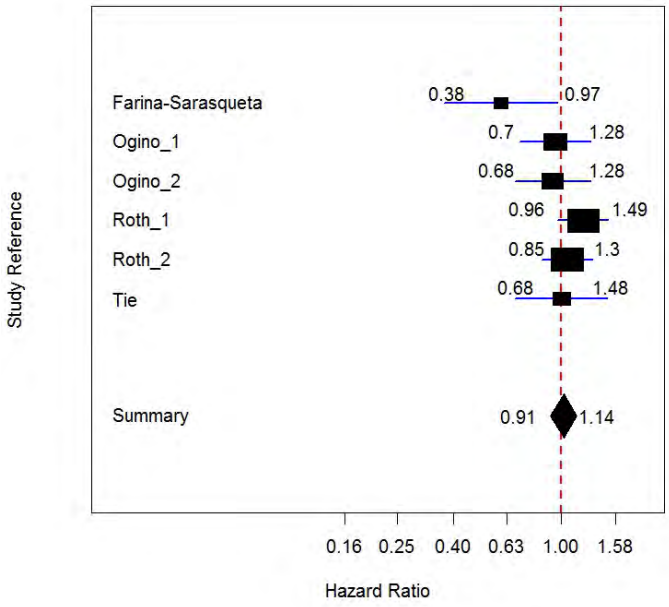
Author, Year, Design, N, Test (Cancer), Risk of Bias	Adjusted Ratios, (95% CI) p-value	Variables Used in Multivariate Model
Farina-Sarasqueta, 2010[92] Cohort 364 Low	DFS HR: 0.6 (0.38 to 0.97) p=NR	Differentiation grade, age, sex, tumor location, tumor stage, node stage, *KRAS* status, *BRAF* status, and MSI status
Ogino, 2009[113] Cohort 508 Medium	DFS: HR: 0.95 (0.70 to 1.28) p=NR RFS: HR: 0.93 (0.68 to 1.28) p=NR	Age, sex, BMI, tumor location, tumor and node stage, presence or absence of perforation and/or obstruction at diagnosis, performance status, MSI status, and treatment arm
Roth, 2010[100] Cohort 1,299 Medium	RFS All subjects HR:1.20 (0.96 to 1.49) p=0.11 Stage II subjects HR: 1.26 (0.75 to 2.13) p=0.38 Stage III subjects HR: 1.21 (0.95 to 1.54) p=0.12	Treatment arm, age, sex, grade, tumor site, nodal stage, MSI, *KRAS*, *BRAF* mutation status
Roth, 2012[107] Cohort 1404 Medium	RFS HR: 1.05 (0.85 to 1.30) p=0.65	Age, sex, grade, stage, number of examined lymph nodes, site, treatment group, MSI status, SMAD4 expression, 18qLOH status, and BRAF
Tie, 2011[103] Cohort 510 Medium	RR HR: 1.00 (0.68 to 1.48) p=1.00	Age, gender, tumor site, stage

Abbreviations: BMI = body mass index; *BRAF* = gene name; CI = confidence interval; DFS = disease-free survival; HR = hazard ratio; *KRAS* = gene name; MSI = microsatellite instability; N = number; p = probability; RFS = recurrence-free survival.

The included studies reported on the prognostic value of testing for *KRAS* after controlling for certain traditional prognostic factors such as stage, sex, and age. Three out of the four studies reported no statistically significant association between *KRAS* and prognosis in adjusted analyses. Farina reported a significant association between the *KRAS* wild-type and improved survival.

Our meta-analysis found no significant added prognostic value of *KRAS* mutation testing for RR in patients with CRC HR, 1.02 (95% CI, 0.91 to 1.14) (Figure 13).

Figure 13. Prognostic value of *KRAS* mutation testing for risk of recurrence in colorectal cancer, meta–analysis of adjusted hazard ratios



KRAS for Colorectal Cancer: Cancer-Specific Mortality

We found two studies (N = 1,174) that looked at the prognostic effect of KRAS mutation on CSS. Eklof[108] examined the effect of KRAS on two different populations; the Colorectal Cancer in Umea Study (CRUMS) and the Northern Sweden Health Disease Study (NSHDS). They report a significant HR in CRUMS and a nonsignificant HR in the NHSDS. Sammader reports a nonsignificant HR (Table 27).

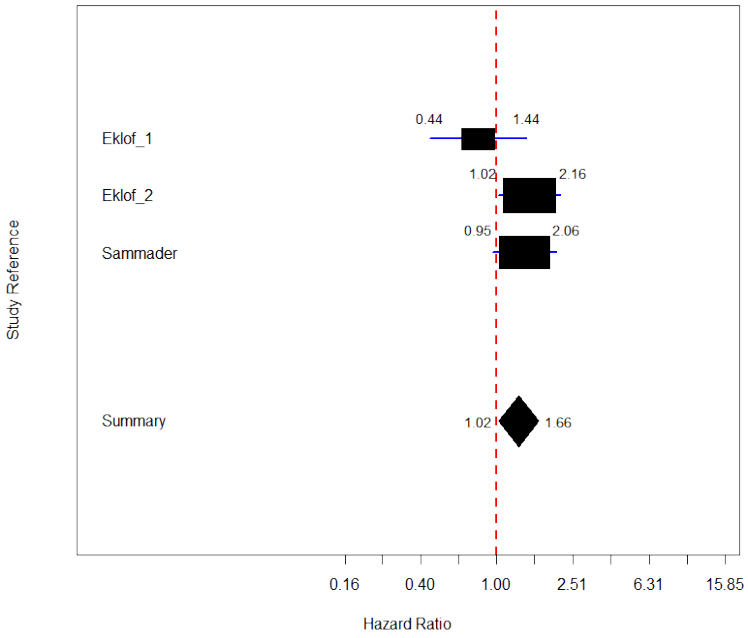
Our meta-analysis found that KRAS mutation has a significant prognostic effect on CSS with a HR of 1.30 (95% CI, 1.02 to 1.66) (Figure 14).

Table 27. Colorectal cancer: *KRAS* cancer-specific survival

Author, Year, Design, Risk of Bias	Adjusted Ratios, (95% CI) p-value	Variables Used in Multivariate Model
Eklof, 2013[108] Cohort 197 (NSHDS) 414 (CRUMS) Medium	(NSDHS, N = 179) HR: 0.798 (0.443 to1.438) p=NR (CRUMS, N = 378) HR: 1.485 (1.023 to 2.15 Colorectal Cancer in Umeå Study (CRUMS)5) p=NR	Sex, age at diagnosis, stage, tumor site
Samadder, 2013[106] Cohort 563 Medium	HR: 1.40 (0.95 to 2.06) p=.08	Age at diagnosis, anatomic subsite, tumor grade, SEER stage, chemotherapy exposure, and radiation therapy exposure

Abbreviations: CRUMS = Colorectal Cancer in Umea Study; HR = hazard ratio; *KRAS* = gene name; N = number; p = probability. NSHDS= Northern Sweden Health Disease Study

Figure 14. Prognostic value of *KRAS* mutation testing for CSS in colorectal cancer, meta–analysis of adjusted hazard ratios



KRAS for Colorectal Cancer: Overall Survival

Ten cohort studies with low or medium RoB[92,95,100,103,106,107,109,111,113,114] (total N=5,328) examined overall survival as an outcome (Table 28). The included studies reported on the prognostic value of testing for *KRAS* after controlling for certain traditional prognostic factors such as stage, sex, and age. Six out of seven studies reported no statistically significant association between *KRAS* mutation status and OS in adjusted analyses. Bazan and Geido[109,111] reported significant associations between *KRAS* gene mutation status and survival.

Our meta-analysis found no significant added prognostic value of *KRAS* mutation testing for OS in patients with CRC HR: 1.22 (0.95, 1.55) (Figure 15).

Table 28. Colorectal cancer: *KRAS* overall survival

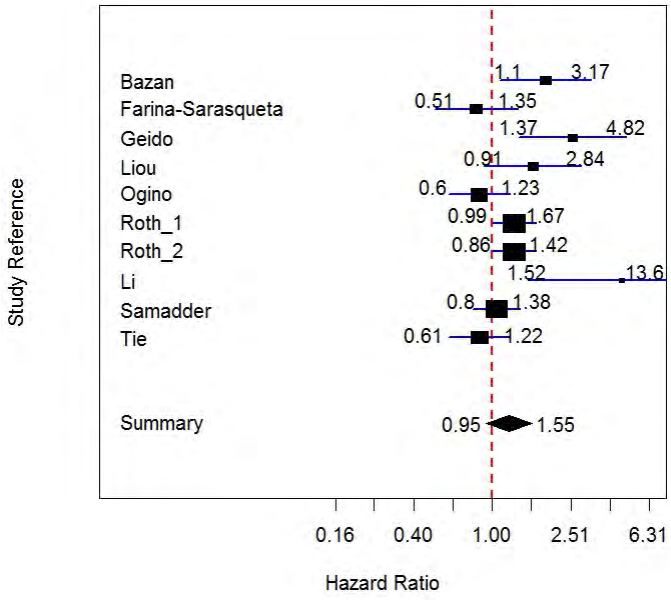
Author, Year, Design, Risk of Bias	Adjusted Ratios, (95% CI) p-value	Variables Used in Multivariate Model
Bazan, 2005[109] Cohort MSI (colorectal) Medium	HR: 1.86 (1.10 to 3.17) p<0.05	Duke's stage, surgical resection, DNA-aneuploidy, high SPF
Farina-Sarasqueta, 2010[92] Cohort 364 Low	HR = 0.83(0.51 to 1.35) p=NR	Differentiation grade, age, sex, tumor location, T stage, nodal stage, *KRAS* status, *BRAF* status, and MSI status
Geido, 2002[111] Cohort 135 Low	Overall RR: 2.57 (1.37 to 4.82) p=0.003 G-A transition mutation subtype RR: 2.29 (1.12 to 4.66) p=0.02 G-C/T transversion mutation subtype RR: 3.34 (1.34 to 8.36) p=0.009	Model #1 (used to calculate RR of overall *KRAS* mutation): age, site, Duke's stages B and C, DNA ploidy, wild-type vs. mutated *KRAS*-2 status Model #2 (used to calculate RRs of G-->A and G-->C/T *KRAS* mutations): Same as Model #1, but with *KRAS* mutations subdivided into two specific types named above
Li, 2012[114] Cohort 78 Medium	KRAS mutation RR: 4.552 (1.522 -13.610) p=0.007	Sex, KRAS mutation, age, growth pattern, location of tumor, tumor differentiation, lymph node metastasis, liver metastasis, TNM stage
Liou, 2011[95] Cohort 314 Medium	HR: 1.61 (0.91 to 2.84) p=0.101	Age, sex, stage, use of adjuvant chemotherapy
Ogino, 2009[113] Cohort 508 Medium	HR: 0.86 (0.60 to 1.23) p=NR	Age, sex, BMI, tumor location, tumor and node stage, presence or absence of perforation and/or obstruction at diagnosis, performance status, MSI status, and treatment arm
Roth, 2010[100] Cohort 1,299 Medium	All subjects: HR: 1.29 (0.99 to 1.67) p=0.060 Stage II subjects: HR: 1.51 (0.79 to 2.90) p=0.21 Stage III subjects: HR:1.28 (0.97 to 1.71) p=0.086	Treatment arm, age, sex, grade, tumor site, nodal stage, MSI, *KRAS*, *BRAF* mutation status

Table 28. Colorectal cancer: *KRAS* overall survival (continued)

Author, Year, Design, Risk of Bias	Adjusted Ratios, (95% CI) p-value	Variables Used in Multivariate Model
Roth, 2012[107] Cohort 1,404 Medium	HR: 1.10 (0.86 to 1.42) p=0.45	Age, sex, grade, stage, number of examined lymph nodes, site, treatment group, MSI status, SMAD4 expression, 18qLOH status, and BRAF
Samadder, 2013[106] Cohort 563 Medium	HR: 1.05 (0.80 to 1.38) p=0.70	Age at diagnosis, anatomic subsite, tumor grade, SEER stage, chemotherapy exposure, and radiation therapy exposure
Tie, 2011[103] Cohort 503 Medium	HR: 0.86 (0.61 to1.22) p=NR	Age, gender, tumor site, stage

Abbreviations: BMI = body mass index; *BRAF* = gene name; CI = confidence interval; DNA = deoxyribonucleic acid; HR = hazard ratio; *KRAS* = gene name; MSI = microsatellite instability; NR = not reported; RR = relative risk; SPF = S-phase Fraction.

Figure 15. Prognostic value of *KRAS* mutation testing for overall survival in colorectal cancer, meta–analysis of adjusted hazard ratios



Colorectal Cancer: Microsatellite Instability (MSI)

Characteristics of Included Studies Assessing the Clinical Validity of MSI

The test for MSI described here uses the five reference microsatellite markers D5S345, D2S123, BAT25, BAT26, and D17S250 (Bethesda markers) to establish microsatellite instability. We included 17 cohort studies[96,103-107,115-125] that examined the added prognostic value of MSI for RR, CSS, or OS in patients with CRC (Table 29). Sample sizes ranged from 55 to 1,175. Median follow up ranged from 3 to 14 years. Studies were conducted in Australia, China, various European countries, Taiwan, and the United States.

Table 29. Characteristics of included studies: MSI for colorectal cancer

Author, Year Study Type Risk of Bias	N Length of Followup	Country(ies)	Disease Stage(s) Other Tumor/ Disease Characteristics	Study Groups	Race Ethnicity	Overall Age (years) % Female
Chang, 2006[115] Cohort Medium	213 Median (range): 208.8 (17.4 to 334.8) weeks	China (Taiwan)	I–IV	MSI-H MSS	NR NR	Median (range): 67.6 (23 to 86)
Donada, 2011[116] Cohort Low	55 Median: 396.72 weeks, 25th–75th percentile=193.1 weeks to 443.5 weeks	Italy	II–III	MSI-H Non-MSI-H	NR NR	Mean (SD) (range): 62.9 (9.1) (35 to 79)
Guibodoni, 2001[117] Cohort Medium	109 Median Recurrence: 74 (50 to 120) months Overall survival: 78 (46 to 120) months	Italy	II–III	MSI-H MSS/MSI-L	NR NR	NR 58.7%
Gyrfe, 2000[118] Cohort Medium	587 Mean (SD): 7.2 (0.1) years	United States	T1–T4	MSI MSS	NR NR	Mean (SD): 43.1 (0.3) 50%
Hong, 2012[119] Cohort Medium	1,125 Median: 42 months	South Korea	I–IV	MSI MSS	NR NR	Median (range): 61 (25 to 92) 3.6%
Jensen, 2009[120] Cohort Medium	311 Median (range): 6.1 (4.1 to 11.3) years	Denmark	II–IV	MSI MSS	NR NR	NR 48.8%
Kim, 2007[121] Cohort Low	542 Censored at 5 years	United States	Duke's Stages B or C	MSI-H MSS/MSI-L	NR NR	NR NR
Lin, 2012[122] Cohort Medium	709 Median (range): 204.9 (4 to 796) weeks	China	I–III	MSI-H MSS/MSI-L	NR NR	Mean (SD): 68.8 (11.5) 32.4%

Table 29. Characteristics of included studies: MSI for colorectal cancer (continued)

Author, Year Study Type Risk of Bias	N Length of Followup	Country(ies)	Disease Stage(s) Other Tumor/ Disease Characteristics	Study Groups	Race Ethnicity	Overall Age (years) % Female
Lochhead, 2012[105] Cohort Medium	1,253 Median:8.2 years, range(3.5-13.1)years	United States	I-IV	MSI-H MSS	NR NR	NR NR

Shia, 2008[123] Cohort High	130 Median (range): 98 (12 to 168) months	United States	I–IV	MSI-H Non-MSI-H	NR NR	Median (range): 65.5 (31 to 85) 47.7%
Soreide, 2009[124] Cohort Medium	186 Range: 291.45 to 495.9 weeks	Norway	I–III	MSS MSI-H	NR NR	Median (IQR): 67 (59 to 73)
Tie, 2011[103] Cohort Medium	503 Recurrence: 38.5 months Cancer specific survival: 12.9 months	Australia	I–IV	MSI MSS	NR NR	MSI median: 75.8 MSS median: 69.4 MSI: 15% MSS: 85%
Yoon, 2011[125] Cohort Low	2,028 43 (1 to 85) months	Korea	II–III	MSI-H MSI-L MSS	NR NR	Mean (SD): 56.7 (12) MSI-H: 10% MSI-L: NR MSS: 90%
Zlobec, 2010[104] Cohort Medium	404 Median: 234.8 weeks (all patients) Median: 260.9 weeks (cancer-specific survival)	Switzerland	T1–T4	MSI-H MSS/MSI-L	NR NR	Mean (range): 69.5 (40 to 95) 53.6%

Abbreviations: IQR = interquartile range; MSI = microsatellite instability; MSI-H = microsatellite instability high; MSS = microsatellite stability; N = number; NR = not reported; SD = standard deviation; WT = wild-type.

All studies compared outcomes of patients with MSI-H with those with MSS/MSI-L. The representation of female patients in the studies where sex is reported ranged from 3.6 percent to 53 percent. Race or ethnicity was not reported in any of the studies.

There were some differences in the populations examined in the different publications. The differences were with respect to stage and whether rectal cancers were included. Eight studies[103-106,115,118,119,123] included patients with colon and rectal cancer at all stages. Four studies[96,107,121,124] included patients with stage II or III colon or rectal cancers. Guidoboni[117] examined a sample of patients with stage I or II proximal colon cancer only; Jensen[120] included patients with stages II, III, and IV colon and rectal cancer; Lin[122] had a sample of only stage III colon cancer; and Yoon[125] included patients with colon and rectal cancer in stages I through III.

MSI for Colorectal Cancer: Risk of Recurrence

Ten cohort studies with low or medium RoB (total N=7,130)[103,107,115,117,119-122,124,125] examined RR as an outcome (Table 30). Several studies[103,115,117,122,125] had DFS or recurrence as an outcome but did not specify whether they were looking at loco-regional or distant recurrence. Hong[119] defined DFS as disease recurrence or progression; Jensen[120] looked at recurrence-free survival, which was defined as relapse of primary disease or death; Kim[121] had RFS as an outcome, which they defined as time to first occurrence of a tumor recurrence; and Soreido[124] looked at any recurrence and separately at loco-regional and distant metastasis.

Table 30. Colorectal cancer: MSI risk of recurrence

Author, Year, Design, N, Test (Cancer), Risk of Bias	Adjusted Ratios, (95% CI) p-value	Variables Used in Multivariate Model
Chang, 2006[115] Cohort 213 Medium	4 year DFS MSI-H vs. MSS HR: 0.49 (0.18 to 1.38) p=0.179	TNM stage, P53 mutation, CEA level, differentiation, MSI, location
Guidoboni, 2001[117] Cohort MSI (colorectal) 109 Medium	DFS HR: 0.32 (0.15 to 0.72) p=0.002	Sex, age as continuous, TNM stage
Hong, 2012[119] Cohort 1,125 Medium	DFS Overall HR: 0.57 (0.32 to 0.96) p=0.034 Colon HR: 0.61 (0.33 to 1.10) p=0.100 Rectum HR: 0.48 (0.12 to1.97) p=0.311	Stage, sex, age
Jensen, 2009[120] Cohort 311 Medium	RR HR: 0.3 (0.2 to 0.7) p=0.0007	Thymidylate synthase, dihydropyrimidine, gender, age, stage, differentiation, peripheral invasion, vascular invasion, perforation ileus

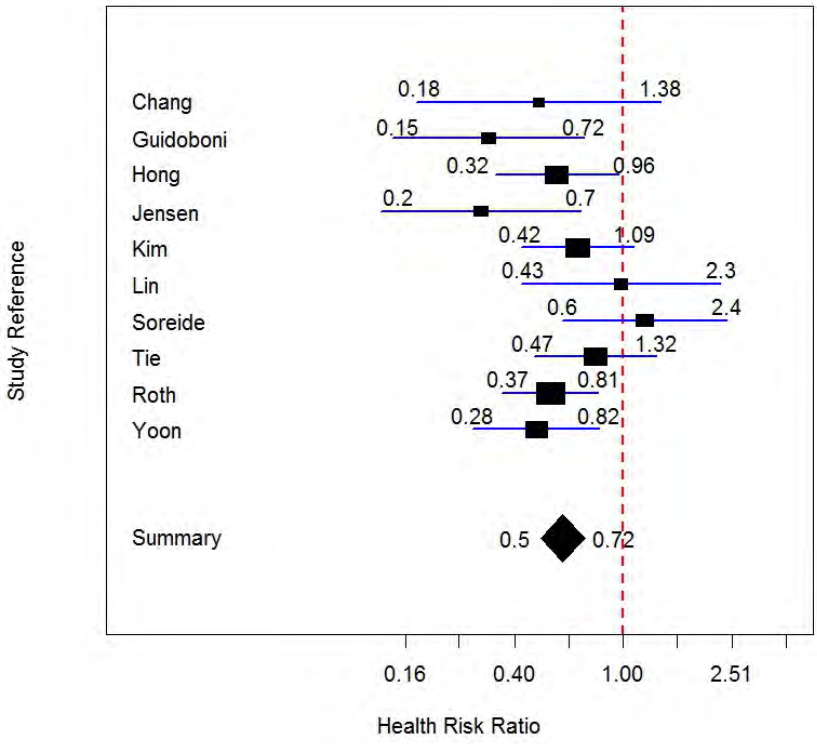
Table 30. Colorectal cancer: MSI risk of recurrence (continued)

Author, Year, Design, N, Test (Cancer), Risk of Bias	Adjusted Ratios, (95% CI) p-value	Variables Used in Multivariate Model
Kim, 2007[121] Cohort 542 Low	RR Overall: RR: 0.68 (0.42 to1.09) p=0.1 RR Untreated group: HR: 0.77 (0.40 to1.48) p=NR RR Treated group: HR: 0.60 (0.30 to 1.19) p=NR	Treatment and MSI/treatment interaction, age, sex, stage, tumor site
Lin, 2012[122] Cohort 709 Medium	DFS HR: 0.982 (0.425 to 2.268) p=0.965	Age, gender, stage, differentiation
Roth, 2012[107] Cohort 1404 Medium	RFS MSI-H vs. MS-L/S HR: 0.54 (0.37 to 0.81) p=0.003	Age, sex, grade, stage, number of examined lymph nodes, site, treatment group, SMAD4 expression, 18qLOH status, BRAF, and KRAS
Soreide, 2009[124] Cohort 186 Medium	LRR MSI adjusted for both age and sex OR: 2.5 (1.0 to 6.1) p=0.047 MSI adjusted for tumor location OR: 3.1 (1.1 to 8.8) p=0 .026 Any recurrence OR 1.2 (0.6 to 2.4) p=0.64	Age, sex, MSI and variables that had p-values <0.1 on univariate analysis
Tie, 2011[103] Cohort 503 Medium	DFS HR: 0.79 (0.47 to1.32) p=0.36	Age, gender, tumor site, stage
Yoon, 2011[125] Cohort 2,028 Low	DFS MSI-H: HR: 0.48 (0.28 to 0.82) p=0.007	Age, location, gender, CEA, node, distant metastases, histology, lympho-vascular invasion, growth type, adjuvant

Abbreviations: CEA = carcinoembryonic antigen; CI = confidence interval; DFS = disease-free survival; HR = hazard ratio; LRR = loco-regional recurrence; MSI = microsatellite instability; MSI-H = microsatellite instability high; MSI-L = microsatellite instability low; MSS = microsatellite stability; N = number; NR = not reported; OR = odds ratio; p = probability; RR = relative risk; TNM = tumor, node, metastases.

The included studies reported on the prognostic value of testing for MSI after controlling for certain traditional prognostic factors such as stage, sex, and age. All but two studies reported point estimates, suggesting an association between MSI-H and lower RR. Four out of nine studies reported statistically significant associations between MSI and RR in adjusted analyses—finding that MSI-H was associated with better prognosis. Our meta-analysis found a lower RR for the patients with MSI-H compared with those with MSS (HR, 0.60; 95% CI, 0.50 to 0.72) (Figure 16).

Figure 16. Prognostic value of microsatellite instability for risk of recurrence in colorectal cancer, meta-analysis of adjusted hazard ratios



MSI for Colorectal Cancer: Cancer-Specific Survival

Six cohort studies rated as medium RoB[96,104-106,122,124] (total N =3,439) reported on CSS as an outcome (Table 31).

Table 31. Colorectal cancer: MSI cancer-specific mortality

Author, Year, Design, N, Risk of Bias	Adjusted Ratios, (95% CI) p-value	Variables Used in Multivariate Model
Lin, 2012[122] Cohort 709 Medium	HR: 0.891 (0.363 to 2.183) p=0.8	Age, sex, stage, differentiation, MSI status
Lochhead, 2013[105] Cohort 1253 Medium	MSI-H vs. MSS HR: 0.28 (0.17-0.46) p<0.001	Age, year of diagnosis, BMI, tumor differentiation LINE-1 methylation),disease stage. KRAS and P1K3CA status
Maestro, 2007[96] Cohort 324 Medium	MSI-L vs. MSS HR: 0.72 (0.29 to 1.80) p=NR MSI-H vs. MSS HR: 0.33 (0.12 to 0.92) p=NR Any MSI vs. MSS: p=0.036	Age, sex, Duke's stage, tumor site, differentiation grade, histology, adjuvant chemotherapy, MSI, and *BRAF*

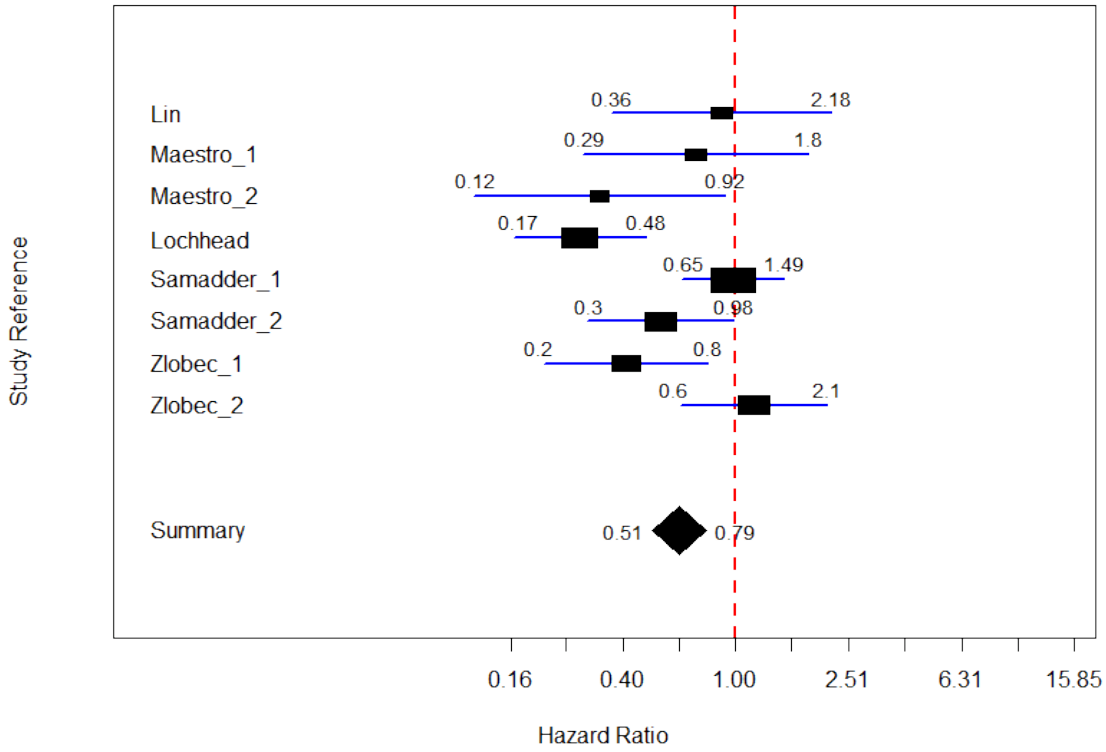
Table 31. Colorectal cancer: MSI cancer-specific mortality (continued)

Author, Year, Design, N, Risk of Bias	Adjusted Ratios, (95% CI) p-value	Variables Used in Multivariate Model
Samadder, 2013[106] 2013 Cohort 563 Medium	MSI –L HR: 0.98 (0.65-1.49) p=.08 MSI-H HR: 0.54 (0.30-0.98) p=.08	Age at diagnosis, anatomic subsite, tumor grade, SEER stage, chemotherapy exposure and radiation therapy exposure
Soreide, 2009[124] Cohort 186 Medium	HR: NR (NR) p=0.722	Age, sex, MSI status, and variables that had p-values <0.1 on univariate analysis
Zlobec, 2010[104] Cohort 404 Medium	Right-sided location MSI-H HR: 0.41 (0.2 to 0.8) p=0.015 Left-sided location MSI-H HR: 1.16 (0.6 to 2.1) p=0.622	pT stage, pN stage, vascular invasion and MSI in right- and left-sided CRC

Abbreviations: *BRAF* = gene name; CI = confidence interval; CRC = colorectal cancer; HR = hazard ratio; MSI = microsatellite instability; MSI-H = microsatellite instability high; MSI-L = microsatellite instability low; MSS = microsatellite stability; NR = not reported; p = probability; pN = pathological node score; pT = pathological tumor score.

The included studies reported on the prognostic value of testing for MSI after controlling for certain traditional prognostic factors such as stage, sex, and age. Two of the four studies reported a statistically significant association between MSI and prognosis of CSS in adjusted analyses. Zlobec[104] reported a positive association (HR 0.41 [0.2 to 0.8]) between MSI-H for right-sided tumors for CSS. Maestro[96] reported a significant HR association between MSI-H and CSS (HR 0.33 [0.12, 0.92]). Our meta-analysis found an overall HR for CSS for patients with MSI-H tumors compared with MSS tumors of 0.63; 95% CI, (0.51 to 0.79) (Figure 17).

Figure 17. Prognostic value of microsatellite instability for cancer specific survival in colorectal cancer, meta-analysis of adjusted hazard ratios



MSI for Colorectal Cancer: Overall Survival

Twelve cohort studies[103,105,107,115-122,125] (total N =8,839) rated as low or medium RoB examined overall survival (Table 32). Populations examined in the different publications varied somewhat.

The included studies reported on the prognostic value of testing for MSI after controlling for certain traditional prognostic factors such as stage, sex, and age. Four out of 10 studies reported a statistically significant association between MSI and prognosis for OS in adjusted analyses. All 4 found that MSI-H is a good prognostic marker for OS.

Our meta-analysis found an overall HR for OS for patients with MSI-H compared with MSS of 0.57; 95% CI (0.43 to 0.77) (Figure 18).

Table 32. Colorectal cancer: Overall survival with MSI

Author, Year, Design, N Risk of Bias	Adjusted Ratios, (95% CI) p-value	Variables Used in Multivariate Model
Chang, 2006[115] Cohort 213 Medium	4-year OS HR: NR MSI-H vs. MSS: p=0.858	TNM (I, II, III, IV), p53 mutation (yes vs. no), CEA level 2 (high vs. low), grade of differentiation (poor vs. well/moderate), MSI status (MSI-H vs. MSS), location (right, left, rectum)
Donada, 2011[116] Cohort 55 Low	MSI-H vs. non-MSI-H HR: 1.34 (0.22 to 8.05) p=0.75	Age, sex, tumor location (left-transverse-right), stage (III vs. II), grading (G3-G2-G1), TS expression (high vs. low), TP expression (high vs. low), DPD expression (high vs. low), MSI status (MSI-H vs. non-MSI-H)
Kim, 2007[121] Cohort 542 Low	MSI-H vs. MSS/MSI-L Stratified by treatment RR=0.91 (0.59, 1.4) Treated group HR=1.02 (0.56 to 1.85) Untreated group HR=0.82 (0.44 to 1.51)	Stratified by treatment: surgery alone vs. surgery + chemotherapy Age, sex, stage, tumor site

Colorectal Cancer: Oncotype DX

Characteristics of Included Studies Assessing the Clinical Validity of Oncotype DX Colon

We included one cohort study[126] that examined the added prognostic value of Oncotype DX Colon for RR, CSS, or OS in patients with CRC (Table 33).

Table 33. Characteristics of included studies: Oncotype DX for colorectal cancer

Author, Year Study Type Risk of Bias	N Length of Followup	Country(ies)	Disease Stage(s) Other Tumor/ Disease Characteristics	Study Groups	Race Ethnicity	Overall Age years) % Female
Venook 2013[126] Cohort Medium	690 NR	United States	II	Recurrent patients Nonrecurrent patients	White: 92% NR	NR 41.9%

Abbreviations: N = number; NR = not reported.

Oncotype DX: Risk of Recurrence

One included cohort study rated as medium RoB (N=690) reported this outcome.[126] The study examined a 12-gene RS as the outcome in stage II CRC patients who were part of the CALGB trial. All patients with recurrence and a random sample of patients with no recurrence were included in the study.

The study reported that the RS from Oncotype DX (treated as a continuous variable) was a significant predictor (HR 1.68; 95% CI, 1.18 to 2.39) after controlling for standard prognostic markers (Table 34).

Table 34. Colorectal cancer: Oncotype DX risk of cancer recurrence/disease-free survival/recurrence-free survival

Author, Year, Design, N, Test (Cancer), Risk of Bias	Adjusted Ratios, (95% CI) p-value	Variables Used in Multivariate Model
Venook 2013[126] Cohort 690 Medium	RS: HR: 68 (1.18 to 2.38) p=0.004	MMR, tumor state, number of nodes examined, grade , LVI, RS

Abbreviations: CI = confidence interval; HR = hazard ratio; LVI = lymphovascular invasion; MMR = mismatch repair; N = number; p = probability; RS = risk score.

Oncotype DX: Cancer-Specific Mortality

We found no studies meeting our inclusion criteria.

Oncotype DX: Overall Survival

We found no studies meeting our inclusion criteria.

Bladder Cancer: UroVysion

Characteristics of Included Studies Assessing the Clinical Validity of UroVysion

UroVysion is a fluorescence in situ hybridization (FISH) test of exfoliated urothelial cells that has been shown to be sensitive in terms of diagnosing urothelial cancer. It was designed as a diagnostic and not a prognostic test. In this report the test is being evaluated for its prognostic value with respect to predicting recurrence.

We included 3 studies[127-129] that examined the added prognostic value of UroVysion for RR, CSS, or OS in patients with bladder cancer (Table 35). Sample sizes ranged from 42 to 138. Studies were conducted in the United States and Switzerland. Race or ethnicity

was not reported in any of the studies. One study was rated as high RoB and was not included in our main data synthesis.[129]

Table 35. Characteristics of included studies: UroVysion for urinary bladder cancer

Author, Year Study Type Risk of Bias	N Length of Followup	Country(ies)	Disease Stage(s) Other Tumor/ Disease Characteristics	Study Groups	Race Ethnicity	Overall Age (years) % Female
Kamat, 2012[127] Cohort Low	126	United States	TA or T1 Nonmuscle invasive bladder cancer (primary or recurrent)	UroVysion+ UroVysion−	NR NR	Median: 67.5 24%
Whitson, 2009[128] Cohort Low	42 Median (range): 91.3 (21.7 to 230.5) weeks	United States	T1 High-risk superficial bladder tumor	UroVysion+ UroVysion−	NR NR	Median (range): 68 (41 to 97) NR
Zellweger, 2006[129] Cohort High	138 Median (range): 19.2 (4 to 52) months	Switzerland	Stage pTa to pT3; 9 tumors without information on stage were also included	UroVysion+ UroVysion−	NR NR	Median (range): 68.5 (33.4 to 92.5) 15.9%

Abbreviations = N = number; NR = not reported.

UroVysion: Risk of recurrence

Two cohort studies (total N = 168) reported on UroVysion and RR. Whitson[128] retrospectively studied patients who underwent intravesical therapy (IVT), and Kamat[127] prospectively enrolled patients who were scheduled to undergo IVT. Both studies reported that the test is a significant predictor after controlling for traditional prognostic factors (Table 36).

Table 36. Key Question 3: Bladder cancer: UroVysion risk of cancer recurrence/disease-free survival/recurrence-free survival

Author, Year, Design, N, Risk of Bias	Adjusted Ratio (95% CI), p-value	Variables Used in Multivariate Model
Kamat, 2012[127] Cohort 126 Low	HR: NR p<0.01	Stage, grade, history of prior tumors, concomitant CIS, use of postoperative mitomycin
Whitson, 2009[128] Cohort 42 Low	Multivariate HR: 6.7 (2.1 to 22.1) p<0.01	Age, smoking, radiotherapy, diabetes mellitus, hypertension, hyperlipidemia, CRI, immunosuppression, recurrence rate, whether the tumor was primary or recurrent, multiple tumors, tumor >3 cm, stage T1, high grade, CIS, EORTC score >6, positive cytology, and positive UroVysion

Abbreviations: CI = confidence interval; CIS = carcinoma in situ; cm = centimeter; CRI = chronic renal insufficiency; EORTC = European Organization for Research and Treatment of Cancer; HR = hazard ratio; N = number; p = probability.

UroVysion Cancer-Specific Survival

We found no studies meeting our inclusion criteria.

UroVysion Overall Survival

We found no studies meeting our inclusion criteria.

Key Question 4a: Influence on Physician Decision

We identified studies evaluating the influence of molecular pathology tests for RR on treatment decisionmaking for three of the tests of interest, the Oncotype DX and MammaPrint assays for breast cancer, and Oncotype DX Colon. For Oncotype DX Colon, none of the included studies were rated as low or medium RoB. For Oncotype DX Breast and MammaPrint, the studies available for review included a mix of prospective and retrospective cohort studies and uncontrolled trial designs, with a larger body of literature examining the use of Oncotype DX than MammaPrint. No studies examined the effect of the two assays compared with each other.

Characteristics of Included Studies Assessing Oncotype DX Breast and Treatment Decisions

For Oncotype DX Breast, we included six cohort studies (total N=990 patients) and ten uncontrolled trials (total N=1,261 patients) rated as low or medium RoB (Table 37). One additional uncontrolled trial[130,131] was excluded from our main analysis because of an unclear RoB rating and is not included in this summary. Most of the studies were performed at single academic centers or in multicenter studies in the United States, but studies performed at centers in Europe, Canada, Australia, Mexico, Japan and Israel were also found. The studies uniformly examined cohorts with hormone-receptor positive breast cancer, and most were limited to women with node-negative cancers. The mean age of patients in the studies varied from 48 to 61 years.

Table 37. Characteristics of included studies: Oncotype DX Breast and treatment decisions

Author, Year Test (Cancer Type) Risk of Bias	N Study Type	Country(ies)	Disease Stage(s) Other Tumor/Disease Characteristics	Overall Age (years) % Female

Results: Oncotype DX and Treatment Decisions

Across studies, the percentage of patients whose recommendation for treatment was changed by the Oncotype test result was generally around 30 percent, ranging from 14 percent to 40 percent. Although treatment decision changes were observed in both directions for individual patients, all studies consistently showed a pattern of a shift to less-intensive treatment recommendations (more patients moving from chemotherapy plus hormonal therapy to hormonal therapy alone than from hormonal therapy to combination therapy) as a result of including the Oncotype score in decisionmaking information (Table 38).

One cohort study[139] also included a nested uncontrolled trial in which a panel of five experts provided treatment recommendations with and without the Oncotype score for patients included in the observational cohort; results were consistent with the other studies.

Characteristics of Included Studies Assessing MammaPrint and Treatment Decisions

We included one cohort study regarding decisionmaking (Table 39). This study was performed entirely in the Netherlands and included 427 women with a median age of 48 years and with node-negative invasive breast cancers. None of the patients were over 65 years of age. In the cohort study, physicians' treatment recommendations based on Dutch clinical guidelines were compared with recommendations based on the combination of clinical guidelines and the MammaPrint result.[148]

Table 39. Characteristics of included studies: MammaPrint and treatment decisions

Author, Year Test (Cancer Type) Risk of Bias	N Study Type	Country(ies)	Disease Stage(s) Other Tumor/Disease Characteristics	Overall Age (years) % Female
Bueno-de-Mesquita, 2007[148] MammaPrint (breast) Low	427 Pre-post-test design an uncontrolled trial	The Netherlands	T I–IIII Node negative	Mean (SD): 48 (7); Median (range) 49 (27 to 60) 100%

Abbreviations: N = number; SD: standard deviation.

Results: MammaPrint and Treatment Decisions

The addition of the MammaPrint test result increased the percentage of patients recommended to receive some form of adjuvant therapy (either hormonal therapy, chemotherapy, or both) from 48 to 62 percent. However, the greatest increase was among women moving from no therapy to hormonal therapy. One significant limitation of this study for application to the U.S. population is that Dutch treatment guidelines during the study period were unusually restrictive in terms of indications for breast cancer adjuvant therapy compared with more widely accepted guidelines in the United States; specifically, women with hormone-receptor positive breast cancers would be uniformly recommended to receive hormonal therapy under U.S. guidelines.

Characteristics of Included Studies Assessing Oncotype DX Colon and Treatment Decisions

We identified three eligible studies (Table 40). Two were conducted in the United States and one in Israel. One cross-sectional survey assessed the treatment decisions of 116 physicians;[149] one uncontrolled trial assessed treatment decisions of 105 oncologists;[150] and one cohort study examined treatment recommendations before assay results compared with actual treatment received after assay results for 269 patients.[151] One study was rated as high RoB and two were rated as unclear RoB. Appendix C provides additional rationale for RoB ratings.

Table 40. Characteristics of included studies: Oncotype DX Colon and treatment decisions

Author, Year Test (Cancer Type) Risk of Bias	N Study Type	Country(ies)	Disease Stage(s) Other Tumor/Disease Characteristics	Overall Age (years) % Female
Brenner, 2013[151] Oncotype DX (colorectal) High	269 patients Cohort	Israel	II	NR (but reported 48% were at least 70 years old) NR
Cartwright, 2012[149] Oncotype DX (colorectal) High	116 physicians 92 patients Cross-sectional survey	United States	II	Mean (SD): 61.3 (11.8) NR
Srivastava, 2013[150] Oncotype DX (colorectal) Unclear	105 oncologists 141 patients Uncontrolled trial	United States	II	NR NR

Abbreviations: N = number; NR = not reported; SD = standard deviation.

Results: Oncotype DX Colon and Treatment Decisions

With no studies rated as low or medium RoB, we found no reliable data to inform conclusions about the impact of the Oncotype DX Colon test on treatment decisions.

Key Question 4b: Clinical Utility—Evidence that Modified Decisions Lead to Improved Outcomes

We found no eligible studies that addressed this question.

Key Question 5. Harms Associated with Treatment Decisions that are Informed by Molecular Pathology Tests

We found no eligible studies that addressed this question.

Discussion

Below, we summarize the main findings and strength of evidence (SOE). We then discuss implications for decision-making, limitations, future research, and conclusions.

Key Findings and Strength of Evidence

We found no studies that directly addressed our overarching question (Key Question [KQ] 1) (i.e., no studies directly assessed the impact of a test of interest on physician decision-making and subsequent health outcomes). Further, no studies directly addressed whether modified decisions lead to improved health outcomes (KQ 4b, clinical utility), and none reported harms associated with treatment decisions that are informed by molecular pathology tests (KQ 5).

The majority of studies meeting inclusion criteria for our review focused on clinical validity (KQ 3), and they evaluated associations between prognostic tests and outcomes. For two tests, MammaPrint and Oncotype DX Breast, we found studies rated as low or medium risk of bias (RoB) addressing whether prognostic information provided by the molecular pathology tests modified treatment decisions (KQ 4a).

Analytic Validity

Of the six molecular pathology tests with studies of low or medium RoB, the *EGFR* and *KRAS* mutation tests for lung cancer, the MammaPrint test for breast cancer, and the *KRAS* mutation test for colorectal cancer (CRC) were determined to have an overall moderate or high SOE for analytic validity (Table 41). Studies of these tests used fairly large panels of samples, were all low RoB, were directly measuring the test, and were consistent in their measurements.

Table 41. Summary of findings and strength of evidence for analytic validity

Test	Parameter	N studies; N subjects	Value	Strength of Evidence
MammaPrint: Breast	SS	2;399	NR	Moderate
	CV	1;100	NA	Low
EGFR: Lung:	SS	5; 898	Sensitivity range: 68–100%; Specificity range: 79–100%	Moderate
	CV	5;636	Kappa score range: 0.20–0.73	High
KRAS: Lung:	SS	2;188	NR	Moderate
	CV	4;686	Kappa score range: 0.15–0.66	High
BRAF: Colorectal	SS	1;117	NR	Insufficient
	CV	3;533	NA	High
KRAS: Colorectal	SS	5;576	Sensitivity range: 69–98%; Specificity range: 90–100%	High
	CV	5;747	Reproducibility: 98%	High
Oncotype DX: Colorectal:	SS	1; NR	NR	Insufficient [
	CV	NA	NA	NA

Abbreviations: *BRAF* = gene name; CV = cross-lab validity; *EGFR* = gene name; *KRAS* = gene name; N = number; NA = not applicable; NR = not reported; SS = sensitivity and specificity.

The SOE for the overall analytic validities of the *BRAF* mutation test for CRC and the Oncotype DX Colon multigene assay for CRC were determined to be low. There were only one or two studies to consider, RoB was generally higher, and consistency was often

unknown (when there was a single study). However, the *BRAF* mutation test for CRC, due to the CAP report data, showed a high SOE for cross-lab validity.

In general, we found limited evidence in the published literature assessing analytic validity of the included tests. For most of these tests, we found evidence from fewer than 200 subjects; just 2 of the tests (*EGFR*/Lung and *KRAS*/CRC) had more than 200 samples contributing to our SOE grade (Table 41).

However, the best data on reproducibility we found is from the College of American Pathologists' report data for *EGFR* mutation testing, *KRAS* mutation testing, *BRAF* mutation testing, microsatellite instability for colorectal cancer, and UroVysion cytogenetics for urinary bladder cancer, which support the analytic validity of these tests.

In general, in most of the studies, tests were developed in the laboratories and compared with the gold standard of direct Sanger sequencing of the gene in formalin-fixed, paraffin-embedded tissue samples. We had very few studies directly assessing the analytic validity (test performance) using direct sequencing of frozen tissue (the current gold standard), which would be of great importance in determining the true analytic validity of the tests.

In general, the studies showed that their tests in comparison with the gold standard were of comparable marker sensitivity/specificity and had similar proportions of valid results (level of detection). Because the analytic validity, sensitivity, and specificity of direct sequencing of frozen tissue have not been established against their "true" tumor diagnosis, the false-positive rate cannot truly be determined for the other tests used in these studies. In Beau-Faller et al.,[35] the false positive rate for direct sequencing of *EGFR* and *KRAS* was stated to be about 10 to 15 percent. Therefore, any numbers we have given for marker sensitivity/specificity and predictive value are estimates, assuming accurate direct sequencing.

Clinical Validity

Included studies provided some evidence on clinical validity for 9 of the included tests, adjusted for known prognostic factors (Table 42). Evidence from multiple studies supports prognostic value , beyond known prognostic factors, for MammaPrint, Oncotype DX Breast, *KRAS* mutation testing for lung cancer, *BRAF* mutation testing for CRC, *KRAS* mutation testing for CRC, and microsatellite instability (MSI) for CRC for at least one of our included outcomes (i.e., risk of recurrence [RR], cancer-specific survival [CSS], or overall survival [OS]). For UroVysion, limited evidence from 2 small studies (total N=168) rated as low or medium RoB supported prognostic value for RR. None of the studies we evaluated suggested that *EGFR* added prognostic value to the traditional factors used to determine prognosis for lung cancer. For CRC, evidence did not adequately support added prognostic value for Oncotype DX Colon.

Table 42. Summary of findings on clinical validity (i.e., Association between Test Result and Prognosis)

Test: Cancer	Outcome	N studies; N subjects	Results Effect Size (95% CI)	Evidence from Multiple Studies Supports Association between Test Result and Prognosis?
MammaPrint: Breast	RR	6; 1,913	HR: 2.84 (2.11 to 3.89) for poor prognosis vs. good prognosis	Yes
	CSS	5; 1,615	HR: 3.3 (2.22 to 4.9) for poor prognosis vs. good prognosis	Yes
	OS	1; 144	HR: 1.67 (0.73 to 3.82) for poor prognosis vs. good prognosis	No
Oncotype DX Breast	RR	6; 3,222	HR: 2.97 (2.19 to 4.02) for high risk vs. low risk	Yes
	CSS	2; 1,234	HR: 2.02 (1.35 to 3.00) for high risk vs. low risk	Yes
	OS	1; 668	HR: 1.65 (1.24 to 2.19) for high risk vs. low risk	No, single study
EGFR: Lung	RR	6; 1,870	HR: 0.87 (0.65 to 1.15); No association	No
	CSS	0; 0	NA	No
	OS	6; 1,820	HR: 0.76 (0.50 to 1.19); No association	No
KRAS: Lung	RR	4; 611	2.84 (1.14, 7.1) *KRAS* mutation associated with greater RR	Yes
	CSS	0; 0	NA	No
	OS	2; 253	2.69 (1.91,3.8); 3.33 (1.03, 10.82)	Yes[a]
BRAF: CRC	RR	5; 4,106	HR 1.07 (0.76 to 1.52) for wild-type vs. mutation	No
	CSS	7; 5,409	HR 1.50 (1.26 to 1.77) for wild-type vs. mutation	Yes
	OS	11;7,610	HR 1.45 (1.29 to 1.62) for wild-type vs. mutation	Yes
KRAS: CRC	RR	5; 4,085	HR 1.02 (0.91 to 1.14) for wild-type vs. mutation	No
	CSS	2; 1,174	HR 1.30 (1.02 to 1.66) for wild-type vs. mutation	Yes
	OS	10; 5,328	HR 1.22 (0.93 to 1.60) for wild-type vs. mutation	No
MSI: CRC	RR	10; 7,130	HR 0.60 (0.50 to 0.72) for MSI-H vs. MSS	Yes
	CSS	6; 3,439	HR 0.65 (0.51 to 0.82) for MSI-H vs. MSS	Yes
	OS	12; 8,839	HR 0.57 (0.43 to 0.77) for MSI-H vs. MSS	Yes
Oncotype DX: CRC	RR	1; 690	HR 1.68 (1.18 to 2.38)	No, single study
	CSS	0; 0	NA	No
	OS	0; 0	NA	No
UroVysion: Bladder	RR	2; 168	Association between mutation and RR in 2 small studies	Yes, but limited to 168 subjects
	CSS	0; 0	NA	No
	OS	0; 0	NA	No

[a] Data synthesiswas done only when we had 3 or more HRs to combine to create a summary.

Notes: Table includes results of our main analyses that were based on studies rated as low or medium RoB. HRs reported are results of our meta-analyses of studies rated as low or medium RoB reporting adjusted associations for clinical validity (KQ 3).

Abbreviations: *BRAF* = gene name; CRC = colorectal cancer; CSS = cancer-specific survival; *EGFR* = gene name; HR = hazard ratio; *KRAS* = gene name; MSI = microsatellite instability; MSI-H = microsatellite instability high; MSS = microsatellite stability: N = number; NA = not applicable; OS = overall survival; RR = risk of recurrence; vs. = versus.

Breast Cancer: MammaPrint

Our meta-analysis suggests that patients classified as having a poor prognosis by MammaPrint consistently do worse than those with a good prognosis signature with respect to distant metastatis-free survival and CSS. Studies included in the search varied somewhat in the subpopulations they tested; the fact that the signature added prognostic

value across these various subpopulations suggests that it has broad applicability. Because no studies looked at the value of MammaPrint with respect to loco-regional recurrence (LRR) and only one considered overall survival, there is scant or no evidence regarding the clinical validity of the MammaPrint signature in terms of these outcomes.

Breast Cancer: Oncotype DX

Some evidence indicates that the risk score (RS) estimated by Oncotype DX adds prognostic value in predicting distant recurrence and CSS. The two included studies that used LRR as an outcome reported that the RS does not add value in determining prognosis (with respect to LRR). Thus, evidence suggests that the Oncotype DX score adds value in determining prognosis for distant metastasis and CSS but not for LRR.

Lung Cancer: KRAS mutation

Some evidence suggest that testing for KRAS mutations has added prognostic value in lung cancer for both RR and OS. Our meta-analysis resulted in significant HRs for both RR and OS. There were no studies that looked at CSS. The results seem to hold for all stages. However, because the studies did not examine differences by race, age, or gender, it is not known if the prognostic value of the mutation varies by any of these factors.

Colorectal Cancer: *BRAF* Mutation

Evidence suggests that *BRAF* mutation does not have added prognostic value for RR. But our meta-analysis found that *BRAF* mutation testing has prognostic value for CSS and OS. The populations studied included proximal and distal colon cancers as well as rectal cancers. The studies did not examine if the risk varied by race, age, or gender. The results seem to hold for proximal, distal, and rectal cancers. However, because the studies did not examine differences by race, age, or gender, it is not known if the prognostic value of the mutation varies by any of these factors.

Colorectal Cancer: *KRAS* Mutation

Evidence suggests that *KRAS* mutation does not have added prognostic value for RR or OS. But our meta-analysis found that *KRAS* mutation testing has prognostic value for CSS. The populations studied included proximal and distal colon cancers as well as rectal cancers. The studies did not examine if the risk varied by race, age, or gender. The results seem to hold for proximal, distal, and rectal cancers. However, because the studies did not examine differences by race, age, or gender, it is not known if the prognostic value of the mutation varies by any of these factors.

Colorectal Cancer: MSI

Our meta-analyses found that testing for MSI adds prognostic value with respect to RR, CSS, and OS in CRC patients. Patients with MSI-H tumors have a lower risk of recurrence, death due to CRC, and death due to any cause compared with patients with MSS tumors.

The studies included looked at proximal, distal, and rectal cancers but did not look for differences by race, age, or gender. Thus, although it is possible to say that in general

MSI-H has a protective effect for CRC patients, evidence was lacking to allow determination of whether protection varies by race, age, or gender.

Clinical Utility and the Overarching Question

We found no studies that directly addressed our overarching question (KQ 1) (i.e., no studies directly assessed the impact of test use on downstream health outcomes). We attempted to construct an indirect chain of evidence to answer the overarching question, but no studies addressed whether modified decisions lead to improved health outcomes (KQ 4b, clinical utility), so we were unable to do so. The furthest downstream evidence that we found addressed whether prognostic information provided by the molecular pathology tests modifies treatment decisions (KQ 4a); we found such evidence for three tests, MammaPrint, Oncotype DX Breast, and Oncotype DX Colon (but the three studies identified for Oncotype DX Colon were rated as high or unclear risk of bias).

For impact on treatment decisions, we found moderate SOE that one test, Oncotype DX Breast, leads to changes in decisions. Although the decision changes were observed in both directions for individual patients, studies consistently showed an overall shift to less-intensive treatment recommendations as a result of using Oncotype DX Breast, with fewer recommendations for chemotherapy (and therefore less exposure to potential harms of chemotherapy; but studies did not follow patients to actually report on harms or to assess the overall balance of clinical benefits and harms).We found just one study of low or medium RoB for the impact of MammaPrint on treatment decisions, and we concluded that evidence was insufficient to determine the impact of MammaPrint on treatment decisions, primarily because of unknown consistency and imprecision.

Table 43 summarizes the evidence on the overarching question, clinical utility, and the impact of test use on treatment decisions. Ultimately, for the reasons described above, we found insufficient SOE to answer the overarching question for most tests. Even in the cases where the tests seemed to add value in determining prognosis (i.e., evidence of clinical validity), we found no direct evidence that using the test was related to improved outcomes for patients. For a few tests, we found low SOE, suggesting that using the test would not improve outcomes for patients—for these tests we found evidence that did not support clinical validity (because with evidence suggesting lack of clinical validity, it is unlikely that the tests will be found to have clinical utility).

Table 43. Summary of findings and strength of evidence for impact on treatment decisions, clinical utility, and our overarching question

Test: Cancer	Outcome	N studies; N subjects	Conclusions	Strength of Evidence
MammaPrint: Breast	RR	6; 1,913	All studies assessed clinical validity; no evidence that test use leads to improved outcomes	Insufficient
	CSS	5; 1,615	All studies assessed clinical validity; no evidence that test use leads to improved CSS	Insufficient
	OS	1; 144	Study assessed clinical validity; no evidence that test use leads to improved morality	Insufficient
	Decisions about Rx	1; 427	Adjuvant therapy was used less if the prognosis signature is used	Insufficient
Oncotype DX Breast	RR	6; 3,222	All studies assessed clinical validity; no evidence that test use leads to improved outcomes	Insufficient
	CSS	2; 1,234	All studies assessed clinical validity; no evidence that test use leads to improved CSS	Insufficient
	OS	1; 668	All studies assessed clinical validity; no evidence that test use leads to improved mortality	Insufficient
	Decisions about Rx	16; 2,251	~30% of treatment decisions changed by the test	Moderate
EGFR: Lung	RR	6; 1,870	All studies assessed clinical validity and found no prognostic value; test is unlikely to improve outcomes	Low
	CSS	0; 0	NA	Insufficient
	OS	6;1,820	No prognostic value; none of the reported HRs were statistically significant; test unlikely to improve mortality	Low
	Decisions about Rx	0; 0	NA	Insufficient
KRAS: Lung	RR	4; 611	All studies assessed clinical validity; no evidence that test use leads to improved outcomes	Insufficient
	CSS	0; 0	NA	Insufficient
	OS	2; 253	Studies assessed clinical validity; no prognostic value; no evidence that test use leads to improved mortality	Insufficient
	Decisions about Rx	0; 0	NA	Insufficient
BRAF: CRC	RR	5; 4,106	All studies assessed clinical validity; no prognostic value; test is unlikely to improve outcomes	Low
	CSS	7; 5,409	All studies assessed clinical validity; no evidence that test use leads to improved CSS	Insufficient
	OS	10; 7,610	All studies assessed clinical validity; no evidence that test use leads to improved mortality	Insufficient
	Decisions about Rx	0; 0	NA	Insufficient
KRAS: CRC	RR	5; 4,085	All studies assessed clinical validity; no prognostic value; test is unlikely to improve outcomes	Low
	CSS	2; 1,174	All studies assessed clinical validity; no evidence that test use leads to improved outcomes	Insufficient
	OS	10; 5,328	All studies assessed clinical validity; no prognostic value; test is unlikely to improve mortality	Low
	Decisions about Rx	0; 0	NA	Insufficient
MSI: CRC	RR	10; 7,130	All studies assessed clinical validity; no evidence that test use leads to improved outcomes	Insufficient
	CSS	6; 3,439	All studies assessed clinical validity; no evidence that test use leads to improved CSS	Insufficient
	OS	12; 8,839	All studies assessed clinical validity; no evidence that test use leads to improved mortality	Insufficient
	Decisions about Rx	0; 0	NA	Insufficient

Table 43. Summary of findings and strength of evidence for impact on treatment decisions, clinical utility, and our overarching question (continued)

Test: Cancer	Outcome	N studies; N subjects	Conclusions	Strength of Evidence
Oncotype DX: CRC	RR	1; 690	Study assessed clinical validity; no evidence that test use leads to improved outcomes	Insufficient
	CSS	0; 0	NA	Insufficient
	OS	0; 0	NA	Insufficient
	Decisions about Rx	0; 0	NA	Insufficient
UroVysion: Bladder	RR	2; 168	Both studies assessed clinical validity; no evidence that test use leads to improved outcomes	Insufficient
	CSS	0; 0	NA	Insufficient
	OS	0; 0	NA	Insufficient
	Decisions about Rx	0; 0	NA	Insufficient

Notes: Table included results of our main analyses that were based on studies rated as low or medium RoB. HRs reported are results of our meta-analyses of studies rated as low or medium RoB reporting adjusted associations for clinical validity (KQ 3).

Strength of evidence grades are for the overarching question not for clinical validity (i.e., not for prognostic value or accuracy).

Abbreviations: *BRAF* = gene name; CRC = colorectal cancer; CSS = cancer-specific survival; *EGFR* = gene name; HR = hazard ratio; *KRAS* = gene name; MSI = microsatellite instability; N = number; NA = not applicable; OS = overall survival; RR = risk of recurrence; Rx = treatment.

Implications for Clinical and Policy Decisionmaking

Our review demonstrated that the weight of published research to date in the area of molecular pathology tests for improving estimates of cancer prognosis has focused on the clinical validity of the tests of interest in giving information about prognosis and little emphasis on how these tests can be integrated into the overall care of cancer patients in terms of measuring changes in management decisions or the effect of those altered decisions on downstream outcomes of value to patients. Such changes in management may be occurring and may be of benefit, or possibly of harm, to patients but have not been measured and studied, with the notable exception of the Oncotype DX assay in breast cancer, which does have a sizeable body of evidence to suggest an effect on treatment decisions (resulting in fewer recommendations for chemotherapy), though not yet a clear effect on downstream outcomes.

At this point, physicians can, in many cases, rely on the prognostic value of molecular pathology tests, can share test results with patients, and discuss whether the test result indicates a better or worse than average prognosis. However, in most cases, physicians cannot be sure whether they should direct management plans based on the results. Although having accurate information about prognosis may be valued by patients independent of its effects on treatment planning or on survival and recurrence outcomes, this has yet to be demonstrated for the tests of interest.

Policymakers may request information and research that not only demonstrate the prognostic value of a test for cancer recurrence, but also evaluate the broader context of how the test fits into the overall plan of care and how information provided by the test changes a patient's long-term outcomes. Because molecular pathology tests for risk of cancer recurrence are relatively recent innovations in cancer care, it is reasonable for

policymakers to expect that their value may be better demonstrated over the next decade as the research base matures.

Limitations of the Comparative Effectiveness Review Process

We did not include studies focused on populations with advanced/metastatic cancer. The focus of this report is on whether the included tests are useful for prognosis as related to the risk of cancer recurrence. People with advanced/metastatic cancer would first have to achieve remission before recurrence is a possibility. Studies of people with advanced/metastatic cancer tend to focus on overall survival and typically do not provide information about the risk of cancer recurrence.

Also publication bias and selective reporting are potential limitations. Although we searched for unpublished studies and unpublished outcomes and did not find direct evidence of either of these biases, many of the included studies were published prior to the availability of registries that would allow for greater certainty in determining the potential for either type of bias.

Finally, although the r eview was focused om the Medicare population we did not find evidence specific to thulation. Many studies included participants from this age group and we did not find any evidence suggesting that the prognostic value of the tests varies with age.

Limitations of the Evidence Base

The evidence base was inadequate to draw conclusions for some of our questions or subquestions of interest. In particular, as described above, we found no direct evidence addressing our overarching question and insufficient evidence to determine whether modified decisions that result from prognostic testing lead to improved health outcomes. Further, we found scant evidence meeting our inclusion criteria regarding ALK translocation testing.

Although we found insufficient evidence to determine whether modified decisions that result from prognostic testing lead to improved health outcomes, studies of the use of Oncotype DX Breast reveal a pattern of less aggressive treatment recommendations as a result of using test information to inform decision-making (i.e., more recommendations for patients to have hormonal therapy alone than hormonal plus chemotherapy). We would expect this to improve quality of life and to decrease the costs of treatment, but we did not find empiric evidence to confirm this, and it might only hold true if recurrence and survival were either unchanged or were improved.

Many of the included studies had methodological limitations introducing some RoB. For example, most of them were observational studies assessing associations between test results and outcomes and are susceptible to potential confounding. To limit such bias, we only included studies for KQ 3 that adjusted for most or all standard prognostic factors. Also, we assessed potential selection bias and confounding in our RoB assessments—limiting our main data syntheses to studies with low or medium RoB.

We were also not able to address the prognostic value of the tests for the Medicare population due to a lack of data that was specific to that age group.

Future Research

We found no direct evidence of the impact of the information provided by these tests on downstream health outcomes such as patients' quality of life or survival. Thus, future research should focus on quality of life, survival, and other health outcomes. There is no information on the differential effects of the test by race or cancer subtype (e.g., ductal versus lobular in breast cancer) or location (e.g., proximal versus distal in CRC). As described in the results, the subpopulations that were represented in the studies varied in terms of stage, tumor type, and location in the case of CRC. Race and location have both been shown to be important predictors of the prognostic value of genetic markers in CRC.[152,153] Similar differences in prognostic value by subpopulations could be a factor in terms of *EGFR* and *KRAS* in the lung. There is thus a need to create an evidence base that replicates results in the same subpopulations, particularly in CRC and lung cancer.

As in many studies in the oncology field, the published literature uses a variety of specific definitions for outcomes such as recurrence and CSS, making comparison of effects across studies more difficult. Future research should take into account careful selection of the most appropriate endpoints, both in the context of the existing body of literature and the endpoints of most clinical relevance to doctors and patients.

Research on the prognostic value of molecular pathology tests, whether existing or novel, is limited by the lack of availability of biologic samples or detailed molecular pathology test result information from large population-based cohorts making assessment and generalizability of genetic prognostic tests difficult. Because many published studies used subsets of the same clinical trial populations, there is overlap in the sample of patients studied (e.g., three of the studies included for Oncotype DX in breast cancer report on the same 668 patients). There is a need to expand the research into independent populations and to incorporate collection of molecular pathology test results and/or biologic samples into the design of registry and prospective cohort studies. Although concerns may arise regarding privacy issues, these may be allayed by understanding that genetic alterations in the carcinomas, rather than those in germline DNA, are the focus of the research, and well-established ethical guidelines exist for handling and storing patient biospecimens.

Conclusions

We found modest evidence supporting added prognostic value (i.e., clinical validity), beyond traditional prognostic factors, for MammaPrint, Oncotype DX Breast, *KRAS* mutation testing for lung, *BRAF* mutation testing for CRC, *KRAS* mutation testing for CRC, and MSI for CRC for RR, CSS, and/or OS. For UroVysion, which is marketed as a diagnostic (not prognostic) test, limited evidence supported an association between test result and prognosis for RR. For the other included tests, evidence either did not support added prognostic value or we found no studies with sufficiently low RoB to support a conclusion about prognostic value.

We found no studies that directly addressed our overarching question (i.e., no studies directly assessed the impact of test use on downstream health outcomes to establish clinical utility). We attempted to construct an indirect chain of evidence to answer the overarching question, but evidence was generally insufficient to do so. Even for the tests

with good evidence supporting clinical validity, we found no evidence that using the test was related to improved outcomes for patients.

For impact of test use on treatment decisions, we found moderate SOE that Oncotype DX Breast leads to changes in decisions. One study of low or medium RoB found a significant impact of MammaPrint on treatment decisions, but evidence was insufficient to draw any firm conclusions, primarily because of unknown consistency and imprecision.

Many of the included tests are currently used to predict response to specific treatments, an aspect that was not evaluated in this report. A determination of whether the tests have clinical utility for predicting therapeutic response is beyond the scope of this review.

Appendix A. Search Strategies

We conducted searches for relevant scientific literature using the following search strategies on 10/29/2012 and found 3,340 articles. We conducted an update literature using the same search terms and databases on 11/12/2013 with the following date limits: 10/29/2011 through 11/12/2013 to find more recently published articles. The update searches yielded a total of 1,233 citations, and after removing duplicates we added 468 new articles. The total number of unique sources found from the original and update searches and other sources such as hand searching and peer and public review comments was 3,850.

Appendix B. Exclusions

Exclusion Code Key:

- EXC1: Systematic Review
- EXC2: Wrong publication type
- EXC3: Wrong population
- EXC4: Wrong intervention
- EXC5: Wrong or no comparator
- EXC6: Wrong or no outcome
- EXC7: Wrong study design
- EXC8: Does not apply to a key question
- EXC9: Irretrievable

1. Bladder cancer surveillance (Structured abstract). Health Technology Assessment Database. 2007(3)PMID: HTA-32010001141. EXC1
2. Epidermal growth factor receptor mutations and tyrosine kinase inhibitor therapy in advanced non-small-cell lung cancer (Structured abstract). Health Technology Assessment Database. 2007(3)PMID: HTA-32010000201. EXC2
3. CYP2D6 pharmacogenomics of tamoxifen treatment (Structured abstract). Health Technology Assessment Database. 2008(3)PMID: HTA-32010000213. EXC2
4. Oncotype DX prognostic and predictive test for early breast cancer (Structured abstract). Health Technology Assessment Database. 2008(3)PMID: HTA-32010000622. EXC2
5. KRAS mutations and epidermal growth factor receptor inhibitor therapy in metastatic colorectal cancer (Structured abstract). Health Technology Assessment Database. 2008(3)PMID: HTA-32010000218. EXC2
6. MammaPrint (gene test) for breast cancer - prognostic test: horizon scanning technology briefing (Project record). Health Technology Assessment Database. 2009(3)PMID: HTA-32008100372. EXC2
7. Gene expression profiling in women with lymph-node-positive breast cancer to select adjuvant chemotherapy treatment (Structured abstract). Health Technology Assessment Database. 2010(3)PMID: HTA-32011000017. EXC2
8. KRAS testing for anti-EGFR therapy in advanced colorectal cancer: an evidence-based and economic analysis (Provisional abstract). Database of Abstracts of Reviews of Effects. 2010(3):1. PMID: DARE-12011004254. EXC2
9. Epidermal growth factor receptor mutation (EGFR) testing for prediction of response to EGFR-targeting tyrosine kinase inhibitor (TKI) drugs in patients with advanced non-small-cell lung cancer: an evidence-based analysis (Provisional abstract). Database of Abstracts of Reviews of Effects. 2010(3):1. PMID: DARE-12011004253. EXC1

ROB RATING: UNCLEAR

Indicate the appropriate risk of bias rating by placing an 'X' in the shaded space to the right of the rating for each KQ that is applicable. If a study does not apply to a KQ, put an 'X' next to N/A.

Risk of bias for KQ 1:	Low		Medium		High		N/A	
Risk of bias for KQ 2:	Low	*	Medium	*	High	*	N/A	
Risk of bias for KQ 3:	Low		Medium		High		N/A	
Risk of bias for KQ 4a:	Low		Medium		High		N/A	
Risk of bias for KQ 4b:	Low		Medium		High		N/A	
Risk of bias for KQ 5:	Low		Medium		High		N/A	
Explain any **High** ratings:								

Low: Study has minimal bias. High degree of confidence that the true effect size is similar in size and direction to that reported.
Medium: Study has at least one significant source of bias, but does not have flaws that are likely to cause major bias. Moderate degree of confidence that the actual effect is in the direction reported by the study; moderate degree of confidence that the true effect size is similar to that reported.
High: Study has at least one major sources of bias or multiple significant sources of bias. Low degree of confidence that the true effect size is similar in size or direction to that reported.
NA: Not applicable to that key question.

Key Questions 1, 3, 4a, 4b, and 5	If the study does NOT apply to any of these KQs, place an 'X' here (__)
KQ 1: Overarching Question Is there direct evidence that the addition of the following genetic tests used alone or in combination with traditional prognostic factors change physician decision making and improve outcomes for adult patients with lung, breast, colorectal, and bladder cancer compared with the use of traditional factors to predict risk of recurrence for adults with these cancers?	
KQ 3. Clinical Validity. Does existing evidence establish the prognostic accuracy of the tests for predicting recurrence?	
KQ 4a. Clinical Utility. What is the evidence that the prognostic information provided by the genetic tests modifies physician decisions regarding use of adjuvant anti-neoplastic chemo- and/or radiotherapy; enhanced diagnostic testing for recurrence; and/or preventive surgery among adult patients with malignant tumors?	
KQ 4b. Clinical Utility. What is the evidence that modified decisions lead to improved overall survival, disease free survival, time to recurrence, quality of life, or incidence of serious side effects of adjuvant therapy in adult patients with malignant tumors?	
KQ 5. Harms. What are the harms associated with treatment decisions that are informed by the genetic tests?	

	RCT	**non-RCT**	**Prospective cohort study**	**Retrospective cohort study**	**Case-control study**	**Case Series**
1. What is the study design?						
If "Other" study design, enter a description in this box:	**Yes**	**No**	**Partially**	**Can't Determine**	**NA**	**Explanation**
2. For RCTs, were randomization and allocation concealment adequate?						
3. Did the study apply inclusion/exclusion criteria uniformly to all comparison groups of the study?						
4. Is the selection of the comparison group appropriate, after taking into account feasibility and ethical considerations?						
5. Were groups similar at baseline?						
6. Were the outcome assessors blinded to the test result/intervention/exposure status of participants?						
7. Were outcomes assessed using valid and reliable measures, implemented consistently						

across all study participants?							
8. Was overall attrition less than 30%?							
9. Was differential attrition less than 15%?							
10. Does the analysis control for baseline differences between groups?							
11. Does the analysis account for differences in treatment received by the groups?							
12. Are the statistical methods used to assess the outcomes appropriate?							
13. **For KQ3 ONLY** – Did analyses adjust for all or most of the standard prognostic markers?							
Comments:							

Key Question 2	If study does NOT apply to this KQ, place an 'X' here (___)						
KQ 2. Analytic Validity. Does existing evidence establish the technical accuracy and reliability of the tests for detecting the relevant genetic markers?							
	Yes	**No**	**Unclear**	**NA**	**Low**	**High**	**Unclear**
Domain 1: Patient Selection							
Was a consecutive or random sample of patients enrolled?			X				
Was a case-control design avoided?	X						
Did the study avoid inappropriate exclusions?			X				
Could the selection of patients have introduced bias?							X
Domain 2: Index Test(s)							
Were the index test results interpreted without knowledge of the results of the reference standard?	X						
If a threshold was used, was it pre-specified?			X				
Could the conduct or interpretation of the index test have introduced bias?							X
Domain 3: Reference Standard							
Is the reference standard likely to correctly classify the genetic markers?				X			
Were the reference standard results interpreted without knowledge of the results of the index test?				X			
Could the reference standard, its conduct, or its interpretation have introduced bias?							X
Domain 4: Flow and Timing							
Did all patients receive a reference standard?				X			
Did patients receive the same reference standard?				X			
Were all patients included in the analysis?				X			
Could the patient flow have introduced bias?							X

KQ 5. Harms. What are the harms associated with treatment decisions that are informed by the genetic tests?	

	RCT	**non-RCT**	**Prospective cohort study**	**Retrospective cohort study**	**Case-control study**	**Case Series**
14. What is the study design?				**x**		
If "Other" study design, enter a description in this box:	**Yes**	**No**	**Partially**	**Can't Determine**	**NA**	**Explanation**
15. For RCTs, were randomization and allocation concealment adequate?					x	
16. Did the study apply inclusion/exclusion criteria uniformly to all comparison groups of the study?	x					
17. Is the selection of the comparison group appropriate, after taking into account feasibility and ethical considerations?	x					
18. Were groups similar at baseline?					x	
19. Were the outcome assessors blinded to the test result/intervention/exposure status of participants?	x					
20. Were outcomes assessed using valid and reliable measures, implemented consistently across all study participants?		x				
21. Was overall attrition less than 30%?					x	
22. Was differential attrition less than 15%?					x	
23. Does the analysis control for baseline	x					

differences between groups?						
24. Does the analysis account for differences in treatment received by the groups?					x	
25. Are the statistical methods used to assess the outcomes appropriate?	x					
26. **For KQ3 ONLY** – Did analyses adjust for all or most of the standard prognostic markers?	x					
Comments: This analysis claims that the Oncotype test changes decision making based on the study of hypotherical treatment decisions made by only TWO medical oncologists who disagreed in 20% of the case on what their treatment recommendation would be, in which case the authors just threw out one opinion. The design of the study is fine, but the conclusions they drew from it are vastly over-inflated.						

Key Question 2	If study does NOT apply to this KQ, place an 'X' here (X__)						
KQ 2. Analytic Validity. Does existing evidence establish the technical accuracy and reliability of the tests for detecting the relevant genetic markers?							
	Yes	**No**	**Unclear**	**NA**	**Low**	**High**	**Unclear**
Domain 1: Patient Selection							
Was a consecutive or random sample of patients enrolled?							
Was a case-control design avoided?							
Did the study avoid inappropriate exclusions?							
Could the selection of patients have introduced bias?

Worksheet for Risk of Bias of Individual Studies – GTRRC (v. 4-23-13)

Ref ID #	Author	Year
4021	Bargallo	2012

Indicate the appropriate risk of bias rating by placing an 'X' in the shaded space to the right of the rating for each KQ that is applicable. If a study does not apply to a KQ, put an 'X' next to N/A.

Risk of bias for KQ 1:	Low		Medium		High		N/A	X
Risk of bias for KQ 2:	Low		Medium		High		N/A	X
Risk of bias for KQ 3:	Low		Medium		High		N/A	X
Risk of bias for KQ 4a:	Low		Medium	X	High		N/A	
Risk of bias for KQ 4b:	Low		Medium		High		N/A	X
Risk of bias for KQ 5:	Low		Medium		High		N/A	X
Explain any **High** ratings:								

Low: Study has minimal bias. High degree of confidence that the true effect size is similar in size and direction to that reported.
Medium: Study has at least one significant source of bias, but does not have flaws that are likely to cause major bias. Moderate degree of confidence that the actual effect is in the direction reported by the study; moderate degree of confidence that the true effect size is similar to that reported.
High: Study has at least one major sources of bias or multiple significant sources of bias. Low degree of confidence that the true effect size is similar in size or direction to that reported.
NA: Not applicable to that key question.

Key Questions 1, 3, 4a, 4b, and 5	If the study does NOT apply to any of these KQs, place an 'X' here (___)

KQ 1: Overarching Question
Is there direct evidence that the addition of the following genetic tests used alone or in combination with traditional prognostic factors change physician decision making and improve outcomes for adult patients with lung, breast, colorectal, and bladder cancer compared with the use of traditional factors to predict risk of recurrence for adults with these cancers?

KQ 3. Clinical Validity. Does existing evidence establish the prognostic accuracy of the tests for predicting recurrence?

KQ 4a. Clinical Utility.
What is the evidence that the prognostic information provided by the genetic tests modifies physician decisions regarding use of adjuvant anti-neoplastic chemo- and/or radiotherapy; enhanced diagnostic testing for recurrence; and/or preventive surgery among adult patients with malignant tumors?

KQ 4b. Clinical Utility.
What is the evidence that modified decisions lead to improved overall survival, disease free survival, time to recurrence, quality of life, or incidence of serious side effects of adjuvant therapy in adult patients with malignant tumors?

KQ 5. Harms.
What are the harms associated with treatment decisions that are informed by the genetic tests?

	RCT	**non-RCT**	**Prospective cohort study**	**Retrospective cohort study**	**Case-control study**	**Case Series**
79. What is the study design?			**X**			
If "Other" study design, enter a description in this box:	**Yes**	**No**	**Partially**	**Can't Determine**	**NA**	**Explanation**
80. For RCTs, were randomization and allocation concealment adequate?					X	
81. Did the study apply inclusion/exclusion criteria uniformly to all comparison groups of the study?	X					Consecutive sample
82. Is the selection of the comparison group appropriate, after taking into account feasibility and ethical considerations?	X					
83. Were groups similar at baseline?				X		
84. Were the outcome assessors blinded to the test result/intervention/exposure status of participants?				X		But, not as important as some studies since the outcome is the questionnaire result
85. Were outcomes assessed using valid and reliable measures, implemented consistently				X		Multidisciplinary team completed

across all study participants?						questionnaires; no other information provided to determine validity and reliability of measures
86. Was overall attrition less than 30%?	X					
87. Was differential attrition less than 15%?	X					
88. Does the analysis control for baseline differences between groups?		X				
89. Does the analysis account for differences in treatment received by the groups?					X	
90. Are the statistical methods used to assess the outcomes appropriate?	X					
91. **For KQ3 ONLY** – Did analyses adjust for all or most of the standard prognostic markers?					X	
Comments:						

Key Question 2	If study does NOT apply to this KQ, place an 'X' here (_X_)						
KQ 2. Analytic Validity. Does existing evidence establish the technical accuracy and reliability of the tests for detecting the relevant genetic markers?							
	Yes	**No**	**Unclear**	**NA**	**Low**	**High**	**Unclear**
Domain 1: Patient Selection							
Was a consecutive or random sample of patients enrolled?							
Was a case-control design avoided?							
Did the study avoid inappropriate exclusions?							
Could the selection of patients have introduced bias?							
Domain 2: Index Test(s)							
Were the index test results interpreted without knowledge of the results of the reference standard?							
If a threshold was used, was it pre-specified?							
Could the conduct or interpretation of the index test have introduced bias?							
Domain 3: Reference Standard							
Is the reference standard likely to correctly classify the genetic markers?							
Were the reference standard results interpreted without knowledge of the results of the index test?							
Could the reference standard, its conduct, or its interpretation have introduced bias?							
Domain 4: Flow and Timing							
Did all patients receive a reference standard?							
Did patients receive the same reference standard?							
Were all patients included in the analysis?							
Could the patient flow have introduced bias?

KQ 5. Harms.
What are the harms associated with treatment decisions that are informed by the genetic tests?

	RCT	**non-RCT**	**Prospective cohort study**	**Retrospective cohort study**	**Case-control study**	**Case Series**
131. What is the study design?			**X**			
If "Other" study design, enter a description in this box:	**Yes**	**No**	**Partially**	**Can't Determine**	**NA**	**Explanation**
132. For RCTs, were randomization and allocation concealment adequate?					X	
133. Did the study apply inclusion/exclusion criteria uniformly to all comparison groups of the study?				X		Unclear, but seems to imply all patients during the time frame listed
134. Is the selection of the comparison group appropriate, after taking into account feasibility and ethical considerations?	X					
135. Were groups similar at baseline?				X		
136. Were the outcome assessors blinded to the test result/intervention/exposure status of participants?				X		They don't report blinding of outcome assessors.
137. Were outcomes assessed using valid and reliable measures, implemented consistently across all study participants?				X		No description of how they

						were ascertained
138. Was overall attrition less than 30%?	X					
139. Was differential attrition less than 15%?	X					
140. Does the analysis control for baseline differences between groups?					X	
141. Does the analysis account for differences in treatment received by the groups?					X	
142. Are the statistical methods used to assess the outcomes appropriate?	X					
143. **For KQ3 ONLY** – Did analyses adjust for all or most of the standard prognostic markers?					X	
Comments: Very limited reporting of study design and methods. At least medium risk of ascertainment/measurement bias. There are multiple reasons why someone might receive a different treatment than initially recommended (e.g., patient preferences, other medical problems limiting ability to undergo treatment). This study assumes that the test result is the reason, without attempting to measure causality accurately. They did not assess treatment recommendation before vs. after; they assessed treatment recommendation before vs. what ultimately happened.						

Key Question 2	If study does NOT apply to this KQ, place an 'X' here (_X_)						
KQ 2. Analytic Validity. Does existing evidence establish the technical accuracy and reliability of the tests for detecting the relevant genetic markers?							
	Yes	**No**	**Unclear**	**NA**	**Low**	**High**	**Unclear**
Domain 1: Patient Selection							
Was a consecutive or random sample of patients enrolled?							
Was a case-control design avoided?							
Did the study avoid inappropriate exclusions?

Worksheet for Risk of Bias of Individual Studies – GTRRC (v. 4-23-13)

Ref ID #	Author	Year
165	Bueno-de-Mesquita	2007

Indicate the appropriate risk of bias rating by placing an 'X' in the shaded space to the right of the rating for each KQ that is applicable. If a study does not apply to a KQ, put an 'X' next to N/A.

Risk of bias for KQ 1:	Low		Medium		High		N/A	X
Risk of bias for KQ 2:	Low		Medium		High		N/A	X
Risk of bias for KQ 3:	Low		Medium		High		N/A	X
Risk of bias for KQ 4a:	Low	X	Medium		High		N/A	
Risk of bias for KQ 4b:	Low		Medium		High		N/A	X
Risk of bias for KQ 5:	Low		Medium		High		N/A	X
Explain any **High** ratings:								

Low: Study has minimal bias. High degree of confidence that the true effect size is similar in size and direction to that reported.
Medium: Study has at least one significant source of bias, but does not have flaws that are likely to cause major bias. Moderate degree of confidence that the actual effect is in the direction reported by the study; moderate degree of confidence that the true effect size is similar to that reported.
High: Study has at least one major sources of bias or multiple significant sources of bias. Low degree of confidence that the true effect size is similar in size or direction to that reported.
NA: Not applicable to that key question.

Key Questions 1, 3, 4a, 4b, and 5	If the study does NOT apply to any of these KQs, place an 'X' here (___)

KQ 1: Overarching Question
Is there direct evidence that the addition of the following genetic tests used alone or in combination with traditional prognostic factors change physician decision making and improve outcomes for adult patients with lung, breast, colorectal, and bladder cancer compared with the use of traditional factors to predict risk of recurrence for adults with these cancers?

KQ 3. Clinical Validity. Does existing evidence establish the prognostic accuracy of the tests for predicting recurrence?

KQ 4a. Clinical Utility.
What is the evidence that the prognostic information provided by the genetic tests modifies physician decisions regarding use of adjuvant anti-neoplastic chemo- and/or radiotherapy; enhanced diagnostic testing for recurrence; and/or preventive surgery among adult patients with malignant tumors?

KQ 4b. Clinical Utility.
What is the evidence that modified decisions lead to improved overall survival, disease free survival, time to recurrence, quality of life, or incidence of serious side effects of adjuvant therapy in adult patients with malignant tumors?

KQ 5. Harms.
What are the harms associated with treatment decisions that are informed by the genetic tests?

	RCT	**non-RCT**	**Prospective cohort study**	**Retrospective cohort study**	**Case-control study**	**Case Series**
144. What is the study design?			**X**			
If "Other" study design, enter a description in this box:	**Yes**	**No**	**Partially**	**Can't Determine**	**NA**	**Explanation**
145. For RCTs, were randomization and allocation concealment adequate?					X	
146. Did the study apply inclusion/exclusion criteria uniformly to all comparison groups of the study?	X					
147. Is the selection of the comparison group appropriate, after taking into account feasibility and ethical considerations?	X					
148. Were groups similar at baseline?		X				
149. Were the outcome assessors blinded to the test result/intervention/exposure status of participants?				X		Pathologists were masked, but the outcomes of relevance for this article were decisions about treatment (NR if the

						investigators handling that data were masked to MammaPrint results)
150. Were outcomes assessed using valid and reliable measures, implemented consistently across all study participants?	X					
151. Was overall attrition less than 30%?	X					
152. Was differential attrition less than 15%?	X					
153. Does the analysis control for baseline differences between groups?		X				But, not essential to do so for the question of whether having the MammaPrint information changes decisions
154. Does the analysis account for differences in treatment received by the groups?		X				But, not essential for this question
155. Are the statistical methods used to assess the outcomes appropriate?	X					
156. **For KQ3 ONLY** – Did analyses adjust for all or most of the standard prognostic markers?					X	
Comments: Low risk of bias for assessing whether treatment decisions differ when using only the Dutch CBO guidelines (clinical information) and when also using MammaPrint results. Related to applicability of this study, the Dutch guidelines only include age, grade, and size, so whether adding MammaPrint result to decisions based on these 3 things doesn't quite get us the information of relevance to current practice in the US. We would need decisions based on all the current known prognostic factors, and then to determine whether they change with adding MammaPrint. In Table 2, they report a similar rate of discordance between Adjuvant! Online and MammaPrint as they report for the Dutch CBO guidelines and MammaPrint. This might suggest that adding MammaPrint to Adjuvant! Online would change a similar proportion of decisions as when adding it to the Dutch guidelines.						

Key Question 2	If study does NOT apply to this KQ, place an 'X' here (_X_)						
KQ 2. Analytic Validity. Does existing evidence establish the technical accuracy and reliability of the tests for detecting the relevant genetic markers?							
	Yes	**No**	**Unclear**	**NA**	**Low**	**High**	**Unclear**
Domain 1: Patient Selection							
Was a consecutive or random sample of patients enrolled?							
Was a case-control design avoided?							
Did the study avoid inappropriate exclusions?							
Could the selection of patients have introduced bias?							
Domain 2: Index Test(s)							
Were the index test results interpreted without knowledge of the results of the reference standard?							
If a threshold was used, was it pre-specified?							
Could the conduct or interpretation of the index test have introduced bias?							
Domain 3: Reference Standard							
Is the reference standard likely to correctly classify the genetic markers?							
Were the reference standard results interpreted without knowledge of the results of the index test?							
Could the reference standard, its conduct, or its interpretation have							

introduced bias?							
Domain 4: Flow and Timing							
Did all patients receive a reference standard?							
Did patients receive the same reference standard?							
Were all patients included in the analysis?							
Could the patient flow have introduced bias?							
Comments:							

Worksheet for Risk of Bias of Individual Studies – GTRRC (v. 4-23-13)

Ref ID #	Author	Year
3363	Bueno de Mesquita	2009

Indicate the appropriate risk of bias rating by placing an 'X' in the shaded space to the right of the rating for each KQ that is applicable. If a study does not apply to a KQ, put an 'X' next to N/A.

Risk of bias for KQ 1:	Low		Medium		High		N/A	
Risk of bias for KQ 2:	Low		Medium		High		N/A	
Risk of bias for KQ 3:	Low	X	Medium		High		N/A	
Risk of bias for KQ 4a:	Low		Medium		High		N/A	
Risk of bias for KQ 4b:	Low		Medium		High		N/A	
Risk of bias for KQ 5:	Low		Medium		High		N/A	
Explain any **High** ratings:								

Low: Study has minimal bias. High degree of confidence that the true effect size is similar in size and direction to that reported.
Medium: Study has at least one significant source of bias, but does not have flaws that are likely to cause major bias. Moderate degree of confidence that the actual effect is in the direction reported by the study; moderate degree of confidence that the true effect size is similar to that reported.
High: Study has at least one major sources of bias or multiple significant sources of bias. Low degree of confidence that the true effect size is similar in size or direction to that reported.
NA: Not applicable to that key question.

Key Questions 1, 3, 4a, 4b, and 5	If the study does NOT apply to any of these KQs, place an 'X' here (___)

KQ 1: Overarching Question
Is there direct evidence that the addition of the following genetic tests used alone or in combination with traditional prognostic factors change physician decision making and improve outcomes for adult patients with lung, breast, colorectal, and bladder cancer compared with the use of traditional factors to predict risk of recurrence for adults with these cancers?

KQ 3. Clinical Validity. Does existing evidence establish the prognostic accuracy of the tests for predicting recurrence?

KQ 4a. Clinical Utility.
What is the evidence that the prognostic information provided by the genetic tests modifies physician decisions regarding use of adjuvant anti-neoplastic chemo- and/or radiotherapy; enhanced diagnostic testing for recurrence; and/or preventive surgery among adult patients with malignant tumors?

KQ 4b. Clinical Utility.
What is the evidence that modified decisions lead to improved overall survival, disease free survival, time to recurrence, quality of life, or incidence of serious side effects of adjuvant therapy in adult patients with malignant tumors?

KQ 5. Harms.
What are the harms associated with treatment decisions that are informed by the genetic tests?

	RCT	**non-RCT**	**Prospective cohort study**	**Retrospective cohort study**	**Case-control study**	**Case Series**
157. What is the study design?			**X**			
If "Other" study design, enter a description in this box:	**Yes**	**No**	**Partially**	**Can't Determine**	**NA**	**Explanation**
158. For RCTs, were randomization and allocation concealment adequate?					X

Worksheet for Risk of Bias of Individual Studies – GTRRC (v. 4-23-13)

Ref ID #	Author	Year
4000	Cronin	2007

Indicate the appropriate risk of bias rating by placing an 'X' in the shaded space to the right of the rating for each KQ that is applicable. If a study does not apply to a KQ, put an 'X' next to N/A.

Risk of bias for KQ 1:	Low		Medium		High				N/A	X
Risk of bias for KQ 2:	Low		Medium		High		Unclear	X	N/A	
Risk of bias for KQ 3:	Low		Medium		High				N/A	X
Risk of bias for KQ 4a:	Low		Medium		High				N/A	X
Risk of bias for KQ 4b:	Low		Medium		High				N/A	X
Risk of bias for KQ 5:	Low		Medium		High				N/A	X
Explain any **High** ratings:										

Low: Study has minimal bias. High degree of confidence that the true effect size is similar in size and direction to that reported.
Medium: Study has at least one significant source of bias, but does not have flaws that are likely to cause major bias. Moderate degree of confidence that the actual effect is in the direction reported by the study; moderate degree of confidence that the true effect size is similar to that reported.
High: Study has at least one major sources of bias or multiple significant sources of bias. Low degree of confidence that the true effect size is similar in size or direction to that reported.
NA: Not applicable to that key question.

Key Questions 1, 3, 4a, 4b, and 5	If the study does NOT apply to any of these KQs, place an 'X' here (_X_)

KQ 1: Overarching Question
Is there direct evidence that the addition of the following genetic tests used alone or in combination with traditional prognostic factors change physician decision making and improve outcomes for adult patients with lung, breast, colorectal, and bladder cancer compared with the use of traditional factors to predict risk of recurrence for adults with these cancers?

KQ 3. Clinical Validity. Does existing evidence establish the prognostic accuracy of the tests for predicting recurrence?

KQ 4a. Clinical Utility.
What is the evidence that the prognostic information provided by the genetic tests modifies physician decisions regarding use of adjuvant anti-neoplastic chemo- and/or radiotherapy; enhanced diagnostic testing for recurrence; and/or preventive surgery among adult patients with malignant tumors?

KQ 4b. Clinical Utility.
What is the evidence that modified decisions lead to improved overall survival, disease free survival, time to recurrence, quality of life, or incidence of serious side effects of adjuvant therapy in adult patients with malignant tumors?

KQ 5. Harms.
What are the harms associated with treatment decisions that are informed by the genetic tests?

	RCT	**non-RCT**	**Prospective cohort study**	**Retrospective cohort study**	**Case-control study**	**Case Series**
222. What is the study design?						
If "Other" study design, enter a description in this box:	**Yes**	**No**	**Partially**	**Can't Determine**	**NA**	**Explanation**
223. For RCTs, were randomization and allocation concealment adequate?						
224. Did the study apply inclusion/exclusion criteria uniformly to all comparison groups of the study?						
225. Is the selection of the comparison group appropriate, after taking into account feasibility and ethical considerations?						
226. Were groups similar at baseline?						
227. Were the outcome assessors blinded to the test result/intervention/exposure status of participants?						
228. Were outcomes assessed using valid and reliable measures, implemented consistently across all study participants?						
229. Was overall attrition less than 30%?						
230. Was differential attrition less than 15%?						
231. Does the analysis control for baseline						

differences between groups?						
232. Does the analysis account for differences in treatment received by the groups?						
233. Are the statistical methods used to assess the outcomes appropriate?						
234. **For KQ3 ONLY** – Did analyses adjust for all or most of the standard prognostic markers?						
Comments:						

Key Question 2	If study does NOT apply to this KQ, place an 'X' here (_X_)						
KQ 2. Analytic Validity. Does existing evidence establish the technical accuracy and reliability of the tests for detecting the relevant genetic markers?							
	Yes	**No**	**Unclear**	**NA**	**Low**	**High**	**Unclear**
Domain 1: Patient Selection							
Was a consecutive or random sample of patients enrolled?			X				
Was a case-control design avoided?	X						
Did the study avoid inappropriate exclusions?			X				
Could the selection of patients have introduced bias?							X
Domain 2: Index Test(s)							
Were the index test results interpreted without knowledge of the results of the reference standard?			X				
If a threshold was used, was it pre-specified?				X			
Could the conduct or interpretation of the index test have introduced bias?							X
Domain 3: Reference Standard							
Is the reference standard likely to correctly classify the genetic markers?			X				
Were the reference standard results interpreted without knowledge of the results of the index test?			X				
Could the reference standard, its conduct, or its interpretation have introduced bias?							X
Domain 4: Flow and Timing							
Did all patients receive a reference standard?			X				
Did patients receive the same reference standard?	X						
Were all patients included in the analysis?			X				
Could the patient flow have introduced bias?							X
Comments: Limited information about patient/sample selection process, flow and timing; regarding the reference standard, as the authors describe, universal standard reference RNAs are not available for the 21 genes (their approach seems possibly reasonable, given the lack of a standard, but still raises some concern for bias).							

Worksheet for Risk of Bias of Individual Studies – GTRRC (v. 4-23-13)

Ref ID #	Author	Year
3461	Davidson	2013

Indicate the appropriate risk of bias rating by placing an 'X' in the shaded space to the right of the rating for each KQ that is applicable. If a study does not apply to a KQ, put an 'X' next to N/A.

Risk of bias for KQ 1:	Low		Medium		High		N/A	X
Risk of bias for KQ 2:	Low		Medium		High		N/A	X
Risk of bias for KQ 3:	Low		Medium		High		N/A	X
Risk of bias for KQ 4a:	Low		Medium	X	High		N/A	
Risk of bias for KQ 4b:	Low		Medium		High		N/A	X
Risk of bias for KQ 5:	Low		Medium		High		N/A	X
Explain any **High** ratings:								

Low: Study has minimal bias. High degree of confidence that the true effect size is similar in size and direction to that reported.
Medium: Study has at least one significant source of bias, but does not have flaws that are likely to cause major bias. Moderate degree of confidence that the actual effect is in the direction reported by the study; moderate degree of confidence that the true effect size is similar to that reported.
High: Study has at least one major sources of bias or multiple significant sources of bias. Low degree of confidence that the true effect size is similar in size or direction to that reported.
NA: Not applicable to that key question.

Key Questions 1, 3, 4a, 4b, and 5	If the study does NOT apply to any of these KQs, place an 'X' here (___)

KQ 1: Overarching Question
Is there direct evidence that the addition of the following genetic tests used alone or in combination with traditional prognostic factors change physician decision making and improve outcomes for adult patients with lung, breast, colorectal, and bladder cancer compared with the use of traditional factors to predict risk of recurrence for adults with these cancers?

KQ 3. Clinical Validity. Does existing evidence establish the prognostic accuracy of the tests for predicting recurrence?

KQ 4a. Clinical Utility.
What is the evidence that the prognostic information provided by the genetic tests modifies physician decisions regarding use of adjuvant anti-neoplastic chemo- and/or radiotherapy; enhanced diagnostic testing for recurrence; and/or preventive surgery among adult patients with malignant tumors?

KQ 4b. Clinical Utility.
What is the evidence that modified decisions lead to improved overall survival, disease free survival, time to recurrence, quality of life, or incidence of serious side effects of adjuvant therapy in adult patients with malignant tumors?

KQ 5. Harms.
What are the harms associated with treatment decisions that are informed by the genetic tests?

	RCT	**non-RCT**	**Prospective cohort study**	**Retrospective cohort study**	**Case-control study**	**Case Series**
235. What is the study design?		**Uncontrolled trial**				
If "Other" study design, enter a description in this box:	**Yes**	**No**	**Partially**	**Can't Determine**	**NA**	**Explanation**
236. For RCTs, were randomization and allocation concealment adequate?					X	
237. Did the study apply inclusion/exclusion criteria uniformly to all comparison groups of the study?	X					
238. Is the selection of the comparison group appropriate, after taking into account feasibility and ethical considerations?	X					Pre-post for change in decisions
239. Were groups similar at baseline?					X	1 group
240. Were the outcome assessors blinded to the test result/intervention/exposure status of participants?		X				
241. Were outcomes assessed using valid and reliable measures, implemented consistently across all study participants?	X					
242. Was overall attrition less than 30%?	X					

243. Was differential attrition less than 15%?	X					
244. Does the analysis control for baseline differences between groups?					X	
245. Does the analysis account for differences in treatment received by the groups?					X	
246. Are the statistical methods used to assess the outcomes appropriate?	X					
247. **For KQ3 ONLY** – Did analyses adjust for all or most of the standard prognostic markers?					X	
Comments: No information reported on the number of physicians making the decisions; unclear how wide a range of decisions this represents. Article does not show what information was provided to physicians with the test results (giving just the test results vs. more information about interpretation or recommendations for treatment that could impact decisions)						

Key Question 2	If study does NOT apply to this KQ, place an 'X' here (_X_)						
KQ 2. Analytic Validity. Does existing evidence establish the technical accuracy and reliability of the tests for detecting the relevant genetic markers?							
	Yes	**No**	**Unclear**	**NA**	**Low**	**High**	**Unclear**
Domain 1: Patient Selection							
Was a consecutive or random sample of patients enrolled?							
Was a case-control design avoided?							
Did the study avoid inappropriate exclusions?							
Could the selection of patients have introduced bias?							
Domain 2: Index Test(s)							
Were the index test results interpreted without knowledge of the results of the reference standard?

Could the patient flow have introduced bias?							X
Comments: Although some domains are unclear here, many methodological strengths described that may not be captured in this form.							

Worksheet for Risk of Bias of Individual Studies – GTRRC (v. 4-23-13)

Ref ID #	Author	Year
1584	Deschoolmeester	2010

Indicate the appropriate risk of bias rating by placing an 'X' in the shaded space to the right of the rating for each KQ that is applicable. If a study does not apply to a KQ, put an 'X' next to N/A.

Risk of bias for KQ 1:	Low		Medium		High		N/A	X
Risk of bias for KQ 2:	Low		Medium		High		N/A	X
Risk of bias for KQ 3:	Low	*	Medium	*	High	*	N/A	
Risk of bias for KQ 4a:	Low		Medium		High		N/A	X
Risk of bias for KQ 4b:	Low		Medium		High		N/A	X
Risk of bias for KQ 5:	Low		Medium		High		N/A	X
Explain any **High** ratings:	Unclear risk of selection bias, ascertainment bias, and confounding							

Low: Study has minimal bias. High degree of confidence that the true effect size is similar in size and direction to that reported.
Medium: Study has at least one significant source of bias, but does not have flaws that are likely to cause major bias. Moderate degree of confidence that the actual effect is in the direction reported by the study; moderate degree of confidence that the true effect size is similar to that reported.
High: Study has at least one major sources of bias or multiple significant sources of bias. Low degree of confidence that the true effect size is similar in size or direction to that reported.
NA: Not applicable to that key question.

Key Questions 1, 3, 4a, 4b, and 5	If the study does NOT apply to any of these KQs, place an 'X' here (___)

KQ 1: Overarching Question
Is there direct evidence that the addition of the following genetic tests used alone or in combination with traditional prognostic factors change physician decision making and improve outcomes for adult patients with lung, breast, colorectal, and bladder cancer compared with the use of traditional factors to predict risk of recurrence for adults with these cancers?

KQ 3. Clinical Validity. Does existing evidence establish the prognostic accuracy of the tests for predicting recurrence?

KQ 4a. Clinical Utility.
What is the evidence that the prognostic information provided by the genetic tests modifies physician decisions regarding use of adjuvant anti-neoplastic chemo- and/or radiotherapy; enhanced diagnostic testing for recurrence; and/or preventive surgery among adult patients with malignant tumors?

KQ 4b. Clinical Utility.
What is the evidence that modified decisions lead to improved overall survival, disease free survival, time to recurrence, quality of life, or incidence of serious side effects of adjuvant therapy in adult patients with malignant tumors?

KQ 5. Harms.
What are the harms associated with treatment decisions that are informed by the genetic tests?

	RCT	**non-RCT**	**Prospective cohort study**	**Retrospective cohort study**	**Case-control study**	**Case Series**
274. What is the study design?				**X**		
If "Other" study design, enter a description in this box:	**Yes**	**No**	**Partially**	**Can't Determine**	**NA**	**Explanation**
275. For RCTs, were randomization and allocation concealment adequate?					X	
276. Did the study apply inclusion/exclusion criteria uniformly to all comparison groups of the study?				X		None reported; unclear how the 164 tissue samples were selected other than that they were sporadic CRC
277. Is the selection of the comparison group appropriate, after taking into account feasibility and ethical considerations?	X					KRAS mutation vs wild-type
278. Were groups similar at baseline?				X		No data reported for the KRAS mutation vs. wild-type groups; only reports

						overall, and separate characteristic for colon and rectum cancers
279. Were the outcome assessors blinded to the test result/intervention/exposure status of participants?		X				
280. Were outcomes assessed using valid and reliable measures, implemented consistently across all study participants?				X		No information reported about how recurrence and death were ascertained
281. Was overall attrition less than 30%?				X		Median f/u was 4.5 years or longer, but data NR about how many subjects were missing outcome data or lost to follow up
282. Was differential attrition less than 15%?				X		
283. Does the analysis control for baseline differences between groups?				X		No baseline information reported, so unable to determine
284. Does the analysis account for differences in treatment received by the groups?				X		See comments
285. Are the statistical methods used to assess the outcomes appropriate?	X					
286. **For KQ3 ONLY** – Did analyses adjust for all or most of the standard prognostic markers?				X		See comments
Comments: For the multivariate analysis, it is unclear what was included. The methods report that they used a stepwise backward binary logistic regression to identify which of the clinicopathological parameters had the strongest impact on survival, but which parameters were considers is NR (possibly the things they report baseline characteristics for in Table 2: age, sex, location, grade, stage, therapy/neo-adjuvant/adjuvant, and MSI status). In the results (p 1630) they report results for multiple Cox regression analyses with age and stage.						

Key Question 2	If study does NOT apply to this KQ, place an 'X' here (_X_)						
KQ 2. Analytic Validity. Does existing evidence establish the technical accuracy and reliability of the tests for detecting the relevant genetic markers?

Worksheet for Risk of Bias of Individual Studies – GTRRC (v. 4-23-13)

Ref ID #	Author	Year
477	Donada	2011

Indicate the appropriate risk of bias rating by placing an 'X' in the shaded space to the right of the rating for each KQ that is applicable. If a study does not apply to a KQ, put an 'X' next to N/A.

Risk of bias for KQ 1:	Low		Medium		High		N/A	
Risk of bias for KQ 2:	Low		Medium		High		N/A	
Risk of bias for KQ 3:	Low	x	Medium		High		N/A	
Risk of bias for KQ 4a:	Low		Medium		High		N/A	
Risk of bias for KQ 4b:	Low		Medium		High		N/A	
Risk of bias for KQ 5:	Low		Medium		High		N/A	
Explain any **High** ratings:								

Low: Study has minimal bias. High degree of confidence that the true effect size is similar in size and direction to that reported.
Medium: Study has at least one significant source of bias, but does not have flaws that are likely to cause major bias. Moderate degree of confidence that the actual effect is in the direction reported by the study; moderate degree of confidence that the true effect size is similar to that reported.
High: Study has at least one major sources of bias or multiple significant sources of bias. Low degree of confidence that the true effect size is similar in size or direction to that reported.
NA: Not applicable to that key question.

Key Questions 1, 3, 4a, 4b, and 5	If the study does NOT apply to any of these KQs, place an 'X' here (___)
KQ 1: Overarching Question Is there direct evidence that the addition of the following genetic tests used alone or in combination with traditional prognostic factors change physician decision making and improve outcomes for adult patients with lung, breast, colorectal, and bladder cancer compared with the use of traditional factors to predict risk of recurrence for adults with these cancers?	
KQ 3. Clinical Validity. Does existing evidence establish the prognostic accuracy of the tests for predicting recurrence?	
KQ 4a. Clinical Utility. What is the evidence that the prognostic information provided by the genetic tests modifies physician decisions regarding use of adjuvant anti-neoplastic chemo- and/or radiotherapy; enhanced diagnostic testing for recurrence; and/or preventive surgery among adult patients with malignant tumors?	
KQ 4b. Clinical Utility. What is the evidence that modified decisions lead to improved overall survival, disease free survival, time to recurrence, quality of life, or incidence of serious side effects of adjuvant therapy in adult patients with malignant tumors?	
KQ 5. Harms. What are the harms associated with treatment decisions that are informed by the genetic tests?	

	RCT	**non-RCT**	**Prospective cohort study**	**Retrospective cohort study**	**Case-control study**	**Case Series**
287. What is the study design?				**X**		
If "Other" study design, enter a description in this box:	**Yes**	**No**	**Partially**	**Can't Determine**	**NA**	**Explanation**
288. For RCTs, were randomization and allocation concealment adequate?					x	
289. Did the study apply inclusion/exclusion criteria uniformly to all comparison groups of the study?	x					
290. Is the selection of the comparison group appropriate, after taking into account feasibility and ethical considerations?	x					
291. Were groups similar at baseline?					x	non-randomized study, MSI+ and MSI – naturally different
292. Were the outcome assessors blinded to the test result/intervention/exposure status of participants?		x				retrospective study, blinding not possible
293. Were outcomes assessed using valid and reliable measures, implemented consistently	x					

across all study participants?						
294. Was overall attrition less than 30%?					x	retrospective study limited to those with followup
295. Was differential attrition less than 15%?					x	
296. Does the analysis control for baseline differences between groups?	x					
297. Does the analysis account for differences in treatment received by the groups?					x	all treated with adjuvant 5FU
298. Are the statistical methods used to assess the outcomes appropriate?	x					
299. **For KQ3 ONLY** – Did analyses adjust for all or most of the standard prognostic markers?	x					
Comments:						

Key Question 2	If study does NOT apply to this KQ, place an 'X' here (___)						
KQ 2. Analytic Validity. Does existing evidence establish the technical accuracy and reliability of the tests for detecting the relevant genetic markers?							
	Yes	**No**	**Unclear**	**NA**	**Low**	**High**	**Unclear**
Domain 1: Patient Selection							
Was a consecutive or random sample of patients enrolled?							
Was a case-control design avoided?							
Did the study avoid inappropriate exclusions?							
Could the selection of patients have introduced bias?							
Domain 2: Index Test(s)							
Were the index test results interpreted without knowledge of the results of the reference standard?							
If a threshold was used, was it pre-specified?							
Could the conduct or interpretation of the index test have introduced bias?							
Domain 3: Reference Standard							
Is the reference standard likely to correctly classify the genetic markers?							
Were the reference standard results interpreted without knowledge of the results of the index test?							
Could the reference standard, its conduct, or its interpretation have introduced bias?							
Domain 4: Flow and Timing							
Did all patients receive a reference standard?							
Did patients receive the same reference standard?							
Were all patients included in the analysis?							
Could the patient flow have introduced bias?							
Comments:							

Worksheet for Risk of Bias of Individual Studies – GTRRC (v. 4-23-13)

Ref ID #	Author	Year
180	Dowsett	2010

Indicate the appropriate risk of bias rating by placing an 'X' in the shaded space to the right of the rating for each KQ that is applicable. If a study does not apply to a KQ, put an 'X' next to N/A.

Risk of bias for KQ 1:	Low		Medium		High		N/A	X
Risk of bias for KQ 2:	Low		Medium		High		N/A	X
Risk of bias for KQ 3:	Low		Medium	X	High		N/A	
Risk of bias for KQ 4a:	Low		Medium		High		N/A	X
Risk of bias for KQ 4b:	Low		Medium		High		N/A	X
Risk of bias for KQ 5:	Low		Medium		High		N/A	X
Explain any **High** ratings:								

Low: Study has minimal bias. High degree of confidence that the true effect size is similar in size and direction to that reported.
Medium: Study has at least one significant source of bias, but does not have flaws that are likely to cause major bias. Moderate degree of confidence that the actual effect is in the direction reported by the study; moderate degree of confidence that the true effect size is similar to that reported.
High: Study has at least one major sources of bias or multiple significant sources of bias. Low degree of confidence that the true effect size is similar in size or direction to that reported.
NA: Not applicable to that key question.

Key Questions 1, 3, 4a, 4b, and 5	If the study does NOT apply to any of these KQs, place an 'X' here (___)

KQ 1: Overarching Question
Is there direct evidence that the addition of the following genetic tests used alone or in combination with traditional prognostic factors change physician decision making and improve outcomes for adult patients with lung, breast, colorectal, and bladder cancer compared with the use of traditional factors to predict risk of recurrence for adults with these cancers?

KQ 3. Clinical Validity. Does existing evidence establish the prognostic accuracy of the tests for predicting recurrence?

KQ 4a. Clinical Utility.
What is the evidence that the prognostic information provided by the genetic tests modifies physician decisions regarding use of adjuvant anti-neoplastic chemo- and/or radiotherapy; enhanced diagnostic testing for recurrence; and/or preventive surgery among adult patients with malignant tumors?

KQ 4b. Clinical Utility.
What is the evidence that modified decisions lead to improved overall survival, disease free survival, time to recurrence, quality of life, or incidence of serious side effects of adjuvant therapy in adult patients with malignant tumors?

KQ 5. Harms.
What are the harms associated with treatment decisions that are informed by the genetic tests?

	RCT	**non-RCT**	**Prospective cohort study**	**Retrospective cohort study**	**Case-control study**	**Case Series**
300. What is the study design?			**X**			
If "Other" study design, enter a description in this box:	**Yes**	**No**	**Partially**	**Can't Determine**	**NA**	**Explanation**
301. For RCTs, were randomization and allocation concealment adequate?					X	
302. Did the study apply inclusion/exclusion criteria uniformly to all comparison groups of the study?	X					
303. Is the selection of the comparison group appropriate, after taking into account feasibility and ethical considerations?	X					
304. Were groups similar at baseline?				X		
305. Were the outcome assessors blinded to the test result/intervention/exposure status of participants?	X					Described in discussion
306. Were outcomes assessed using valid and reliable measures, implemented consistently across all study participants?				X		
307. Was overall attrition less than 30%?				X		
308. Was differential attrition less than 15%?				X		
309. Does the analysis control for baseline				X		

differences between groups?						
310. Does the analysis account for differences in treatment received by the groups?		X				
311. Are the statistical methods used to assess the outcomes appropriate?	X					
312. **For KQ3 ONLY** – Did analyses adjust for all or most of the standard prognostic markers?	X					
Comments: Analysis adjusted for tumor size, central grade, age, and positive nodes (>=4 vs. 1-3 nodes) (essentially looked at added value of RS beyond using Adjuvant! online. Positive nodes variable was only included in analyses for N+ patients. All subjects were hormone receptor + from a trial of tamoxifen vs. anastrozole. In this study the HR for RS was similar for patients receiving either treatment and there was no significant interaction of RS with treatment arm, reducing concern that treatment differences account for findings.						

Key Question 2	If study does NOT apply to this KQ, place an 'X' here (_X_)						
KQ 2. Analytic Validity. Does existing evidence establish the technical accuracy and reliability of the tests for detecting the relevant genetic markers?							
	Yes	**No**	**Unclear**	**NA**	**Low**	**High**	**Unclear**
Domain 1: Patient Selection							
Was a consecutive or random sample of patients enrolled?							
Was a case-control design avoided?							
Did the study avoid inappropriate exclusions?							
Could the selection of patients have introduced bias?							
Domain 2: Index Test(s)							
Were the index test results interpreted without knowledge of the results of the reference standard?							
If a threshold was used, was it pre-specified?							
Could the conduct or interpretation of the index test have introduced bias?							
Domain 3: Reference Standard							
Is the reference standard likely to correctly classify the genetic markers?							
Were the reference standard results interpreted without knowledge of the results of the index test?							
Could the reference standard, its conduct, or its interpretation have introduced bias?							
Domain 4: Flow and Timing

Did all patients receive a reference standard?	X						
Did patients receive the same reference standard?	X						
Were all patients included in the analysis?	X						
Could the patient flow have introduced bias?					X		
Comments: The study was looking at inter lab concordance. So not quite sure how the questions here apply. Some differences in techniques betweebn labs and LLD is different but still achieved 90% concordance in detection. Sample size is small.							

Worksheet for Risk of Bias of Individual Studies – GTRRC (v. 4-23-13)

Ref ID #	Author	Year
534	Gao	2010

Indicate the appropriate risk of bias rating by placing an 'X' in the shaded space to the right of the rating for each KQ that is applicable. If a study does not apply to a KQ, put an 'X' next to N/A.

Risk of bias for KQ 1:	Low		Medium		High		N/A	X
Risk of bias for KQ 2:	Low	*	Medium	*	High	*	N/A	
Risk of bias for KQ 3:	Low		Medium		High		N/A	X
Risk of bias for KQ 4a:	Low		Medium		High		N/A	X
Risk of bias for KQ 4b:	Low		Medium		High		N/A	X
Risk of bias for KQ 5:	Low		Medium		High		N/A	X
Explain any **High** ratings:	Unclear risk of bias due to inadequate reporting of patient selection and other methods							

Low: Study has minimal bias. High degree of confidence that the true effect size is similar in size and direction to that reported.
Medium: Study has at least one significant source of bias, but does not have flaws that are likely to cause major bias. Moderate degree of confidence that the actual effect is in the direction reported by the study; moderate degree of confidence that the true effect size is similar to that reported.
High: Study has at least one major sources of bias or multiple significant sources of bias. Low degree of confidence that the true effect size is similar in size or direction to that reported.
NA: Not applicable to that key question.

Key Questions 1, 3, 4a, 4b, and 5	If the study does NOT apply to any of these KQs, place an 'X' here (_X_)

KQ 1: Overarching Question
Is there direct evidence that the addition of the following genetic tests used alone or in combination with traditional prognostic factors change physician decision making and improve outcomes for adult patients with lung, breast, colorectal, and bladder cancer compared with the use of traditional factors to predict risk of recurrence for adults with these cancers?

KQ 3. Clinical Validity. Does existing evidence establish the prognostic accuracy of the tests for predicting recurrence?

KQ 4a. Clinical Utility.
What is the evidence that the prognostic information provided by the genetic tests modifies physician decisions regarding use of adjuvant anti-neoplastic chemo- and/or radiotherapy; enhanced diagnostic testing for recurrence; and/or preventive surgery among adult patients with malignant tumors?

KQ 4b. Clinical Utility.
What is the evidence that modified decisions lead to improved overall survival, disease free survival, time to recurrence, quality of life, or incidence of serious side effects of adjuvant therapy in adult patients with malignant tumors?

KQ 5. Harms.
What are the harms associated with treatment decisions that are informed by the genetic tests?

	RCT	**non-RCT**	**Prospective cohort study**	**Retrospective cohort study**	**Case-control study**	**Case Series**
365. What is the study design?						
If "Other" study design, enter a description in this box:	**Yes**	**No**	**Partially**	**Can't Determine**	**NA**	**Explanation**
366. For RCTs, were randomization and allocation concealment adequate?						
367. Did the study apply inclusion/exclusion criteria uniformly to all comparison groups of the study?						
368. Is the selection of the comparison group appropriate, after taking into account feasibility and ethical considerations?						
369. Were groups similar at baseline?						
370. Were the outcome assessors blinded to the test result/intervention/exposure status of participants?						
371. Were outcomes assessed using valid and reliable measures, implemented consistently across all study participants?						
372. Was overall attrition less than 30%?						
373. Was differential attrition less than 15%?						

374. Does the analysis control for baseline differences between groups?							
375. Does the analysis account for differences in treatment received by the groups?							
376. Are the statistical methods used to assess the outcomes appropriate?							
377. **For KQ3 ONLY** – Did analyses adjust for all or most of the standard prognostic markers?							
Comments:							

Key Question 2					If study does NOT apply to this KQ, place an 'X' here (___)		
KQ 2. Analytic Validity. Does existing evidence establish the technical accuracy and reliability of the tests for detecting the relevant genetic markers?							
	Yes	**No**	**Unclear**	**NA**	**Low**	**High**	**Unclear**
Domain 1: Patient Selection							
Was a consecutive or random sample of patients enrolled?			X				
Was a case-control design avoided?	X						
Did the study avoid inappropriate exclusions?			X				
Could the selection of patients have introduced bias?							X
Domain 2: Index Test(s)							
Were the index test results interpreted without knowledge of the results of the reference standard?			X				
If a threshold was used, was it pre-specified?				X			
Could the conduct or interpretation of the index test have introduced bias?							X
Domain 3: Reference Standard							
Is the reference standard likely to correctly classify the genetic markers?	X						
Were the reference standard results interpreted without knowledge of the results of the index test?			X				
Could the reference standard, its conduct, or its interpretation have introduced bias?							X
Domain 4: Flow and Timing							
Did all patients receive a reference standard?	X						
Did patients receive the same reference standard?	X						
Were all patients included in the analysis?	X						
Could the patient flow have introduced bias?					X		
Comments: Unclear risk of bias due to incomplete reporting							

Worksheet for Risk of Bias of Individual Studies – GTRRC (v. 4-23-13)

Ref ID #	Author	Year
183	Geffen	2011

Indicate the appropriate risk of bias rating by placing an 'X' in the shaded space to the right of the rating for each KQ that is applicable. If a study does not apply to a KQ, put an 'X' next to N/A.

Risk of bias for KQ 1:	Low		Medium		High		N/A	
Risk of bias for KQ 2:	Low		Medium		High		N/A	
Risk of bias for KQ 3:	Low		Medium		High		N/A	
Risk of bias for KQ 4a:	Low		Medium	x	High		N/A	
Risk of bias for KQ 4b:	Low		Medium		High		N/A	
Risk of bias for KQ 5:	Low		Medium		High		N/A	
Explain any **High** ratings:								

Low: Study has minimal bias. High degree of confidence that the true effect size is similar in size and direction to that reported.
Medium: Study has at least one significant source of bias, but does not have flaws that are likely to cause major bias. Moderate degree of confidence that the actual effect is in the direction reported by the study; moderate degree of confidence that the true effect size is similar to that reported.
High: Study has at least one major sources of bias or multiple significant sources of bias. Low degree of confidence that the true effect size is similar in size or direction to that reported.
NA: Not applicable to that key question.

Key Questions 1, 3, 4a, 4b, and 5	If the study does NOT apply to any of these KQs, place an 'X' here (___)
KQ 1: Overarching Question Is there direct evidence that the addition of the following genetic tests used alone or in combination with traditional prognostic factors change physician decision making and improve outcomes for adult patients with lung, breast, colorectal, and bladder cancer compared with the use of traditional factors to predict risk of recurrence for adults with these cancers?	
KQ 3. Clinical Validity. Does existing evidence establish the prognostic accuracy of the tests for predicting recurrence?	
KQ 4a. Clinical Utility. What is the evidence that the prognostic information provided by the genetic tests modifies physician decisions regarding use of adjuvant anti-neoplastic chemo- and/or radiotherapy; enhanced diagnostic testing for recurrence; and/or preventive surgery among adult patients with malignant tumors?	
KQ 4b. Clinical Utility. What is the evidence that modified decisions lead to improved overall survival, disease free survival, time to recurrence, quality of life, or incidence of serious side effects of adjuvant therapy in adult patients with malignant tumors?	
KQ 5. Harms. What are the harms associated with treatment decisions that are informed by the genetic tests?	

	RCT	**non-RCT**	**Prospective cohort study**	**Retrospective cohort study**	**Case-control study**	**Case Series**
378. What is the study design?				**xx**		
If "Other" study design, enter a description in this box:	**Yes**	**No**	**Partially**	**Can't Determine**	**NA**	**Explanation**
379. For RCTs, were randomization and allocation concealment adequate?					x	
380. Did the study apply inclusion/exclusion criteria uniformly to all comparison groups of the study?			x			All women tested were examined but authors acknowledge that some eligible women were not tested
381. Is the selection of the comparison group appropriate, after taking into account feasibility and ethical considerations?					x	Pre/post comparison same subjects
382. Were groups similar at baseline?					x	Pre/post comparison
383. Were the outcome assessors blinded to the test result/intervention/exposure status of participants?		x				

384. Were outcomes assessed using valid and reliable measures, implemented consistently across all study participants?			x			Authors state they determined "pre test" recommendation on based on usual clinical practice but acknowledge this included clinical judgement, actual recommendation was not recorded before getting RS
385. Was overall attrition less than 30%?					x	
386. Was differential attrition less than 15%?					x	
387. Does the analysis control for baseline differences between groups?					x	
388. Does the analysis account for differences in treatment received by the groups?					x	
389. Are the statistical methods used to assess the outcomes appropriate?						
390. **For KQ3 ONLY** – Did analyses adjust for all or most of the standard prognostic markers?	x					
Comments:						

Key Question 2	If study does NOT apply to this KQ, place an 'X' here (X__)						
KQ 2. Analytic Validity. Does existing evidence establish the technical accuracy and reliability of the tests for detecting the relevant genetic markers?

Worksheet for Risk of Bias of Individual Studies – GTRRC (v. 4-23-13)

Ref ID #	Author	Year
579	Gryfe	2000

Indicate the appropriate risk of bias rating by placing an 'X' in the shaded space to the right of the rating for each KQ that is applicable. If a study does not apply to a KQ, put an 'X' next to N/A.

Risk of bias for KQ 1:	Low		Medium		High		N/A	X
Risk of bias for KQ 2:	Low		Medium		High		N/A	X
Risk of bias for KQ 3:	Low		Medium	X	High		N/A	
Risk of bias for KQ 4a:	Low		Medium		High		N/A	X
Risk of bias for KQ 4b:	Low		Medium		High		N/A	X
Risk of bias for KQ 5:	Low		Medium		High		N/A	X
Explain any **High** ratings:								

Low: Study has minimal bias. High degree of confidence that the true effect size is similar in size and direction to that reported.
Medium: Study has at least one significant source of bias, but does not have flaws that are likely to cause major bias. Moderate degree of confidence that the actual effect is in the direction reported by the study; moderate degree of confidence that the true effect size is similar to that reported.
High: Study has at least one major sources of bias or multiple significant sources of bias. Low degree of confidence that the true effect size is similar in size or direction to that reported.
NA: Not applicable to that key question.

Key Questions 1, 3, 4a, 4b, and 5	If the study does NOT apply to any of these KQs, place an 'X' here (___)

KQ 1: Overarching Question
Is there direct evidence that the addition of the following genetic tests used alone or in combination with traditional prognostic factors change physician decision making and improve outcomes for adult patients with lung, breast, colorectal, and bladder cancer compared with the use of traditional factors to predict risk of recurrence for adults with these cancers?

KQ 3. Clinical Validity. Does existing evidence establish the prognostic accuracy of the tests for predicting recurrence?

KQ 4a. Clinical Utility.
What is the evidence that the prognostic information provided by the genetic tests modifies physician decisions regarding use of adjuvant anti-neoplastic chemo- and/or radiotherapy; enhanced diagnostic testing for recurrence; and/or preventive surgery among adult patients with malignant tumors?

KQ 4b. Clinical Utility.
What is the evidence that modified decisions lead to improved overall survival, disease free survival, time to recurrence, quality of life, or incidence of serious side effects of adjuvant therapy in adult patients with malignant tumors?

KQ 5. Harms.
What are the harms associated with treatment decisions that are informed by the genetic tests?

	RCT	**non-RCT**	**Prospective cohort study**	**Retrospective cohort study**	**Case-control study**	**Case Series**
430. What is the study design?			**X**			
If "Other" study design, enter a description in this box:	**Yes**	**No**	**Partially**	**Can't Determine**	**NA**	**Explanation**
431. For RCTs, were randomization and allocation concealment adequate?					X	
432. Did the study apply inclusion/exclusion criteria uniformly to all comparison groups of the study?	X					
433. Is the selection of the comparison group appropriate, after taking into account feasibility and ethical considerations?	X					
434. Were groups similar at baseline?			X			Differences for synchronous or metachronous, location (more proximal among the MSI group), grade (more poorly

						differentiated among MSI group), and stage (fewer stage 4 in MSI group)
435. Were the outcome assessors blinded to the test result/intervention/exposure status of participants?	X					
436. Were outcomes assessed using valid and reliable measures, implemented consistently across all study participants?	X					
437. Was overall attrition less than 30%?	X					
438. Was differential attrition less than 15%?	X					
439. Does the analysis control for baseline differences between groups?	X					
440. Does the analysis account for differences in treatment received by the groups?		X				Treatment differences were not included in the multivariate analysis; and information on chemo initiated within 120 days was only available for 65% of subjects
441. Are the statistical methods used to assess the outcomes appropriate?	X					
442. **For KQ3 ONLY** – Did analyses adjust for all or most of the standard prognostic markers?	X					See comments below
Comments: Multivariate model obtained with step-down variable selection, in which all prognostic factors were initially entered and those with P>0.1 were rejected. Model did not include treatment differences and the outcome of the model is OS, not recurrence, so there are still a number of other potential confounders that could alter risk of death that the study does not consider (e.g., heart disease, diabetes).						

Key Question 2	If study does NOT apply to this KQ, place an 'X' here (_X_)						
KQ 2. Analytic Validity. Does existing evidence establish the technical accuracy and reliability of the tests for detecting the relevant genetic markers?							
	Yes	**No**	**Unclear**	**NA**	**Low**	**High**	**Unclear**
Domain 1: Patient Selection							
Was a consecutive or random sample of patients enrolled?							
Was a case-control design avoided?							
Did the study avoid inappropriate exclusions?							
Could the selection of patients have introduced bias?							
Domain 2: Index Test(s)							
Were the index test results interpreted without knowledge of the results of the reference standard?							
If a threshold was used, was it pre-specified?							
Could the conduct or interpretation of the index test have introduced bias?							
Domain 3: Reference Standard							
Is the reference standard likely to correctly classify the genetic markers?							

Were the reference standard results interpreted without knowledge of the results of the index test?							
Could the reference standard, its conduct, or its interpretation have introduced bias?							
Domain 4: Flow and Timing							
Did all patients receive a reference standard?							
Did patients receive the same reference standard?							
Were all patients included in the analysis?							
Could the patient flow have introduced bias?

Worksheet for Risk of Bias of Individual Studies – GTRRC (v. 4-23-13)

Ref ID #	Author	Year
3751	Guan	2013

Indicate the appropriate quality rating by placing an 'X' in the shaded space to the right of the rating for each KQ that is applicable **AND** for an Overall rating. If a study does not apply to a KQ, put an 'X' next to N/A.

Risk of bias for KQ 1:	Low		Medium		High		N/A	X
Risk of bias for KQ 2:	Low		Medium		High		N/A	X
Risk of bias for KQ 3:	Low		Medium	X	High		N/A	
Risk of bias for KQ 4a:	Low		Medium		High		N/A	X
Risk of bias for KQ 4b:	Low		Medium		High		N/A	X
Risk of bias for KQ 5:	Low		Medium		High		N/A	X
Explain any **High** ratings:								

Low: Study has minimal bias. High degree of confidence that the true effect size is similar in size and direction to that reported.
Medium: Study has at least one significant source of bias, but does not have flaws that are likely to cause major bias. Moderate degree of confidence that the actual effect is in the direction reported by the study; moderate degree of confidence that the true effect size is similar to that reported.
High: Study has at least one major sources of bias or multiple significant sources of bias. Low degree of confidence that the true effect size is similar in size or direction to that reported.
NA: Not applicable to that key question.

Key Questions 1, 3, 4a, 4b, and 5	If the study does NOT apply to any of these KQs, place an 'X' here (___)

KQ 1: Overarching Question
Is there direct evidence that the addition of the following genetic tests used alone or in combination with traditional prognostic factors change physician decision making and improve outcomes for adult patients with lung, breast, colorectal, and bladder cancer compared with the use of traditional factors to predict risk of recurrence for adults with these cancers?

KQ 3. Clinical Validity. Does existing evidence establish the prognostic accuracy of the tests for predicting recurrence?

KQ 4a. Clinical Utility.
What is the evidence that the prognostic information provided by the genetic tests modifies physician decisions regarding use of adjuvant anti-neoplastic chemo- and/or radiotherapy; enhanced diagnostic testing for recurrence; and/or preventive surgery among adult patients with malignant tumors?

KQ 4b. Clinical Utility.
What is the evidence that modified decisions lead to improved overall survival, disease free survival, time to recurrence, quality of life, or incidence of serious side effects of adjuvant therapy in adult patients with malignant tumors?

KQ 5. Harms.
What are the harms associated with treatment decisions that are informed by the genetic tests?

	RCT	**non-RCT**	**Prospective cohort study**	**Retrospective cohort study**	**Case-control study**	**Case Series**
443. What is the study design?			**X**			
If "Other" study design, enter a description in this box:	**Yes**	**No**	**Partially**	**Can't Determine**	**NA**	**Explanation**
444. For RCTs, were randomization and allocation concealment adequate?					X	
445. Did the study apply inclusion/exclusion criteria uniformly to all comparison groups of the study?	X					
446. Is the selection of the comparison group appropriate, after taking into account feasibility and ethical considerations?			X			Some confusion in the description of the exclusion criteria which eliminated patients with EGFR mutations at exon 18 or 20 and the matched EGFR mutation group.

447. Were groups similar at baseline?	X					
448. Were the outcome assessors blinded to the test result/intervention/exposure status of participants?				X		
449. Were outcomes assessed using valid and reliable measures, implemented consistently across all study participants?	X					
450. Was overall attrition less than 30%?	X					
451. Was differential attrition less than 15%?	X					
452. Does the analysis control for baseline differences between groups?	X					
453. Does the analysis account for differences in treatment received by the groups?		X				
454. Are the statistical methods used to assess the outcomes appropriate?	X					
455. **For KQ3 ONLY** – Did analyses adjust for all or most of the standard prognostic markers?	X					
Comments: Primary analysis for OS did not control for treatment. Matching description a little confusing						

Key Question 2	If study does NOT apply to this KQ, place an 'X' here (___)						
KQ 2. Analytic Validity. Does existing evidence establish the technical accuracy and reliability of the tests for detecting the relevant genetic markers?							
	Yes	**No**	**Unclear**	**NA**	**Low**	**High**	**Unclear**
Domain 1: Patient Selection							
Was a consecutive or random sample of patients enrolled?							
Was a case-control design avoided?							
Did the study avoid inappropriate exclusions?							
Could the selection of patients have introduced bias?							
Domain 2: Index Test(s)							
Were the index test results interpreted without knowledge of the results of the reference standard?							
If a threshold was used, was it pre-specified?							
Could the conduct or interpretation of the index test have introduced bias?							
Domain 3: Reference Standard							
Is the reference standard likely to correctly classify the genetic markers?							
Were the reference standard results interpreted without knowledge of the results of the index test?							
Could the reference standard, its conduct, or its interpretation have introduced bias?							
Domain 4: Flow and Timing							
Did all patients receive a reference standard?							
Did patients receive the same reference standard?							
Were all patients included in the analysis?							
Could the patient flow have introduced bias?							
Comments:							

Worksheet for Risk of Bias of Individual Studies – GTRRC (v. 4-23-13)

Ref ID #	Author	Year
581	Guidoboni	2001

Indicate the appropriate risk of bias rating by placing an 'X' in the shaded space to the right of the rating for each KQ that is applicable. If a study does not apply to a KQ, put an 'X' next to N/A.

Risk of bias for KQ 1:	Low		Medium		High		N/A	X
Risk of bias for KQ 2:	Low		Medium		High		N/A	X
Risk of bias for KQ 3:	Low		Medium	X	High		N/A	
Risk of bias for KQ 4a:	Low		Medium		High		N/A	X
Risk of bias for KQ 4b:	Low		Medium		High		N/A	X
Risk of bias for KQ 5:	Low		Medium		High		N/A	X
Explain any **High** ratings:								

Low: Study has minimal bias. High degree of confidence that the true effect size is similar in size and direction to that reported.
Medium: Study has at least one significant source of bias, but does not have flaws that are likely to cause major bias. Moderate degree of confidence that the actual effect is in the direction reported by the study; moderate degree of confidence that the true effect size is similar to that reported.
High: Study has at least one major sources of bias or multiple significant sources of bias. Low degree of confidence that the true effect size is similar in size or direction to that reported.
NA: Not applicable to that key question.

Key Questions 1, 3, 4a, 4b, and 5	If the study does NOT apply to any of these KQs, place an 'X' here (___)

KQ 1: Overarching Question
Is there direct evidence that the addition of the following genetic tests used alone or in combination with traditional prognostic factors change physician decision making and improve outcomes for adult patients with lung, breast, colorectal, and bladder cancer compared with the use of traditional factors to predict risk of recurrence for adults with these cancers?

KQ 3. Clinical Validity. Does existing evidence establish the prognostic accuracy of the tests for predicting recurrence?

KQ 4a. Clinical Utility.
What is the evidence that the prognostic information provided by the genetic tests modifies physician decisions regarding use of adjuvant anti-neoplastic chemo- and/or radiotherapy; enhanced diagnostic testing for recurrence; and/or preventive surgery among adult patients with malignant tumors?

KQ 4b. Clinical Utility.
What is the evidence that modified decisions lead to improved overall survival, disease free survival, time to recurrence, quality of life, or incidence of serious side effects of adjuvant therapy in adult patients with malignant tumors?

KQ 5. Harms.
What are the harms associated with treatment decisions that are informed by the genetic tests?

	RCT	**non-RCT**	**Prospective cohort study**	**Retrospective cohort study**	**Case-control study**	**Case Series**
456. What is the study design?				**X**		
If "Other" study design, enter a description in this box:	**Yes**	**No**	**Partially**	**Can't Determine**	**NA**	**Explanation**
457. For RCTs, were randomization and allocation concealment adequate?					X	
458. Did the study apply inclusion/exclusion criteria uniformly to all comparison groups of the study?	X					
459. Is the selection of the comparison group appropriate, after taking into account feasibility and ethical considerations?	X					
460. Were groups similar at baseline?		X				Higher proportion 60 and older, with poorly differentiated tumor, and with mucoid histological type in the MSI-H group
461. Were the outcome assessors blinded to the test result/intervention/exposure status of				X		

participants?						
462. Were outcomes assessed using valid and reliable measures, implemented consistently across all study participants?	X					
463. Was overall attrition less than 30%?	X					
464. Was differential attrition less than 15%?	X					
465. Does the analysis control for baseline differences between groups?		X				Other than age, the things listed above were not included in the analysis
466. Does the analysis account for differences in treatment received by the groups?		X				But a very similar proportion of subjects in both groups received adjuvant chemo
467. Are the statistical methods used to assess the outcomes appropriate?	X					
468. **For KQ3 ONLY** – Did analyses adjust for all or most of the standard prognostic markers?	X					Adjusted for age, sex, and stage (and all tumors were right sided/proximal); did not adjust for grade or cellular subtypes
Comments: Small to moderate risk of measurement bias with unclear masking of outcome assessors; moderate risk of confounding with some baseline differences between groups not considered in the analysis						

Key Question 2	If study does NOT apply to this KQ, place an 'X' here (_X_)						
KQ 2. Analytic Validity. Does existing evidence establish the technical accuracy and reliability of the tests for detecting the relevant genetic markers?							
	Yes	**No**	**Unclear**	**NA**	**Low**	**High**	**Unclear**
Domain 1: Patient Selection							
Was a consecutive or random sample of patients enrolled?							
Was a case-control design avoided?							
Did the study avoid inappropriate exclusions?							
Could the selection of patients have introduced bias?							
Domain 2: Index Test(s)							
Were the index test results interpreted without knowledge of the results of the reference standard?

Worksheet for Risk of Bias of Individual Studies – GTRRC (v. 4-23-13)

Ref ID #	Author	Year
2051	Hiramatsu	2010

Indicate the appropriate risk of bias rating by placing an 'X' in the shaded space to the right of the rating for each KQ that is applicable. If a study does not apply to a KQ, put an 'X' next to N/A.

Risk of bias for KQ 1:	Low		Medium		High		N/A	X
Risk of bias for KQ 2:	Low		Medium		High		N/A	X
Risk of bias for KQ 3:	Low		Medium		High	X	N/A	
Risk of bias for KQ 4a:	Low		Medium		High		N/A	X
Risk of bias for KQ 4b:	Low		Medium		High		N/A	X
Risk of bias for KQ 5:	Low		Medium		High		N/A	X
Explain any **High** ratings:	High risk of selection bias, ascertainment bias, and confounding.							

Low: Study has minimal bias. High degree of confidence that the true effect size is similar in size and direction to that reported.
Medium: Study has at least one significant source of bias, but does not have flaws that are likely to cause major bias. Moderate degree of confidence that the actual effect is in the direction reported by the study; moderate degree of confidence that the true effect size is similar to that reported.
High: Study has at least one major sources of bias or multiple significant sources of bias. Low degree of confidence that the true effect size is similar in size or direction to that reported.
NA: Not applicable to that key question.

Key Questions 1, 3, 4a, 4b, and 5	If the study does NOT apply to any of these KQs, place an 'X' here (___)
KQ 1: Overarching Question Is there direct evidence that the addition of the following genetic tests used alone or in combination with traditional prognostic factors change physician decision making and improve outcomes for adult patients with lung, breast, colorectal, and bladder cancer compared with the use of traditional factors to predict risk of recurrence for adults with these cancers?	
KQ 3. Clinical Validity. Does existing evidence establish the prognostic accuracy of the tests for predicting recurrence?	
KQ 4a. Clinical Utility. What is the evidence that the prognostic information provided by the genetic tests modifies physician decisions regarding use of adjuvant anti-neoplastic chemo- and/or radiotherapy; enhanced diagnostic testing for recurrence; and/or preventive surgery among adult patients with malignant tumors?	
KQ 4b. Clinical Utility. What is the evidence that modified decisions lead to improved overall survival, disease free survival, time to recurrence, quality of life, or incidence of serious side effects of adjuvant therapy in adult patients with malignant tumors?	
KQ 5. Harms. What are the harms associated with treatment decisions that are informed by the genetic tests?	

	RCT	**non-RCT**	**Prospective cohort study**	**Retrospective cohort study**	**Case-control study**	**Case Series**
508. What is the study design?				**X**		
If "Other" study design, enter a description in this box:	**Yes**	**No**	**Partially**	**Can't Determine**	**NA**	**Explanation**
509. For RCTs, were randomization and allocation concealment adequate?					X	
510. Did the study apply inclusion/exclusion criteria uniformly to all comparison groups of the study?				X		Methods of selecting included cases NR
511. Is the selection of the comparison group appropriate, after taking into account feasibility and ethical considerations?	X					Probably, but methods of selecting the full sample are not described
512. Were groups similar at baseline?				X		Baseline data are not reported by mutation status
513. Were the outcome assessors blinded to the test result/intervention/exposure status of participants?				X		

514. Were outcomes assessed using valid and reliable measures, implemented consistently across all study participants?				X		No methods reported for how the prognostic outcomes were defined or ascertained
515. Was overall attrition less than 30%?		X				
516. Was differential attrition less than 15%?				X		
517. Does the analysis control for baseline differences between groups?				X		
518. Does the analysis account for differences in treatment received by the groups?		X				
519. Are the statistical methods used to assess the outcomes appropriate?	X					
520. **For KQ3 ONLY** – Did analyses adjust for all or most of the standard prognostic markers?	X					
Comments: High risk of selection bias, ascertainment bias, and confounding. Methods of selecting the 193 lung cancer cases NR; only evaluated EGFR and KRAS mutation status for 93/193 (48%) and reasons for selecting those 93 were NR; no description of how outcomes were defined or ascertained (it is described in the results as "survival", but unclear if it is disease-specific or overall survival; but seems more likely overall survival); analyses don't account for differences in treatment received.						

Key Question 2	If study does NOT apply to this KQ, place an 'X' here (_X_)						
KQ 2. Analytic Validity. Does existing evidence establish the technical accuracy and reliability of the tests for detecting the relevant genetic markers?							
	Yes	**No**	**Unclear**	**NA**	**Low**	**High**	**Unclear**
Domain 1: Patient Selection							
Was a consecutive or random sample of patients enrolled?							
Was a case-control design avoided?							
Did the study avoid inappropriate exclusions?							
Could the selection of patients have introduced bias?							
Domain 2: Index Test(s)							
Were the index test results interpreted without knowledge of the results of the reference standard?							
If a threshold was used, was it pre-specified?							
Could the conduct or interpretation of the index test have introduced bias?							
Domain 3: Reference Standard							
Is the reference standard likely to correctly classify the genetic markers?							
Were the reference standard results interpreted without knowledge of the results of the index test?							
Could the reference standard, its conduct, or its interpretation have introduced bias?							
Domain 4: Flow and Timing							
Did all patients receive a reference standard?							
Did patients receive the same reference standard?							
Were all patients included in the analysis?							
Could the patient flow have introduced bias?							
Comments:							

Worksheet for Risk of Bias of Individual Studies – GTRRC (v. 4-23-13)

Ref ID #	Author	Year
3507	Holt	2013

Indicate the appropriate risk of bias rating by placing an 'X' in the shaded space to the right of the rating for each KQ that is applicable. If a study does not apply to a KQ, put an 'X' next to N/A.

Risk of bias for KQ 1:	Low		Medium		High		N/A	X
Risk of bias for KQ 2:	Low		Medium		High		N/A	X
Risk of bias for KQ 3:	Low		Medium		High		N/A	X
Risk of bias for KQ 4a:	Low		Medium	X	High		N/A	
Risk of bias for KQ 4b:	Low		Medium		High		N/A	X
Risk of bias for KQ 5:	Low		Medium		High		N/A	X
Explain any **High** ratings:								

Low: Study has minimal bias. High degree of confidence that the true effect size is similar in size and direction to that reported.
Medium: Study has at least one significant source of bias, but does not have flaws that are likely to cause major bias. Moderate degree of confidence that the actual effect is in the direction reported by the study; moderate degree of confidence that the true effect size is similar to that reported.
High: Study has at least one major sources of bias or multiple significant sources of bias. Low degree of confidence that the true effect size is similar in size or direction to that reported.
NA: Not applicable to that key question.

Key Questions 1, 3, 4a, 4b, and 5	If the study does NOT apply to any of these KQs, place an 'X' here (___)

KQ 1: Overarching Question
Is there direct evidence that the addition of the following genetic tests used alone or in combination with traditional prognostic factors change physician decision making and improve outcomes for adult patients with lung, breast, colorectal, and bladder cancer compared with the use of traditional factors to predict risk of recurrence for adults with these cancers?

KQ 3. Clinical Validity. Does existing evidence establish the prognostic accuracy of the tests for predicting recurrence?

KQ 4a. Clinical Utility.
What is the evidence that the prognostic information provided by the genetic tests modifies physician decisions regarding use of adjuvant anti-neoplastic chemo- and/or radiotherapy; enhanced diagnostic testing for recurrence; and/or preventive surgery among adult patients with malignant tumors?

KQ 4b. Clinical Utility.
What is the evidence that modified decisions lead to improved overall survival, disease free survival, time to recurrence, quality of life, or incidence of serious side effects of adjuvant therapy in adult patients with malignant tumors?

KQ 5. Harms.
What are the harms associated with treatment decisions that are informed by the genetic tests?

	RCT	**non-RCT**	**Prospective cohort study**	**Retrospective cohort study**	**Case-control study**	**Case Series**
521. What is the study design?		**Uncontrolled trial**				
If "Other" study design, enter a description in this box:	**Yes**	**No**	**Partially**	**Can't Determine**	**NA**	**Explanation**
522. For RCTs, were randomization and allocation concealment adequate?					X	
523. Did the study apply inclusion/exclusion criteria uniformly to all comparison groups of the study?	X					
524. Is the selection of the comparison group appropriate, after taking into account feasibility and ethical considerations?	X					
525. Were groups similar at baseline?				X		
526. Were the outcome assessors blinded to the test result/intervention/exposure status of participants?				X		
527. Were outcomes assessed using valid and reliable measures, implemented consistently across all study participants?				X		
528. Was overall attrition less than 30%?	X					

529. Was differential attrition less than 15%?	X					
530. Does the analysis control for baseline differences between groups?		X				
531. Does the analysis account for differences in treatment received by the groups?	X					
532. Are the statistical methods used to assess the outcomes appropriate?	X					
533. **For KQ3 ONLY** – Did analyses adjust for all or most of the standard prognostic markers?					X	
Comments:

KQ 5. Harms.
What are the harms associated with treatment decisions that are informed by the genetic tests?

	RCT	**non-RCT**	**Prospective cohort study**	**Retrospective cohort study**	**Case-control study**	**Case Series**
534. What is the study design?				**X**		
If "Other" study design, enter a description in this box:	**Yes**	**No**	**Partially**	**Can't Determine**	**NA**	**Explanation**
535. For RCTs, were randomization and allocation concealment adequate?					X	
536. Did the study apply inclusion/exclusion criteria uniformly to all comparison groups of the study?	X					
537. Is the selection of the comparison group appropriate, after taking into account feasibility and ethical considerations?	X					
538. Were groups similar at baseline?		X				Differences for age, family history, stage, tumor type (colon or rectum), site of tumor, grade, CEA level
539. Were the outcome assessors blinded to the test result/intervention/exposure status of participants?				X		

540. Were outcomes assessed using valid and reliable measures, implemented consistently across all study participants?				X		
541. Was overall attrition less than 30%?	X					
542. Was differential attrition less than 15%?	X					
543. Does the analysis control for baseline differences between groups?			X			Controls for age, sex, stage
544. Does the analysis account for differences in treatment received by the groups?		X				Table 5 shows additional analysis stratified by whether they got 5-FU chemo, but these are set up to focus on prediction, not to adjust for differences in treatment within the multivariate analysis of MSI-H vs. MSS/MSI-L (and nothing to account for radiation)
545. Are the statistical methods used to assess the outcomes appropriate?	X					
546. **For KQ3 ONLY** – Did analyses adjust for all or most of the standard prognostic markers?			X			It controls for age, sex, stage, but not for grade, cellular type, CEA, location; they also stratify colon and rectal cancers
Comments:						

Key Question 2				If study does NOT apply to this KQ, place an 'X' here (_X_)			
KQ 2. Analytic Validity. Does existing evidence establish the technical accuracy and reliability of the tests for detecting the relevant genetic markers?

KQ 4b. Clinical Utility.
What is the evidence that modified decisions lead to improved overall survival, disease free survival, time to recurrence, quality of life, or incidence of serious side effects of adjuvant therapy in adult patients with malignant tumors?

KQ 5. Harms.
What are the harms associated with treatment decisions that are informed by the genetic tests?

	RCT	**non-RCT**	**Prospective cohort study**	**Retrospective cohort study**	**Case-control study**	**Case Series**
547. What is the study design?			**X**			
If "Other" study design, enter a description in this box:	**Yes**	**No**	**Partially**	**Can't Determine**	**NA**	**Explanation**
548. For RCTs, were randomization and allocation concealment adequate?					X	
549. Did the study apply inclusion/exclusion criteria uniformly to all comparison groups of the study?	X					
550. Is the selection of the comparison group appropriate, after taking into account feasibility and ethical considerations?	X					
551. Were groups similar at baseline?		X				Baseline differences for sex, tumor location, stage, differentiation, MSI status
552. Were the outcome assessors blinded to the test result/intervention/exposure status of participants?				X		
553. Were outcomes assessed using valid and	X					

reliable measures, implemented consistently across all study participants?						
554. Was overall attrition less than 30%?				X		
555. Was differential attrition less than 15%?				X		
556. Does the analysis control for baseline differences between groups?	X					
557. Does the analysis account for differences in treatment received by the groups?		X				
558. Are the statistical methods used to assess the outcomes appropriate?	X					
559. **For KQ3 ONLY** – Did analyses adjust for all or most of the standard prognostic markers?				X		Unable to determine what was in the final model. They report what went into the initial model, and process for selecting final model (but not what was in it)
Comments: High risk of selection bias and confounding. The variables in the final model were not reported, but the process described for selecting the variables seems reasonable. The article reports that the regression model was stage-stratified, but the results reported in Table 3 and in the text are not stage-stratified (there is just one HR for codon 12 mutants and one for codon 13 mutants for each outcome); so it is unclear that the HRs reported did anything to account for stage. Given these issues, high risk of confounding bias. With the codon 12 mutants found to have HRs just above 1 (1.30 and 1.24 for cancer-specific mortality and overall mortality), the findings might become non-significant with relatively minor changes in what was adjusted for in the model, and how stage was handled.						

Key Question 2	If study does NOT apply to this KQ, place an 'X' here (_X_)						
KQ 2. Analytic Validity. Does existing evidence establish the technical accuracy and reliability of the tests for detecting the relevant genetic markers?							
	Yes	**No**	**Unclear**	**NA**	**Low**	**High**	**Unclear**
Domain 1: Patient Selection							
Was a consecutive or random sample of patients enrolled?							
Was a case-control design avoided?							
Did the study avoid inappropriate exclusions?							
Could the selection of patients have introduced bias?							
Domain 2: Index Test(s)							
Were the index test results interpreted without knowledge of the results of the reference standard?							
If a threshold was used, was it pre-specified?							
Could the conduct or interpretation of the index test have introduced bias?							
Domain 3: Reference Standard							
Is the reference standard likely to correctly classify the genetic markers?							
Were the reference standard results interpreted without knowledge of the results of the index test?							
Could the reference standard, its conduct, or its interpretation have introduced bias?

Worksheet for Risk of Bias of Individual Studies – GTRRC (v. 4-23-13)

Ref ID #	Author	Year
3281	Iwamoto	2011

Indicate the appropriate risk of bias rating by placing an 'X' in the shaded space to the right of the rating for each KQ that is applicable. If a study does not apply to a KQ, put an 'X' next to N/A.

RoB Rating: Unclear

Risk of bias for KQ 1:	Low		Medium		High		N/A	X
Risk of bias for KQ 2:	Low		Medium		High		N/A	X
Risk of bias for KQ 3:	Low	*	Medium	*	High	*	N/A	
Risk of bias for KQ 4a:	Low		Medium		High		N/A	X
Risk of bias for KQ 4b:	Low		Medium		High		N/A	X
Risk of bias for KQ 5:	Low		Medium		High		N/A	X
Explain any **High** ratings:								

Low: Study has minimal bias. High degree of confidence that the true effect size is similar in size and direction to that reported.
Medium: Study has at least one significant source of bias, but does not have flaws that are likely to cause major bias. Moderate degree of confidence that the actual effect is in the direction reported by the study; moderate degree of confidence that the true effect size is similar to that reported.
High: Study has at least one major sources of bias or multiple significant sources of bias. Low degree of confidence that the true effect size is similar in size or direction to that reported.
NA: Not applicable to that key question.

Key Questions 1, 3, 4a, 4b, and 5	If the study does NOT apply to any of these KQs, place an 'X' here (__)

Worksheet for Risk of Bias of Individual Studies – GTRRC (v. 4-23-13)

Ref ID #	Author	Year
673	Jensen	2009

Indicate the appropriate risk of bias rating by placing an 'X' in the shaded space to the right of the rating for each KQ that is applicable. If a study does not apply to a KQ, put an 'X' next to N/A.

Risk of bias for KQ 1:	Low		Medium		High		N/A	X
Risk of bias for KQ 2:	Low		Medium		High		N/A	X
Risk of bias for KQ 3:	Low		Medium	X	High		N/A	
Risk of bias for KQ 4a:	Low		Medium		High		N/A	X
Risk of bias for KQ 4b:	Low		Medium		High		N/A	X
Risk of bias for KQ 5:	Low		Medium		High		N/A	X
Explain any **High** ratings:								

Low: Study has minimal bias. High degree of confidence that the true effect size is similar in size and direction to that reported.
Medium: Study has at least one significant source of bias, but does not have flaws that are likely to cause major bias. Moderate degree of confidence that the actual effect is in the direction reported by the study; moderate degree of confidence that the true effect size is similar to that reported.
High: Study has at least one major sources of bias or multiple significant sources of bias. Low degree of confidence that the true effect size is similar in size or direction to that reported.
NA: Not applicable to that key question.

Key Questions 1, 3, 4a, 4b, and 5	If the study does NOT apply to any of these KQs, place an 'X' here (___)
KQ 1: Overarching Question Is there direct evidence that the addition of the following genetic tests used alone or in combination with traditional prognostic factors change physician decision making and improve outcomes for adult patients with lung, breast, colorectal, and bladder cancer compared with the use of traditional factors to predict risk of recurrence for adults with these cancers?	
KQ 3. Clinical Validity. Does existing evidence establish the prognostic accuracy of the tests for predicting recurrence?	
KQ 4a. Clinical Utility. What is the evidence that the prognostic information provided by the genetic tests modifies physician decisions regarding use of adjuvant anti-neoplastic chemo- and/or radiotherapy; enhanced diagnostic testing for recurrence; and/or preventive surgery among adult patients with malignant tumors?	
KQ 4b. Clinical Utility. What is the evidence that modified decisions lead to improved overall survival, disease free survival, time to recurrence, quality of life, or incidence of serious side effects of adjuvant therapy in adult patients with malignant tumors?	
KQ 5. Harms. What are the harms associated with treatment decisions that are informed by the genetic tests?	

	RCT	**non-RCT**	**Prospective cohort study**	**Retrospective cohort study**	**Case-control study**	**Case Series**
586. What is the study design?				**X**		
If "Other" study design, enter a description in this box:	**Yes**	**No**	**Partially**	**Can't Determine**	**NA**	**Explanation**
587. For RCTs, were randomization and allocation concealment adequate?					X	
588. Did the study apply inclusion/exclusion criteria uniformly to all comparison groups of the study?	X					
589. Is the selection of the comparison group appropriate, after taking into account feasibility and ethical considerations?	X					
590. Were groups similar at baseline?		X				Differences for age, tumor site, grade, and bowel obstruction
591. Were the outcome assessors blinded to the test result/intervention/exposure status of participants?				X		
592. Were outcomes assessed using valid and reliable measures, implemented consistently across all study participants?			X			Yes for death, unclear for recurrence (used

						databases on hospital admission)
593. Was overall attrition less than 30%?	X					
594. Was differential attrition less than 15%?	X					
595. Does the analysis control for baseline differences between groups?			X			Initial model reported to include all candidate prognostic variables; final model did not include age, site, grade (and all were different at baseline)
596. Does the analysis account for differences in treatment received by the groups?					X	All received same adjuvant treatment
597. Are the statistical methods used to assess the outcomes appropriate?	X					
598. **For KQ3 ONLY** – Did analyses adjust for all or most of the standard prognostic markers?		X				Final model adjusted for stage, vascular invasion, perineural invasion, and ileus.
Comments: Final model adjusted for stage, vascular invasion, perineural invasion, and ileus. Initial model reported to include all candidate prognostic variables (but they don't report what that full list included), and they used step-down variable selection; final model did not include age, site, grade (and all were different in baseline characteristics) or cellular subtypes (NR at baseline or as something included in models) or sex.						

Key Question 2	If study does NOT apply to this KQ, place an 'X' here (_X_)						
KQ 2. Analytic Validity. Does existing evidence establish the technical accuracy and reliability of the tests for detecting the relevant genetic markers?							
	Yes	**No**	**Unclear**	**NA**	**Low**	**High**	**Unclear**
Domain 1: Patient Selection							
Was a consecutive or random sample of patients enrolled?							
Was a case-control design avoided?							
Did the study avoid inappropriate exclusions?							
Could the selection of patients have introduced bias?							
Domain 2: Index Test(s)							
Were the index test results interpreted without knowledge of the results of the reference standard?							
If a threshold was used, was it pre-specified?							
Could the conduct or interpretation of the index test have introduced bias?							
Domain 3: Reference Standard							
Is the reference standard likely to correctly classify the genetic markers?							
Were the reference standard results interpreted without knowledge of the results of the index test?							
Could the reference standard, its conduct, or its interpretation have							

introduced bias?							
Domain 4: Flow and Timing							
Did all patients receive a reference standard?							
Did patients receive the same reference standard?							
Were all patients included in the analysis?							
Could the patient flow have introduced bias?							
Comments:							

Worksheet for Risk of Bias of Individual Studies – GTRRC (v. 4-23-13)

Ref ID #	Author	Year
110	Joh	2011

Indicate the appropriate risk of bias rating by placing an 'X' in the shaded space to the right of the rating for each KQ that is applicable. If a study does not apply to a KQ, put an 'X' next to N/A.

Risk of bias for KQ 1:	Low		Medium		High		N/A	
Risk of bias for KQ 2:	Low		Medium		High		N/A	
Risk of bias for KQ 3:	Low		Medium		High		N/A	
Risk of bias for KQ 4a:	Low	x	Medium		High		N/A	
Risk of bias for KQ 4b:	Low		Medium		High		N/A	
Risk of bias for KQ 5:	Low		Medium		High		N/A	
Explain any **High** ratings:								

Low: Study has minimal bias. High degree of confidence that the true effect size is similar in size and direction to that reported.
Medium: Study has at least one significant source of bias, but does not have flaws that are likely to cause major bias. Moderate degree of confidence that the actual effect is in the direction reported by the study; moderate degree of confidence that the true effect size is similar to that reported.
High: Study has at least one major sources of bias or multiple significant sources of bias. Low degree of confidence that the true effect size is similar in size or direction to that reported.
NA: Not applicable to that key question.

Key Questions 1, 3, 4a, 4b, and 5	If the study does NOT apply to any of these KQs, place an 'X' here (___)
KQ 1: Overarching Question Is there direct evidence that the addition of the following genetic tests used alone or in combination with traditional prognostic factors change physician decision making and improve outcomes for adult patients with lung, breast, colorectal, and bladder cancer compared with the use of traditional factors to predict risk of recurrence for adults with these cancers?	
KQ 3. Clinical Validity. Does existing evidence establish the prognostic accuracy of the tests for predicting recurrence?	
KQ 4a. Clinical Utility. What is the evidence that the prognostic information provided by the genetic tests modifies physician decisions regarding use of adjuvant anti-neoplastic chemo- and/or radiotherapy; enhanced diagnostic testing for recurrence; and/or preventive surgery among adult patients with malignant tumors?	
KQ 4b. Clinical Utility. What is the evidence that modified decisions lead to improved overall survival, disease free survival, time to recurrence, quality of life, or incidence of serious side effects of adjuvant therapy in adult patients with malignant tumors?	
KQ 5. Harms. What are the harms associated with treatment decisions that are informed by the genetic tests?	

	RCT	**non-RCT**	**Prospective cohort study**	**Retrospective cohort study**	**Case-control study**	**Case Series**
599. What is the study design?				**X**		
If "Other" study design, enter a description in this box:	**Yes**	**No**	**Partially**	**Can't Determine**	**NA**	**Explanation**
600. For RCTs, were randomization and allocation concealment adequate?					X	
601. Did the study apply inclusion/exclusion criteria uniformly to all comparison groups of the study?	X					
602. Is the selection of the comparison group appropriate, after taking into account feasibility and ethical considerations?	x					
603. Were groups similar at baseline?		x				would not be expected to be similar in retrospective design
604. Were the outcome assessors blinded to the test result/intervention/exposure status of participants?	x					
605. Were outcomes assessed using valid and reliable measures, implemented consistently across all study participants?						

606. Was overall attrition less than 30%?					x	
607. Was differential attrition less than 15%?					x	
608. Does the analysis control for baseline differences between groups?					x	
609. Does the analysis account for differences in treatment received by the groups?					x	
610. Are the statistical methods used to assess the outcomes appropriate?	x					
611. **For KQ3 ONLY** – Did analyses adjust for all or most of the standard prognostic markers?					x	
Comments: Study was a survey of providers regarding treatment recommendations with or without information from the oncotype test. Answered these questions with patients as "participants" and providers as "assessors" since no comparative data were given regarding demographics of the small # of providers in the study.						

Key Question 2	If study does NOT apply to this KQ, place an 'X' here (_X_)						
KQ 2. Analytic Validity. Does existing evidence establish the technical accuracy and reliability of the tests for detecting the relevant genetic markers?							
	Yes	**No**	**Unclear**	**NA**	**Low**	**High**	**Unclear**
Domain 1: Patient Selection

Comments:							

Worksheet for Risk of Bias of Individual Studies – GTRRC (v. 4-23-13)

Ref ID #	Author	Year
691	Kakar	2008

Indicate the appropriate risk of bias rating by placing an 'X' in the shaded space to the right of the rating for each KQ that is applicable. If a study does not apply to a KQ, put an 'X' next to N/A.

Risk of bias for KQ 1:	Low		Medium		High		N/A	X
Risk of bias for KQ 2:	Low		Medium		High		N/A	X
Risk of bias for KQ 3:	Low		Medium		High	X	N/A	
Risk of bias for KQ 4a:	Low		Medium		High		N/A	X
Risk of bias for KQ 4b:	Low		Medium		High		N/A	X
Risk of bias for KQ 5:	Low		Medium		High		N/A	X
Explain any **High** ratings:	High risk of selection bias and confounding. Small sample size and it's unclear how subjects were selected from among those undergoing resection from 1996 to 2000 (NR whether consecutive or what the criteria were). Some baseline differences between groups and some known prognostic factors were not considered in the analyses (i.e., multivariate analysis did not adjust for some important factors). Just 10 subjects with BRAF mutation. Unable to assess potential for measurement bias because little information reported. The magnitude of benefit is large (HR above 5), but with such a small sample size, still high risk of confounding.							

Low: Study has minimal bias. High degree of confidence that the true effect size is similar in size and direction to that reported.
Medium: Study has at least one significant source of bias, but does not have flaws that are likely to cause major bias. Moderate degree of confidence that the actual effect is in the direction reported by the study; moderate degree of confidence that the true effect size is similar to that reported.
High: Study has at least one major sources of bias or multiple significant sources of bias. Low degree of confidence that the true effect size is similar in size or direction to that reported.
NA: Not applicable to that key question.

Key Questions 1, 3, 4a, 4b, and 5	If the study does NOT apply to any of these KQs, place an 'X' here (__)
KQ 1: Overarching Question Is there direct evidence that the addition of the following genetic tests used alone or in combination with traditional prognostic factors change physician decision making and improve outcomes for adult patients with lung, breast, colorectal, and bladder cancer compared with the use of traditional factors to predict risk of recurrence for adults with these cancers?	
KQ 3. Clinical Validity. Does existing evidence establish the prognostic accuracy of the tests for predicting recurrence?	
KQ 4a. Clinical Utility. What is the evidence that the prognostic information provided by the genetic tests modifies physician decisions regarding use of adjuvant anti-neoplastic chemo- and/or radiotherapy; enhanced diagnostic testing for recurrence; and/or preventive surgery among adult patients with malignant tumors?	
KQ 4b. Clinical Utility. What is the evidence that modified decisions lead to improved overall survival, disease free survival, time to recurrence, quality of life, or incidence of serious side effects of adjuvant therapy in adult patients with malignant tumors?	
KQ 5. Harms. What are the harms associated with treatment decisions that are informed by the genetic tests?	

	RCT	**non-RCT**	**Prospective cohort study**	**Retrospective cohort study**	**Case-control study**	**Case Series**
612. What is the study design?				**X**		
If "Other" study design, enter a description in this box:	**Yes**	**No**	**Partially**	**Can't Determine**	**NA**	**Explanation**
613. For RCTs, were randomization and allocation concealment adequate?					X	
614. Did the study apply inclusion/exclusion criteria uniformly to all comparison groups of the study?				X		
615. Is the selection of the comparison group appropriate, after taking into account feasibility and ethical considerations?				X		
616. Were groups similar at baseline?			X			Similar for sex, age, all were MSS; higher proportion of

						those with BRAF mutation (than those without BRAF mutation) had right sided cancer and stage III or IV cancer
617. Were the outcome assessors blinded to the test result/intervention/exposure status of participants?				X		
618. Were outcomes assessed using valid and reliable measures, implemented consistently across all study participants?				X		
619. Was overall attrition less than 30%?				X		
620. Was differential attrition less than 15%?				X		
621. Does the analysis control for baseline differences between groups?			X			Not for differences in tumor location
622. Does the analysis account for differences in treatment received by the groups?		X				
623. Are the statistical methods used to assess the outcomes appropriate?	X					
624. **For KQ3 ONLY** – Did analyses adjust for all or most of the standard prognostic markers?			X			Adjusted for age, sex, stage; did not adjust for grade, cellular subtypes, lymphovascular invastion, location, margin status
Comments:						

Key Question 2	If study does NOT apply to this KQ, place an 'X' here (_X_)

Worksheet for Risk of Bias of Individual Studies – GTRRC (v. 4-23-13)

Ref ID #	Author	Year
693	Kalady	2012

Indicate the appropriate risk of bias rating by placing an 'X' in the shaded space to the right of the rating for each KQ that is applicable. If a study does not apply to a KQ, put an 'X' next to N/A.

Risk of bias for KQ 1:	Low		Medium		High		N/A	X
Risk of bias for KQ 2:	Low		Medium		High		N/A	X
Risk of bias for KQ 3:	Low		Medium	X	High		N/A	
Risk of bias for KQ 4a:	Low		Medium		High		N/A	X
Risk of bias for KQ 4b:	Low		Medium		High		N/A	X
Risk of bias for KQ 5:	Low		Medium		High		N/A	X
Explain any **High** ratings:								

Low: Study has minimal bias. High degree of confidence that the true effect size is similar in size and direction to that reported.
Medium: Study has at least one significant source of bias, but does not have flaws that are likely to cause major bias. Moderate degree of confidence that the actual effect is in the direction reported by the study; moderate degree of confidence that the true effect size is similar to that reported.
High: Study has at least one major sources of bias or multiple significant sources of bias. Low degree of confidence that the true effect size is similar in size or direction to that reported.
NA: Not applicable to that key question.

Key Questions 1, 3, 4a, 4b, and 5	If the study does NOT apply to any of these KQs, place an 'X' here (___)
KQ 1: Overarching Question Is there direct evidence that the addition of the following genetic tests used alone or in combination with traditional prognostic factors change physician decision making and improve outcomes for adult patients with lung, breast, colorectal, and bladder cancer compared with the use of traditional factors to predict risk of recurrence for adults with these cancers?	
KQ 3. Clinical Validity. Does existing evidence establish the prognostic accuracy of the tests for predicting recurrence?	
KQ 4a. Clinical Utility. What is the evidence that the prognostic information provided by the genetic tests modifies physician decisions regarding use of adjuvant anti-neoplastic chemo- and/or radiotherapy; enhanced diagnostic testing for recurrence; and/or preventive surgery among adult patients with malignant tumors?	
KQ 4b. Clinical Utility. What is the evidence that modified decisions lead to improved overall survival, disease free survival, time to recurrence, quality of life, or incidence of serious side effects of adjuvant therapy in adult patients with malignant tumors?	
KQ 5. Harms. What are the harms associated with treatment decisions that are informed by the genetic tests?	

	RCT	**non-RCT**	**Prospective cohort study**	**Retrospective cohort study**	**Case-control study**	**Case Series**
625. What is the study design?				**X**		
If "Other" study design, enter a description in this box:	**Yes**	**No**	**Partially**	**Can't Determine**	**NA**	**Explanation**
626. For RCTs, were randomization and allocation concealment adequate?					X	
627. Did the study apply inclusion/exclusion criteria uniformly to all comparison groups of the study?				X		Unclear how they got from 475 included subjects down to 322 to include in the analyses (59 were not included because they were stage 4, but another 94 that were not included)
628. Is the selection of the comparison group appropriate, after taking into account feasibility and ethical considerations?	X					
629. Were groups similar at baseline?		X				Differences for age, sex,

						location, differentiation, MSI status
630. Were the outcome assessors blinded to the test result/intervention/exposure status of participants?				X		
631. Were outcomes assessed using valid and reliable measures, implemented consistently across all study participants?				X		No information reported for how outcomes were ascertained
632. Was overall attrition less than 30%?		X				23% of Stage I to III subjects were not included in the survival analyses
633. Was differential attrition less than 15%?				X		NR
634. Does the analysis control for baseline differences between groups?	X					
635. Does the analysis account for differences in treatment received by the groups?		X				
636. Are the statistical methods used to assess the outcomes appropriate?	X					
637. **For KQ3 ONLY** – Did analyses adjust for all or most of the standard prognostic markers?	X					
Comments: 475 included in Table 1, but just 322 included in the survival analyses (related to comments above). Note: Included for KQ3 only and for BRAF only--MSI used the 10 marker panel						

Key Question 2	If study does NOT apply to this KQ, place an 'X' here (_X_)						
KQ 2. Analytic Validity. Does existing evidence establish the technical accuracy and reliability of the tests for detecting the relevant genetic markers?

Could the patient flow have introduced bias?							
Comments:							

Worksheet for Risk of Bias of Individual Studies – GTRRC (v. 4-23-13)

Ref ID #	Author	Year
170	Kamal	2011

Indicate the appropriate risk of bias rating by placing an 'X' in the shaded space to the right of the rating for each KQ that is applicable. If a study does not apply to a KQ, put an 'X' next to N/A.

Risk of bias for KQ 1:	Low		Medium		High		N/A	X
Risk of bias for KQ 2:	Low		Medium		High		N/A	X
Risk of bias for KQ 3:	Low		Medium		High		N/A	X
Risk of bias for KQ 4a:	Low		Medium	X	High		N/A	
Risk of bias for KQ 4b:	Low		Medium		High		N/A	X
Risk of bias for KQ 5:	Low		Medium		High		N/A	X
Explain any **High** ratings:								

Low: Study has minimal bias. High degree of confidence that the true effect size is similar in size and direction to that reported.
Medium: Study has at least one significant source of bias, but does not have flaws that are likely to cause major bias. Moderate degree of confidence that the actual effect is in the direction reported by the study; moderate degree of confidence that the true effect size is similar to that reported.
High: Study has at least one major sources of bias or multiple significant sources of bias. Low degree of confidence that the true effect size is similar in size or direction to that reported.
NA: Not applicable to that key question.

Key Questions 1, 3, 4a, 4b, and 5	If the study does NOT apply to any of these KQs, place an 'X' here (___)
KQ 1: Overarching Question Is there direct evidence that the addition of the following genetic tests used alone or in combination with traditional prognostic factors change physician decision making and improve outcomes for adult patients with lung, breast, colorectal, and bladder cancer compared with the use of traditional factors to predict risk of recurrence for adults with these cancers?	
KQ 3. Clinical Validity. Does existing evidence establish the prognostic accuracy of the tests for predicting recurrence?	
KQ 4a. Clinical Utility. What is the evidence that the prognostic information provided by the genetic tests modifies physician decisions regarding use of adjuvant anti-neoplastic chemo- and/or radiotherapy; enhanced diagnostic testing for recurrence; and/or preventive surgery among adult patients with malignant tumors?	
KQ 4b. Clinical Utility. What is the evidence that modified decisions lead to improved overall survival, disease free survival, time to recurrence, quality of life, or incidence of serious side effects of adjuvant therapy in adult patients with malignant tumors?	
KQ 5. Harms. What are the harms associated with treatment decisions that are informed by the genetic tests?	

	RCT	**non-RCT**	**Prospective cohort study**	**Retrospective cohort study**	**Case-control study**	**Case Series**
638. What is the study design?						Other: uncontrolled trial
If "Other" study design, enter a description in this box:	**Yes**	**No**	**Partially**	**Can't Determine**	**NA**	**Explanation**
639. For RCTs, were randomization and allocation concealment adequate?					X	
640. Did the study apply inclusion/exclusion criteria uniformly to all comparison groups of the study?					X	study did not form comparison groups for the subjects (the 6 oncologists are the subjects)
641. Is the selection of the comparison group appropriate, after taking into account feasibility and ethical considerations?					X	
642. Were groups similar at baseline?					X	
643. Were the outcome assessors blinded to the test result/intervention/exposure status of participants?					X	
644. Were outcomes assessed using valid and				X		Details NR

reliable measures, implemented consistently across all study participants?						about how they really gathered data on the oncologists decisions
645. Was overall attrition less than 30%?	X					
646. Was differential attrition less than 15%?	X					
647. Does the analysis control for baseline differences between groups?					X	
648. Does the analysis account for differences in treatment received by the groups?					X	
649. Are the statistical methods used to assess the outcomes appropriate?	X					
650. **For KQ3 ONLY** – Did analyses adjust for all or most of the standard prognostic markers?					X	
Comments: uncontrolled trial evaluating whether 6 medical oncologists would change treatment recommendations when given Oncotype Dx RS result in addition to information about standard demographic and tumor prognostic criteria (as opposed to just being given standard prognostic criteria); some risk of measurement bias (no detailed description of how they gathered outcomes; unlike some other studies that used a formal questionnaire, this sounds less formal and perhaps more subject to social desirability bias, ascertainment bias); relatively small sample (6 oncologists) and no information provided about those 6 (e.g., whether they were from multiple centers or just from 1 group with like-minded approach)						

Key Question 2	If study does NOT apply to this KQ, place an 'X' here (_X_)						
KQ 2. Analytic Validity. Does existing evidence establish the technical accuracy and reliability of the tests for detecting the relevant genetic markers?

Worksheet for Risk of Bias of Individual Studies – GTRRC (v. 4-23-13)

Ref ID #	Author	Year
3369	Kamat	2011

Indicate the appropriate risk of bias rating by placing an 'X' in the shaded space to the right of the rating for each KQ that is applicable. If a study does not apply to a KQ, put an 'X' next to N/A.

Risk of bias for KQ 1:	Low		Medium		High		N/A	X
Risk of bias for KQ 2:	Low		Medium		High		N/A	X
Risk of bias for KQ 3:	Low	X	Medium		High		N/A	
Risk of bias for KQ 4a:	Low		Medium		High		N/A	X
Risk of bias for KQ 4b:	Low		Medium		High		N/A	X
Risk of bias for KQ 5:	Low		Medium		High		N/A	X
Explain any **High** ratings:								

Low: Study has minimal bias. High degree of confidence that the true effect size is similar in size and direction to that reported.
Medium: Study has at least one significant source of bias, but does not have flaws that are likely to cause major bias. Moderate degree of confidence that the actual effect is in the direction reported by the study; moderate degree of confidence that the true effect size is similar to that reported.
High: Study has at least one major sources of bias or multiple significant sources of bias. Low degree of confidence that the true effect size is similar in size or direction to that reported.
NA: Not applicable to that key question.

Key Questions 1, 3, 4a, 4b, and 5	If the study does NOT apply to any of these KQs, place an 'X' here (___)

KQ 1: Overarching Question
Is there direct evidence that the addition of the following genetic tests used alone or in combination with traditional prognostic factors change physician decision making and improve outcomes for adult patients with lung, breast, colorectal, and bladder cancer compared with the use of traditional factors to predict risk of recurrence for adults with these cancers?

KQ 3. Clinical Validity. Does existing evidence establish the prognostic accuracy of the tests for predicting recurrence?

KQ 4a. Clinical Utility.
What is the evidence that the prognostic information provided by the genetic tests modifies physician decisions regarding use of adjuvant anti-neoplastic chemo- and/or radiotherapy; enhanced diagnostic testing for recurrence; and/or preventive surgery among adult patients with malignant tumors?

KQ 4b. Clinical Utility.
What is the evidence that modified decisions lead to improved overall survival, disease free survival, time to recurrence, quality of life, or incidence of serious side effects of adjuvant therapy in adult patients with malignant tumors?

KQ 5. Harms.
What are the harms associated with treatment decisions that are informed by the genetic tests?

	RCT	**non-RCT**	**Prospective cohort study**	**Retrospective cohort study**	**Case-control study**	**Case Series**
651. What is the study design?			**X**			
If "Other" study design, enter a description in this box:	**Yes**	**No**	**Partially**	**Can't Determine**	**NA**	**Explanation**
652. For RCTs, were randomization and allocation concealment adequate?					X	
653. Did the study apply inclusion/exclusion criteria uniformly to all comparison groups of the study?	X					
654. Is the selection of the comparison group appropriate, after taking into account feasibility and ethical considerations?	X					
655. Were groups similar at baseline?					X	
656. Were the outcome assessors blinded to the test result/intervention/exposure status of participants?				X		
657. Were outcomes assessed using valid and reliable measures, implemented consistently across all study participants?	X					
658. Was overall attrition less than 30%?	X					
659. Was differential attrition less than 15%?	X					
660. Does the analysis control for baseline					X	

differences between groups?						
661. Does the analysis account for differences in treatment received by the groups?					X	
662. Are the statistical methods used to assess the outcomes appropriate?	X					
663. **For KQ3 ONLY** – Did analyses adjust for all or most of the standard prognostic markers?	X					
Comments:						

Key Question 2					If study does NOT apply to this KQ, place an 'X' here (X__)		
KQ 2. Analytic Validity. Does existing evidence establish the technical accuracy and reliability of the tests for detecting the relevant genetic markers?							
	Yes	**No**	**Unclear**	**NA**	**Low**	**High**	**Unclear**
Domain 1: Patient Selection							
Was a consecutive or random sample of patients enrolled?							
Was a case-control design avoided?							
Did the study avoid inappropriate exclusions?							
Could the selection of patients have introduced bias?							
Domain 2: Index Test(s)							
Were the index test results interpreted without knowledge of the results of the reference standard?							
If a threshold was used, was it pre-specified?							
Could the conduct or interpretation of the index test have introduced bias?							
Domain 3: Reference Standard							
Is the reference standard likely to correctly classify the genetic markers?							
Were the reference standard results interpreted without knowledge of the results of the index test?							
Could the reference standard, its conduct, or its interpretation have introduced bias?							
Domain 4: Flow and Timing							
Did all patients receive a reference standard?							
Did patients receive the same reference standard?							
Were all patients included in the analysis?							
Could the patient flow have introduced bias?							
Comments:							

Worksheet for Risk of Bias of Individual Studies – GTRRC (v. 4-23-13)

Ref ID #	Author	Year
715	Kim	2007

Indicate the appropriate risk of bias rating by placing an 'X' in the shaded space to the right of the rating for each KQ that is applicable. If a study does not apply to a KQ, put an 'X' next to N/A.

Risk of bias for KQ 1:	Low		Medium		High		N/A	x
Risk of bias for KQ 2:	Low		Medium		High		N/A	x
Risk of bias for KQ 3:	Low	x	Medium		High		N/A	
Risk of bias for KQ 4a:	Low		Medium		High		N/A	x
Risk of bias for KQ 4b:	Low		Medium		High		N/A	x
Risk of bias for KQ 5:	Low		Medium		High		N/A	x
Explain any **High** ratings:								

Low: Study has minimal bias. High degree of confidence that the true effect size is similar in size and direction to that reported.
Medium: Study has at least one significant source of bias, but does not have flaws that are likely to cause major bias. Moderate degree of confidence that the actual effect is in the direction reported by the study; moderate degree of confidence that the true effect size is similar to that reported.
High: Study has at least one major sources of bias or multiple significant sources of bias. Low degree of confidence that the true effect size is similar in size or direction to that reported.
NA: Not applicable to that key question.

Key Questions 1, 3, 4a, 4b, and 5	If the study does NOT apply to any of these KQs, place an 'X' here (___)

KQ 1: Overarching Question
Is there direct evidence that the addition of the following genetic tests used alone or in combination with traditional prognostic factors change physician decision making and improve outcomes for adult patients with lung, breast, colorectal, and bladder cancer compared with the use of traditional factors to predict risk of recurrence for adults with these cancers?

KQ 3. Clinical Validity. Does existing evidence establish the prognostic accuracy of the tests for predicting recurrence?

KQ 4a. Clinical Utility.
What is the evidence that the prognostic information provided by the genetic tests modifies physician decisions regarding use of adjuvant anti-neoplastic chemo- and/or radiotherapy; enhanced diagnostic testing for recurrence; and/or preventive surgery among adult patients with malignant tumors?

KQ 4b. Clinical Utility.
What is the evidence that modified decisions lead to improved overall survival, disease free survival, time to recurrence, quality of life, or incidence of serious side effects of adjuvant therapy in adult patients with malignant tumors?

KQ 5. Harms.
What are the harms associated with treatment decisions that are informed by the genetic tests?

	RCT	**non-RCT**	**Prospective cohort study**	**Retrospective cohort study**	**Case-control study**	**Case Series**
664. What is the study design?				**x**		
If "Other" study design, enter a description in this box:	**Yes**	**No**	**Partially**	**Can't Determine**	**NA**	**Explanation**
665. For RCTs, were randomization and allocation concealment adequate?					x	
666. Did the study apply inclusion/exclusion criteria uniformly to all comparison groups of the study?	x					
667. Is the selection of the comparison group appropriate, after taking into account feasibility and ethical considerations?	x					
668. Were groups similar at baseline?				x		
669. Were the outcome assessors blinded to the test result/intervention/exposure status of participants?	x					
670. Were outcomes assessed using valid and reliable measures, implemented consistently across all study participants?	x					
671. Was overall attrition less than 30%?	x					
672. Was differential attrition less than 15%?	x					
673. Does the analysis control for baseline				x		Since

differences between groups?						baseline differences not reported
674. Does the analysis account for differences in treatment received by the groups?	x					
675. Are the statistical methods used to assess the outcomes appropriate?						
676. **For KQ3 ONLY** – Did analyses adjust for all or most of the standard prognostic markers?	x					
Comments:

Worksheet for Risk of Bias of Individual Studies – GTRRC (v. 4-23-13)

Ref ID #	Author	Year
2165	Kim	2008

Indicate the appropriate risk of bias rating by placing an 'X' in the shaded space to the right of the rating for each KQ that is applicable. If a study does not apply to a KQ, put an 'X' next to N/A.

Risk of bias for KQ 1:	Low		Medium		High		N/A	X
Risk of bias for KQ 2:	Low		Medium		High		N/A	X
Risk of bias for KQ 3:	Low		Medium	X	High		N/A	
Risk of bias for KQ 4a:	Low		Medium		High		N/A	X
Risk of bias for KQ 4b:	Low		Medium		High		N/A	X
Risk of bias for KQ 5:	Low		Medium		High		N/A	X
Explain any **High** ratings:								

Low: Study has minimal bias. High degree of confidence that the true effect size is similar in size and direction to that reported.
Medium: Study has at least one significant source of bias, but does not have flaws that are likely to cause major bias. Moderate degree of confidence that the actual effect is in the direction reported by the study; moderate degree of confidence that the true effect size is similar to that reported.
High: Study has at least one major sources of bias or multiple significant sources of bias. Low degree of confidence that the true effect size is similar in size or direction to that reported.
NA: Not applicable to that key question.

Key Questions 1, 3, 4a, 4b, and 5	If the study does NOT apply to any of these KQs, place an 'X' here (___)

KQ 1: Overarching Question
Is there direct evidence that the addition of the following genetic tests used alone or in combination with traditional prognostic factors change physician decision making and improve outcomes for adult patients with lung, breast, colorectal, and bladder cancer compared with the use of traditional factors to predict risk of recurrence for adults with these cancers?

KQ 3. Clinical Validity. Does existing evidence establish the prognostic accuracy of the tests for predicting recurrence?

KQ 4a. Clinical Utility.
What is the evidence that the prognostic information provided by the genetic tests modifies physician decisions regarding use of adjuvant anti-neoplastic chemo- and/or radiotherapy; enhanced diagnostic testing for recurrence; and/or preventive surgery among adult patients with malignant tumors?

KQ 4b. Clinical Utility.
What is the evidence that modified decisions lead to improved overall survival, disease free survival, time to recurrence, quality of life, or incidence of serious side effects of adjuvant therapy in adult patients with malignant tumors?

KQ 5. Harms.
What are the harms associated with treatment decisions that are informed by the genetic tests?

	RCT	**non-RCT**	**Prospective cohort study**	**Retrospective cohort study**	**Case-control study**	**Case Series**
677. What is the study design?				**X**		
If "Other" study design, enter a description in this box:	**Yes**	**No**	**Partially**	**Can't Determine**	**NA**	**Explanation**
678. For RCTs, were randomization and allocation concealment adequate?					X	
679. Did the study apply inclusion/exclusion criteria uniformly to all comparison groups of the study?	X					Criteria were that they underwent surgical resection for primary lung cancer between Dec 2000 and Apr 2004 at their University Hospital, path diagnosis of lung adenocarcinoma, and frozen specimens available

680. Is the selection of the comparison group appropriate, after taking into account feasibility and ethical considerations?	X					
681. Were groups similar at baseline?		X (for EGFR mutation status)		X (for KRAS)		Table 2 only provided gender, age, smoking, BAC features, and stage for EGFR status (some differences for gender, smoking status, and BAC); information is NR for KRAS
682. Were the outcome assessors blinded to the test result/intervention/exposure status of participants?		X				
683. Were outcomes assessed using valid and reliable measures, implemented consistently across all study participants?			X			Methods of detecting recurrence seem valid and reliable; for deaths, no description of methods to ensure capturing all deaths (and article does not describe completeness of follow up)
684. Was overall attrition less than 30%?				X		Missing data and loss to follow up not described in detail for the 71 patients (mean f/u was 25.3 months, range 2.9 to 47.5)
685. Was differential attrition less than 15%?				X		
686. Does the analysis control for baseline differences between groups?	X					
687. Does the analysis account for differences in treatment received by the groups?		X				
688. Are the statistical methods used to assess the outcomes appropriate?	X					
689. **For KQ3 ONLY** – Did analyses adjust for all or most of the standard prognostic markers?	X					Most
Comments: no details reported for reasons that most of the 653 patients who underwent surgical resection from primary lung cancer were not included; 71 were included in this study (perhaps availability of frozen specimens was the main reason)						

Key Question 2	If study does NOT apply to this KQ, place an 'X' here (_X_)
KQ 2. Analytic Validity. Does existing evidence establish the technical accuracy and reliability of the tests for detecting the relevant genetic markers?	

	Yes	No	Unclear	NA	Low	High	Unclear

Ref ID #	Author	Year
3784	Kim	2013

Indicate the appropriate quality rating by placing an 'X' in the shaded space to the right of the rating for each KQ that is applicable **AND** for an Overall rating. If a study does not apply to a KQ, put an 'X' next to N/A.

Risk of bias for KQ 1:	Low		Medium		High		N/A	X
Risk of bias for KQ 2:	Low		Medium		High		N/A	X
Risk of bias for KQ 3:	Low		Medium	X	High		N/A	
Risk of bias for KQ 4a:	Low		Medium		High		N/A	X
Risk of bias for KQ 4b:	Low		Medium		High		N/A	X
Risk of bias for KQ 5:	Low		Medium		High		N/A	X
Explain any **High** ratings:								

Low: Study has minimal bias. High degree of confidence that the true effect size is similar in size and direction to that reported.
Medium: Study has at least one significant source of bias, but does not have flaws that are likely to cause major bias. Moderate degree of confidence that the actual effect is in the direction reported by the study; moderate degree of confidence that the true effect size is similar to that reported.
High: Study has at least one major sources of bias or multiple significant sources of bias. Low degree of confidence that the true effect size is similar in size or direction to that reported.
NA: Not applicable to that key question.

Key Questions 1, 3, 4a, 4b, and 5	If the study does NOT apply to any of these KQs, place an 'X' here (___)

KQ 1: Overarching Question
Is there direct evidence that the addition of the following genetic tests used alone or in combination with traditional prognostic factors change physician decision making and improve outcomes for adult patients with lung, breast, colorectal, and bladder cancer compared with the use of traditional factors to predict risk of recurrence for adults with these cancers?

KQ 3. Clinical Validity. Does existing evidence establish the prognostic accuracy of the tests for predicting recurrence?

KQ 4a. Clinical Utility.
What is the evidence that the prognostic information provided by the genetic tests modifies physician decisions regarding use of adjuvant anti-neoplastic chemo- and/or radiotherapy; enhanced diagnostic testing for recurrence; and/or preventive surgery among adult patients with malignant tumors?

KQ 4b. Clinical Utility.
What is the evidence that modified decisions lead to improved overall survival, disease free survival, time to recurrence, quality of life, or incidence of serious side effects of adjuvant therapy in adult patients with malignant tumors?

KQ 5. Harms.
What are the harms associated with treatment decisions that are informed by the genetic tests?

	RCT	**non-RCT**	**Prospective cohort study**	**Retrospective cohort study**	**Case-control study**	**Case Series**
690. What is the study design?				**X**		
If "Other" study design, enter a description in this box:	**Yes**	**No**	**Partially**	**Can't Determine**	**NA**	**Explanation**
691. For RCTs, were randomization and allocation concealment adequate?					X	
692. Did the study apply inclusion/exclusion criteria uniformly to all comparison groups of the study?	X					
693. Is the selection of the comparison group appropriate, after taking into account feasibility and ethical considerations?	X					
694. Were groups similar at baseline?		X				
695. Were the outcome assessors blinded to the test result/intervention/exposure status of participants?				X		
696. Were outcomes assessed using valid and reliable measures, implemented consistently across all study participants?				X		
697. Was overall attrition less than 30%?	X					
698. Was differential attrition less than 15%?	X					
699. Does the analysis control for baseline	X					

differences between groups?						
700. Does the analysis account for differences in treatment received by the groups?		X				
701. Are the statistical methods used to assess the outcomes appropriate?	X					
702. **For KQ3 ONLY** – Did analyses adjust for all or most of the standard prognostic markers?	X					
Comments: Do not seem to have controlled for size, differentiation but do not think that introduces much bias.						

Key Question 2	If study does NOT apply to this KQ, place an 'X' here (___)						
KQ 2. Analytic Validity. Does existing evidence establish the technical accuracy and reliability of the tests for detecting the relevant genetic markers?							
	Yes	**No**	**Unclear**	**NA**	**Low**	**High**	**Unclear**

Worksheet for Risk of Bias of Individual Studies – GTRRC (v. 4-23-13)

Ref ID #	Author	Year
179	Knauer	2010

Indicate the appropriate risk of bias rating by placing an 'X' in the shaded space to the right of the rating for each KQ that is applicable. If a study does not apply to a KQ, put an 'X' next to N/A.

Risk of bias for KQ 1:	Low		Medium		High		N/A	X
Risk of bias for KQ 2:	Low		Medium		High		N/A	X
Risk of bias for KQ 3:	Low		Medium	X	High		N/A	
Risk of bias for KQ 4a:	Low		Medium		High		N/A	X
Risk of bias for KQ 4b:	Low		Medium		High		N/A	X
Risk of bias for KQ 5:	Low		Medium		High		N/A	X
Explain any **High** ratings:								

Low: Study has minimal bias. High degree of confidence that the true effect size is similar in size and direction to that reported.
Medium: Study has at least one significant source of bias, but does not have flaws that are likely to cause major bias. Moderate degree of confidence that the actual effect is in the direction reported by the study; moderate degree of confidence that the true effect size is similar to that reported.
High: Study has at least one major sources of bias or multiple significant sources of bias. Low degree of confidence that the true effect size is similar in size or direction to that reported.
NA: Not applicable to that key question.

Key Questions 1, 3, 4a, 4b, and 5	If the study does NOT apply to any of these KQs, place an 'X' here (___)

KQ 1: Overarching Question
Is there direct evidence that the addition of the following genetic tests used alone or in combination with traditional prognostic factors change physician decision making and improve outcomes for adult patients with lung, breast, colorectal, and bladder cancer compared with the use of traditional factors to predict risk of recurrence for adults with these cancers?

KQ 3. Clinical Validity. Does existing evidence establish the prognostic accuracy of the tests for predicting recurrence?

KQ 4a. Clinical Utility.
What is the evidence that the prognostic information provided by the genetic tests modifies physician decisions regarding use of adjuvant anti-neoplastic chemo- and/or radiotherapy; enhanced diagnostic testing for recurrence; and/or preventive surgery among adult patients with malignant tumors?

KQ 4b. Clinical Utility.
What is the evidence that modified decisions lead to improved overall survival, disease free survival, time to recurrence, quality of life, or incidence of serious side effects of adjuvant therapy in adult patients with malignant tumors?

KQ 5. Harms.
What are the harms associated with treatment decisions that are informed by the genetic tests?

	RCT	**non-RCT**	**Prospective cohort study**	**Retrospective cohort study**	**Case-control study**	**Case Series**
716. What is the study design?				**X**		
If "Other" study design, enter a description in this box:	**Yes**	**No**	**Partially**	**Can't Determine**	**NA**	**Explanation**
717. For RCTs, were randomization and allocation concealment adequate?					X	
718. Did the study apply inclusion/exclusion criteria uniformly to all comparison groups of the study?	X					
719. Is the selection of the comparison group appropriate, after taking into account feasibility and ethical considerations?	X					
720. Were groups similar at baseline?				X		
721. Were the outcome assessors blinded to the test result/intervention/exposure status of participants?				X		
722. Were outcomes assessed using valid and reliable measures, implemented consistently across all study participants?				X		
723. Was overall attrition less than 30%?				X		
724. Was differential attrition less than 15%?				X		
725. Does the analysis control for baseline				X		

differences between groups?						
726. Does the analysis account for differences in treatment received by the groups?	X					
727. Are the statistical methods used to assess the outcomes appropriate?	X					
728. **For KQ3 ONLY** – Did analyses adjust for all or most of the standard prognostic markers?	X					

Comments: For the study design, they defined their cohort as a subset (unilateral stage pT1 to 3, HER-2 positive, etc.) of a database comprised of subjects from previous studies. Medium or greater risk of measurement bias (no information presented about whether assessment of outcomes was equal, valid, and reliable) and whether outcome assessors were aware of test results. Difficult to assess selection bias and confounding since they don't report attrition data (overall or differential) or baseline characteristics for the two groups separately. But, their multivariate analysis does account for most or all of the standard prognostic markers, decreasing the concern for confounding somewhat. Was on the fence between medium and high risk of bias, but went with medium for this.

Key Question 2	If study does NOT apply to this KQ, place an 'X' here (_X_)						
KQ 2. Analytic Validity. Does existing evidence establish the technical accuracy and reliability of the tests for detecting the relevant genetic markers?							
	Yes	**No**	**Unclear**	**NA**	**Low**	**High**	**Unclear**
Domain 1: Patient Selection

Worksheet for Risk of Bias of Individual Studies – GTRRC (v. 4-23-13)

Ref ID #	Author	Year
2176	Kobayashi	2008

Indicate the appropriate risk of bias rating by placing an 'X' in the shaded space to the right of the rating for each KQ that is applicable. If a study does not apply to a KQ, put an 'X' next to N/A.

Risk of bias for KQ 1:	Low		Medium		High		N/A	X
Risk of bias for KQ 2:	Low		Medium	X	High		N/A	X
Risk of bias for KQ 3:	Low		Medium		High		N/A	
Risk of bias for KQ 4a:	Low		Medium		High		N/A	X
Risk of bias for KQ 4b:	Low		Medium		High		N/A	X
Risk of bias for KQ 5:	Low		Medium		High		N/A	X
Explain any **High** ratings:								

Low: Study has minimal bias. High degree of confidence that the true effect size is similar in size and direction to that reported.
Medium: Study has at least one significant source of bias, but does not have flaws that are likely to cause major bias. Moderate degree of confidence that the actual effect is in the direction reported by the study; moderate degree of confidence that the true effect size is similar to that reported.
High: Study has at least one major sources of bias or multiple significant sources of bias. Low degree of confidence that the true effect size is similar in size or direction to that reported.
NA: Not applicable to that key question.

Key Questions 1, 3, 4a, 4b, and 5	If the study does NOT apply to any of these KQs, place an 'X' here (___)
KQ 1: Overarching Question Is there direct evidence that the addition of the following genetic tests used alone or in combination with traditional prognostic factors change physician decision making and improve outcomes for adult patients with lung, breast, colorectal, and bladder cancer compared with the use of traditional factors to predict risk of recurrence for adults with these cancers?	
KQ 3. Clinical Validity. Does existing evidence establish the prognostic accuracy of the tests for predicting recurrence?	
KQ 4a. Clinical Utility. What is the evidence that the prognostic information provided by the genetic tests modifies physician decisions regarding use of adjuvant anti-neoplastic chemo- and/or radiotherapy; enhanced diagnostic testing for recurrence; and/or preventive surgery among adult patients with malignant tumors?	
KQ 4b. Clinical Utility. What is the evidence that modified decisions lead to improved overall survival, disease free survival, time to recurrence, quality of life, or incidence of serious side effects of adjuvant therapy in adult patients with malignant tumors?	
KQ 5. Harms. What are the harms associated with treatment decisions that are informed by the genetic tests?	

	RCT	**non-RCT**	**Prospective cohort study**	**Retrospective cohort study**	**Case-control study**	**Case Series**
729. What is the study design?						
If "Other" study design, enter a description in this box:	**Yes**	**No**	**Partially**	**Can't Determine**	**NA**	**Explanation**
730. For RCTs, were randomization and allocation concealment adequate?					X	
731. Did the study apply inclusion/exclusion criteria uniformly to all comparison groups of the study?	X					
732. Is the selection of the comparison group appropriate, after taking into account feasibility and ethical considerations?	X					
733. Were groups similar at baseline?		X				Table 2 doesn't report all the numbers and percents for the wild-type group to easily compare them, but they give enough information to

						do the calculations ourselves; groups were different for sex and smoking status at baseline, similar for age CEA level, tumor size (all were same Stage)
734. Were the outcome assessors blinded to the test result/intervention/exposure status of participants?				X		
735. Were outcomes assessed using valid and reliable measures, implemented consistently across all study participants?			X			If people continued to follow up as planned, then the measures are valid and reliable. But, nothing additional done to ensure capturing all deaths beyond using data from scheduled routine follow up (and from the f/u information reported, unable to determine how many subjects only had 1 to 3 years of follow up time captured).
736. Was overall attrition less than 30%?				X		Median f/u among surviving patients 67 months (range 12-134 months); loss to follow up details otherwise NR.
737. Was differential attrition less than 15%?				X		Data NR to allow determination
738. Does the analysis control for baseline differences between groups?	X					
739. Does the analysis account for differences in treatment received by the groups?	X					Since all were Stage IA and <20mm,

						treatment was surgical without chemo or radiotherapy
740. Are the statistical methods used to assess the outcomes appropriate?	X					
741. **For KQ3 ONLY** – Did analyses adjust for all or most of the standard prognostic markers?	X					All were stage IA; analyses adjust for age, sex, smoking status, CEA, tumor size, Non-BAC component, and EGFR
Comments: some concern for selection bias, adequacy of follow up information (missing data), and ascertainment bias						

Key Question 2	If study does NOT apply to this KQ, place an 'X' here (_X_)						
KQ 2. Analytic Validity. Does existing evidence establish the technical accuracy and reliability of the tests for detecting the relevant genetic markers?							
	Yes	**No**	**Unclear**	**NA**	**Low**	**High**	**Unclear**
Domain 1: Patient Selection							
Was a consecutive or random sample of patients enrolled?							
Was a case-control design avoided?							
Did the study avoid inappropriate exclusions?							
Could the selection of patients have introduced bias?							
Domain 2: Index Test(s)							
Were the index test results interpreted without knowledge of the results of the reference standard?							
If a threshold was used, was it pre-specified?							
Could the conduct or interpretation of the index test have introduced bias?							
Domain 3: Reference Standard							
Is the reference standard likely to correctly classify the genetic markers?							
Were the reference standard results interpreted without knowledge of the results of the index test?							
Could the reference standard, its conduct, or its interpretation have introduced bias?							
Domain 4: Flow and Timing							
Did all patients receive a reference standard?							
Did patients receive the same reference standard?							
Were all patients included in the analysis?							
Could the patient flow have introduced bias?							
Comments:							

Worksheet for Risk of Bias of Individual Studies – GTRRC (v. 4-23-13)

Ref ID #	Author	Year
741	Kobunai	2010

Indicate the appropriate risk of bias rating by placing an 'X' in the shaded space to the right of the rating for each KQ that is applicable. If a study does not apply to a KQ, put an 'X' next to N/A.

Risk of bias for KQ 1:	Low		Medium		High		N/A	
Risk of bias for KQ 2:	Low	X	Medium		High		N/A	
Risk of bias for KQ 3:	Low		Medium		High		N/A	
Risk of bias for KQ 4a:	Low		Medium		High		N/A	
Risk of bias for KQ 4b:	Low		Medium		High		N/A	
Risk of bias for KQ 5:	Low		Medium		High		N/A	
Explain any **High** ratings:								

Low: Study has minimal bias. High degree of confidence that the true effect size is similar in size and direction to that reported.
Medium: Study has at least one significant source of bias, but does not have flaws that are likely to cause major bias. Moderate degree of confidence that the actual effect is in the direction reported by the study; moderate degree of confidence that the true effect size is similar to that reported.
High: Study has at least one major sources of bias or multiple significant sources of bias. Low degree of confidence that the true effect size is similar in size or direction to that reported.
NA: Not applicable to that key question.

Key Questions 1, 3, 4a, 4b, and 5	If the study does NOT apply to any of these KQs, place an 'X' here (X__)
KQ 1: Overarching Question Is there direct evidence that the addition of the following genetic tests used alone or in combination with traditional prognostic factors change physician decision making and improve outcomes for adult patients with lung, breast, colorectal, and bladder cancer compared with the use of traditional factors to predict risk of recurrence for adults with these cancers?	
KQ 3. Clinical Validity. Does existing evidence establish the prognostic accuracy of the tests for predicting recurrence?	
KQ 4a. Clinical Utility. What is the evidence that the prognostic information provided by the genetic tests modifies physician decisions regarding use of adjuvant anti-neoplastic chemo- and/or radiotherapy; enhanced diagnostic testing for recurrence; and/or preventive surgery among adult patients with malignant tumors?	
KQ 4b. Clinical Utility. What is the evidence that modified decisions lead to improved overall survival, disease free survival, time to recurrence, quality of life, or incidence of serious side effects of adjuvant therapy in adult patients with malignant tumors?	
KQ 5. Harms. What are the harms associated with treatment decisions that are informed by the genetic tests?	

	RCT	**non-RCT**	**Prospective cohort study**	**Retrospective cohort study**	**Case-control study**	**Case Series**
742. What is the study design?				**X**		
If "Other" study design, enter a description in this box:	**Yes**	**No**	**Partially**	**Can't Determine**	**NA**	**Explanation**
743. For RCTs, were randomization and allocation concealment adequate?						
744. Did the study apply inclusion/exclusion criteria uniformly to all comparison groups of the study?						
745. Is the selection of the comparison group appropriate, after taking into account feasibility and ethical considerations?						
746. Were groups similar at baseline?						
747. Were the outcome assessors blinded to the test result/intervention/exposure status of participants?						
748. Were outcomes assessed using valid and reliable measures, implemented consistently across all study participants?						
749. Was overall attrition less than 30%?						
750. Was differential attrition less than 15%?						
751. Does the analysis control for baseline						

differences between groups?							
752. Does the analysis account for differences in treatment received by the groups?							
753. Are the statistical methods used to assess the outcomes appropriate?							
754. **For KQ3 ONLY** – Did analyses adjust for all or most of the standard prognostic markers?							
Comments:							

Key Question 2	If study does NOT apply to this KQ, place an 'X' here (___)						
KQ 2. Analytic Validity. Does existing evidence establish the technical accuracy and reliability of the tests for detecting the relevant genetic markers?							
	Yes	**No**	**Unclear**	**NA**	**Low**	**High**	**Unclear**
Domain 1: Patient Selection							
Was a consecutive or random sample of patients enrolled?			X				
Was a case-control design avoided?	X						
Did the study avoid inappropriate exclusions?	X						
Could the selection of patients have introduced bias?					X		
Domain 2: Index Test(s)							
Were the index test results interpreted without knowledge of the results of the reference standard?	X						
If a threshold was used, was it pre-specified?	X						
Could the conduct or interpretation of the index test have introduced bias?					X		
Domain 3: Reference Standard							
Is the reference standard likely to correctly classify the genetic markers?			X				
Were the reference standard results interpreted without knowledge of the results of the index test?	X						
Could the reference standard, its conduct, or its interpretation have introduced bias?							X
Domain 4: Flow and Timing							
Did all patients receive a reference standard?	X						
Did patients receive the same reference standard?	X						
Were all patients included in the analysis?	X						
Could the patient flow have introduced bias?					X		
Comments: it is unclear in this paper which is the reference standard – direct sequencing is generally thought of as a standard, but the alternative test (real time PCR using PNA clamping) appears to be more sensitive							

Worksheet for Risk of Bias of Individual Studies – GTRRC (v. 4-23-13)

Ref ID #	Author	Year
2180	Koh	2010

Indicate the appropriate risk of bias rating by placing an 'X' in the shaded space to the right of the rating for each KQ that is applicable. If a study does not apply to a KQ, put an 'X' next to N/A.

Risk of bias for KQ 1:	Low		Medium		High		N/A	
Risk of bias for KQ 2:	Low		Medium		High		N/A	
Risk of bias for KQ 3:	Low		Medium		High	x	N/A	
Risk of bias for KQ 4a:	Low		Medium		High		N/A	
Risk of bias for KQ 4b:	Low		Medium		High		N/A	
Risk of bias for KQ 5:	Low		Medium		High		N/A	
Explain any **High** ratings:								

Low: Study has minimal bias. High degree of confidence that the true effect size is similar in size and direction to that reported.
Medium: Study has at least one significant source of bias, but does not have flaws that are likely to cause major bias. Moderate degree of confidence that the actual effect is in the direction reported by the study; moderate degree of confidence that the true effect size is similar to that reported.
High: Study has at least one major sources of bias or multiple significant sources of bias. Low degree of confidence that the true effect size is similar in size or direction to that reported.
NA: Not applicable to that key question.

Key Questions 1, 3, 4a, 4b, and 5	If the study does NOT apply to any of these KQs, place an 'X' here (___)
KQ 1: Overarching Question Is there direct evidence that the addition of the following genetic tests used alone or in combination with traditional prognostic factors change physician decision making and improve outcomes for adult patients with lung, breast, colorectal, and bladder cancer compared with the use of traditional factors to predict risk of recurrence for adults with these cancers?	
KQ 3. Clinical Validity. Does existing evidence establish the prognostic accuracy of the tests for predicting recurrence?	
KQ 4a. Clinical Utility. What is the evidence that the prognostic information provided by the genetic tests modifies physician decisions regarding use of adjuvant anti-neoplastic chemo- and/or radiotherapy; enhanced diagnostic testing for recurrence; and/or preventive surgery among adult patients with malignant tumors?	
KQ 4b. Clinical Utility. What is the evidence that modified decisions lead to improved overall survival, disease free survival, time to recurrence, quality of life, or incidence of serious side effects of adjuvant therapy in adult patients with malignant tumors?	
KQ 5. Harms. What are the harms associated with treatment decisions that are informed by the genetic tests?	

	RCT	**non-RCT**	**Prospective cohort study**	**Retrospective cohort study**	**Case-control study**	**Case Series**
755. What is the study design?				**x**		
If "Other" study design, enter a description in this box:	**Yes**	**No**	**Partially**	**Can't Determine**	**NA**	**Explanation**
756. For RCTs, were randomization and allocation concealment adequate?					x	
757. Did the study apply inclusion/exclusion criteria uniformly to all comparison groups of the study?	x					
758. Is the selection of the comparison group appropriate, after taking into account feasibility and ethical considerations?	x					
759. Were groups similar at baseline?				x		Demographics not reported by EGFR status
760. Were the outcome assessors blinded to the test result/intervention/exposure status of participants?		x				Outcome is death
761. Were outcomes assessed using valid and reliable measures, implemented consistently across all study participants?						Outcome is death
762. Was overall attrition less than 30%?					X	

763. Was differential attrition less than 15%?					X	
764. Does the analysis control for baseline differences between groups?	X					
765. Does the analysis account for differences in treatment received by the groups?		X				Excluded patients who got chemo
766. Are the statistical methods used to assess the outcomes appropriate?	X					
767. **For KQ3 ONLY** – Did analyses adjust for all or most of the standard prognostic markers?	x					
Comments: methods of measuring EGFR not described. % of sample with EGFR mutations not described, limiting the ability to determine whether sample size is a problem. Also unclear how the inclusion of novel markers with uncertain interactions with EGFR positivity in the model would change the effect size/direction with respect to EGFR.						

Key Question 2	If study does NOT apply to this KQ, place an 'X' here (_X_)						
KQ 2. Analytic Validity. Does existing evidence establish the technical accuracy and reliability of the tests for detecting the relevant genetic markers?							
	Yes	**No**	**Unclear**	**NA**	**Low**	**High**	**Unclear**

Worksheet for Risk of Bias of Individual Studies – GTRRC (v. 4-23-13)

Ref ID #	Author	Year
843	Lin	2011

Indicate the appropriate risk of bias rating by placing an 'X' in the shaded space to the right of the rating for each KQ that is applicable. If a study does not apply to a KQ, put an 'X' next to N/A.

Risk of bias for KQ 1:	Low		Medium		High		N/A	X
Risk of bias for KQ 2:	Low		Medium		High		N/A	X
Risk of bias for KQ 3:	Low		Medium	X	High		N/A	
Risk of bias for KQ 4a:	Low		Medium		High		N/A	X
Risk of bias for KQ 4b:	Low		Medium		High		N/A	X
Risk of bias for KQ 5:	Low		Medium		High		N/A	X
Explain any **High** ratings:								

Low: Study has minimal bias. High degree of confidence that the true effect size is similar in size and direction to that reported.
Medium: Study has at least one significant source of bias, but does not have flaws that are likely to cause major bias. Moderate degree of confidence that the actual effect is in the direction reported by the study; moderate degree of confidence that the true effect size is similar to that reported.
High: Study has at least one major sources of bias or multiple significant sources of bias. Low degree of confidence that the true effect size is similar in size or direction to that reported.
NA: Not applicable to that key question.

Key Questions 1, 3, 4a, 4b, and 5	If the study does NOT apply to any of these KQs, place an 'X' here (___)

KQ 1: Overarching Question
Is there direct evidence that the addition of the following genetic tests used alone or in combination with traditional prognostic factors change physician decision making and improve outcomes for adult patients with lung, breast, colorectal, and bladder cancer compared with the use of traditional factors to predict risk of recurrence for adults with these cancers?

KQ 3. Clinical Validity. Does existing evidence establish the prognostic accuracy of the tests for predicting recurrence?

KQ 4a. Clinical Utility.
What is the evidence that the prognostic information provided by the genetic tests modifies physician decisions regarding use of adjuvant anti-neoplastic chemo- and/or radiotherapy; enhanced diagnostic testing for recurrence; and/or preventive surgery among adult patients with malignant tumors?

KQ 4b. Clinical Utility.
What is the evidence that modified decisions lead to improved overall survival, disease free survival, time to recurrence, quality of life, or incidence of serious side effects of adjuvant therapy in adult patients with malignant tumors?

KQ 5. Harms.
What are the harms associated with treatment decisions that are informed by the genetic tests?

	RCT	**non-RCT**	**Prospective cohort study**	**Retrospective cohort study**	**Case-control study**	**Case Series**
781. What is the study design?				**X**		
If "Other" study design, enter a description in this box:	**Yes**	**No**	**Partially**	**Can't Determine**	**NA**	**Explanation**
782. For RCTs, were randomization and allocation concealment adequate?					X	
783. Did the study apply inclusion/exclusion criteria uniformly to all comparison groups of the study?	X					
784. Is the selection of the comparison group appropriate, after taking into account feasibility and ethical considerations?	X					
785. Were groups similar at baseline?		X				Differences for histology, mucin-containing tumors, location (proximal), sex, and stage
786. Were the outcome assessors blinded to the test result/intervention/exposure status of participants?				X		

787. Were outcomes assessed using valid and reliable measures, implemented consistently across all study participants?				X		
788. Was overall attrition less than 30%?	X					Follow up was 98% for at least 3 years (not certain beyond 3 years)
789. Was differential attrition less than 15%?	X					
790. Does the analysis control for baseline differences between groups?			X			Yes, for the variables listed below; no for mucinous component, location (proximal or distal), but those were NS in the univariate
791. Does the analysis account for differences in treatment received by the groups?		X				
792. Are the statistical methods used to assess the outcomes appropriate?	X					
793. **For KQ3 ONLY** – Did analyses adjust for all or most of the standard prognostic markers?	X					Most, not all
Comments: Some risk of measurement bias and confounding. Not large effect size in multivariate analyses for OS (the only one that remained statistically significant). Possible that it also would have been NS with further adjustment for other potential confounders.						

Key Question 2	If study does NOT apply to this KQ, place an 'X' here (_X_)						
KQ 2. Analytic Validity. Does existing evidence establish the technical accuracy and reliability of the tests for detecting the relevant genetic markers?							
	Yes	**No**	**Unclear**	**NA**	**Low**	**High**	**Unclear**

Did all patients receive a reference standard?							
Did patients receive the same reference standard?							

Were all patients included in the analysis?							
Could the patient flow have introduced bias?							
Comments:							

Worksheet for Risk of Bias of Individual Studies – GTRRC (v. 4-23-13)

Ref ID #	Author	Year
851	Liou	2011

Indicate the appropriate risk of bias rating by placing an 'X' in the shaded space to the right of the rating for each KQ that is applicable. If a study does not apply to a KQ, put an 'X' next to N/A.

Risk of bias for KQ 1:	Low		Medium		High		N/A	X
Risk of bias for KQ 2:	Low		Medium		High		N/A	X
Risk of bias for KQ 3:	Low		Medium	X	High		N/A	
Risk of bias for KQ 4a:	Low		Medium		High		N/A	X
Risk of bias for KQ 4b:	Low		Medium		High		N/A	X
Risk of bias for KQ 5:	Low		Medium		High		N/A	X
Explain any **High** ratings:								

Low: Study has minimal bias. High degree of confidence that the true effect size is similar in size and direction to that reported.
Medium: Study has at least one significant source of bias, but does not have flaws that are likely to cause major bias. Moderate degree of confidence that the actual effect is in the direction reported by the study; moderate degree of confidence that the true effect size is similar to that reported.
High: Study has at least one major sources of bias or multiple significant sources of bias. Low degree of confidence that the true effect size is similar in size or direction to that reported.
NA: Not applicable to that key question.

Key Questions 1, 3, 4a, 4b, and 5	If the study does NOT apply to any of these KQs, place an 'X' here (___)

KQ 1: Overarching Question
Is there direct evidence that the addition of the following genetic tests used alone or in combination with traditional prognostic factors change physician decision making and improve outcomes for adult patients with lung, breast, colorectal, and bladder cancer compared with the use of traditional factors to predict risk of recurrence for adults with these cancers?

KQ 3. Clinical Validity. Does existing evidence establish the prognostic accuracy of the tests for predicting recurrence?

KQ 4a. Clinical Utility.
What is the evidence that the prognostic information provided by the genetic tests modifies physician decisions regarding use of adjuvant anti-neoplastic chemo- and/or radiotherapy; enhanced diagnostic testing for recurrence; and/or preventive surgery among adult patients with malignant tumors?

KQ 4b. Clinical Utility.
What is the evidence that modified decisions lead to improved overall survival, disease free survival, time to recurrence, quality of life, or incidence of serious side effects of adjuvant therapy in adult patients with malignant tumors?

KQ 5. Harms.
What are the harms associated with treatment decisions that are informed by the genetic tests?

	RCT	**non-RCT**	**Prospective cohort study**	**Retrospective cohort study**	**Case-control study**	**Case Series**
794. What is the study design?				**X**		
If "Other" study design, enter a description in this box:	**Yes**	**No**	**Partially**	**Can't Determine**	**NA**	**Explanation**
795. For RCTs, were randomization and allocation concealment adequate?					X	
796. Did the study apply inclusion/exclusion criteria uniformly to all comparison groups of the study?	X					
797. Is the selection of the comparison group appropriate, after taking into account feasibility and ethical considerations?	X					
798. Were groups similar at baseline?		X				For the KRAS groups, differences for smoking, age, BMI, alcohol drinking, DM, and location of cancer (proximal vs. distal). For the BRAF groups,

						differences for location of cancer, differentiation.
799. Were the outcome assessors blinded to the test result/intervention/exposure status of participants?		X				
800. Were outcomes assessed using valid and reliable measures, implemented consistently across all study participants?	X			X		Death ascertained by National Taiwan Mortality Registry. It was equal, probably valid and reliable for death/overall survival, but uncertain if it is valid and reliable to determine cause of death (for cancer-specific death outcomes)
801. Was overall attrition less than 30%?	X					Exact attrition data NR, but median followup range was from 49 to 82 months (suggesting that they had at least 4 years of follow up for all subjects)
802. Was differential attrition less than 15%?	X					
803. Does the analysis control for baseline differences between groups?			X			
804. Does the analysis account for differences in treatment received by the groups?		X				Yes for KRAS for OS, but no for BRAF analyses. But, more than 85% of patients for whom adjuvant chemo was indicated (stage 3 or 4) got the same regimen—5FU, LV, and oxaliplatin; the other 15% got 5FU and LV.
805. Are the statistical methods used to assess	X					

the outcomes appropriate?						
806. **For KQ3 ONLY** – Did analyses adjust for all or most of the standard prognostic markers?	X					For BRAF, adjusted for age, sex, stage, lymphatic invasion, venous invasion, tumor differentiation, CEA level (>5 vs. ≤5 ng/mL); For KRAS overall survival analysis: age, sex, stage, use of adjuvant chemotherapy
Comments: Moderate risk of selection bias, measurement bias, and confounding						

Key Question 2	If study does NOT apply to this KQ, place an 'X' here (_X_)						
KQ 2. Analytic Validity. Does existing evidence establish the technical accuracy and reliability of the tests for detecting the relevant genetic markers?							
	Yes	**No**	**Unclear**	**NA**	**Low**	**High**	**Unclear**
Domain 1: Patient Selection							
Was a consecutive or random sample of patients enrolled?							
Was a case-control design avoided?							
Did the study avoid inappropriate exclusions?							
Could the selection of patients have introduced bias?							
Domain 2: Index Test(s)							
Were the index test results interpreted without knowledge of the results of the reference standard?							
If a threshold was used, was it pre-specified?							
Could the conduct or interpretation of the index test have introduced bias?							
Domain 3: Reference Standard							
Is the reference standard likely to correctly classify the genetic markers?							
Were the reference standard results interpreted without knowledge of the results of the index test?							
Could the reference standard, its conduct, or its interpretation have introduced bias?							
Domain 4: Flow and Timing							
Did all patients receive a reference standard?							
Did patients receive the same reference standard?							
Were all patients included in the analysis?							
Could the patient flow have introduced bias?							
Comments:							

Worksheet for Risk of Bias of Individual Studies – GTRRC (v. 4-23-13)

Ref ID #	Author	Year
2249	Liu	2010

Indicate the appropriate risk of bias rating by placing an 'X' in the shaded space to the right of the rating for each KQ that is applicable. If a study does not apply to a KQ, put an 'X' next to N/A.

Risk of bias for KQ 1:	Low		Medium		High		N/A	
Risk of bias for KQ 2:	Low		Medium		High		N/A	
Risk of bias for KQ 3:	Low		Medium	x	High		N/A	
Risk of bias for KQ 4a:	Low		Medium		High		N/A	
Risk of bias for KQ 4b:	Low		Medium		High		N/A	
Risk of bias for KQ 5:	Low		Medium		High		N/A	
Explain any **High** ratings:								

Low: Study has minimal bias. High degree of confidence that the true effect size is similar in size and direction to that reported.
Medium: Study has at least one significant source of bias, but does not have flaws that are likely to cause major bias. Moderate degree of confidence that the actual effect is in the direction reported by the study; moderate degree of confidence that the true effect size is similar to that reported.
High: Study has at least one major sources of bias or multiple significant sources of bias. Low degree of confidence that the true effect size is similar in size or direction to that reported.
NA: Not applicable to that key question.

Key Questions 1, 3, 4a, 4b, and 5	If the study does NOT apply to any of these KQs, place an 'X' here (___)
KQ 1: Overarching Question Is there direct evidence that the addition of the following genetic tests used alone or in combination with traditional prognostic factors change physician decision making and improve outcomes for adult patients with lung, breast, colorectal, and bladder cancer compared with the use of traditional factors to predict risk of recurrence for adults with these cancers?	
KQ 3. Clinical Validity. Does existing evidence establish the prognostic accuracy of the tests for predicting recurrence?	
KQ 4a. Clinical Utility. What is the evidence that the prognostic information provided by the genetic tests modifies physician decisions regarding use of adjuvant anti-neoplastic chemo- and/or radiotherapy; enhanced diagnostic testing for recurrence; and/or preventive surgery among adult patients with malignant tumors?	
KQ 4b. Clinical Utility. What is the evidence that modified decisions lead to improved overall survival, disease free survival, time to recurrence, quality of life, or incidence of serious side effects of adjuvant therapy in adult patients with malignant tumors?	
KQ 5. Harms. What are the harms associated with treatment decisions that are informed by the genetic tests?	

	RCT	**non-RCT**	**Prospective cohort study**	**Retrospective cohort study**	**Case-control study**	**Case Series**
807. What is the study design?				**X**		
If "Other" study design, enter a description in this box:	**Yes**	**No**	**Partially**	**Can't Determine**	**NA**	**Explanation**
808. For RCTs, were randomization and allocation concealment adequate?					X	
809. Did the study apply inclusion/exclusion criteria uniformly to all comparison groups of the study?	X					
810. Is the selection of the comparison group appropriate, after taking into account feasibility and ethical considerations?	X					
811. Were groups similar at baseline?				x		Detailed demographics by group not reported
812. Were the outcome assessors blinded to the test result/intervention/exposure status of participants?		X				Outcome is survival
813. Were outcomes assessed using valid and reliable measures, implemented consistently across all study participants?	x					Outcome is survival
814. Was overall attrition less than 30%?					X	

815. Was differential attrition less than 15%?					X	
816. Does the analysis control for baseline differences between groups?	X					
817. Does the analysis account for differences in treatment received by the groups?		x				Some pts received radiation or chemo and these were not controlled for
818. Are the statistical methods used to assess the outcomes appropriate?	X					
819. **For KQ3 ONLY** – Did analyses adjust for all or most of the standard prognostic markers?	X					
Comments:						

Key Question 2	If study does NOT apply to this KQ, place an 'X' here (X__)						
KQ 2. Analytic Validity. Does existing evidence establish the technical accuracy and reliability of the tests for detecting the relevant genetic markers?

	RCT	**non-RCT**	**Prospective cohort study**	**Retrospective cohort study**	**Case-control study**	**Case Series**
820. What is the study design?						Other, design is an uncontrolled trial
If "Other" study design, enter a description in this box:	**Yes**	**No**	**Partially**	**Can't Determine**	**NA**	**Explanation**
821. For RCTs, were randomization and allocation concealment adequate?					X	
822. Did the study apply inclusion/exclusion criteria uniformly to all comparison groups of the study?					X	Just one group
823. Is the selection of the comparison group appropriate, after taking into account feasibility and ethical considerations?					X	
824. Were groups similar at baseline?					X	
825. Were the outcome assessors blinded to the test result/intervention/exposure status of participants?					X	
826. Were outcomes assessed using valid and reliable measures, implemented consistently across all study participants?	X					
827. Was overall attrition less than 30%?	X					

828. Was differential attrition less than 15%?	X					
829. Does the analysis control for baseline differences between groups?					X	
830. Does the analysis account for differences in treatment received by the groups?					X	
831. Are the statistical methods used to assess the outcomes appropriate?	X					
832. **For KQ3 ONLY** – Did analyses adjust for all or most of the standard prognostic markers?					X	
Comments: uncontrolled trial (with the intervention being giving the oncologists the Oncotype Dx information) evaluating whether Oncotype Dx information changes decisions. Good that they attempted to get oncologists from several centers (4 centers in 3 different states—California, Michigan, Illinois) to avoid just representing the opinion of 1 group. Formal questionnaire to assess treatment recommendations and confidence in those recommendations.						

Key Question 2	If study does NOT apply to this KQ, place an 'X' here (_X_)						
KQ 2. Analytic Validity. Does existing evidence establish the technical accuracy and reliability of the tests for detecting the relevant genetic markers?

Worksheet for Risk of Bias of Individual Studies – GTRRC (v. 4-23-13)

Ref ID #	Author	Year
3605	Lochhead	2013

Indicate the appropriate quality rating by placing an 'X' in the shaded space to the right of the rating for each KQ that is applicable **AND** for an Overall rating. If a study does not apply to a KQ, put an 'X' next to N/A.

Risk of bias for KQ 1:	Low		Medium		High		N/A	X
Risk of bias for KQ 2:	Low		Medium		High		N/A	X
Risk of bias for KQ 3:	Low		Medium	X	High		N/A	
Risk of bias for KQ 4a:	Low		Medium		High		N/A	X
Risk of bias for KQ 4b:	Low		Medium		High		N/A	X
Risk of bias for KQ 5:	Low		Medium		High		N/A	X
Explain any **High** ratings:								

Low: Study has minimal bias. High degree of confidence that the true effect size is similar in size and direction to that reported.
Medium: Study has at least one significant source of bias, but does not have flaws that are likely to cause major bias. Moderate degree of confidence that the actual effect is in the direction reported by the study; moderate degree of confidence that the true effect size is similar to that reported.
High: Study has at least one major sources of bias or multiple significant sources of bias. Low degree of confidence that the true effect size is similar in size or direction to that reported.
NA: Not applicable to that key question.

Key Questions 1, 3, 4a, 4b, and 5	If the study does NOT apply to any of these KQs, place an 'X' here (___)

KQ 1: Overarching Question
Is there direct evidence that the addition of the following genetic tests used alone or in combination with traditional prognostic factors change physician decision making and improve outcomes for adult patients with lung, breast, colorectal, and bladder cancer compared with the use of traditional factors to predict risk of recurrence for adults with these cancers?

KQ 3. Clinical Validity. Does existing evidence establish the prognostic accuracy of the tests for predicting recurrence?

KQ 4a. Clinical Utility.
What is the evidence that the prognostic information provided by the genetic tests modifies physician decisions regarding use of adjuvant anti-neoplastic chemo- and/or radiotherapy; enhanced diagnostic testing for recurrence; and/or preventive surgery among adult patients with malignant tumors?

KQ 4b. Clinical Utility.
What is the evidence that modified decisions lead to improved overall survival, disease free survival, time to recurrence, quality of life, or incidence of serious side effects of adjuvant therapy in adult patients with malignant tumors?

KQ 5. Harms.
What are the harms associated with treatment decisions that are informed by the genetic tests?

	RCT	**non-RCT**	**Prospective cohort study**	**Retrospective cohort study**	**Case-control study**	**Case Series**
833. What is the study design?				**X**		
If "Other" study design, enter a description in this box:	**Yes**	**No**	**Partially**	**Can't Determine**	**NA**	**Explanation**
834. For RCTs, were randomization and allocation concealment adequate?					X	
835. Did the study apply inclusion/exclusion criteria uniformly to all comparison groups of the study?	X					
836. Is the selection of the comparison group appropriate, after taking into account feasibility and ethical considerations?	X					
837. Were groups similar at baseline?		X				
838. Were the outcome assessors blinded to the test result/intervention/exposure status of participants?				X		
839. Were outcomes assessed using valid and reliable measures, implemented consistently across all study participants?			X			National Death Index is valid and reliable for all-cause mortality, but it is not clear

						whether having the study physicians determine the cause of death is valid and reliable for cancer-specific mortality
840. Was overall attrition less than 30%?	X					
841. Was differential attrition less than 15%?	X					
842. Does the analysis control for baseline differences between groups?	X					
843. Does the analysis account for differences in treatment received by the groups?		X				
844. Are the statistical methods used to assess the outcomes appropriate?	X					
845. **For KQ3 ONLY** – Did analyses adjust for all or most of the standard prognostic markers?	X					
Comments:

Worksheet for Risk of Bias of Individual Studies – GTRRC (v. 4-23-13)

Ref ID #	Author	Year
2267	Mak	2011

Indicate the appropriate risk of bias rating by placing an 'X' in the shaded space to the right of the rating for each KQ that is applicable. If a study does not apply to a KQ, put an 'X' next to N/A.

Risk of bias for KQ 1:	Low		Medium		High		N/A	X
Risk of bias for KQ 2:	Low		Medium		High		N/A	X
Risk of bias for KQ 3:	Low		Medium	X	High		N/A	
Risk of bias for KQ 4a:	Low		Medium		High		N/A	X
Risk of bias for KQ 4b:	Low		Medium		High		N/A	X
Risk of bias for KQ 5:	Low		Medium		High		N/A	X
Explain any **High** ratings:								

Low: Study has minimal bias. High degree of confidence that the true effect size is similar in size and direction to that reported.
Medium: Study has at least one significant source of bias, but does not have flaws that are likely to cause major bias. Moderate degree of confidence that the actual effect is in the direction reported by the study; moderate degree of confidence that the true effect size is similar to that reported.
High: Study has at least one major sources of bias or multiple significant sources of bias. Low degree of confidence that the true effect size is similar in size or direction to that reported.
NA: Not applicable to that key question.

Key Questions 1, 3, 4a, 4b, and 5	If the study does NOT apply to any of these KQs, place an 'X' here (___)

KQ 1: Overarching Question
Is there direct evidence that the addition of the following genetic tests used alone or in combination with traditional prognostic factors change physician decision making and improve outcomes for adult patients with lung, breast, colorectal, and bladder cancer compared with the use of traditional factors to predict risk of recurrence for adults with these cancers?

KQ 3. Clinical Validity. Does existing evidence establish the prognostic accuracy of the tests for predicting recurrence?

KQ 4a. Clinical Utility.
What is the evidence that the prognostic information provided by the genetic tests modifies physician decisions regarding use of adjuvant anti-neoplastic chemo- and/or radiotherapy; enhanced diagnostic testing for recurrence; and/or preventive surgery among adult patients with malignant tumors?

KQ 4b. Clinical Utility.
What is the evidence that modified decisions lead to improved overall survival, disease free survival, time to recurrence, quality of life, or incidence of serious side effects of adjuvant therapy in adult patients with malignant tumors?

KQ 5. Harms.
What are the harms associated with treatment decisions that are informed by the genetic tests?

	RCT	**non-RCT**	**Prospective cohort study**	**Retrospective cohort study**	**Case-control study**	**Case Series**
872. What is the study design?				**X**		
If "Other" study design, enter a description in this box:	**Yes**	**No**	**Partially**	**Can't Determine**	**NA**	**Explanation**
873. For RCTs, were randomization and allocation concealment adequate?					X	
874. Did the study apply inclusion/exclusion criteria uniformly to all comparison groups of the study?	X					
875. Is the selection of the comparison group appropriate, after taking into account feasibility and ethical considerations?	X					
876. Were groups similar at baseline?		X				Differences for smoking status, Stage, tumor size, radiotherapy treatment mode, and whether they had surgical resection of the primary tumor.

877. Were the outcome assessors blinded to the test result/intervention/exposure status of participants?		X				
878. Were outcomes assessed using valid and reliable measures, implemented consistently across all study participants?			X			The definitions of the outcomes are reasonable, but unclear whether reviewing their medical records provided valid and reliable assessments of recurrence and survival; unclear how complete the data was from their medical record review (e.g., how many patients lacked complete f/u or went to other hospitals). No description of methods to ensure capturing deaths.
879. Was overall attrition less than 30%?				X		
880. Was differential attrition less than 15%?				X		
881. Does the analysis control for baseline differences between groups?	X					
882. Does the analysis account for differences in treatment received by the groups?	X					
883. Are the statistical methods used to assess the outcomes appropriate?	X					
884. **For KQ3 ONLY** – Did analyses adjust for all or most of the standard prognostic markers?	X					Final model didn't have most of them, but they started with considering most of them, and used appropriate stepwise selection to determine those in the final model.
Comments:						

Key Question 2	If study does NOT apply to this KQ, place an 'X' here (_X_)

KQ 2. Analytic Validity. Does existing evidence establish the technical accuracy and reliability of the tests for detecting the relevant genetic markers?							
	Yes	**No**	**Unclear**	**NA**	**Low**	**High**	**Unclear**
Domain 1: Patient Selection							
Was a consecutive or random sample of patients enrolled?							
Was a case-control design avoided?							
Did the study avoid inappropriate exclusions?							
Could the selection of patients have introduced bias?							
Domain 2: Index Test(s)							
Were the index test results interpreted without knowledge of the results of the reference standard?							
If a threshold was used, was it pre-specified?							
Could the conduct or interpretation of the index test have introduced bias?							
Domain 3: Reference Standard							
Is the reference standard likely to correctly classify the genetic markers?							
Were the reference standard results interpreted without knowledge of the results of the index test?							
Could the reference standard, its conduct, or its interpretation have introduced bias?							
Domain 4: Flow and Timing							
Did all patients receive a reference standard?							
Did patients receive the same reference standard?							
Were all patients included in the analysis?							
Could the patient flow have introduced bias?							
Comments:							

Worksheet for Risk of Bias of Individual Studies – GTRRC (v. 4-23-13)

Ref ID #	Author	Year
176	Mamounas	2010

Indicate the appropriate risk of bias rating by placing an 'X' in the shaded space to the right of the rating for each KQ that is applicable. If a study does not apply to a KQ, put an 'X' next to N/A.

Risk of bias for KQ 1:	Low		Medium		High		N/A	X
Risk of bias for KQ 2:	Low		Medium		High		N/A	X
Risk of bias for KQ 3:	Low		Medium	X	High		N/A	
Risk of bias for KQ 4a:	Low		Medium		High		N/A	X
Risk of bias for KQ 4b:	Low		Medium		High		N/A	X
Risk of bias for KQ 5:	Low		Medium		High		N/A	X
Explain any **High** ratings:								

Low: Study has minimal bias. High degree of confidence that the true effect size is similar in size and direction to that reported.
Medium: Study has at least one significant source of bias, but does not have flaws that are likely to cause major bias. Moderate degree of confidence that the actual effect is in the direction reported by the study; moderate degree of confidence that the true effect size is similar to that reported.
High: Study has at least one major sources of bias or multiple significant sources of bias. Low degree of confidence that the true effect size is similar in size or direction to that reported.
NA: Not applicable to that key question.

Key Questions 1, 3, 4a, 4b, and 5	If the study does NOT apply to any of these KQs, place an 'X' here (___)

KQ 1: Overarching Question
Is there direct evidence that the addition of the following genetic tests used alone or in combination with traditional prognostic factors change physician decision making and improve outcomes for adult patients with lung, breast, colorectal, and bladder cancer compared with the use of traditional factors to predict risk of recurrence for adults with these cancers?

KQ 3. Clinical Validity. Does existing evidence establish the prognostic accuracy of the tests for predicting recurrence?

KQ 4a. Clinical Utility.
What is the evidence that the prognostic information provided by the genetic tests modifies physician decisions regarding use of adjuvant anti-neoplastic chemo- and/or radiotherapy; enhanced diagnostic testing for recurrence; and/or preventive surgery among adult patients with malignant tumors?

KQ 4b. Clinical Utility.
What is the evidence that modified decisions lead to improved overall survival, disease free survival, time to recurrence, quality of life, or incidence of serious side effects of adjuvant therapy in adult patients with malignant tumors?

KQ 5. Harms.
What are the harms associated with treatment decisions that are informed by the genetic tests?

	RCT	**non-RCT**	**Prospective cohort study**	**Retrospective cohort study**	**Case-control study**	**Case Series**
885. What is the study design?				**X**		
If "Other" study design, enter a description in this box:	**Yes**	**No**	**Partially**	**Can't Determine**	**NA**	**Explanation**
886. For RCTs, were randomization and allocation concealment adequate?					X	
887. Did the study apply inclusion/exclusion criteria uniformly to all comparison groups of the study?	X					
888. Is the selection of the comparison group appropriate, after taking into account feasibility and ethical considerations?	X					
889. Were groups similar at baseline?				X		
890. Were the outcome assessors blinded to the test result/intervention/exposure status of participants?				X		
891. Were outcomes assessed using valid and reliable measures, implemented consistently across all study participants?				X		The 2 RCTs that they obtained subjects from might have more description of

						how LRR was determined
892. Was overall attrition less than 30%?				X		
893. Was differential attrition less than 15%?				X		
894. Does the analysis control for baseline differences between groups?				X		
895. Does the analysis account for differences in treatment received by the groups?	X					
896. Are the statistical methods used to assess the outcomes appropriate?	X					
897. **For KQ3 ONLY** – Did analyses adjust for all or most of the standard prognostic markers?	X					
Comments: multivariate adjusted analysis included age, tumor size, tumor grade, and treatment differences (all subjects were node negative and ER+ so those did not need to be considered)						

Key Question 2	If study does NOT apply to this KQ, place an 'X' here (_X_)						
KQ 2. Analytic Validity. Does existing evidence establish the technical accuracy and reliability of the tests for detecting the relevant genetic markers?							
	Yes	**No**	**Unclear**	**NA**	**Low**	**High**	**Unclear**
Domain 1: Patient Selection							
Was a consecutive or random sample of patients enrolled?							
Was a case-control design avoided?

Comments:							

Worksheet for Risk of Bias of Individual Studies – GTRRC (v. 4-23-13)

Ref ID #	Author	Year
3415	Mamounas	2012

Indicate the appropriate risk of bias rating by placing an 'X' in the shaded space to the right of the rating for each KQ that is applicable. If a study does not apply to a KQ, put an 'X' next to N/A.

Risk of bias for KQ 1:	Low		Medium		High		N/A	X
Risk of bias for KQ 2:	Low		Medium		High		N/A	X
Risk of bias for KQ 3:	Low		Medium		High	Unclear	N/A	
Risk of bias for KQ 4a:	Low		Medium		High		N/A	X
Risk of bias for KQ 4b:	Low		Medium		High		N/A	X
Risk of bias for KQ 5:	Low		Medium		High		N/A	X
Explain any **High** ratings:	Unclear risk of bias; abstract only from conference; insufficient information presented to assess risk of selection bias, confounding, and measurement bias.							

Low: Study has minimal bias. High degree of confidence that the true effect size is similar in size and direction to that reported.
Medium: Study has at least one significant source of bias, but does not have flaws that are likely to cause major bias. Moderate degree of confidence that the actual effect is in the direction reported by the study; moderate degree of confidence that the true effect size is similar to that reported.
High: Study has at least one major sources of bias or multiple significant sources of bias. Low degree of confidence that the true effect size is similar in size or direction to that reported.
NA: Not applicable to that key question.

KQ 4b. Clinical Utility.
What is the evidence that modified decisions lead to improved overall survival, disease free survival, time to recurrence, quality of life, or incidence of serious side effects of adjuvant therapy in adult patients with malignant tumors?

KQ 5. Harms.
What are the harms associated with treatment decisions that are informed by the genetic tests?

	RCT	**non-RCT**	**Prospective cohort study**	**Retrospective cohort study**	**Case-control study**	**Case Series**
911. What is the study design?						
If "Other" study design, enter a description in this box:	**Yes**	**No**	**Partially**	**Can't Determine**	**NA**	**Explanation**
912. For RCTs, were randomization and allocation concealment adequate?						
913. Did the study apply inclusion/exclusion criteria uniformly to all comparison groups of the study?						
914. Is the selection of the comparison group appropriate, after taking into account feasibility and ethical considerations?						
915. Were groups similar at baseline?						
916. Were the outcome assessors blinded to the test result/intervention/exposure status of participants?						
917. Were outcomes assessed using valid and reliable measures, implemented consistently across all study participants?						
918. Was overall attrition less than 30%?						
919. Was differential attrition less than 15%?						
920. Does the analysis control for baseline						

differences between groups?						
921. Does the analysis account for differences in treatment received by the groups?						
922. Are the statistical methods used to assess the outcomes appropriate?						
923. **For KQ3 ONLY** – Did analyses adjust for all or most of the standard prognostic markers?						
Comments:						

Key Question 2					If study does NOT apply to this KQ, place an 'X' here (___)		
KQ 2. Analytic Validity. Does existing evidence establish the technical accuracy and reliability of the tests for detecting the relevant genetic markers?							
	Yes	**No**	**Unclear**	**NA**	**Low**	**High**	**Unclear**
Domain 1: Patient Selection							
Was a consecutive or random sample of patients enrolled?	X						
Was a case-control design avoided?	X						
Did the study avoid inappropriate exclusions?	X						
Could the selection of patients have introduced bias?					X		
Domain 2: Index Test(s)							
Were the index test results interpreted without knowledge of the results of the reference standard?			X				
If a threshold was used, was it pre-specified?	X						
Could the conduct or interpretation of the index test have introduced bias?							X
Domain 3: Reference Standard							
Is the reference standard likely to correctly classify the genetic markers?	X						
Were the reference standard results interpreted without knowledge of the results of the index test?			X				
Could the reference standard, its conduct, or its interpretation have introduced bias?							X
Domain 4: Flow and Timing							
Did all patients receive a reference standard?	X						
Did patients receive the same reference standard?	X						
Were all patients included in the analysis?	X						
Could the patient flow have introduced bias?					X		
Comments: For the aspects that were reported, risk of bias seems low. Although it is not clear whether the various tests were interpreted without knowledge of the reference standard result and vice versa, the article implies that there was no masking of outcome assessors to the results of the other tests.							

Worksheet for Risk of Bias of Individual Studies – GTRRC (v. 4-23-13)

Ref ID #	Author	Year
2288	Matsumoto	2005

Indicate the appropriate risk of bias rating by placing an 'X' in the shaded space to the right of the rating for each KQ that is applicable. If a study does not apply to a KQ, put an 'X' next to N/A.

Risk of bias for KQ 1:	Low		Medium		High		N/A	
Risk of bias for KQ 2:	Low		Medium		High		N/A	
Risk of bias for KQ 3:	Low		Medium	x	High		N/A	
Risk of bias for KQ 4a:	Low		Medium		High		N/A	
Risk of bias for KQ 4b:	Low		Medium		High		N/A	
Risk of bias for KQ 5:	Low		Medium		High		N/A	
Explain any **High** ratings:								

Low: Study has minimal bias. High degree of confidence that the true effect size is similar in size and direction to that reported.
Medium: Study has at least one significant source of bias, but does not have flaws that are likely to cause major bias. Moderate degree of confidence that the actual effect is in the direction reported by the study; moderate degree of confidence that the true effect size is similar to that reported.
High: Study has at least one major sources of bias or multiple significant sources of bias. Low degree of confidence that the true effect size is similar in size or direction to that reported.
NA: Not applicable to that key question.

Key Questions 1, 3, 4a, 4b, and 5	If the study does NOT apply to any of these KQs, place an 'X' here (___)
KQ 1: Overarching Question Is there direct evidence that the addition of the following genetic tests used alone or in combination with traditional prognostic factors change physician decision making and improve outcomes for adult patients with lung, breast, colorectal, and bladder cancer compared with the use of traditional factors to predict risk of recurrence for adults with these cancers?	
KQ 3. Clinical Validity. Does existing evidence establish the prognostic accuracy of the tests for predicting recurrence?	
KQ 4a. Clinical Utility. What is the evidence that the prognostic information provided by the genetic tests modifies physician decisions regarding use of adjuvant anti-neoplastic chemo- and/or radiotherapy; enhanced diagnostic testing for recurrence; and/or preventive surgery among adult patients with malignant tumors?	
KQ 4b. Clinical Utility. What is the evidence that modified decisions lead to improved overall survival, disease free survival, time to recurrence, quality of life, or incidence of serious side effects of adjuvant therapy in adult patients with malignant tumors?	
KQ 5. Harms. What are the harms associated with treatment decisions that are informed by the genetic tests?	

	RCT	**non-RCT**	**Prospective cohort study**	**Retrospective cohort study**	**Case-control study**	**Case Series**
924. What is the study design?				**X**		
If "Other" study design, enter a description in this box:	**Yes**	**No**	**Partially**	**Can't Determine**	**NA**	**Explanation**
925. For RCTs, were randomization and allocation concealment adequate?					X	
926. Did the study apply inclusion/exclusion criteria uniformly to all comparison groups of the study?	X					
927. Is the selection of the comparison group appropriate, after taking into account feasibility and ethical considerations?	X					
928. Were groups similar at baseline?		x				Not expected in nonrandomized study
929. Were the outcome assessors blinded to the test result/intervention/exposure status of participants?				x		Outcome is death, not relevant
930. Were outcomes assessed using valid and reliable measures, implemented consistently across all study participants?	x					
931. Was overall attrition less than 30%?				X		

932. Was differential attrition less than 15%?				X		
933. Does the analysis control for baseline differences between groups?	X					
934. Does the analysis account for differences in treatment received by the groups?		x				All pts treated pretty similarly
935. Are the statistical methods used to assess the outcomes appropriate?	X					
936. **For KQ3 ONLY** – Did analyses adjust for all or most of the standard prognostic markers?	X					
Comments: my only concern regarding this paper is the sample size, confidence interval was quite wide for main effect of interest. Also, restricted to stage I cancers which have an overall very good prognosis, should not generalize to the entire stage I-III population						

Key Question 2	If study does NOT apply to this KQ, place an 'X' here (_X_)

Worksheet for Risk of Bias of Individual Studies – GTRRC (v. 4-23-13)

Ref ID #	Author	Year
133	Mook	2009

Indicate the appropriate risk of bias rating by placing an 'X' in the shaded space to the right of the rating for each KQ that is applicable. If a study does not apply to a KQ, put an 'X' next to N/A.

Risk of bias for KQ 1:	Low		Medium		High		N/A	
Risk of bias for KQ 2:	Low		Medium		High		N/A	
Risk of bias for KQ 3:	Low	X	Medium		High		N/A	
Risk of bias for KQ 4a:	Low		Medium		High		N/A	
Risk of bias for KQ 4b:	Low		Medium		High		N/A	
Risk of bias for KQ 5:	Low		Medium		High		N/A	
Explain any **High** ratings:								

Low: Study has minimal bias. High degree of confidence that the true effect size is similar in size and direction to that reported.
Medium: Study has at least one significant source of bias, but does not have flaws that are likely to cause major bias. Moderate degree of confidence that the actual effect is in the direction reported by the study; moderate degree of confidence that the true effect size is similar to that reported.
High: Study has at least one major sources of bias or multiple significant sources of bias. Low degree of confidence that the true effect size is similar in size or direction to that reported.
NA: Not applicable to that key question.

Key Questions 1, 3, 4a, 4b, and 5	If the study does NOT apply to any of these KQs, place an 'X' here (___)

KQ 1: Overarching Question
Is there direct evidence that the addition of the following genetic tests used alone or in combination with traditional prognostic factors change physician decision making and improve outcomes for adult patients with lung, breast, colorectal, and bladder cancer compared with the use of traditional factors to predict risk of recurrence for adults with these cancers?

KQ 3. Clinical Validity. Does existing evidence establish the prognostic accuracy of the tests for predicting recurrence?

KQ 4a. Clinical Utility.
What is the evidence that the prognostic information provided by the genetic tests modifies physician decisions regarding use of adjuvant anti-neoplastic chemo- and/or radiotherapy; enhanced diagnostic testing for recurrence; and/or preventive surgery among adult patients with malignant tumors?

KQ 4b. Clinical Utility.
What is the evidence that modified decisions lead to improved overall survival, disease free survival, time to recurrence, quality of life, or incidence of serious side effects of adjuvant therapy in adult patients with malignant tumors?

KQ 5. Harms.
What are the harms associated with treatment decisions that are informed by the genetic tests?

	RCT	**non-RCT**	**Prospective cohort study**	**Retrospective cohort study**	**Case-control study**	**Case Series**
937. What is the study design?				**X**		
If "Other" study design, enter a description in this box:	**Yes**	**No**	**Partially**	**Can't Determine**	**NA**	**Explanation**
938. For RCTs, were randomization and allocation concealment adequate?					X	
939. Did the study apply inclusion/exclusion criteria uniformly to all comparison groups of the study?	X					
940. Is the selection of the comparison group appropriate, after taking into account feasibility and ethical considerations?	X					
941. Were groups similar at baseline?		X				not expected in a retrospective observational design
942. Were the outcome assessors blinded to the test result/intervention/exposure status of participants?					X	
943. Were outcomes assessed using valid and reliable measures, implemented consistently across all study participants?	X					

944. Was overall attrition less than 30%?				X		
945. Was differential attrition less than 15%?				X		
946. Does the analysis control for baseline differences between groups?	X					
947. Does the analysis account for differences in treatment received by the groups?	X					
948. Are the statistical methods used to assess the outcomes appropriate?	X					
949. **For KQ3 ONLY** – Did analyses adjust for all or most of the standard prognostic markers?	X					
Comments:

Worksheet for Risk of Bias of Individual Studies – GTRRC (v. 4-23-13)

Ref ID #	Author	Year
109	Mook	2010

Indicate the appropriate risk of bias rating by placing an 'X' in the shaded space to the right of the rating for each KQ that is applicable. If a study does not apply to a KQ, put an 'X' next to N/A.

Risk of bias for KQ 1:	Low		Medium		High		N/A	
Risk of bias for KQ 2:	Low		Medium		High		N/A	
Risk of bias for KQ 3:	Low	X	Medium		High		N/A	
Risk of bias for KQ 4a:	Low		Medium		High		N/A	
Risk of bias for KQ 4b:	Low		Medium		High		N/A	
Risk of bias for KQ 5:	Low		Medium		High		N/A	
Explain any **High** ratings:								

Low: Study has minimal bias. High degree of confidence that the true effect size is similar in size and direction to that reported.
Medium: Study has at least one significant source of bias, but does not have flaws that are likely to cause major bias. Moderate degree of confidence that the actual effect is in the direction reported by the study; moderate degree of confidence that the true effect size is similar to that reported.
High: Study has at least one major sources of bias or multiple significant sources of bias. Low degree of confidence that the true effect size is similar in size or direction to that reported.
NA: Not applicable to that key question.

Key Questions 1, 3, 4a, 4b, and 5	If the study does NOT apply to any of these KQs, place an 'X' here (___)
KQ 1: Overarching Question Is there direct evidence that the addition of the following genetic tests used alone or in combination with traditional prognostic factors change physician decision making and improve outcomes for adult patients with lung, breast, colorectal, and bladder cancer compared with the use of traditional factors to predict risk of recurrence for adults with these cancers?	
KQ 3. Clinical Validity. Does existing evidence establish the prognostic accuracy of the tests for predicting recurrence?	
KQ 4a. Clinical Utility. What is the evidence that the prognostic information provided by the genetic tests modifies physician decisions regarding use of adjuvant anti-neoplastic chemo- and/or radiotherapy; enhanced diagnostic testing for recurrence; and/or preventive surgery among adult patients with malignant tumors?	
KQ 4b. Clinical Utility. What is the evidence that modified decisions lead to improved overall survival, disease free survival, time to recurrence, quality of life, or incidence of serious side effects of adjuvant therapy in adult patients with malignant tumors?	
KQ 5. Harms. What are the harms associated with treatment decisions that are informed by the genetic tests?	

	RCT	**non-RCT**	**Prospective cohort study**	**Retrospective cohort study**	**Case-control study**	**Case Series**
950. What is the study design?				**X**		
If "Other" study design, enter a description in this box:	**Yes**	**No**	**Partially**	**Can't Determine**	**NA**	**Explanation**
951. For RCTs, were randomization and allocation concealment adequate?					X	
952. Did the study apply inclusion/exclusion criteria uniformly to all comparison groups of the study?		X				pooled analysis of 7 cohorts with slightly different criteria
953. Is the selection of the comparison group appropriate, after taking into account feasibility and ethical considerations?	X					
954. Were groups similar at baseline?		X				in non RCT comparison groups would not be expected to be similar
955. Were the outcome assessors blinded to the test result/intervention/exposure status of participants?					X	

956. Were outcomes assessed using valid and reliable measures, implemented consistently across all study participants?	X					
957. Was overall attrition less than 30%?				X		
958. Was differential attrition less than 15%?				X		
959. Does the analysis control for baseline differences between groups?	X					
960. Does the analysis account for differences in treatment received by the groups?	X					
961. Are the statistical methods used to assess the outcomes appropriate?	X					
962. **For KQ3 ONLY** – Did analyses adjust for all or most of the standard prognostic markers?	X					
Comments:						

Key Question 2	If study does NOT apply to this KQ, place an 'X' here (___)						
KQ 2. Analytic Validity. Does existing evidence establish the technical accuracy and reliability of the tests for detecting the relevant genetic markers?							
	Yes	**No**	**Unclear**	**NA**	**Low**	**High**	**Unclear**
Domain 1: Patient Selection							
Was a consecutive or random sample of patients enrolled?							
Was a case-control design avoided?							
Did the study avoid inappropriate exclusions?							
Could the selection of patients have introduced bias?							
Domain 2: Index Test(s)							
Were the index test results interpreted without knowledge of the results of the reference standard?							
If a threshold was used, was it pre-specified?							
Could the conduct or interpretation of the index test have introduced bias?							
Domain 3: Reference Standard							
Is the reference standard likely to correctly classify the genetic markers?							
Were the reference standard results interpreted without knowledge of the results of the index test?

NA: Not applicable to that key question.

Key Questions 1, 3, 4a, 4b, and 5	If the study does NOT apply to any of these KQs, place an 'X' here (___)

KQ 1: Overarching Question
Is there direct evidence that the addition of the following genetic tests used alone or in combination with traditional prognostic factors change physician decision making and improve outcomes for adult patients with lung, breast, colorectal, and bladder cancer compared with the use of traditional factors to predict risk of recurrence for adults with these cancers?

KQ 3. Clinical Validity. Does existing evidence establish the prognostic accuracy of the tests for predicting recurrence?

KQ 4a. Clinical Utility.
What is the evidence that the prognostic information provided by the genetic tests modifies physician decisions regarding use of adjuvant anti-neoplastic chemo- and/or radiotherapy; enhanced diagnostic testing for recurrence; and/or preventive surgery among adult patients with malignant tumors?

KQ 4b. Clinical Utility.
What is the evidence that modified decisions lead to improved overall survival, disease free survival, time to recurrence, quality of life, or incidence of serious side effects of adjuvant therapy in adult patients with malignant tumors?

KQ 5. Harms.
What are the harms associated with treatment decisions that are informed by the genetic tests?

	RCT	**non-RCT**	**Prospective cohort study**	**Retrospective cohort study**	**Case-control study**	**Case Series**
963. What is the study design?				**X**		
If "Other" study design, enter a description in this box:	**Yes**	**No**	**Partially**	**Can't Determine**	**NA**	**Explanation**
964. For RCTs, were randomization and allocation concealment adequate?					x	
965. Did the study apply inclusion/exclusion criteria uniformly to all comparison groups of the study?	x					
966. Is the selection of the comparison group appropriate, after taking into account feasibility and ethical considerations?			x			
967. Were groups similar at baseline?				x		
968. Were the outcome assessors blinded to the test result/intervention/exposure status of participants?					x	
969. Were outcomes assessed using valid and reliable measures, implemented consistently across all study participants?	x					
970. Was overall attrition less than 30%?				x		
971. Was differential attrition less than 15%?				x		
972. Does the analysis control for baseline		x				used a

differences between groups?						composite of common prognostic factors including age and overall health, but do not appear to have adjusted for other baseline differences
973. Does the analysis account for differences in treatment received by the groups?		x				
974. Are the statistical methods used to assess the outcomes appropriate?	x					
975. **For KQ3 ONLY** – Did analyses adjust for all or most of the standard prognostic markers?						see above, did not control separately for prognostic variables, used a composite score
Comments:

KQ 4b. Clinical Utility. What is the evidence that modified decisions lead to improved overall survival, disease free survival, time to recurrence, quality of life, or incidence of serious side effects of adjuvant therapy in adult patients with malignant tumors?	
KQ 5. Harms. What are the harms associated with treatment decisions that are informed by the genetic tests?	

	RCT	**non-RCT**	**Prospective cohort study**	**Retrospective cohort study**	**Case-control study**	**Case Series**
989. What is the study design?				**X**		
If "Other" study design, enter a description in this box:	**Yes**	**No**	**Partially**	**Can't Determine**	**NA**	**Explanation**
990. For RCTs, were randomization and allocation concealment adequate?					X	
991. Did the study apply inclusion/exclusion criteria uniformly to all comparison groups of the study?	X					
992. Is the selection of the comparison group appropriate, after taking into account feasibility and ethical considerations?			X			odd comparison of the test of interest (MammaPrint) to an alternative gene signature
993. Were groups similar at baseline?						
994. Were the outcome assessors blinded to the test result/intervention/exposure status of participants?						
995. Were outcomes assessed using valid and reliable measures, implemented consistently						

across all study participants?						
996. Was overall attrition less than 30%?				X		
997. Was differential attrition less than 15%?				X		
998. Does the analysis control for baseline differences between groups?	X					
999. Does the analysis account for differences in treatment received by the groups?	X					
1000. Are the statistical methods used to assess the outcomes appropriate?	X					
1001. **For KQ3 ONLY** – Did analyses adjust for all or most of the standard prognostic markers?	X					
Comments: biggest concern about this study is that another gene signature with prognostic value and likely overlapping genetic info was included as a covariate, and this alternate signature is not a standard prognostic marker, skewing the analysis toward non-significance for the test of interest						

Key Question 2	If study does NOT apply to this KQ, place an 'X' here (___)						
KQ 2. Analytic Validity. Does existing evidence establish the technical accuracy and reliability of the tests for detecting the relevant genetic markers?

1002. What is the study design?			**X**			
If "Other" study design, enter a description in this box:	**Yes**	**No**	**Partially**	**Can't Determine**	**NA**	**Explanation**
1003. For RCTs, were randomization and allocation concealment adequate?					X	
1004. Did the study apply inclusion/exclusion criteria uniformly to all comparison groups of the study?	X					
1005. Is the selection of the comparison group appropriate, after taking into account feasibility and ethical considerations?	X					
1006. Were groups similar at baseline?			X			Similar for most characteristics; some small differences for MSI status and treatment arm
1007. Were the outcome assessors blinded to the test result/intervention/exposure status of participants?				X		

1008. Were outcomes assessed using valid and reliable measures, implemented consistently across all study participants?				X		Just report how DFS, RFS, OS were defined, but don't report information on how outcomes were ascertained
1009. Was overall attrition less than 30%?	X					
1010. Was differential attrition less than 15%?	X					
1011. Does the analysis control for baseline differences between groups?	X					
1012. Does the analysis account for differences in treatment received by the groups?	X					
1013. Are the statistical methods used to assess the outcomes appropriate?	X					
1014. **For KQ3 ONLY** – Did analyses adjust for all or most of the standard prognostic markers?	X					
Comments: they created cohort from among subjects enrolled in an RCT comparing adjuvant chemotherapies for stage III CRC. This was 508 of the 1264 (those with tumor tissue available for KRAS sequencing). Article does nice job of exploring and addressing potential confounding through multivariate adjustment, stratification, and other statistical analyses. Group enrolled in this study were similar to the 700+ subjects that were in the RCT but not in this trial. Some risk of measurement bias as details are not reported for ascertainment.						

Key Question 2	If study does NOT apply to this KQ, place an 'X' here (_X_)						
KQ 2. Analytic Validity. Does existing evidence establish the technical accuracy and reliability of the tests for detecting the relevant genetic markers?							
	Yes	**No**	**Unclear**	**NA**	**Low**	**High**	**Unclear**
Domain 1: Patient Selection							
Was a consecutive or random sample of patients enrolled?							
Was a case-control design avoided?							
Did the study avoid inappropriate exclusions?							
Could the selection of patients have introduced bias?							
Domain 2: Index Test(s)							
Were the index test results interpreted without knowledge of the results of the reference standard?							
If a threshold was used, was it pre-specified?							
Could the conduct or interpretation of the index test have introduced bias?							
Domain 3: Reference Standard							
Is the reference standard likely to correctly classify the genetic markers?							
Were the reference standard results interpreted without knowledge of the results of the index test?							
Could the reference standard, its conduct, or its interpretation have introduced bias?							
Domain 4: Flow and Timing							
Did all patients receive a reference standard?							
Did patients receive the same reference standard?							
Were all patients included in the analysis?							
Could the patient flow have introduced bias?							
Comments:							

Worksheet for Risk of Bias of Individual Studies – GTRRC (v. 4-23-13)

Ref ID #	Author	Year
1043	Ogino	2012

Indicate the appropriate risk of bias rating by placing an 'X' in the shaded space to the right of the rating for each KQ that is applicable. If a study does not apply to a KQ, put an 'X' next to N/A.

Risk of bias for KQ 1:	Low		Medium		High		N/A	X
Risk of bias for KQ 2:	Low		Medium		High		N/A	X
Risk of bias for KQ 3:	Low		Medium	X	High		N/A	
Risk of bias for KQ 4a:	Low		Medium		High		N/A	X
Risk of bias for KQ 4b:	Low		Medium		High		N/A	X
Risk of bias for KQ 5:	Low		Medium		High		N/A	X
Explain any **High** ratings:								

Low: Study has minimal bias. High degree of confidence that the true effect size is similar in size and direction to that reported.
Medium: Study has at least one significant source of bias, but does not have flaws that are likely to cause major bias. Moderate degree of confidence that the actual effect is in the direction reported by the study; moderate degree of confidence that the true effect size is similar to that reported.
High: Study has at least one major sources of bias or multiple significant sources of bias. Low degree of confidence that the true effect size is similar in size or direction to that reported.
NA: Not applicable to that key question.

Key Questions 1, 3, 4a, 4b, and 5	If the study does NOT apply to any of these KQs, place an 'X' here (___)
KQ 1: Overarching Question Is there direct evidence that the addition of the following genetic tests used alone or in combination with traditional prognostic factors change physician decision making and improve outcomes for adult patients with lung, breast, colorectal, and bladder cancer compared with the use of traditional factors to predict risk of recurrence for adults with these cancers?	
KQ 3. Clinical Validity. Does existing evidence establish the prognostic accuracy of the tests for predicting recurrence?	
KQ 4a. Clinical Utility. What is the evidence that the prognostic information provided by the genetic tests modifies physician decisions regarding use of adjuvant anti-neoplastic chemo- and/or radiotherapy; enhanced diagnostic testing for recurrence; and/or preventive surgery among adult patients with malignant tumors?	
KQ 4b. Clinical Utility. What is the evidence that modified decisions lead to improved overall survival, disease free survival, time to recurrence, quality of life, or incidence of serious side effects of adjuvant therapy in adult patients with malignant tumors?	
KQ 5. Harms. What are the harms associated with treatment decisions that are informed by the genetic tests?	

	RCT	**non-RCT**	**Prospective cohort study**	**Retrospective cohort study**	**Case-control study**	**Case Series**
1015. What is the study design?			**X**			
If "Other" study design, enter a description in this box:	**Yes**	**No**	**Partially**	**Can't Determine**	**NA**	**Explanation**
1016. For RCTs, were randomization and allocation concealment adequate?					X	
1017. Did the study apply inclusion/exclusion criteria uniformly to all comparison groups of the study?	X					
1018. Is the selection of the comparison group appropriate, after taking into account feasibility and ethical considerations?	X					
1019. Were groups similar at baseline?		X				For BRAF mutation vs. wild-type, differences for sex, age, tumor location, MSI status, and KRAS
1020. Were the outcome assessors blinded to the test result/intervention/exposure status of participants?				X		

1021. Were outcomes assessed using valid and reliable measures, implemented consistently across all study participants?				X		
1022. Was overall attrition less than 30%?	X					
1023. Was differential attrition less than 15%?	X					
1024. Does the analysis control for baseline differences between groups?	X					
1025. Does the analysis account for differences in treatment received by the groups?	X					
1026. Are the statistical methods used to assess the outcomes appropriate?	X					
1027. **For KQ3 ONLY** – Did analyses adjust for all or most of the standard prognostic markers?	X					
Comments: they created cohort from among subjects enrolled in an RCT comparing adjuvant chemotherapies for stage III CRC. This was 506 of the 1264 (those with tumor tissue available). Article does nice job of exploring and addressing potential confounding through multivariate adjustment, stratification, and other statistical analyses. Group enrolled in this study were similar to the 700+ subjects that were in the RCT but not in this trial. Some risk of measurement bias as details are not reported for ascertainment. For overall survival, the only outcome that remained statistically significantly different between BRAF mutation vs. wild-type, the risk of bias may be higher than for other outcomes because they did not adjust for many potential confounders that would influence overall survival.						

Key Question 2	If study does NOT apply to this KQ, place an 'X' here (_X_)						
KQ 2. Analytic Validity. Does existing evidence establish the technical accuracy and reliability of the tests for detecting the relevant genetic markers?							
	Yes	**No**	**Unclear**	**NA**	**Low**	**High**	**Unclear**
Domain 1: Patient Selection							
Was a consecutive or random sample of patients enrolled?							
Was a case-control design avoided?							
Did the study avoid inappropriate exclusions?							
Could the selection of patients have introduced bias?							
Domain 2: Index Test(s)							
Were the index test results interpreted without knowledge of the results of the reference standard?							
If a threshold was used, was it pre-specified?							
Could the conduct or interpretation of the index test have introduced bias?							
Domain 3: Reference Standard							
Is the reference standard likely to correctly classify the genetic markers?							
Were the reference standard results interpreted without knowledge of the results of the index test?							
Could the reference standard, its conduct, or its interpretation have introduced bias?							
Domain 4: Flow and Timing							
Did all patients receive a reference standard?							
Did patients receive the same reference standard?							
Were all patients included in the analysis?							
Could the patient flow have introduced bias?							
Comments:							

Worksheet for Risk of Bias of Individual Studies – GTRRC (v. 4-23-13)

Ref ID #	Author	Year
1071	Pai	2012

Indicate the appropriate risk of bias rating by placing an 'X' in the shaded space to the right of the rating for each KQ that is applicable. If a study does not apply to a KQ, put an 'X' next to N/A.

Risk of bias for KQ 1:	Low		Medium		High		N/A	X
Risk of bias for KQ 2:	Low		Medium		High		N/A	X
Risk of bias for KQ 3:	Low		Medium		High	X	N/A	
Risk of bias for KQ 4a:	Low		Medium		High		N/A	X
Risk of bias for KQ 4b:	Low		Medium		High		N/A	X
Risk of bias for KQ 5:	Low		Medium		High		N/A	X
Explain any **High** ratings:	High risk of selection bias, confounding, attrition bias, and measurement bias. See comments box below for details.							

Low: Study has minimal bias. High degree of confidence that the true effect size is similar in size and direction to that reported.
Medium: Study has at least one significant source of bias, but does not have flaws that are likely to cause major bias. Moderate degree of confidence that the actual effect is in the direction reported by the study; moderate degree of confidence that the true effect size is similar to that reported.
High: Study has at least one major sources of bias or multiple significant sources of bias. Low degree of confidence that the true effect size is similar in size or direction to that reported.
NA: Not applicable to that key question.

Key Questions 1, 3, 4a, 4b, and 5	If the study does NOT apply to any of these KQs, place an 'X' here (__)
KQ 1: Overarching Question Is there direct evidence that the addition of the following genetic tests used alone or in combination with traditional prognostic factors change physician decision making and improve outcomes for adult patients with lung, breast, colorectal, and bladder cancer compared with the use of traditional factors to predict risk of recurrence for adults with these cancers?	
KQ 3. Clinical Validity. Does existing evidence establish the prognostic accuracy of the tests for predicting recurrence?	
KQ 4a. Clinical Utility. What is the evidence that the prognostic information provided by the genetic tests modifies physician decisions regarding use of adjuvant anti-neoplastic chemo- and/or radiotherapy; enhanced diagnostic testing for recurrence; and/or preventive surgery among adult patients with malignant tumors?	
KQ 4b. Clinical Utility. What is the evidence that modified decisions lead to improved overall survival, disease free survival, time to recurrence, quality of life, or incidence of serious side effects of adjuvant therapy in adult patients with malignant tumors?	
KQ 5. Harms. What are the harms associated with treatment decisions that are informed by the genetic tests?	

	RCT	**non-RCT**	**Prospective cohort study**	**Retrospective cohort study**	**Case-control study**	**Case Series**
1028. What is the study design?				**X**		
If "Other" study design, enter a description in this box:	**Yes**	**No**	**Partially**	**Can't Determine**	**NA**	**Explanation**
1029. For RCTs, were randomization and allocation concealment adequate?					X	
1030. Did the study apply inclusion/exclusion criteria uniformly to all comparison groups of the study?	X					
1031. Is the selection of the comparison group appropriate, after taking into account feasibility and ethical considerations?	X					
1032. Were groups similar at baseline?		X				
1033. Were the outcome assessors blinded to the test result/intervention/exposure status of participants?		X				
1034. Were outcomes assessed using valid and reliable measures, implemented consistently across all study participants?		X				
1035. Was overall attrition less than 30%?				X		
1036. Was differential attrition less than 15%?				X		

1037. Does the analysis control for baseline differences between groups?			X			
1038. Does the analysis account for differences in treatment received by the groups?		X				
1039. Are the statistical methods used to assess the outcomes appropriate?			X			
1040. **For KQ3 ONLY** – Did analyses adjust for all or most of the standard prognostic markers?		X				
Comments: High risk of selection bias and confounding. The multivariate analysis only adjusted for stage. It did not consider sex, age, grade, cellular subtype (e.g. signet ring histology), or lymphovascular invasion. The baseline characteristics show potentially important differences for sex, lymph invasion, lymph node metastases, histology. Very little description of methods of assessing outcomes (DFS and OS) in this retrospective cohort. No reporting of masking of outcome assessors to genotypes. High risk of attrition bias as they do not report numbers lost to follow up clearly for the 3 different groups. For the OS analyses, lost to followup was treated the same as death. Not clear how missing data was handled for the DFS analysis.						

Key Question 2	If study does NOT apply to this KQ, place an 'X' here (_X_)						
KQ 2. Analytic Validity. Does existing evidence establish the technical accuracy and reliability of the tests for detecting the relevant genetic markers?							
	Yes	**No**	**Unclear**	**NA**	**Low**	**High**	**Unclear**
Domain 1: Patient Selection							
Was a consecutive or random sample of patients enrolled?							
Was a case-control design avoided?							
Did the study avoid inappropriate exclusions?							
Could the selection of patients have introduced bias?							
Domain 2: Index Test(s)							
Were the index test results interpreted without knowledge of the results of the reference standard?							
If a threshold was used, was it pre-specified?							
Could the conduct or interpretation of the index test have introduced bias?							
Domain 3: Reference Standard							
Is the reference standard likely to correctly classify the genetic markers?							
Were the reference standard results interpreted without knowledge of the results of the index test?							
Could the reference standard, its conduct, or its interpretation have introduced bias?							
Domain 4: Flow and Timing							
Did all patients receive a reference standard?							
Did patients receive the same reference standard?							
Were all patients included in the analysis?							
Could the patient flow have introduced bias?

Worksheet for Risk of Bias of Individual Studies – GTRRC (v. 4-23-13)

Ref ID #	Author	Year
3276	Paik	2004

Indicate the appropriate risk of bias rating by placing an 'X' in the shaded space to the right of the rating for each KQ that is applicable. If a study does not apply to a KQ, put an 'X' next to N/A.

Risk of bias for KQ 1:	Low		Medium		High		N/A	X
Risk of bias for KQ 2:	Low		Medium		High		N/A	X
Risk of bias for KQ 3:	Low		Medium	X	High		N/A	
Risk of bias for KQ 4a:	Low		Medium		High		N/A	X
Risk of bias for KQ 4b:	Low		Medium		High		N/A	X
Risk of bias for KQ 5:	Low		Medium		High		N/A	X
Explain any **High** ratings:								

Low: Study has minimal bias. High degree of confidence that the true effect size is similar in size and direction to that reported.
Medium: Study has at least one significant source of bias, but does not have flaws that are likely to cause major bias. Moderate degree of confidence that the actual effect is in the direction reported by the study; moderate degree of confidence that the true effect size is similar to that reported.
High: Study has at least one major sources of bias or multiple significant sources of bias. Low degree of confidence that the true effect size is similar in size or direction to that reported.
NA: Not applicable to that key question.

Key Questions 1, 3, 4a, 4b, and 5	If the study does NOT apply to any of these KQs, place an 'X' here (___)

KQ 1: Overarching Question
Is there direct evidence that the addition of the following genetic tests used alone or in combination with traditional prognostic factors change physician decision making and improve outcomes for adult patients with lung, breast, colorectal, and bladder cancer compared with the use of traditional factors to predict risk of recurrence for adults with these cancers?

KQ 3. Clinical Validity. Does existing evidence establish the prognostic accuracy of the tests for predicting recurrence?

KQ 4a. Clinical Utility.
What is the evidence that the prognostic information provided by the genetic tests modifies physician decisions regarding use of adjuvant anti-neoplastic chemo- and/or radiotherapy; enhanced diagnostic testing for recurrence; and/or preventive surgery among adult patients with malignant tumors?

KQ 4b. Clinical Utility.
What is the evidence that modified decisions lead to improved overall survival, disease free survival, time to recurrence, quality of life, or incidence of serious side effects of adjuvant therapy in adult patients with malignant tumors?

KQ 5. Harms.
What are the harms associated with treatment decisions that are informed by the genetic tests?

	RCT	**non-RCT**	**Prospective cohort study**	**Retrospective cohort study**	**Case-control study**	**Case Series**
1041. What is the study design?			**X**			
If "Other" study design, enter a description in this box:	**Yes**	**No**	**Partially**	**Can't Determine**	**NA**	**Explanation**
1042. For RCTs, were randomization and allocation concealment adequate?					X	
1043. Did the study apply inclusion/exclusion criteria uniformly to all comparison groups of the study?				X		
1044. Is the selection of the comparison group appropriate, after taking into account feasibility and ethical considerations?	X					
1045. Were groups similar at baseline?				X		
1046. Were the outcome assessors blinded to the test result/intervention/exposure status of participants?				X		
1047. Were outcomes assessed using valid and reliable measures, implemented consistently across all study participants?				X		Unclear ascertainment methods
1048. Was overall attrition less than 30%?				X		
1049. Was differential attrition less than 15%?				X		
1050. Does the analysis control for baseline				X		Data NR

differences between groups?						
1051. Does the analysis account for differences in treatment received by the groups?		X				
1052. Are the statistical methods used to assess the outcomes appropriate?	X					
1053. **For KQ3 ONLY** – Did analyses adjust for all or most of the standard prognostic markers?			X			
Comments: Concern for selection bias, measurement bias, and confounding, but insufficient reporting of Methods, subject characteristics, and Results to adequately determine risk of bias.						

Key Question 2					If study does NOT apply to this KQ, place an 'X' here (___)		
KQ 2. Analytic Validity. Does existing evidence establish the technical accuracy and reliability of the tests for detecting the relevant genetic markers?							
	Yes	**No**	**Unclear**	**NA**	**Low**	**High**	**Unclear**
Domain 1: Patient Selection							
Was a consecutive or random sample of patients enrolled?

Comments:							

Worksheet for Risk of Bias of Individual Studies – GTRRC (v. 4-23-13)

Ref ID #	Author	Year
1081	Pang	2011

Indicate the appropriate risk of bias rating by placing an 'X' in the shaded space to the right of the rating for each KQ that is applicable. If a study does not apply to a KQ, put an 'X' next to N/A.

Risk of bias for KQ 1:	Low		Medium		High		N/A	X
Risk of bias for KQ 2:	Low		Medium		High	X	N/A	
Risk of bias for KQ 3:	Low		Medium		High		N/A	X
Risk of bias for KQ 4a:	Low		Medium		High		N/A	X
Risk of bias for KQ 4b:	Low		Medium		High		N/A	X
Risk of bias for KQ 5:	Low		Medium		High		N/A	X
Explain any **High** ratings:	See comments below. This article isn't really designed to answer our questions of interest. I see why we may have included it (although it would be reasonable to exclude it for wrong comparison because it is mainly about comparing results of testing metastases with results of the primary tumor) because there is a small detail that we could mention, but for our questions, this has a high risk of bias given the design and selection.							

Low: Study has minimal bias. High degree of confidence that the true effect size is similar in size and direction to that reported.
Medium: Study has at least one significant source of bias, but does not have flaws that are likely to cause major bias. Moderate degree of confidence that the actual effect is in the direction reported by the study; moderate degree of confidence that the true effect size is similar to that reported.
High: Study has at least one major sources of bias or multiple significant sources of bias. Low degree of confidence that the true effect size is similar in size or direction to that reported.
NA: Not applicable to that key question.

Key Questions 1, 3, 4a, 4b, and 5	If the study does NOT apply to any of these KQs, place an 'X' here (_X_)

KQ 1: Overarching Question
Is there direct evidence that the addition of the following genetic tests used alone or in combination with traditional prognostic factors change physician decision making and improve outcomes for adult patients with lung, breast, colorectal, and bladder cancer compared with the use of traditional factors to predict risk of recurrence for adults with these cancers?

KQ 3. Clinical Validity. Does existing evidence establish the prognostic accuracy of the tests for predicting recurrence?

KQ 4a. Clinical Utility.
What is the evidence that the prognostic information provided by the genetic tests modifies physician decisions regarding use of adjuvant anti-neoplastic chemo- and/or radiotherapy; enhanced diagnostic testing for recurrence; and/or preventive surgery among adult patients with malignant tumors?

KQ 4b. Clinical Utility.
What is the evidence that modified decisions lead to improved overall survival, disease free survival, time to recurrence, quality of life, or incidence of serious side effects of adjuvant therapy in adult patients with malignant tumors?

KQ 5. Harms.
What are the harms associated with treatment decisions that are informed by the genetic tests?

	RCT	**non-RCT**	**Prospective cohort study**	**Retrospective cohort study**	**Case-control study**	**Case Series**
1054. What is the study design?						
If "Other" study design, enter a description in this box:	**Yes**	**No**	**Partially**	**Can't Determine**	**NA**	**Explanation**
1055. For RCTs, were randomization and allocation concealment adequate?						
1056. Did the study apply inclusion/exclusion criteria uniformly to all comparison groups of the study?						
1057. Is the selection of the comparison group appropriate, after taking into account feasibility and ethical considerations?						
1058. Were groups similar at baseline?						
1059. Were the outcome assessors blinded to the test result/intervention/exposure status of participants?						
1060. Were outcomes assessed using valid and reliable measures, implemented consistently						

across all study participants?						
1061. Was overall attrition less than 30%?						
1062. Was differential attrition less than 15%?						
1063. Does the analysis control for baseline differences between groups?						
1064. Does the analysis account for differences in treatment received by the groups?						
1065. Are the statistical methods used to assess the outcomes appropriate?						
1066. **For KQ3 ONLY** – Did analyses adjust for all or most of the standard prognostic markers?						
Comments:						

Key Question 2					If study does NOT apply to this KQ, place an 'X' here (___)		
KQ 2. Analytic Validity. Does existing evidence establish the technical accuracy and reliability of the tests for detecting the relevant genetic markers?							
	Yes	**No**	**Unclear**	**NA**	**Low**	**High**	**Unclear**
Domain 1: Patient Selection							
Was a consecutive or random sample of patients enrolled?		X					
Was a case-control design avoided?	X						
Did the study avoid inappropriate exclusions?			X				
Could the selection of patients have introduced bias?						X	
Domain 2: Index Test(s)							
Were the index test results interpreted without knowledge of the results of the reference standard?				X			
If a threshold was used, was it pre-specified?				X			
Could the conduct or interpretation of the index test have introduced bias?					X		
Domain 3: Reference Standard							
Is the reference standard likely to correctly classify the genetic markers?	X						
Were the reference standard results interpreted without knowledge of the results of the index test?			X				
Could the reference standard, its conduct, or its interpretation have introduced bias?					X		
Domain 4: Flow and Timing							
Did all patients receive a reference standard?	X						
Did patients receive the same reference standard?	X						
Were all patients included in the analysis?		X					
Could the patient flow have introduced bias?						X	
Comments: High risk of bias for our questions, with just 11 cases chosen by an unclear method. It's hard to find any relevant, useful information in this article for the questions that we're asking. If we were interested in how similar the results from testing of metastases are to results of testing primary tumors, this would possibly be more useful. Note: Many of the risk of bias questions are not relevant for this particular article because it is not looking at a test of interest compared with a gold standard. It just contributes a very small piece of potentially relevant data about how many samples returned a valid result (8 of 11) and about tissue acceptance criteria (which was something that was predetermined in their methods, not something determined by the results of the study).							

Worksheet for Risk of Bias of Individual Studies – GTRRC (v. 4-23-13)

Ref ID #	Author	Year
1683	Phipps	2012

Indicate the appropriate risk of bias rating by placing an 'X' in the shaded space to the right of the rating for each KQ that is applicable. If a study does not apply to a KQ, put an 'X' next to N/A.

Risk of bias for KQ 1:	Low		Medium		High		N/A	X
Risk of bias for KQ 2:	Low		Medium		High		N/A	X
Risk of bias for KQ 3:	Low		Medium	X	High		N/A	
Risk of bias for KQ 4a:	Low		Medium		High		N/A	X
Risk of bias for KQ 4b:	Low		Medium		High		N/A	X
Risk of bias for KQ 5:	Low		Medium		High		N/A	X
Explain any **High** ratings:								

Low: Study has minimal bias. High degree of confidence that the true effect size is similar in size and direction to that reported.
Medium: Study has at least one significant source of bias, but does not have flaws that are likely to cause major bias. Moderate degree of confidence that the actual effect is in the direction reported by the study; moderate degree of confidence that the true effect size is similar to that reported.
High: Study has at least one major sources of bias or multiple significant sources of bias. Low degree of confidence that the true effect size is similar in size or direction to that reported.
NA: Not applicable to that key question.

Key Questions 1, 3, 4a, 4b, and 5	If the study does NOT apply to any of these KQs, place an 'X' here (___)

KQ 1: Overarching Question
Is there direct evidence that the addition of the following genetic tests used alone or in combination with traditional prognostic factors change physician decision making and improve outcomes for adult patients with lung, breast, colorectal, and bladder cancer compared with the use of traditional factors to predict risk of recurrence for adults with these cancers?

KQ 3. Clinical Validity. Does existing evidence establish the prognostic accuracy of the tests for predicting recurrence?

KQ 4a. Clinical Utility.
What is the evidence that the prognostic information provided by the genetic tests modifies physician decisions regarding use of adjuvant anti-neoplastic chemo- and/or radiotherapy; enhanced diagnostic testing for recurrence; and/or preventive surgery among adult patients with malignant tumors?

KQ 4b. Clinical Utility.
What is the evidence that modified decisions lead to improved overall survival, disease free survival, time to recurrence, quality of life, or incidence of serious side effects of adjuvant therapy in adult patients with malignant tumors?

KQ 5. Harms.
What are the harms associated with treatment decisions that are informed by the genetic tests?

	RCT	**non-RCT**	**Prospective cohort study**	**Retrospective cohort study**	**Case-control study**	**Case Series**
1067. What is the study design?			**X**			
If "Other" study design, enter a description in this box:	**Yes**	**No**	**Partially**	**Can't Determine**	**NA**	**Explanation**
1068. For RCTs, were randomization and allocation concealment adequate?					X	
1069. Did the study apply inclusion/exclusion criteria uniformly to all comparison groups of the study?	X					
1070. Is the selection of the comparison group appropriate, after taking into account feasibility and ethical considerations?	X					
1071. Were groups similar at baseline?		X				Differences for age, sex, tumor site, stage, MSI status
1072. Were the outcome assessors blinded to the test result/intervention/exposure status of participants?				X		
1073. Were outcomes assessed using valid and reliable measures, implemented consistently across all study participants?	X					SEER and National Death Index

1074. Was overall attrition less than 30%?	X					
1075. Was differential attrition less than 15%?				X		Of the 27% without BRAF status, no information available to determine differential attrition
1076. Does the analysis control for baseline differences between groups?	X					
1077. Does the analysis account for differences in treatment received by the groups?		X				They did not have treatment information and did not adjust for differences in treatment
1078. Are the statistical methods used to assess the outcomes appropriate?	X					
1079. **For KQ3 ONLY** – Did analyses adjust for all or most of the standard prognostic markers?	X					
Comments: Moderate potential risk of survivor bias; BRAF mutation status was not determined in 27% of enrolled cases, nor was it determined in cases who were eligible for the study but were not enrolled; analyses were based on the 1980/2708 with BRAF results determined; analyses did not account for differences in treatment						

Key Question 2	If study does NOT apply to this KQ, place an 'X' here (_X_)						
KQ 2. Analytic Validity. Does existing evidence establish the technical accuracy and reliability of the tests for detecting the relevant genetic markers?							
	Yes	**No**	**Unclear**	**NA**	**Low**	**High**	**Unclear**
Domain 1: Patient Selection							
Was a consecutive or random sample of patients enrolled?

Comments:							

Worksheet for Risk of Bias of Individual Studies – GTRRC (v. 4-23-13)

Ref ID #	Author	Year
3417	Poulet	2012

Indicate the appropriate risk of bias rating by placing an 'X' in the shaded space to the right of the rating for each KQ that is applicable. If a study does not apply to a KQ, put an 'X' next to N/A.

Risk of bias for KQ 1:	Low		Medium		High		N/A	X
Risk of bias for KQ 2:	Low	*	Medium	*	High	*	N/A	
Risk of bias for KQ 3:	Low		Medium		High		N/A	X
Risk of bias for KQ 4a:	Low		Medium		High		N/A	X
Risk of bias for KQ 4b:	Low		Medium		High		N/A	X
Risk of bias for KQ 5:	Low		Medium		High		N/A	X
Explain any **High** ratings:	unclear							

Low: Study has minimal bias. High degree of confidence that the true effect size is similar in size and direction to that reported.
Medium: Study has at least one significant source of bias, but does not have flaws that are likely to cause major bias. Moderate degree of confidence that the actual effect is in the direction reported by the study; moderate degree of confidence that the true effect size is similar to that reported.
High: Study has at least one major sources of bias or multiple significant sources of bias. Low degree of confidence that the true effect size is similar in size or direction to that reported.
NA: Not applicable to that key question.

Key Questions 1, 3, 4a, 4b, and 5	If the study does NOT apply to any of these KQs, place an 'X' here (_X_)

KQ 1: Overarching Question
Is there direct evidence that the addition of the following genetic tests used alone or in combination with traditional prognostic factors change physician decision making and improve outcomes for adult patients with lung, breast, colorectal, and bladder cancer compared with the use of traditional factors to predict risk of recurrence for adults with these cancers?

KQ 3. Clinical Validity. Does existing evidence establish the prognostic accuracy of the tests for predicting recurrence?

Could the selection of patients have introduced bias?							X
Domain 2: Index Test(s)							
Were the index test results interpreted without knowledge of the results of the reference standard?	X						
If a threshold was used, was it pre-specified?			X				
Could the conduct or interpretation of the index test have introduced bias?					X		
Domain 3: Reference Standard							
Is the reference standard likely to correctly classify the genetic markers?				X			
Were the reference standard results interpreted without knowledge of the results of the index test?				X			
Could the reference standard, its conduct, or its interpretation have introduced bias?					NA	NA	NA
Domain 4: Flow and Timing							
Did all patients receive a reference standard?				X			
Did patients receive the same reference standard?				X			
Were all patients included in the analysis?	X						
Could the patient flow have introduced bias?					X		
Comments: No reference standard in this because it's just reporting how many times a valid result was returned for Mammaprint and for Oncotype Dx, and comparing that, as well as how many times they both got low, intermed, or high risk on the same samples.							

Worksheet for Risk of Bias of Individual Studies – GTRRC (v. 4-23-13)

Ref ID #	Author	Year
161	Rayhanabad	2012

Indicate the appropriate risk of bias rating by placing an 'X' in the shaded space to the right of the rating for each KQ that is applicable. If a study does not apply to a KQ, put an 'X' next to N/A.

Risk of bias for KQ 1:	Low		Medium		High		N/A	X
Risk of bias for KQ 2:	Low		Medium		High		N/A	X
Risk of bias for KQ 3:	Low		Medium		High		N/A	X
Risk of bias for KQ 4a:	Low	x	Medium		High		N/A	
Risk of bias for KQ 4b:	Low		Medium		High		N/A	X
Risk of bias for KQ 5:	Low		Medium		High		N/A	X
Explain any **High** ratings:								

Low: Study has minimal bias. High degree of confidence that the true effect size is similar in size and direction to that reported.
Medium: Study has at least one significant source of bias, but does not have flaws that are likely to cause major bias. Moderate degree of confidence that the actual effect is in the direction reported by the study; moderate degree of confidence that the true effect size is similar to that reported.
High: Study has at least one major sources of bias or multiple significant sources of bias. Low degree of confidence that the true effect size is similar in size or direction to that reported.
NA: Not applicable to that key question.

Key Questions 1, 3, 4a, 4b, and 5	If the study does NOT apply to any of these KQs, place an 'X' here (___)

KQ 1: Overarching Question
Is there direct evidence that the addition of the following genetic tests used alone or in combination with traditional prognostic factors change physician decision making and improve outcomes for adult patients with lung, breast, colorectal, and bladder cancer compared with the use of traditional factors to predict risk of recurrence for adults with these cancers?

KQ 3. Clinical Validity. Does existing evidence establish the prognostic accuracy of the tests for predicting recurrence?

KQ 4a. Clinical Utility.
What is the evidence that the prognostic information provided by the genetic tests modifies physician decisions regarding use of adjuvant anti-neoplastic chemo- and/or radiotherapy; enhanced diagnostic testing for recurrence; and/or preventive surgery among adult patients with malignant tumors?

KQ 4b. Clinical Utility.
What is the evidence that modified decisions lead to improved overall survival, disease free survival, time to recurrence, quality of life, or incidence of serious side effects of adjuvant therapy in adult patients with malignant tumors?

KQ 5. Harms.
What are the harms associated with treatment decisions that are informed by the genetic tests?

	RCT	**non-RCT**	**Prospective cohort study**	**Retrospective cohort study**	**Case-control study**	**Case Series**
1093. What is the study design?						**X**
If "Other" study design, enter a description in this box:	**Yes**	**No**	**Partially**	**Can't Determine**	**NA**	**Explanation**
1094. For RCTs, were randomization and allocation concealment adequate?					X	
1095. Did the study apply inclusion/exclusion criteria uniformly to all comparison groups of the study?	X					
1096. Is the selection of the comparison group appropriate, after taking into account feasibility and ethical considerations?					X	
1097. Were groups similar at baseline?					X	
1098. Were the outcome assessors blinded to the test result/intervention/exposure status of participants?					X	
1099. Were outcomes assessed using valid and reliable measures, implemented consistently across all study participants?	X					
1100. Was overall attrition less than 30%?					X	
1101. Was differential attrition less than 15%?					X	
1102. Does the analysis control for baseline					X	

differences between groups?						
1103. Does the analysis account for differences in treatment received by the groups?					X	
1104. Are the statistical methods used to assess the outcomes appropriate?	X					
1105. **For KQ3 ONLY** – Did analyses adjust for all or most of the standard prognostic markers?						
Comments: Altho retrospective decision of change in management is based on comparing the NCCN guidelines so do not think there is a risk of bias						

Key Question 2					If study does NOT apply to this KQ, place an 'X' here (_X_)		
KQ 2. Analytic Validity. Does existing evidence establish the technical accuracy and reliability of the tests for detecting the relevant genetic markers?							
	Yes	**No**	**Unclear**	**NA**	**Low**	**High**	**Unclear**
Domain 1: Patient Selection							
Was a consecutive or random sample of patients enrolled?							
Was a case-control design avoided?							
Did the study avoid inappropriate exclusions?							
Could the selection of patients have introduced bias?							
Domain 2: Index Test(s)							
Were the index test results interpreted without knowledge of the results of the reference standard?							
If a threshold was used, was it pre-specified?							
Could the conduct or interpretation of the index test have introduced bias?							
Domain 3: Reference Standard							
Is the reference standard likely to correctly classify the genetic markers?							
Were the reference standard results interpreted without knowledge of the results of the index test?							
Could the reference standard, its conduct, or its interpretation have introduced bias?							
Domain 4: Flow and Timing							
Did all patients receive a reference standard?							
Did patients receive the same reference standard?							
Were all patients included in the analysis?							
Could the patient flow have introduced bias?							
Comments:							

Worksheet for Risk of Bias of Individual Studies – GTRRC (v. 4-23-13)

Ref ID #	Author	Year
1194	Roth	2010

Indicate the appropriate risk of bias rating by placing an 'X' in the shaded space to the right of the rating for each KQ that is applicable. If a study does not apply to a KQ, put an 'X' next to N/A.

Risk of bias for KQ 1:	Low		Medium		High		N/A	X
Risk of bias for KQ 2:	Low		Medium		High		N/A	X
Risk of bias for KQ 3:	Low		Medium	X	High		N/A	
Risk of bias for KQ 4a:	Low		Medium		High		N/A	X
Risk of bias for KQ 4b:	Low		Medium		High		N/A	X
Risk of bias for KQ 5:	Low		Medium		High		N/A	X
Explain any **High** ratings:								

Low: Study has minimal bias. High degree of confidence that the true effect size is similar in size and direction to that reported.
Medium: Study has at least one significant source of bias, but does not have flaws that are likely to cause major bias. Moderate degree of confidence that the actual effect is in the direction reported by the study; moderate degree of confidence that the true effect size is similar to that reported.
High: Study has at least one major sources of bias or multiple significant sources of bias. Low degree of confidence that the true effect size is similar in size or direction to that reported.
NA: Not applicable to that key question.

Key Questions 1, 3, 4a, 4b, and 5	If the study does NOT apply to any of these KQs, place an 'X' here (___)

KQ 1: Overarching Question
Is there direct evidence that the addition of the following genetic tests used alone or in combination with traditional prognostic factors change physician decision making and improve outcomes for adult patients with lung, breast, colorectal, and bladder cancer compared with the use of traditional factors to predict risk of recurrence for adults with these cancers?

KQ 3. Clinical Validity. Does existing evidence establish the prognostic accuracy of the tests for predicting recurrence?

KQ 4a. Clinical Utility.
What is the evidence that the prognostic information provided by the genetic tests modifies physician decisions regarding use of adjuvant anti-neoplastic chemo- and/or radiotherapy; enhanced diagnostic testing for recurrence; and/or preventive surgery among adult patients with malignant tumors?

KQ 4b. Clinical Utility.
What is the evidence that modified decisions lead to improved overall survival, disease free survival, time to recurrence, quality of life, or incidence of serious side effects of adjuvant therapy in adult patients with malignant tumors?

KQ 5. Harms.
What are the harms associated with treatment decisions that are informed by the genetic tests?

	RCT	**non-RCT**	**Prospective cohort study**	**Retrospective cohort study**	**Case-control study**	**Case Series**
1106. What is the study design?			**X**			
If "Other" study design, enter a description in this box:	**Yes**	**No**	**Partially**	**Can't Determine**	**NA**	**Explanation**
1107. For RCTs, were randomization and allocation concealment adequate?					X	
1108. Did the study apply inclusion/exclusion criteria uniformly to all comparison groups of the study?	X					
1109. Is the selection of the comparison group appropriate, after taking into account feasibility and ethical considerations?	X					
1110. Were groups similar at baseline?				X		
1111. Were the outcome assessors blinded to the test result/intervention/exposure status of participants?				X		
1112. Were outcomes assessed using valid and reliable measures, implemented consistently across all study participants?	X					
1113. Was overall attrition less than 30%?	X					
1114. Was differential attrition less than 15%?	X					
1115. Does the analysis control for baseline				X		

differences between groups?						
1116. Does the analysis account for differences in treatment received by the groups?	X					
1117. Are the statistical methods used to assess the outcomes appropriate?	X					
1118. **For KQ3 ONLY** – Did analyses adjust for all or most of the standard prognostic markers?	X					
Comments: Unable to determine baseline comparison for the comparison we're interested in (BRAF mutation vs. wild-type and KRAS mutation vs. wildtype); Study reports baseline data for 3 groups (all subjects, stage II, and stage III). Can't determine if analysis controls for baseline differences between groups, but it does control for many variables, including most known prognostic factors.						

Key Question 2	If study does NOT apply to this KQ, place an 'X' here (_X_)						
KQ 2. Analytic Validity. Does existing evidence establish the technical accuracy and reliability of the tests for detecting the relevant genetic markers?							
	Yes	**No**	**Unclear**	**NA**	**Low**	**High**	**Unclear**

Worksheet for Risk of Bias of Individual Studies – GTRRC (v. 4-23-13)

Ref ID #	Author	Year
2992	Rouquette	2012

Indicate the appropriate risk of bias rating by placing an 'X' in the shaded space to the right of the rating for each KQ that is applicable. If a study does not apply to a KQ, put an 'X' next to N/A.

Risk of bias for KQ 1:	Low		Medium		High		N/A	
Risk of bias for KQ 2:	Low		Medium		High		N/A	
Risk of bias for KQ 3:	Low	X	Medium		High		N/A	
Risk of bias for KQ 4a:	Low		Medium		High		N/A	
Risk of bias for KQ 4b:	Low		Medium		High		N/A	
Risk of bias for KQ 5:	Low		Medium		High		N/A	
Explain any **High** ratings:								

Low: Study has minimal bias. High degree of confidence that the true effect size is similar in size and direction to that reported.
Medium: Study has at least one significant source of bias, but does not have flaws that are likely to cause major bias. Moderate degree of confidence that the actual effect is in the direction reported by the study; moderate degree of confidence that the true effect size is similar to that reported.
High: Study has at least one major sources of bias or multiple significant sources of bias. Low degree of confidence that the true effect size is similar in size or direction to that reported.
NA: Not applicable to that key question.

Key Questions 1, 3, 4a, 4b, and 5	If the study does NOT apply to any of these KQs, place an 'X' here (___)
KQ 1: Overarching Question Is there direct evidence that the addition of the following genetic tests used alone or in combination with traditional prognostic factors change physician decision making and improve outcomes for adult patients with lung, breast, colorectal, and bladder cancer compared with the use of traditional factors to predict risk of recurrence for adults with these cancers?	
KQ 3. Clinical Validity. Does existing evidence establish the prognostic accuracy of the tests for predicting recurrence?	
KQ 4a. Clinical Utility. What is the evidence that the prognostic information provided by the genetic tests modifies physician decisions regarding use of adjuvant anti-neoplastic chemo- and/or radiotherapy; enhanced diagnostic testing for recurrence; and/or preventive surgery among adult patients with malignant tumors?	
KQ 4b. Clinical Utility. What is the evidence that modified decisions lead to improved overall survival, disease free survival, time to recurrence, quality of life, or incidence of serious side effects of adjuvant therapy in adult patients with malignant tumors?	
KQ 5. Harms. What are the harms associated with treatment decisions that are informed by the genetic tests?	

	RCT	**non-RCT**	**Prospective cohort study**	**Retrospective cohort study**	**Case-control study**	**Case Series**
1132. What is the study design?			**x**			
If "Other" study design, enter a description in this box:	**Yes**	**No**	**Partially**	**Can't Determine**	**NA**	**Explanation**
1133. For RCTs, were randomization and allocation concealment adequate?					x	
1134. Did the study apply inclusion/exclusion criteria uniformly to all comparison groups of the study?	x					
1135. Is the selection of the comparison group appropriate, after taking into account feasibility and ethical considerations?	x					
1136. Were groups similar at baseline?				x		
1137. Were the outcome assessors blinded to the test result/intervention/exposure status of participants?					x	death is outcome blinding unlikely to matter
1138. Were outcomes assessed using valid and reliable measures, implemented consistently across all study participants?	x					
1139. Was overall attrition less than 30%?				x		
1140. Was differential attrition less than 15%?				x		

1141. Does the analysis control for baseline differences between groups?				x		
1142. Does the analysis account for differences in treatment received by the groups?	x					
1143. Are the statistical methods used to assess the outcomes appropriate?	x					
1144. **For KQ3 ONLY** – Did analyses adjust for all or most of the standard prognostic markers?	x					
Comments: survival analysis was not the primary focus of the study and risk ratios were not presented, so very difficult to determine if sample size or other factors were drivers of non-significant findings						

Key Question 2	If study does NOT apply to this KQ, place an 'X' here (_X_)						
KQ 2. Analytic Validity. Does existing evidence establish the technical accuracy and reliability of the tests for detecting the relevant genetic markers?							
	Yes	**No**	**Unclear**	**NA**	**Low**	**High**	**Unclear**
Domain 1: Patient Selection

Worksheet for Risk of Bias of Individual Studies – GTRRC (v. 4-23-13)

Ref ID #	Author	Year
3652	Samadder	2013

Indicate the appropriate risk of bias rating by placing an 'X' in the shaded space to the right of the rating for each KQ that is applicable. If a study does not apply to a KQ, put an 'X' next to N/A.

Risk of bias for KQ 1:	Low		Medium		High		N/A	X
Risk of bias for KQ 2:	Low		Medium		High		N/A	X
Risk of bias for KQ 3:	Low		Medium	X	High		N/A	
Risk of bias for KQ 4a:	Low		Medium		High		N/A	X
Risk of bias for KQ 4b:	Low		Medium		High		N/A	X
Risk of bias for KQ 5:	Low		Medium		High		N/A	X
Explain any **High** ratings:								

Low: Study has minimal bias. High degree of confidence that the true effect size is similar in size and direction to that reported.
Medium: Study has at least one significant source of bias, but does not have flaws that are likely to cause major bias. Moderate degree of confidence that the actual effect is in the direction reported by the study; moderate degree of confidence that the true effect size is similar to that reported.
High: Study has at least one major sources of bias or multiple significant sources of bias. Low degree of confidence that the true effect size is similar in size or direction to that reported.
NA: Not applicable to that key question.

Key Questions 1, 3, 4a, 4b, and 5	If the study does NOT apply to any of these KQs, place an 'X' here (___)

KQ 1: Overarching Question
Is there direct evidence that the addition of the following genetic tests used alone or in combination with traditional prognostic factors change physician decision making and improve outcomes for adult patients with lung, breast, colorectal, and bladder cancer compared with the use of traditional factors to predict risk of recurrence for adults with these cancers?

KQ 3. Clinical Validity. Does existing evidence establish the prognostic accuracy of the tests for predicting recurrence?

KQ 4a. Clinical Utility.
What is the evidence that the prognostic information provided by the genetic tests modifies physician decisions regarding use of adjuvant anti-neoplastic chemo- and/or radiotherapy; enhanced diagnostic testing for recurrence; and/or preventive surgery among adult patients with malignant tumors?

KQ 4b. Clinical Utility.
What is the evidence that modified decisions lead to improved overall survival, disease free survival, time to recurrence, quality of life, or incidence of serious side effects of adjuvant therapy in adult patients with malignant tumors?

KQ 5. Harms.
What are the harms associated with treatment decisions that are informed by the genetic tests?

	RCT	**non-RCT**	**Prospective cohort study**	**Retrospective cohort study**	**Case-control study**	**Case Series**
1158. What is the study design?				**X**		
If "Other" study design, enter a description in this box:	**Yes**	**No**	**Partially**	**Can't Determine**	**NA**	**Explanation**
1159. For RCTs, were randomization and allocation concealment adequate?					X	
1160. Did the study apply inclusion/exclusion criteria uniformly to all comparison groups of the study?	X					
1161. Is the selection of the comparison group appropriate, after taking into account feasibility and ethical considerations?	X					
1162. Were groups similar at baseline?				X		
1163. Were the outcome assessors blinded to the test result/intervention/exposure status of participants?				X		
1164. Were outcomes assessed using valid and reliable measures, implemented consistently across all study participants?	X					
1165. Was overall attrition less than 30%?	X					
1166. Was differential attrition less than 15%?				X

differences between groups?						
1168. Does the analysis account for differences in treatment received by the groups?	X					Adjusted for chemo exposure and radiation exposure
1169. Are the statistical methods used to assess the outcomes appropriate?	X					
1170. **For KQ3 ONLY** – Did analyses adjust for all or most of the standard prognostic markers?	X					
Comments:						

Key Question 2	If study does NOT apply to this KQ, place an 'X' here (_X_)						
KQ 2. Analytic Validity. Does existing evidence establish the technical accuracy and reliability of the tests for detecting the relevant genetic markers?							
	Yes	**No**	**Unclear**	**NA**	**Low**	**High**	**Unclear**
Domain 1: Patient Selection							
Was a consecutive or random sample of patients enrolled?							
Was a case-control design avoided?							
Did the study avoid inappropriate exclusions?							
Could the selection of patients have introduced bias?							
Domain 2: Index Test(s)							
Were the index test results interpreted without knowledge of the results of the reference standard?							
If a threshold was used, was it pre-specified?							
Could the conduct or interpretation of the index test have introduced bias?							
Domain 3: Reference Standard							
Is the reference standard likely to correctly classify the genetic markers?							
Were the reference standard results interpreted without knowledge of the results of the index test?							
Could the reference standard, its conduct, or its interpretation have introduced bias?							
Domain 4: Flow and Timing							
Did all patients receive a reference standard?							
Did patients receive the same reference standard?							
Were all patients included in the analysis?							
Could the patient flow have introduced bias?							
Comments:							

Worksheet for Risk of Bias of Individual Studies – GTRRC (v. 4-23-13)

Ref ID #	Author	Year
1226	Samowitz	2005

Indicate the appropriate risk of bias rating by placing an 'X' in the shaded space to the right of the rating for each KQ that is applicable. If a study does not apply to a KQ, put an 'X' next to N/A.

Risk of bias for KQ 1:	Low		Medium		High		N/A	X
Risk of bias for KQ 2:	Low		Medium		High		N/A	X
Risk of bias for KQ 3:	Low		Medium		High	X	N/A	
Risk of bias for KQ 4a:	Low		Medium		High		N/A	X
Risk of bias for KQ 4b:	Low		Medium		High		N/A	X
Risk of bias for KQ 5:	Low		Medium		High		N/A	X
Explain any **High** ratings:	High risk of selection bias and confounding. See comments below.							

Low: Study has minimal bias. High degree of confidence that the true effect size is similar in size and direction to that reported.
Medium: Study has at least one significant source of bias, but does not have flaws that are likely to cause major bias. Moderate degree of confidence that the actual effect is in the direction reported by the study; moderate degree of confidence that the true effect size is similar to that reported.
High: Study has at least one major sources of bias or multiple significant sources of bias. Low degree of confidence that the true effect size is similar in size or direction to that reported.
NA: Not applicable to that key question.

Key Questions 1, 3, 4a, 4b, and 5	If the study does NOT apply to any of these KQs, place an 'X' here (___)

KQ 1: Overarching Question
Is there direct evidence that the addition of the following genetic tests used alone or in combination with traditional prognostic factors change physician decision making and improve outcomes for adult patients with lung, breast, colorectal, and bladder cancer compared with the use of traditional factors to predict risk of recurrence for adults with these cancers?

KQ 3. Clinical Validity. Does existing evidence establish the prognostic accuracy of the tests for predicting recurrence?

KQ 4a. Clinical Utility.
What is the evidence that the prognostic information provided by the genetic tests modifies physician decisions regarding use of adjuvant anti-neoplastic chemo- and/or radiotherapy; enhanced diagnostic testing for recurrence; and/or preventive surgery among adult patients with malignant tumors?

KQ 4b. Clinical Utility.
What is the evidence that modified decisions lead to improved overall survival, disease free survival, time to recurrence, quality of life, or incidence of serious side effects of adjuvant therapy in adult patients with malignant tumors?

KQ 5. Harms.
What are the harms associated with treatment decisions that are informed by the genetic tests?

	RCT	**non-RCT**	**Prospective cohort study**	**Retrospective cohort study**	**Case-control study**	**Case Series**
1171. What is the study design?				**X**		
If "Other" study design, enter a description in this box:	**Yes**	**No**	**Partially**	**Can't Determine**	**NA**	**Explanation**
1172. For RCTs, were randomization and allocation concealment adequate?					X	
1173. Did the study apply inclusion/exclusion criteria uniformly to all comparison groups of the study?	X					
1174. Is the selection of the comparison group appropriate, after taking into account feasibility and ethical considerations?	X					
1175. Were groups similar at baseline?		X				
1176. Were the outcome assessors blinded to the test result/intervention/exposure status of participants?				X		
1177. Were outcomes assessed using valid and reliable measures, implemented consistently across all study participants?	X					
1178. Was overall attrition less than 30%?				X		
1179. Was differential attrition less than 15%?				X		
1180. Does the analysis control for baseline			X			

differences between groups?						
1181. Does the analysis account for differences in treatment received by the groups?		X				
1182. Are the statistical methods used to assess the outcomes appropriate?	X					
1183. **For KQ3 ONLY** – Did analyses adjust for all or most of the standard prognostic markers?		X				
Comments: Analysis adjusted for age, stage, tumor site, and CIMP; did not consider other prognostic factors, such as grade, cellular subtypes, LV invasion, location (rectum vs. colon), sex, margin status—and there were significant baseline differences between the groups for some of these factors (tumor site, differentiation, mucinous histology). High risk of selection bias and confounding given the baseline differences and many factors not included in the multivariate analysis.						

Key Question 2	If study does NOT apply to this KQ, place an 'X' here (_X_)						
KQ 2. Analytic Validity. Does existing evidence establish the technical accuracy and reliability of the tests for detecting the relevant genetic markers?							
	Yes	**No**	**Unclear**	**NA**	**Low**	**High**	**Unclear**
Domain 1: Patient Selection							
Was a consecutive or random sample of patients enrolled?							
Was a case-control design avoided?							
Did the study avoid inappropriate exclusions?

Worksheet for Risk of Bias of Individual Studies – GTRRC (v. 4-23-13)

Ref ID #	Author	Year
3012	Scoccianti	

Indicate the appropriate risk of bias rating by placing an 'X' in the shaded space to the right of the rating for each KQ that is applicable. If a study does not apply to a KQ, put an 'X' next to N/A.

Risk of bias for KQ 1:	Low		Medium		High		N/A	
Risk of bias for KQ 2:	Low		Medium		High		N/A	
Risk of bias for KQ 3:	Low		Medium	X	High		N/A	
Risk of bias for KQ 4a:	Low		Medium		High		N/A	
Risk of bias for KQ 4b:	Low		Medium		High		N/A	
Risk of bias for KQ 5:	Low		Medium		High		N/A	
Explain any **High** ratings:								

Low: Study has minimal bias. High degree of confidence that the true effect size is similar in size and direction to that reported.
Medium: Study has at least one significant source of bias, but does not have flaws that are likely to cause major bias. Moderate degree of confidence that the actual effect is in the direction reported by the study; moderate degree of confidence that the true effect size is similar to that reported.
High: Study has at least one major sources of bias or multiple significant sources of bias. Low degree of confidence that the true effect size is similar in size or direction to that reported.
NA: Not applicable to that key question.

Key Questions 1, 3, 4a, 4b, and 5	If the study does NOT apply to any of these KQs, place an 'X' here (___)
KQ 1: Overarching Question Is there direct evidence that the addition of the following genetic tests used alone or in combination with traditional prognostic factors change physician decision making and improve outcomes for adult patients with lung, breast, colorectal, and bladder cancer compared with the use of traditional factors to predict risk of recurrence for adults with these cancers?	
KQ 3. Clinical Validity. Does existing evidence establish the prognostic accuracy of the tests for predicting recurrence?	
KQ 4a. Clinical Utility. What is the evidence that the prognostic information provided by the genetic tests modifies physician decisions regarding use of adjuvant anti-neoplastic chemo- and/or radiotherapy; enhanced diagnostic testing for recurrence; and/or preventive surgery among adult patients with malignant tumors?	
KQ 4b. Clinical Utility. What is the evidence that modified decisions lead to improved overall survival, disease free survival, time to recurrence, quality of life, or incidence of serious side effects of adjuvant therapy in adult patients with malignant tumors?	
KQ 5. Harms. What are the harms associated with treatment decisions that are informed by the genetic tests?	

	RCT	**non-RCT**	**Prospective cohort study**	**Retrospective cohort study**	**Case-control study**	**Case Series**
1197. What is the study design?			**x**			
If "Other" study design, enter a description in this box:	**Yes**	**No**	**Partially**	**Can't Determine**	**NA**	**Explanation**
1198. For RCTs, were randomization and allocation concealment adequate?					x	
1199. Did the study apply inclusion/exclusion criteria uniformly to all comparison groups of the study?	x					
1200. Is the selection of the comparison group appropriate, after taking into account feasibility and ethical considerations?	x					
1201. Were groups similar at baseline?		x				non-randomized study
1202. Were the outcome assessors blinded to the test result/intervention/exposure status of participants?					x	outcome is survival
1203. Were outcomes assessed using valid and reliable measures, implemented consistently across all study participants?	x					
1204. Was overall attrition less than 30%?	x					

1205. Was differential attrition less than 15%?					x	
1206. Does the analysis control for baseline differences between groups?			x			
1207. Does the analysis account for differences in treatment received by the groups?		x				
1208. Are the statistical methods used to assess the outcomes appropriate?	x					
1209. **For KQ3 ONLY** – Did analyses adjust for all or most of the standard prognostic markers?	x					
Comments: most standard prognostic markers were used in multivariable analysis (T and N size) however only covariates with significant univariate associations were included in the multivariable model, iffy way of reducing a model						

Key Question 2	If study does NOT apply to this KQ, place an 'X' here (_X_)						
KQ 2. Analytic Validity. Does existing evidence establish the technical accuracy and reliability of the tests for detecting the relevant genetic markers?							
	Yes	**No**	**Unclear**	**NA**	**Low**	**High**	**Unclear**

Worksheet for Risk of Bias of Individual Studies – GTRRC (v. 4-23-13)

Ref ID #	Author	Year
1272	Shia	2008

Indicate the appropriate risk of bias rating by placing an 'X' in the shaded space to the right of the rating for each KQ that is applicable. If a study does not apply to a KQ, put an 'X' next to N/A.

Risk of bias for KQ 1:	Low		Medium		High		N/A	X
Risk of bias for KQ 2:	Low		Medium		High		N/A	X
Risk of bias for KQ 3:	Low		Medium		High	X	N/A	
Risk of bias for KQ 4a:	Low		Medium		High		N/A	X
Risk of bias for KQ 4b:	Low		Medium		High		N/A	X
Risk of bias for KQ 5:	Low		Medium		High		N/A	X
Explain any **High** ratings:	High risk of selection bias, attrition bias, measurement bias, and confounding. See comments below for additional details.							

Low: Study has minimal bias. High degree of confidence that the true effect size is similar in size and direction to that reported.
Medium: Study has at least one significant source of bias, but does not have flaws that are likely to cause major bias. Moderate degree of confidence that the actual effect is in the direction reported by the study; moderate degree of confidence that the true effect size is similar to that reported.
High: Study has at least one major sources of bias or multiple significant sources of bias. Low degree of confidence that the true effect size is similar in size or direction to that reported.
NA: Not applicable to that key question.

Key Questions 1, 3, 4a, 4b, and 5	If the study does NOT apply to any of these KQs, place an 'X' here (__)
KQ 1: Overarching Question Is there direct evidence that the addition of the following genetic tests used alone or in combination with traditional prognostic factors change physician decision making and improve outcomes for adult patients with lung, breast, colorectal, and bladder cancer compared with the use of traditional factors to predict risk of recurrence for adults with these cancers?	
KQ 3. Clinical Validity. Does existing evidence establish the prognostic accuracy of the tests for predicting recurrence?	
KQ 4a. Clinical Utility. What is the evidence that the prognostic information provided by the genetic tests modifies physician decisions regarding use of adjuvant anti-neoplastic chemo- and/or radiotherapy; enhanced diagnostic testing for recurrence; and/or preventive surgery among adult patients with malignant tumors?	
KQ 4b. Clinical Utility. What is the evidence that modified decisions lead to improved overall survival, disease free survival, time to recurrence, quality of life, or incidence of serious side effects of adjuvant therapy in adult patients with malignant tumors?	
KQ 5. Harms. What are the harms associated with treatment decisions that are informed by the genetic tests?	

	RCT	**non-RCT**	**Prospective cohort study**	**Retrospective cohort study**	**Case-control study**	**Case Series**
1223. What is the study design?				**X**		
If "Other" study design, enter a description in this box:	**Yes**	**No**	**Partially**	**Can't Determine**	**NA**	**Explanation**
1224. For RCTs, were randomization and allocation concealment adequate?					X	
1225. Did the study apply inclusion/exclusion criteria uniformly to all comparison groups of the study?	X					
1226. Is the selection of the comparison group appropriate, after taking into account feasibility and ethical considerations?	X					
1227. Were groups similar at baseline?				X		For our comparison of interest (by MSI status), no information reported
1228. Were the outcome assessors blinded to the test result/intervention/exposure status of participants?				X		
1229. Were outcomes assessed using valid and				X		Used a surgical

reliable measures, implemented consistently across all study participants?						database to gather clinical information and outcomes; no further information reported on ascertainment, definitions of outcomes, masking of outcome assessors
1230. Was overall attrition less than 30%?		X				Of 236 patients included, complete clinical information available for only 130 (55%) and MSI detection completed in just 77 (32.6%)
1231. Was differential attrition less than 15%?				X		
1232. Does the analysis control for baseline differences between groups?				X		
1233. Does the analysis account for differences in treatment received by the groups?		X				
1234. Are the statistical methods used to assess the outcomes appropriate?	X					
1235. **For KQ3 ONLY** – Did analyses adjust for all or most of the standard prognostic markers?				X		
Comments: High risk of selection bias, attrition bias, measurement bias, and confounding. Just 32.6% of the sample had MSI results and just 55% of the sample had complete clinical information. Because the article is focused on FR alpha, it reports little information about the MSI results and analyses. The multivariate model is not reported, nor are the outcomes data for MSI from the multivariate model. It just tells us that only TNM staging remained significant predictor for DSS in the multivariate analysis (Cox regression with forward selection, which was limited to 3 covariated due to the limited number of events).						

Key Question 2	If study does NOT apply to this KQ, place an 'X' here (_X_)						
KQ 2. Analytic Validity. Does existing evidence establish the technical accuracy and reliability of the tests for detecting the relevant genetic markers?							
	Yes	**No**	**Unclear**	**NA**	**Low**	**High**	**Unclear**
Domain 1: Patient Selection							
Was a consecutive or random sample of patients enrolled?							
Was a case-control design avoided?							
Did the study avoid inappropriate exclusions?							
Could the selection of patients have introduced bias?							
Domain 2: Index Test(s)							
Were the index test results interpreted without knowledge of the results of the reference standard?							
If a threshold was used, was it pre-specified?							
Could the conduct or interpretation of the index test have introduced bias?							
Domain 3: Reference Standard							

Is the reference standard likely to correctly classify the genetic markers?							
Were the reference standard results interpreted without knowledge of the results of the index test?							
Could the reference standard, its conduct, or its interpretation have introduced bias?							
Domain 4: Flow and Timing							
Did all patients receive a reference standard?							
Did patients receive the same reference standard?							
Were all patients included in the analysis?							
Could the patient flow have introduced bias?

Ref ID #	Author	Year
3348	Solin	2012

Indicate the appropriate risk of bias rating by placing an 'X' in the shaded space to the right of the rating for each KQ that is applicable. If a study does not apply to a KQ, put an 'X' next to N/A.

Risk of bias for KQ 1:	Low		Medium		High		N/A	X
Risk of bias for KQ 2:	Low		Medium		High		N/A	X
Risk of bias for KQ 3:	Low		Medium	X	High		N/A	
Risk of bias for KQ 4a:	Low		Medium		High		N/A	X
Risk of bias for KQ 4b:	Low		Medium		High		N/A	X
Risk of bias for KQ 5:	Low		Medium		High		N/A	X
Explain any **High** ratings:								

Low: Study has minimal bias. High degree of confidence that the true effect size is similar in size and direction to that reported.
Medium: Study has at least one significant source of bias, but does not have flaws that are likely to cause major bias. Moderate degree of confidence that the actual effect is in the direction reported by the study; moderate degree of confidence that the true effect size is similar to that reported.
High: Study has at least one major sources of bias or multiple significant sources of bias. Low degree of confidence that the true effect size is similar in size or direction to that reported.
NA: Not applicable to that key question.

Key Questions 1, 3, 4a, 4b, and 5	If the study does NOT apply to any of these KQs, place an 'X' here (___)

KQ 1: Overarching Question
Is there direct evidence that the addition of the following genetic tests used alone or in combination with traditional prognostic factors change physician decision making and improve outcomes for adult patients with lung, breast, colorectal, and bladder cancer compared with the use of traditional factors to predict risk of recurrence for adults with these cancers?

KQ 3. Clinical Validity. Does existing evidence establish the prognostic accuracy of the tests for predicting recurrence?

KQ 4a. Clinical Utility.
What is the evidence that the prognostic information provided by the genetic tests modifies physician decisions regarding use of adjuvant anti-neoplastic chemo- and/or radiotherapy; enhanced diagnostic testing for recurrence; and/or preventive surgery among adult patients with malignant tumors?

KQ 4b. Clinical Utility.
What is the evidence that modified decisions lead to improved overall survival, disease free survival, time to recurrence, quality of life, or incidence of serious side effects of adjuvant therapy in adult patients with malignant tumors?

KQ 5. Harms.
What are the harms associated with treatment decisions that are informed by the genetic tests?

	RCT	**non-RCT**	**Prospective cohort study**	**Retrospective cohort study**	**Case-control study**	**Case Series**
1236. What is the study design?			**X**			
If "Other" study design, enter a description in this box:	**Yes**	**No**	**Partially**	**Can't Determine**	**NA**	**Explanation**
1237. For RCTs, were randomization and allocation concealment adequate?					X	
1238. Did the study apply inclusion/exclusion criteria uniformly to all comparison groups of the study?	X					
1239. Is the selection of the comparison group appropriate, after taking into account feasibility and ethical considerations?	X					
1240. Were groups similar at baseline?					X	
1241. Were the outcome assessors blinded to the test result/intervention/exposure status of participants?	X					
1242. Were outcomes assessed using valid and reliable measures, implemented consistently across all study participants?	X					
1243. Was overall attrition less than 30%?	X					
1244. Was differential attrition less than 15%?	X					
1245. Does the analysis control for baseline					X	

differences between groups?						
1246. Does the analysis account for differences in treatment received by the groups?					X	
1247. Are the statistical methods used to assess the outcomes appropriate?			X – Since there were differences by ER positive and negative. Should have stratified or used an interaction term			
1248. **For KQ3 ONLY** – Did analyses adjust for all or most of the standard prognostic markers?						
Comments:						

Key Question 2	X						
KQ 2. Analytic Validity. Does existing evidence establish the technical accuracy and reliability of the tests for detecting the relevant genetic markers?							
	Yes	**No**	**Unclear**	**NA**	**Low**	**High**	**Unclear**
Domain 1: Patient Selection							
Was a consecutive or random sample of patients enrolled?							
Was a case-control design avoided?							
Did the study avoid inappropriate exclusions?							
Could the selection of patients have introduced bias?							
Domain 2: Index Test(s)							
Were the index test results interpreted without knowledge of the results of the reference standard?							
If a threshold was used, was it pre-specified?							
Could the conduct or interpretation of the index test have introduced bias?							
Domain 3: Reference Standard							
Is the reference standard likely to correctly classify the genetic markers?							
Were the reference standard results interpreted without knowledge of the results of the index test?							
Could the reference standard, its conduct, or its interpretation have introduced bias?							
Domain 4: Flow and Timing							
Did all patients receive a reference standard?							
Did patients receive the same reference standard?							
Were all patients included in the analysis?							
Could the patient flow have introduced bias?							
Comments:							

Worksheet for Risk of Bias of Individual Studies – GTRRC (v. 4-23-13)

Ref ID #	Author	Year
1311	Soreide	2009

Indicate the appropriate risk of bias rating by placing an 'X' in the shaded space to the right of the rating for each KQ that is applicable. If a study does not apply to a KQ, put an 'X' next to N/A.

Risk of bias for KQ 1:	Low		Medium		High		N/A	X
Risk of bias for KQ 2:	Low		Medium		High		N/A	X
Risk of bias for KQ 3:	Low		Medium	X	High		N/A	
Risk of bias for KQ 4a:	Low		Medium		High		N/A	X
Risk of bias for KQ 4b:	Low		Medium		High		N/A	X
Risk of bias for KQ 5:	Low		Medium		High		N/A	X
Explain any **High** ratings:								

Low: Study has minimal bias. High degree of confidence that the true effect size is similar in size and direction to that reported.
Medium: Study has at least one significant source of bias, but does not have flaws that are likely to cause major bias. Moderate degree of confidence that the actual effect is in the direction reported by the study; moderate degree of confidence that the true effect size is similar to that reported.
High: Study has at least one major sources of bias or multiple significant sources of bias. Low degree of confidence that the true effect size is similar in size or direction to that reported.
NA: Not applicable to that key question.

Key Questions 1, 3, 4a, 4b, and 5	If the study does NOT apply to any of these KQs, place an 'X' here (___)

KQ 1: Overarching Question
Is there direct evidence that the addition of the following genetic tests used alone or in combination with traditional prognostic factors change physician decision making and improve outcomes for adult patients with lung, breast, colorectal, and bladder cancer compared with the use of traditional factors to predict risk of recurrence for adults with these cancers?

KQ 3. Clinical Validity. Does existing evidence establish the prognostic accuracy of the tests for predicting recurrence?

KQ 4a. Clinical Utility.
What is the evidence that the prognostic information provided by the genetic tests modifies physician decisions regarding use of adjuvant anti-neoplastic chemo- and/or radiotherapy; enhanced diagnostic testing for recurrence; and/or preventive surgery among adult patients with malignant tumors?

KQ 4b. Clinical Utility.
What is the evidence that modified decisions lead to improved overall survival, disease free survival, time to recurrence, quality of life, or incidence of serious side effects of adjuvant therapy in adult patients with malignant tumors?

KQ 5. Harms.
What are the harms associated with treatment decisions that are informed by the genetic tests?

	RCT	**non-RCT**	**Prospective cohort study**	**Retrospective cohort study**	**Case-control study**	**Case Series**
1249. What is the study design?				**X**		
If "Other" study design, enter a description in this box:	**Yes**	**No**	**Partially**	**Can't Determine**	**NA**	**Explanation**
1250. For RCTs, were randomization and allocation concealment adequate?					X	
1251. Did the study apply inclusion/exclusion criteria uniformly to all comparison groups of the study?	X					
1252. Is the selection of the comparison group appropriate, after taking into account feasibility and ethical considerations?	X					
1253. Were groups similar at baseline?		X				Differences for site, size, LN status, grade, ploidy, stage
1254. Were the outcome assessors blinded to the test result/intervention/exposure status of participants?				X		
1255. Were outcomes assessed using valid and reliable measures, implemented consistently across all study participants?				X		Unclear how outcomes were assessed. No

						reporting of followup plans/schedule; only reports that recurrence was recorded during follow up and was defined as any locoregional recurrence, distant metastases, or both; no description of how recurrence was determined
1256. Was overall attrition less than 30%?	X					
1257. Was differential attrition less than 15%?	X					
1258. Does the analysis control for baseline differences between groups?	X					
1259. Does the analysis account for differences in treatment received by the groups?		X				But the methods suggests that there was little variation in treatment
1260. Are the statistical methods used to assess the outcomes appropriate?	X					
1261. **For KQ3 ONLY** – Did analyses adjust for all or most of the standard prognostic markers?	X					
Comments: Unclear if this was prospective or retrospective; it sounds like some information was collected retrospectively; difficult to assess risk of ascertainment bias as very little information reported; no attempt to consider differences in treatment						

Key Question 2	If study does NOT apply to this KQ, place an 'X' here (_X_)						
KQ 2. Analytic Validity. Does existing evidence establish the technical accuracy and reliability of the tests for detecting the relevant genetic markers?							
	Yes	**No**	**Unclear**	**NA**	**Low**	**High**	**Unclear**

Worksheet for Risk of Bias of Individual Studies – GTRRC (v. 4-23-13)

Ref ID #	Author	Year
1373	Tie	2010

Indicate the appropriate risk of bias rating by placing an 'X' in the shaded space to the right of the rating for each KQ that is applicable. If a study does not apply to a KQ, put an 'X' next to N/A.

Risk of bias for KQ 1:	Low		Medium		High		N/A	X
Risk of bias for KQ 2:	Low		Medium		High		N/A	X
Risk of bias for KQ 3:	Low		Medium	X	High		N/A	
Risk of bias for KQ 4a:	Low		Medium		High		N/A	X
Risk of bias for KQ 4b:	Low		Medium		High		N/A	X
Risk of bias for KQ 5:	Low		Medium		High		N/A	X
Explain any **High** ratings:								

Low: Study has minimal bias. High degree of confidence that the true effect size is similar in size and direction to that reported.
Medium: Study has at least one significant source of bias, but does not have flaws that are likely to cause major bias. Moderate degree of confidence that the actual effect is in the direction reported by the study; moderate degree of confidence that the true effect size is similar to that reported.
High: Study has at least one major sources of bias or multiple significant sources of bias. Low degree of confidence that the true effect size is similar in size or direction to that reported.
NA: Not applicable to that key question.

Key Questions 1, 3, 4a, 4b, and 5	If the study does NOT apply to any of these KQs, place an 'X' here (___)

KQ 1: Overarching Question
Is there direct evidence that the addition of the following genetic tests used alone or in combination with traditional prognostic factors change physician decision making and improve outcomes for adult patients with lung, breast, colorectal, and bladder cancer compared with the use of traditional factors to predict risk of recurrence for adults with these cancers?

KQ 3. Clinical Validity. Does existing evidence establish the prognostic accuracy of the tests for predicting recurrence?

KQ 4a. Clinical Utility.
What is the evidence that the prognostic information provided by the genetic tests modifies physician decisions regarding use of adjuvant anti-neoplastic chemo- and/or radiotherapy; enhanced diagnostic testing for recurrence; and/or preventive surgery among adult patients with malignant tumors?

KQ 4b. Clinical Utility.
What is the evidence that modified decisions lead to improved overall survival, disease free survival, time to recurrence, quality of life, or incidence of serious side effects of adjuvant therapy in adult patients with malignant tumors?

KQ 5. Harms.
What are the harms associated with treatment decisions that are informed by the genetic tests?

	RCT	**non-RCT**	**Prospective cohort study**	**Retrospective cohort study**	**Case-control study**	**Case Series**
1301. What is the study design?				**X**		
If "Other" study design, enter a description in this box:	**Yes**	**No**	**Partially**	**Can't Determine**	**NA**	**Explanation**
1302. For RCTs, were randomization and allocation concealment adequate?					X	
1303. Did the study apply inclusion/exclusion criteria uniformly to all comparison groups of the study?				X		Unclear how they selected the 600 cases from the 1674 in the database
1304. Is the selection of the comparison group appropriate, after taking into account feasibility and ethical considerations?	X					
1305. Were groups similar at baseline?		X				
1306. Were the outcome assessors blinded to the test result/intervention/exposure status of participants?				X		
1307. Were outcomes assessed using valid and reliable measures, implemented consistently across all study participants?				X		Details of methods of ascertaining outcomes NR; we know they

						used a database (BioGrid Austrialia), but no information about validity of that database is provided, or about how they determined recurrence, etc. to input into the database
1308. Was overall attrition less than 30%?	X					
1309. Was differential attrition less than 15%?	X					
1310. Does the analysis control for baseline differences between groups?			X			Did for age, site, stage, but did not adjust for gender
1311. Does the analysis account for differences in treatment received by the groups?	X					
1312. Are the statistical methods used to assess the outcomes appropriate?	X					
1313. **For KQ3 ONLY** – Did analyses adjust for all or most of the standard prognostic markers?	X					Adjusted for age, stage, site, adjuvant treatment; did not adjust for grade, cellular subtypes, sex, lymphovascular invasion
Comments: Follow up was perhaps too short to collect good outcomes data on recurrence and mortality (median 38.5 months for stage I to III patients)						

Key Question 2	If study does NOT apply to this KQ, place an 'X' here (_X_)						
KQ 2. Analytic Validity. Does existing evidence establish the technical accuracy and reliability of the tests for detecting the relevant genetic markers?							
	Yes	**No**	**Unclear**	**NA**	**Low**	**High**	**Unclear**
Domain 1: Patient Selection							
Was a consecutive or random sample of patients enrolled?							
Was a case-control design avoided?							
Did the study avoid inappropriate exclusions?							
Could the selection of patients have introduced bias?							
Domain 2: Index Test(s)							
Were the index test results interpreted without knowledge of the results of the reference standard?							
If a threshold was used, was it pre-specified?							
Could the conduct or interpretation of the index test have introduced bias?							
Domain 3: Reference Standard							
Is the reference standard likely to correctly classify the genetic							

markers?							
Were the reference standard results interpreted without knowledge of the results of the index test?							
Could the reference standard, its conduct, or its interpretation have introduced bias?							
Domain 4: Flow and Timing							
Did all patients receive a reference standard?							
Did patients receive the same reference standard?							
Were all patients included in the analysis?							
Could the patient flow have introduced bias?							
Comments:							

Worksheet for Risk of Bias of Individual Studies – GTRRC (v. 4-23-13)

Ref ID #	Author	Year
3057	Tsao	2011

Indicate the appropriate risk of bias rating by placing an 'X' in the shaded space to the right of the rating for each KQ that is applicable. If a study does not apply to a KQ, put an 'X' next to N/A.

Risk of bias for KQ 1:	Low		Medium		High		N/A	
Risk of bias for KQ 2:	Low		Medium		High		N/A	
Risk of bias for KQ 3:	Low	x	Medium		High		N/A	
Risk of bias for KQ 4a:	Low		Medium		High		N/A	
Risk of bias for KQ 4b:	Low		Medium		High		N/A	
Risk of bias for KQ 5:	Low		Medium		High		N/A	
Explain any **High** ratings:								

Low: Study has minimal bias. High degree of confidence that the true effect size is similar in size and direction to that reported.
Medium: Study has at least one significant source of bias, but does not have flaws that are likely to cause major bias. Moderate degree of confidence that the actual effect is in the direction reported by the study; moderate degree of confidence that the true effect size is similar to that reported.
High: Study has at least one major sources of bias or multiple significant sources of bias. Low degree of confidence that the true effect size is similar in size or direction to that reported.
NA: Not applicable to that key question.

Key Questions 1, 3, 4a, 4b, and 5	If the study does NOT apply to any of these KQs, place an 'X' here (___)

KQ 1: Overarching Question
Is there direct evidence that the addition of the following genetic tests used alone or in combination with traditional prognostic factors change physician decision making and improve outcomes for adult patients with lung, breast, colorectal, and bladder cancer compared with the use of traditional factors to predict risk of recurrence for adults with these cancers?

KQ 3. Clinical Validity. Does existing evidence establish the prognostic accuracy of the tests for predicting recurrence?

KQ 4a. Clinical Utility.
What is the evidence that the prognostic information provided by the genetic tests modifies physician decisions regarding use of adjuvant anti-neoplastic chemo- and/or radiotherapy; enhanced diagnostic testing for recurrence; and/or preventive surgery among adult patients with malignant tumors?

KQ 4b. Clinical Utility.
What is the evidence that modified decisions lead to improved overall survival, disease free survival, time to recurrence, quality of life, or incidence of serious side effects of adjuvant therapy in adult patients with malignant tumors?

KQ 5. Harms.
What are the harms associated with treatment decisions that are informed by the genetic tests?

	RCT	**non-RCT**	**Prospective cohort study**	**Retrospective cohort study**	**Case-control study**	**Case Series**
1314. What is the study design?			**x**			
If "Other" study design, enter a description in this box:	**Yes**	**No**	**Partially**	**Can't Determine**	**NA**	**Explanation**
1315. For RCTs, were randomization and allocation concealment adequate?					x	
1316. Did the study apply inclusion/exclusion criteria uniformly to all comparison groups of the study?	x					
1317. Is the selection of the comparison group appropriate, after taking into account feasibility and ethical considerations?	x					
1318. Were groups similar at baseline?		x				Not expected in non-randomized trial
1319. Were the outcome assessors blinded to the test result/intervention/exposure status of participants?		x				Outcome is survival
1320. Were outcomes assessed using valid and reliable measures, implemented consistently across all study participants?	X					
1321. Was overall attrition less than 30%?				X		

1322. Was differential attrition less than 15%?				X		
1323. Does the analysis control for baseline differences between groups?	X					
1324. Does the analysis account for differences in treatment received by the groups?			x			Controls for type of resection, on a clinical trial so distribution of chemo should be similar between groups
1325. Are the statistical methods used to assess the outcomes appropriate?	x					
1326. **For KQ3 ONLY** – Did analyses adjust for all or most of the standard prognostic markers?	x					
Comments:

1348. Was differential attrition less than 15%?				X		
1349. Does the analysis control for baseline				X		

differences between groups?						
1350. Does the analysis account for differences in treatment received by the groups?				X		
1351. Are the statistical methods used to assess the outcomes appropriate?	X					
1352. **For KQ3 ONLY** – Did analyses adjust for all or most of the standard prognostic markers?	X					
Comments: only one paragraph in short article describes multivariate analysis, many details not shown						

Key Question 2					If study does NOT apply to this KQ, place an 'X' here (___)		
KQ 2. Analytic Validity. Does existing evidence establish the technical accuracy and reliability of the tests for detecting the relevant genetic markers?							
	Yes	**No**	**Unclear**	**NA**	**Low**	**High**	**Unclear**
Domain 1: Patient Selection							
Was a consecutive or random sample of patients enrolled?			X				
Was a case-control design avoided?		X					
Did the study avoid inappropriate exclusions?		X					
Could the selection of patients have introduced bias?						X	
Domain 2: Index Test(s)							
Were the index test results interpreted without knowledge of the results of the reference standard?				X			
If a threshold was used, was it pre-specified?		X					
Could the conduct or interpretation of the index test have introduced bias?							X
Domain 3: Reference Standard							
Is the reference standard likely to correctly classify the genetic markers?	X						
Were the reference standard results interpreted without knowledge of the results of the index test?	X						
Could the reference standard, its conduct, or its interpretation have introduced bias?					X		
Domain 4: Flow and Timing							
Did all patients receive a reference standard?	X						
Did patients receive the same reference standard?	X						
Were all patients included in the analysis?	X						
Could the patient flow have introduced bias?					X		
Comments: Reference standard was ascertainment of actual outcome from medical records, test was not compared to another prognostic test. Patients were selected based on whether they had metastases or not case-control) and article does not state whether they were randomly, consecutively or otherwise selected. All patients were <55 years old and reason for this exclusion is not stated.

Worksheet for Risk of Bias of Individual Studies – GTRRC (v. 4-23-13)

Ref ID #	Author	Year
2684	Woo	2009

Indicate the appropriate risk of bias rating by placing an 'X' in the shaded space to the right of the rating for each KQ that is applicable. If a study does not apply to a KQ, put an 'X' next to N/A.

Risk of bias for KQ 1:	Low		Medium		High		N/A	
Risk of bias for KQ 2:	Low		Medium		High		N/A	
Risk of bias for KQ 3:	Low		Medium	X	High		N/A	
Risk of bias for KQ 4a:	Low		Medium		High		N/A	
Risk of bias for KQ 4b:	Low		Medium		High		N/A	
Risk of bias for KQ 5:	Low		Medium		High		N/A	
Explain any **High** ratings:								

Low: Study has minimal bias. High degree of confidence that the true effect size is similar in size and direction to that reported.
Medium: Study has at least one significant source of bias, but does not have flaws that are likely to cause major bias. Moderate degree of confidence that the actual effect is in the direction reported by the study; moderate degree of confidence that the true effect size is similar to that reported.
High: Study has at least one major sources of bias or multiple significant sources of bias. Low degree of confidence that the true effect size is similar in size or direction to that reported.
NA: Not applicable to that key question.

Key Questions 1, 3, 4a, 4b, and 5	If the study does NOT apply to any of these KQs, place an 'X' here (__)
KQ 1: Overarching Question Is there direct evidence that the addition of the following genetic tests used alone or in combination with traditional prognostic factors change physician decision making and improve outcomes for adult patients with lung, breast, colorectal, and bladder cancer compared with the use of traditional factors to predict risk of recurrence for adults with these cancers?	
KQ 3. Clinical Validity. Does existing evidence establish the prognostic accuracy of the tests for predicting recurrence?	
KQ 4a. Clinical Utility. What is the evidence that the prognostic information provided by the genetic tests modifies physician decisions regarding use of adjuvant anti-neoplastic chemo- and/or radiotherapy; enhanced diagnostic testing for recurrence; and/or preventive surgery among adult patients with malignant tumors?	
KQ 4b. Clinical Utility. What is the evidence that modified decisions lead to improved overall survival, disease free survival, time to recurrence, quality of life, or incidence of serious side effects of adjuvant therapy in adult patients with malignant tumors?	
KQ 5. Harms. What are the harms associated with treatment decisions that are informed by the genetic tests?	

	RCT	**non-RCT**	**Prospective cohort study**	**Retrospective cohort study**	**Case-control study**	**Case Series**
1379. What is the study design?			**X**			
If "Other" study design, enter a description in this box: Uncontrolled trial	**Yes**	**No**	**Partially**	**Can't Determine**	**NA**	**Explanation**
1380. For RCTs, were randomization and allocation concealment adequate?					X	
1381. Did the study apply inclusion/exclusion criteria uniformly to all comparison groups of the study?	X					
1382. Is the selection of the comparison group appropriate, after taking into account feasibility and ethical considerations?	X					
1383. Were groups similar at baseline?		X				
1384. Were the outcome assessors blinded to the test result/intervention/exposure status of participants?				X		
1385. Were outcomes assessed using valid and reliable measures, implemented consistently across all study participants?	X					
1386. Was overall attrition less than 30%?				X		
1387. Was differential attrition less than 15%?				X		

1388. Does the analysis control for baseline differences between groups?		X				
1389. Does the analysis account for differences in treatment received by the groups?					X	
1390. Are the statistical methods used to assess the outcomes appropriate?	X					
1391. **For KQ3 ONLY** – Did analyses adjust for all or most of the standard prognostic markers?	X					
Comments:						

Key Question 2	If study does NOT apply to this KQ, place an 'X' here (___)						
KQ 2. Analytic Validity. Does existing evidence establish the technical accuracy and reliability of the tests for detecting the relevant genetic markers?							
	Yes	**No**	**Unclear**	**NA**	**Low**	**High**	**Unclear**
Domain 1: Patient Selection							
Was a consecutive or random sample of patients enrolled?							
Was a case-control design avoided?							
Did the study avoid inappropriate exclusions?							
Could the selection of patients have introduced bias?							
Domain 2: Index Test(s)							
Were the index test results interpreted without knowledge of the results of the reference standard?							
If a threshold was used, was it pre-specified?							
Could the conduct or interpretation of the index test have introduced bias?							
Domain 3: Reference Standard							
Is the reference standard likely to correctly classify the genetic markers?							
Were the reference standard results interpreted without knowledge of the results of the index test?							
Could the reference standard, its conduct, or its interpretation have introduced bias?							
Domain 4: Flow and Timing							
Did all patients receive a reference standard?							
Did patients receive the same reference standard?							
Were all patients included in the analysis?							
Could the patient flow have introduced bias?							
Comments:							

Worksheet for Risk of Bias of Individual Studies – GTRRC (v. 4-23-13)

Ref ID #	Author	Year
4004	Yamauchi	2013

Indicate the appropriate risk of bias rating by placing an 'X' in the shaded space to the right of the rating for each KQ that is applicable. If a study does not apply to a KQ, put an 'X' next to N/A.

Risk of bias for KQ 1:	Low		Medium		High		N/A	X
Risk of bias for KQ 2:	Low		Medium		High		N/A	X
Risk of bias for KQ 3:	Low		Medium		High		N/A	X
Risk of bias for KQ 4a:	Low		Medium	X	High		N/A	
Risk of bias for KQ 4b:	Low		Medium		High		N/A	X
Risk of bias for KQ 5:	Low		Medium		High		N/A	X
Explain any **High** ratings:								

Low: Study has minimal bias. High degree of confidence that the true effect size is similar in size and direction to that reported.
Medium: Study has at least one significant source of bias, but does not have flaws that are likely to cause major bias. Moderate degree of confidence that the actual effect is in the direction reported by the study; moderate degree of confidence that the true effect size is similar to that reported.
High: Study has at least one major sources of bias or multiple significant sources of bias. Low degree of confidence that the true effect size is similar in size or direction to that reported.
NA: Not applicable to that key question.

Key Questions 1, 3, 4a, 4b, and 5	If the study does NOT apply to any of these KQs, place an 'X' here (___)
KQ 1: Overarching Question Is there direct evidence that the addition of the following genetic tests used alone or in combination with traditional prognostic factors change physician decision making and improve outcomes for adult patients with lung, breast, colorectal, and bladder cancer compared with the use of traditional factors to predict risk of recurrence for adults with these cancers?	
KQ 3. Clinical Validity. Does existing evidence establish the prognostic accuracy of the tests for predicting recurrence?	
KQ 4a. Clinical Utility. What is the evidence that the prognostic information provided by the genetic tests modifies physician decisions regarding use of adjuvant anti-neoplastic chemo- and/or radiotherapy; enhanced diagnostic testing for recurrence; and/or preventive surgery among adult patients with malignant tumors?	
KQ 4b. Clinical Utility. What is the evidence that modified decisions lead to improved overall survival, disease free survival, time to recurrence, quality of life, or incidence of serious side effects of adjuvant therapy in adult patients with malignant tumors?	
KQ 5. Harms. What are the harms associated with treatment decisions that are informed by the genetic tests?	

	RCT	**non-RCT**	**Prospective cohort study**	**Retrospective cohort study**	**Case-control study**	**Case Series**
1392. What is the study design?			**X**			
If "Other" study design, enter a description in this box:	**Yes**	**No**	**Partially**	**Can't Determine**	**NA**	**Explanation**
1393. For RCTs, were randomization and allocation concealment adequate?					X	
1394. Did the study apply inclusion/exclusion criteria uniformly to all comparison groups of the study?	X					Consecutive sample was offered entry, To participate in the study, patients were required to incur the costs of the assay as an out-of-pocket expense
1395. Is the selection of the comparison group appropriate, after taking into account feasibility and ethical considerations?	X					
1396. Were groups similar at baseline?				X		Not reported by test result
1397. Were the outcome assessors blinded to				X		But, not as important as

the test result/intervention/exposure status of participants?						some studies since the outcome is the questionnaire result
1398. Were outcomes assessed using valid and reliable measures, implemented consistently across all study participants?				X		Modified a published questionnaire; no information provided on the validity and reliability
1399. Was overall attrition less than 30%?	X					
1400. Was differential attrition less than 15%?	X					
1401. Does the analysis control for baseline differences between groups?		X				
1402. Does the analysis account for differences in treatment received by the groups?					X	
1403. Are the statistical methods used to assess the outcomes appropriate?			X			Some concern for stopping enrollment early, and their justification for doing so. See comments below
1404. **For KQ3 ONLY** – Did analyses adjust for all or most of the standard prognostic markers?					X	
Comments: The study was designed to enroll 200 patients, with the original intent to estimate a decision change rate of 20% with a precision of `5% to 6%. However, it was decided to halt enrollment after 124 patients were enrolled because the accumulating data indicated that there were statistically significant reductions in treatment recommendations for chemotherapy in N0 and Nþ patient subgroups.						

Key Question 2	If study does NOT apply to this KQ, place an 'X' here (_X_)						
KQ 2. Analytic Validity. Does existing evidence establish the technical accuracy and reliability of the tests for detecting the relevant genetic markers?							
	Yes	**No**	**Unclear**	**NA**	**Low**	**High**	**Unclear**
Domain 1: Patient Selection							
Was a consecutive or random sample of patients enrolled?							
Was a case-control design avoided?							
Did the study avoid inappropriate exclusions?							
Could the selection of patients have introduced bias?							
Domain 2: Index Test(s)							
Were the index test results interpreted without knowledge of the results of the reference standard?							
If a threshold was used, was it pre-specified?							
Could the conduct or interpretation of the index test have introduced bias?							
Domain 3: Reference Standard							
Is the reference standard likely to correctly classify the genetic markers?							
Were the reference standard results interpreted without knowledge of the results of the index test?							
Could the reference standard, its conduct, or its interpretation have							

introduced bias?							
Domain 4: Flow and Timing							
Did all patients receive a reference standard?							
Did patients receive the same reference standard?							
Were all patients included in the analysis?							
Could the patient flow have introduced bias?							
Comments:							

Worksheet for Risk of Bias of Individual Studies – GTRRC (v. 4-23-13)

Ref ID #	Author	Year
1516	Yoon	2011

Indicate the appropriate risk of bias rating by placing an 'X' in the shaded space to the right of the rating for each KQ that is applicable. If a study does not apply to a KQ, put an 'X' next to N/A.

Risk of bias for KQ 1:	Low		Medium		High		N/A	X
Risk of bias for KQ 2:	Low		Medium		High		N/A	X
Risk of bias for KQ 3:	Low	X	Medium		High		N/A	
Risk of bias for KQ 4a:	Low		Medium		High		N/A	X
Risk of bias for KQ 4b:	Low		Medium		High		N/A	X
Risk of bias for KQ 5:	Low		Medium		High		N/A	X
Explain any **High** ratings:								

Low: Study has minimal bias. High degree of confidence that the true effect size is similar in size and direction to that reported.
Medium: Study has at least one significant source of bias, but does not have flaws that are likely to cause major bias. Moderate degree of confidence that the actual effect is in the direction reported by the study; moderate degree of confidence that the true effect size is similar to that reported.
High: Study has at least one major sources of bias or multiple significant sources of bias. Low degree of confidence that the true effect size is similar in size or direction to that reported.
NA: Not applicable to that key question.

Key Questions 1, 3, 4a, 4b, and 5	If the study does NOT apply to any of these KQs, place an 'X' here (___)

KQ 1: Overarching Question
Is there direct evidence that the addition of the following genetic tests used alone or in combination with traditional prognostic factors change physician decision making and improve outcomes for adult patients with lung, breast, colorectal, and bladder cancer compared with the use of traditional factors to predict risk of recurrence for adults with these cancers?

KQ 3. Clinical Validity. Does existing evidence establish the prognostic accuracy of the tests for predicting recurrence?

KQ 4a. Clinical Utility.
What is the evidence that the prognostic information provided by the genetic tests modifies physician decisions regarding use of adjuvant anti-neoplastic chemo- and/or radiotherapy; enhanced diagnostic testing for recurrence; and/or preventive surgery among adult patients with malignant tumors?

KQ 4b. Clinical Utility.
What is the evidence that modified decisions lead to improved overall survival, disease free survival, time to recurrence, quality of life, or incidence of serious side effects of adjuvant therapy in adult patients with malignant tumors?

KQ 5. Harms.
What are the harms associated with treatment decisions that are informed by the genetic tests?

	RCT	**non-RCT**	**Prospective cohort study**	**Retrospective cohort study**	**Case-control study**	**Case Series**
1405. What is the study design?			**X**			
If "Other" study design, enter a description in this box:	**Yes**	**No**	**Partially**	**Can't Determine**	**NA**	**Explanation**
1406. For RCTs, were randomization and allocation concealment adequate?					X	
1407. Did the study apply inclusion/exclusion criteria uniformly to all comparison groups of the study?	X					
1408. Is the selection of the comparison group appropriate, after taking into account feasibility and ethical considerations?	X					
1409. Were groups similar at baseline?		X				Differences for age, site, size, LN metastases, histology and synchronous adenomas
1410. Were the outcome assessors blinded to the test result/intervention/exposure status of participants?				X		
1411. Were outcomes assessed using valid and	X					

reliable measures, implemented consistently across all study participants?						
1412. Was overall attrition less than 30%?	X					
1413. Was differential attrition less than 15%?	X					
1414. Does the analysis control for baseline differences between groups?	X					
1415. Does the analysis account for differences in treatment received by the groups?			X			Accounts for differences in adjuvant chemo, but not differences in radiation (among the 770 with rectal cancer, 41% got postop radiation); however, not too concerning because 97% of the rectal cancer cases were MSS and analyses found MSI-H to have better outcomes
1416. Are the statistical methods used to assess the outcomes appropriate?	X					
1417. **For KQ3 ONLY** – Did analyses adjust for all or most of the standard prognostic markers?	X					Table 3
Comments: age, sex, location, CEA, growth type, LN metastasis, distant metastasis, lymphovascular invasion, histology, and adjuvant chemotherapy included in the multivariate analysis in Table 3 for DFS and OS.						

Key Question 2	If study does NOT apply to this KQ, place an 'X' here (_X_)						
KQ 2. Analytic Validity. Does existing evidence establish the technical accuracy and reliability of the tests for detecting the relevant genetic markers?							
	Yes	**No**	**Unclear**	**NA**	**Low**	**High**	**Unclear**
Domain 1: Patient Selection							
Was a consecutive or random sample of patients enrolled?							
Was a case-control design avoided?							
Did the study avoid inappropriate exclusions?							
Could the selection of patients have introduced bias?

Worksheet for Risk of Bias of Individual Studies – GTRRC (v. 4-23-13)

Ref ID #	Author	Year
67	Zellweger	2006

Indicate the appropriate risk of bias rating by placing an 'X' in the shaded space to the right of the rating for each KQ that is applicable. If a study does not apply to a KQ, put an 'X' next to N/A.

Risk of bias for KQ 1:	Low		Medium		High		N/A	X
Risk of bias for KQ 2:	Low		Medium		High		N/A	X
Risk of bias for KQ 3:	Low		Medium		High	X	N/A	
Risk of bias for KQ 4a:	Low		Medium		High		N/A	X
Risk of bias for KQ 4b:	Low		Medium		High		N/A	X
Risk of bias for KQ 5:	Low		Medium		High		N/A	X
Explain any **High** ratings:	See comments below in comments box							

Low: Study has minimal bias. High degree of confidence that the true effect size is similar in size and direction to that reported.
Medium: Study has at least one significant source of bias, but does not have flaws that are likely to cause major bias. Moderate degree of confidence that the actual effect is in the direction reported by the study; moderate degree of confidence that the true effect size is similar to that reported.
High: Study has at least one major sources of bias or multiple significant sources of bias. Low degree of confidence that the true effect size is similar in size or direction to that reported.
NA: Not applicable to that key question.

Key Questions 1, 3, 4a, 4b, and 5	If the study does NOT apply to any of these KQs, place an 'X' here (___)

KQ 1: Overarching Question
Is there direct evidence that the addition of the following genetic tests used alone or in combination with traditional prognostic factors change physician decision making and improve outcomes for adult patients with lung, breast, colorectal, and bladder cancer compared with the use of traditional factors to predict risk of recurrence for adults with these cancers?

KQ 3. Clinical Validity. Does existing evidence establish the prognostic accuracy of the tests for predicting recurrence?

KQ 4a. Clinical Utility.
What is the evidence that the prognostic information provided by the genetic tests modifies physician decisions regarding use of adjuvant anti-neoplastic chemo- and/or radiotherapy; enhanced diagnostic testing for recurrence; and/or preventive surgery among adult patients with malignant tumors?

KQ 4b. Clinical Utility.
What is the evidence that modified decisions lead to improved overall survival, disease free survival, time to recurrence, quality of life, or incidence of serious side effects of adjuvant therapy in adult patients with malignant tumors?

KQ 5. Harms.
What are the harms associated with treatment decisions that are informed by the genetic tests?

	RCT	**non-RCT**	**Prospective cohort study**	**Retrospective cohort study**	**Case-control study**	**Case Series**
1431. What is the study design?			**X**			
If "Other" study design, enter a description in this box:	**Yes**	**No**	**Partially**	**Can't Determine**	**NA**	**Explanation**
1432. For RCTs, were randomization and allocation concealment adequate?					X	
1433. Did the study apply inclusion/exclusion criteria uniformly to all comparison groups of the study?				X		
1434. Is the selection of the comparison group appropriate, after taking into account feasibility and ethical considerations?	X					
1435. Were groups similar at baseline?				X		
1436. Were the outcome assessors blinded to the test result/intervention/exposure status of participants?		X				
1437. Were outcomes assessed using valid and reliable measures, implemented consistently across all study participants?				X		
1438. Was overall attrition less than 30%?				X		
1439. Was differential attrition less than 15%?				X		
1440. Does the analysis control for baseline				X		

differences between groups?						
1441. Does the analysis account for differences in treatment received by the groups?		X				
1442. Are the statistical methods used to assess the outcomes appropriate?			X			
1443. **For KQ3 ONLY** – Did analyses adjust for all or most of the standard prognostic markers?				X		

Comments: High risk of selection bias as the article does not report inclusion/exclusion criteria, method of selecting the 138 subjects (e.g. was it consecutive? Random? Other?), or comparison of groups at baseline. There is no information provided that allows us to determine how similar/different the FISH + vs. FISH – groups were at baseline. Also, no information about attrition provided: of the 138, median follow up was 19 months (range 4 - 52), but no data reported about how many were lost early in the study and whether it was differential for the FISH + vs. FISH – groups. High risk of measurement bias as they don't give any information about how recurrence was determined and they don't describe any masking of outcome assessors. Although it's hard to assess their multivariate analysis because they don't report what they adjusted for in the Cox model, I would probably consider the analysis to have a high risk of confounding because they don't describe adjustment for known prognostic factors (e.g., stage, presence of CIS). In addition, since we don't have information on how demographics or potential confounders were distributed at baseline, we can't even assess what else they should have adjusted for.

Key Question 2	If study does NOT apply to this KQ, place an 'X' here (_X_)						
KQ 2. Analytic Validity. Does existing evidence establish the technical accuracy and reliability of the tests for detecting the relevant genetic markers?							
	Yes	**No**	**Unclear**	**NA**	**Low**	**High**	**Unclear**
Domain 1: Patient Selection							
Was a consecutive or random sample of patients enrolled?							
Was a case-control design avoided?							
Did the study avoid inappropriate exclusions?							
Could the selection of patients have introduced bias?							
Domain 2: Index Test(s)							
Were the index test results interpreted without knowledge of the results of the reference standard?							
If a threshold was used, was it pre-specified?							
Could the conduct or interpretation of the index test have introduced bias?							
Domain 3: Reference Standard							
Is the reference standard likely to correctly classify the genetic markers?							
Were the reference standard results interpreted without knowledge of the results of the index test?							
Could the reference standard, its conduct, or its interpretation have introduced bias?

Worksheet for Risk of Bias of Individual Studies – GTRRC (v. 4-23-13)

Ref ID #	Author	Year
1533	Zlobec	2009

Indicate the appropriate risk of bias rating by placing an 'X' in the shaded space to the right of the rating for each KQ that is applicable. If a study does not apply to a KQ, put an 'X' next to N/A.

Risk of bias for KQ 1:	Low		Medium		High		N/A	X
Risk of bias for KQ 2:	Low		Medium		High		N/A	X
Risk of bias for KQ 3:	Low		Medium	X	High		N/A	
Risk of bias for KQ 4a:	Low		Medium		High		N/A	X
Risk of bias for KQ 4b:	Low		Medium		High		N/A	X
Risk of bias for KQ 5:	Low		Medium		High		N/A	X
Explain any **High** ratings:								

Low: Study has minimal bias. High degree of confidence that the true effect size is similar in size and direction to that reported.
Medium: Study has at least one significant source of bias, but does not have flaws that are likely to cause major bias. Moderate degree of confidence that the actual effect is in the direction reported by the study; moderate degree of confidence that the true effect size is similar to that reported.
High: Study has at least one major sources of bias or multiple significant sources of bias. Low degree of confidence that the true effect size is similar in size or direction to that reported.
NA: Not applicable to that key question.

Key Questions 1, 3, 4a, 4b, and 5	If the study does NOT apply to any of these KQs, place an 'X' here (___)

KQ 1: Overarching Question
Is there direct evidence that the addition of the following genetic tests used alone or in combination with traditional prognostic factors change physician decision making and improve outcomes for adult patients with lung, breast, colorectal, and bladder cancer compared with the use of traditional factors to predict risk of recurrence for adults with these cancers?

KQ 3. Clinical Validity. Does existing evidence establish the prognostic accuracy of the tests for predicting recurrence?

KQ 4a. Clinical Utility.
What is the evidence that the prognostic information provided by the genetic tests modifies physician decisions regarding use of adjuvant anti-neoplastic chemo- and/or radiotherapy; enhanced diagnostic testing for recurrence; and/or preventive surgery among adult patients with malignant tumors?

KQ 4b. Clinical Utility.
What is the evidence that modified decisions lead to improved overall survival, disease free survival, time to recurrence, quality of life, or incidence of serious side effects of adjuvant therapy in adult patients with malignant tumors?

KQ 5. Harms.
What are the harms associated with treatment decisions that are informed by the genetic tests?

	RCT	**non-RCT**	**Prospective cohort study**	**Retrospective cohort study**	**Case-control study**	**Case Series**
1444. What is the study design?				**X**		
If "Other" study design, enter a description in this box:	**Yes**	**No**	**Partially**	**Can't Determine**	**NA**	**Explanation**
1445. For RCTs, were randomization and allocation concealment adequate?					X	
1446. Did the study apply inclusion/exclusion criteria uniformly to all comparison groups of the study?	X					
1447. Is the selection of the comparison group appropriate, after taking into account feasibility and ethical considerations?	X					
1448. Were groups similar at baseline?		X				
1449. Were the outcome assessors blinded to the test result/intervention/exposure status of participants?	X					
1450. Were outcomes assessed using valid and reliable measures, implemented consistently across all study participants?	X					
1451. Was overall attrition less than 30%?	X					
1452. Was differential attrition less than 15%?	X					
1453. Does the analysis control for baseline	X					

differences between groups?						
1454. Does the analysis account for differences in treatment received by the groups?		X				Tissues were from pre-operatively untreated patients. No information about treatment
1455. Are the statistical methods used to assess the outcomes appropriate?	X					
1456. **For KQ3 ONLY** – Did analyses adjust for all or most of the standard prognostic markers?	X					
Comments: Treatment & Distant metastasis information not available. Both factors affect CSS.						

Key Question 2	If study does NOT apply to this KQ, place an 'X' here (___)						
KQ 2. Analytic Validity. Does existing evidence establish the technical accuracy and reliability of the tests for detecting the relevant genetic markers?							
	Yes	**No**	**Unclear**	**NA**	**Low**	**High**	**Unclear**
Domain 1: Patient Selection							
Was a consecutive or random sample of patients enrolled?							
Was a case-control design avoided?							
Did the study avoid inappropriate exclusions?							
Could the selection of patients have introduced bias?							
Domain 2: Index Test(s)							
Were the index test results interpreted without knowledge of the results of the reference standard?							
If a threshold was used, was it pre-specified?							
Could the conduct or interpretation of the index test have introduced bias?							
Domain 3: Reference Standard							
Is the reference standard likely to correctly classify the genetic markers?							
Were the reference standard results interpreted without knowledge of the results of the index test?							
Could the reference standard, its conduct, or its interpretation have introduced bias?							
Domain 4: Flow and Timing							
Did all patients receive a reference standard?							
Did patients receive the same reference standard?							
Were all patients included in the analysis?							
Could the patient flow have introduced bias?							
Comments:							

Appendix D. Strength of Evidence (SOE)

Table D-1. EGFR for lung carcinoma

Outcome	Study Design: No. Studies (N)	Risk of Bias	Directness	Consistency	Precision	Other	Result/ Effect Size (CI)	Strength of Evidence
Risk of Recurrence	Cohort: 6 (1,870)	Medium	Indirect	Consistent	Imprecise	None	0.87(0.65,1.15) No Association[a]	Low
Cancer-specific mortality	None	NA	NA	NA	NA	NA	NA	NA

1 Recommendations

1.1 Oncotype DX is recommended as an option for guiding adjuvant chemotherapy decisions for people with oestrogen receptor positive (ER+), lymph node negative (LN−) and human epidermal growth factor receptor 2 negative (HER2−) early breast cancer if:

- the person is assessed as being at intermediate risk **and**
- information on the biological features of the cancer provided by Oncotype DX is likely to help in predicting the course of the disease and would therefore help when making the decision about prescribing chemotherapy **and**
- the manufacturer provides Oncotype DX to NHS organisations according to the confidential arrangement agreed with NICE.

1.2 NICE encourages further data collection on the use of Oncotype DX in the NHS (see section 7).

1.3 MammaPrint, IHC4 and Mammostrat are only recommended for use in research in people with ER+, LN− and HER2− early breast cancer, to collect evidence about potentially important clinical outcomes and to determine the ability of the tests to predict the benefit of chemotherapy (see section 7). The tests are not recommended for general use in these people because of uncertainty about their overall clinical benefit and consequently their cost effectiveness.

> The analysis leading to recommendation 1.1 was based on intermediate risk of distant recurrence being defined as a Nottingham Prognostic Index (NPI) score above 3.4. It is anticipated that an NPI score can be simply calculated from information that is routinely collected about people with breast cancer. Other decision-making tools or protocols are also currently used in the NHS and these may also be used to identify people at intermediate risk.

© NICE 2013. All rights reserved. Last modified September 2013

2 The technologies

2.1 Four tests available to the NHS were evaluated. Two are based on gene expression profiling: MammaPrint (Agendia) and Oncotype DX (Genomic Health). Two are based on immunohistochemistry (also known as protein expression profiling): IHC4 (academic sponsor – Royal Marsden Hospital and Queen Mary University, London) and Mammostrat (Clarient). These tests measure multiple markers within the tumour that may indicate how the tumour is likely to develop. Additional details are provided in section 4.

© NICE 2013. All rights reserved. Last modified September 2013

3 Clinical need and practice

The problem addressed

3.1 Gene expression profiling and immunohistochemistry tests aim to improve the targeting of chemotherapy in breast cancer by more accurately identifying patients who will gain the most benefit. This rationale is based on the knowledge that certain biological features of cancers may indicate an increased likelihood of rapid growth and metastasis (in particular, distant recurrence). Distant recurrence is the return of detectable cancer in another part of the body. The tests may also identify, in some instances, which patients are most likely to benefit from chemotherapy. Some tools or tests provide mainly prognostic information (such as the Nottingham Prognostic Index [NPI] and Adjuvant! Online). Others may or may not be able to predict the extent to which the patient could benefit from chemotherapy (such as Oncotype DX, MammaPrint, Mammostrat and IHC4). Breast cancer patients face significant emotional and psychological strain when considering chemotherapy. It can be particularly distressing for patients in whom the decision to have chemotherapy is unclear using currently available tools (especially for people with an intermediate risk of distant recurrence). Tools or tests that help people decide whether or not to have chemotherapy are likely to be greatly appreciated by patients. The aim of this evaluation is to determine whether using gene expression profiling and expanded immunohistochemistry tests (MammaPrint, Oncotype DX, IHC4 and Mammostrat), in conjunction with current decision-making protocols (including tools such as the NPI and Adjuvant! Online) to guide the use of adjuvant chemotherapy, cost-effectively improves health outcomes and quality of life of people with early stage breast cancer, compared with current decision-making protocols alone.

The condition

Epidemiology and incidence

3.2 Breast cancer is the most commonly diagnosed cancer in women in England and Wales, but it can affect both men and women. In 2010 there were approximately 49,600 new cases in women and 400 in men. For both sexes,

© NICE 2013. All rights reserved. Last modified September 2013

incidence varies with age. Just over 80% of cases occur in women aged 50 years and over. In England and Wales, 2006–2008 data demonstrate highest incidence rates for women in the 60- to 70-year age range.

3.3 Incidence also varies with family origin. In England, people of Asian, Chinese and black family origin and those with mixed heritage have a lower incidence than those of white family origin. Incidences are 0.65, 0.75, 0.49 and 0.58 that of those of white family origin respectively.

3.4 Breast cancer is the second largest cause of cancer-related death in women after lung cancer, with an age-standardised mortality rate of 24 per 100,000 women. In 2010 this constituted 10,328 deaths for women in England and Wales.

Prognosis

3.5 Overall, 5-year age-standardised survival rates for breast cancer are around 80%. Breast cancer survival rates have improved over the last 2 decades and now almost 2 out of 3 women with breast cancer survive beyond 20 years. Survival varies with age, stage of disease, family origin, socioeconomic status and tumour characteristics.

3.6 Clinicians currently estimate prognosis using tools such as the NPI (see section 4.10) or Adjuvant! Online (see section 4.11). The NPI takes into account grade as well as size and spread of the tumour, whereas Adjuvant! Online uses age of the patient, tumour size, nodal involvement, hormonal receptor status, histological grade and comorbidities to predict disease course and treatment options. Better prognosis is associated with small tumour size, younger age, lymph node negative (LN−), oestrogen receptor positive (ER+) and progesterone receptor positive (PR+) status. Human epidermal growth factor receptor 2 (HER2) over-expression (also known as HER2+) is associated with a poor prognosis. A tool called PREDICT, which is based on cancer registry data for women treated in England (East Anglia) and includes HER2 and Ki-67 status, has recently become available to the NHS.

3.7 Some patients considered to have a 'good' prognosis using current tools may still have recurrence after curative surgery and adjuvant therapy. Some

© NICE 2013. All rights reserved. Last modified September 2013

patients considered to have a 'poor' prognosis may never develop metastatic disease. It is therefore challenging to decide whether to treat early stage breast cancer with adjuvant chemotherapy.

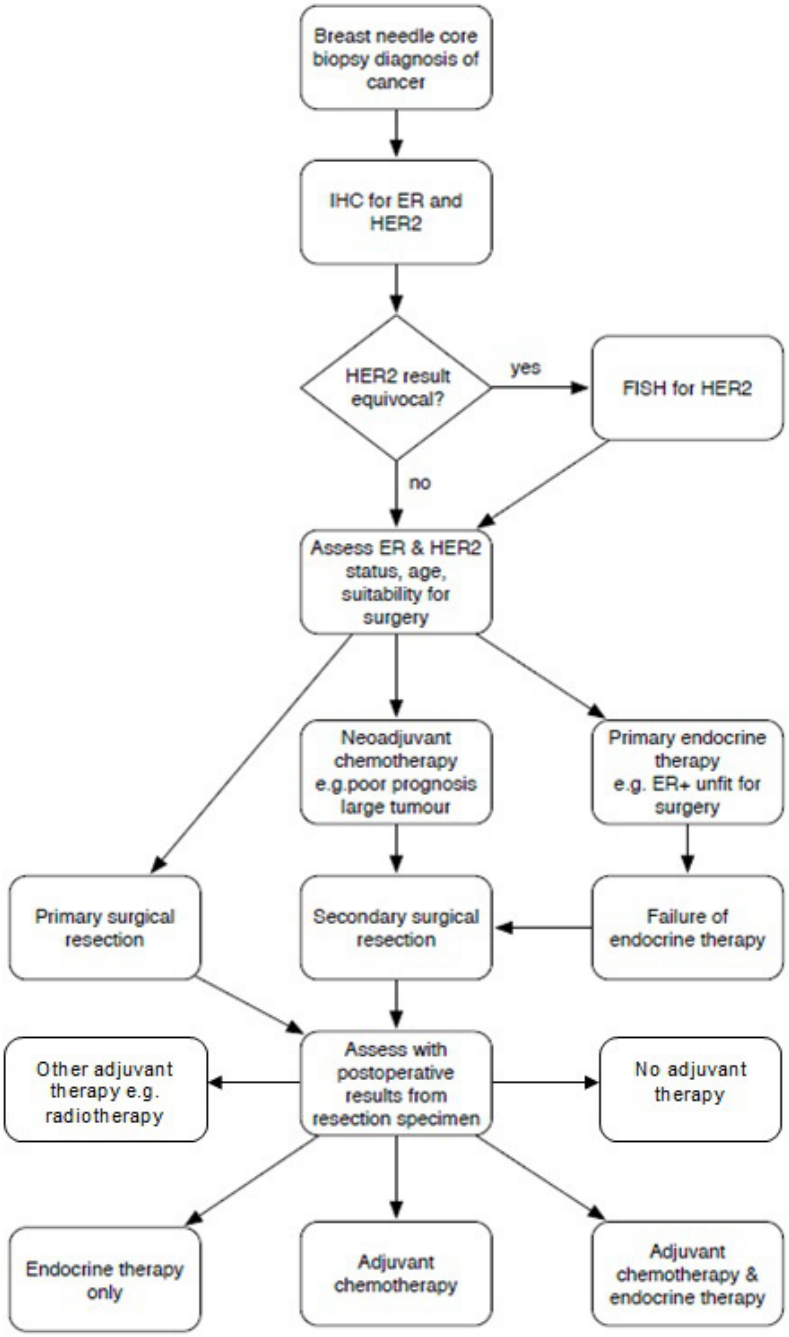
3.8 The decision whether to offer adjuvant chemotherapy is uncertain in people with ER+, LN− and HER2− early breast cancer. The External Assessment Group and clinical specialists who were consulted advised that the tests being evaluated would most likely be of benefit to the NHS in this patient group. Moreover, the evidence base was most robust for this population. Therefore the economic analysis for this evaluation focused on people with ER+, LN− and HER2− early breast cancer.

The diagnostic and care pathways

3.9 Patients diagnosed with early breast cancer currently follow the diagnosis/ treatment pathway described in figure 1.

© NICE 2013. All rights reserved. Last modified September 2013

Figure 1 Diagnosis and management pathway in breast cancer



FISH: fluorescence in situ hybridisation

3.10 For the purposes of this assessment, chemotherapy is defined as the use of cytotoxic drugs with the intention of preventing cancer recurrence and does not include other forms of systemic therapy such as endocrine treatments or

© NICE 2013. All rights reserved. Last modified September 2013

targeted biological therapy. Generally, chemotherapy regimens containing anthracyclines are used after cancer surgery (in the adjuvant setting).

Current guidelines

3.11 NICE cancer service guidance Improving outcomes in breast cancer recommends that women at intermediate or high risk of recurrence who have not had neoadjuvant chemotherapy should normally be offered multi-agent chemotherapy, which includes anthracyclines.

3.12 Early and locally advanced breast cancer: diagnosis and treatment (NICE clinical guideline 80) recommends that adjuvant therapy should be considered for all patients with early invasive breast cancer after surgery, based on assessment of the prognostic and predictive factors, and the potential benefits and side effects of the treatment. These guidelines do not refer to the use of gene expression profiling and expanded immunohistochemistry tests to aid decision making. NICE clinical guideline 80 recommends that decisions should be made following discussion of these predictive and prognostic factors with the patient and that Adjuvant! Online should be considered to support estimations of individual prognosis and the absolute benefit of adjuvant treatment. The NPI is also commonly used locally to aid decisions about chemotherapy for patients with early stage breast cancer and is discussed in NICE clinical guideline 80.

3.13 In the UK, local guidance based on the NPI and Adjuvant! Online has been developed to help clinicians decide about the benefits of adjuvant chemotherapy for a particular patient. However, it has been suggested that these tools may be imperfect and different local approaches to the use and interpretation of these tools leads to a proportion of people with early stage breast cancer being over- or under-treated. This may result in unnecessary use of expensive chemotherapy with its associated adverse effects for people who derive little or no benefit. In addition, there may be avoidable deaths in people who would have benefitted from chemotherapy had it been offered.

© NICE 2013. All rights reserved. Last modified September 2013

4 The diagnostic tests

The individual tests: MammaPrint, Oncotype DX, IHC4, Mammostrat

4.1 Gene expression profiling and immunohistochemistry tests typically report 1 or 2 types of information – breast cancer subtype and risk of recurrence. Tests developed to provide information on subtypes can be used either before surgery to inform decisions on neoadjuvant therapy or after primary surgery (for removal of the tumour, which may also be used for further assessment of the tumour characteristics) to inform decisions on adjuvant chemotherapy (see figure 1). Tests predicting the risk of recurrence in a specific population are typically used after surgery, in conjunction with other information such as tumour size and grade, to guide the use of adjuvant chemotherapy. Such tests are typically indicated for women with oestrogen receptor positive (ER+) and lymph node negative (LN−) (and sometimes LN+ if the number of nodes is small) breast cancer in whom there is significant uncertainty about the value of chemotherapy. The current evaluation addresses the use of MammaPrint, Oncotype DX, IHC4 and Mammostrat after primary surgery to inform decisions on the use of adjuvant chemotherapy.

4.2 Three tests (MammaPrint, Oncotype DX and Mammostrat) require that samples are sent to a central laboratory for processing following surgery, with an estimated shipping and processing time of up to 7–10 days. IHC4 is processed in a local laboratory with estimated turnaround times of less than 1 week.

Gene expression profiling

4.3 Some gene expression profiling tests work by identifying and quantifying mRNA transcripts in a specific tissue sample. Because only a fraction of the genes encoded in the genome of a cell are transcribed into mRNA, gene expression profiling provides information about the activity of genes that give rise to these mRNA transcripts. Other gene expression profiling tests work by measuring levels of cDNA, which is synthesised from mRNA. There are a

© NICE 2013. All rights reserved. Last modified September 2013

range of different techniques for measuring mRNA levels in breast cancer tumour samples, including real-time reverse transcription polymerase chain reaction (RT-PCR) and DNA microarrays.

4.4 Different tests use different protocols for preparing the samples (for example, formalin fixation, paraffin embedding, snap freezing and fresh samples) and different methods for preparing the RNA. Furthermore, there are different algorithms for combining the raw data into a summary profile. All of these factors can affect the reproducibility and reliability of gene expression profiling tests.

4.5 The 2 gene expression profiling tests included in this evaluation are described below:

- MammaPrint is based on microarray technology and uses an expression profile of 70 genes. MammaPrint is intended as a prognostic test for women of all ages, with LN− and LN+ (up to 3 nodes positive) breast cancer with a tumour size of 5 cm or less. MammaPrint is used to estimate the risk of distant recurrence of early breast cancer. It stratifies patients into 2 distinct groups – low risk (good prognosis) or high risk (poor prognosis) of distant recurrence. MammaPrint has been cleared by the Food and Drug Administration as an In Vitro Diagnostic Multivariate Index Assay. The test uses fresh or formalin-fixed paraffin-embedded samples that are processed centrally at laboratories run by the manufacturer in the USA or The Netherlands.
- Oncotype DX quantifies the expression of 21 genes in breast cancer tissue by RT-PCR. It predicts the likelihood of recurrence in women of all ages with newly diagnosed stage I or II, ER+, LN− or LN+ (up to 3 nodes positive) breast cancer treated with tamoxifen. The test assigns the breast cancer a continuous recurrence score (RS) and a risk category – low (RS<18), intermediate (18≤RS≤30) or high (RS≥31). The test also reports ER, progesterone receptor (PR) and human epidermal growth factor receptor 2 (HER2) status. The test uses formalin-fixed paraffin-embedded samples that are processed centrally at a laboratory run by the manufacturer in the USA.

© NICE 2013. All rights reserved. Last modified September 2013

Immunohistochemistry (protein expression profiling)

4.6 Immunohistochemistry tests measure protein levels in the tumour sample rather than RNA or cDNA. Some of these tests offer the advantage of using existing immunohistochemical markers (such as ER and HER2), which are routinely tested in UK pathology departments. The term 'expanded' has been used to describe the immunohistochemistry tests evaluated in this assessment that are used in addition to standard immunohistochemistry testing (such as ER and HER2) for early invasive breast cancer. Immunohistochemistry uses staining to identify protein expression and reports the level of protein expression in tumour tissue. Differences in immunohistochemistry values can be caused by variability in several factors, including fixation of tissue, antigen retrieval (used to enhance staining), reagents, and interpretation.

4.7 The expanded immunohistochemistry tests included in this evaluation are described below:

- IHC4 measures the levels of 4 key proteins (ER, PR, HER2 and Ki-67) in addition to classical clinical and pathological variables (for example, age, nodal status, tumour size and grade) and calculates a risk score for distant recurrence using an algorithm. Quantitative assessments of ER, PR, and Ki-67 are needed for the IHC4 test. An online calculator for IHC4 is in development. The test uses formalin-fixed paraffin-embedded samples that can be processed in local NHS laboratories.
- Mammostrat uses 5 immunohistochemical markers (SLC7A5, HTF9C, P53, NDRG1 and CEACAM5) to stratify patients into risk groups to inform treatment decisions. These markers are independent of one another and do not directly measure either proliferation or hormone receptor status. The test calculates the relative risk of recurrence by using a weighted algorithm that is interpreted in the context of published clinical studies of appropriate patient populations. Patients are classified into 3 risk categories: prognostic index ≤0 defined as the 'low risk' group; prognostic index >0 and ≤0.7 defined as the 'moderate-risk' group; prognostic index >0.7 defined as the 'high risk' group. The test uses formalin-fixed paraffin-embedded samples that are processed centrally at a laboratory run by the manufacturer in the USA.

© NICE 2013. All rights reserved. Last modified September 2013

The comparator

4.8 The comparator is standard practice in England. Although this varies between hospitals, Adjuvant! Online and/or the Nottingham Prognostic Index (NPI) are often used to guide decisions on which patients with early breast cancer should be offered adjuvant chemotherapy. The economic analysis used cancer registry data on levels of chemotherapy prescribing to reflect standard practice in England and, therefore, is likely to incorporate the impact on the decision to use chemotherapy based on a range of different decision tools currently used in the NHS.

4.9 Further information on the importance of individual molecular markers (for example, ER and HER2, which are routinely assessed for early breast cancer) in the decision to offer adjuvant chemotherapy (and other therapies such as endocrine therapy) has led to varying local practice. Although some hospitals use Adjuvant! Online and the NPI in their original forms, others use adaptations of these tools. Adjuvant! Online is often used in conjunction with the HER2 score. Management algorithms based on the combined use of the NPI and molecular markers such as ER and HER2 are also used.

Nottingham Prognostic Index

4.10 The NPI is a composite prognostic parameter involving both time-dependent factors and aspects of tumour aggressiveness. The NPI score is based on a mix of grade, lymph node involvement and tumour size. The score is calculated by adding numerical grade (1, 2 or 3), lymph node score (negative=1, 1 to 3 nodes=2, >3 nodes=3) and 0.2 times tumour size in centimetres. Patients can be divided into 3 prognostic groups (other subdivisions are also possible, for example 5 prognostic groups) on the basis of the NPI score: a good prognostic group (NPI≤3.4), a moderate prognostic group (3.4<NPI≤5.4) and a poor prognostic group (NPI>5.4).

Adjuvant! Online

4.11 The Adjuvant! Online computer programme is designed to provide estimates of the benefits of adjuvant endocrine therapy and chemotherapy. The current version of Adjuvant! Online does not include HER2 status. Patient and tumour

© NICE 2013. All rights reserved. Last modified September 2013

characteristics are entered into the programme and provide an estimate of the baseline risk of mortality or relapse for patients without adjuvant therapy. Information about the efficacy of different therapy options was derived from the Early Breast Cancer Trialists' Collaborative Group (EBCTCG) meta-analyses and provides estimates of reduction in risk of breast cancer-related death or relapse at 10 years for selected treatments. These estimates are then provided on printed sheets in simple graphical and text formats to be used in consultations.

5 Outcomes

5.1 The Diagnostics Advisory Committee (section 11) considered evidence from a number of sources (section 12).

How outcomes were assessed

5.2 The assessment consisted of a systematic review of the evidence on test performance and clinical-effectiveness data for the 4 tests included in the evaluation. The outcome measures included:

- Analytical validity, defined as the ability of the test to accurately and reliably measure the expression of mRNA or proteins by breast cancer tumour cells (that is, repeatability and reproducibility).
- Clinical validity, defined as prognostic ability or the degree to which the test can accurately predict the risk of an outcome (for example, the risk of distant metastases in 10 years).
- Clinical utility, defined as the ability of the test to improve clinical outcomes such as overall survival. This includes direct harms arising from the test, reclassification of risk compared with existing tools, its impact on clinical decision-making and the ability of the test to predict benefit from chemotherapy. Within the context of clinical utility, the predictive ability of a test refers to the capability of the test to accurately predict patients who will benefit most, in relative terms, from chemotherapy, that is, whether patients classified as high risk benefit more in relative terms than patients classified as low risk.

5.3 In the base-case economic analysis, the External Assessment Group used the available data on the clinical validity and clinical utility of the tests to populate the model. The risk of distant recurrence (prognosis) was computed from data on the clinical validity of the tests. The reclassification of risk by the new tests (presented as 2 Nottingham Prognostic Index [NPI] subgroups), the impact of the test results on clinical decision-making (the proportion of patients receiving adjuvant chemotherapy) and the predicted benefit of chemotherapy by risk group (reduction in the risk of distant recurrence) were based on data on the clinical utility of the tests. In all cases, the systematic review showed that data

© NICE 2013. All rights reserved. Last modified September 2013

on the clinical validity of the tests were more robust than data on their clinical utility. Therefore the External Assessment Group used sensitivity analysis to explore alternative scenarios with different assumptions of the clinical utility of the tests and, in some cases alternative assumptions of clinical validity.

5.4 For 2 of the 4 tests (Oncotype DX and MammaPrint), the current systematic review updated an existing systematic review of gene expression profiling tests for breast cancer. Two previous systematic reviews (one an update of the other) reviewed the literature relating to both Oncotype DX and MammaPrint. Marchionni et al. (2008) is an exhaustive literature review of various electronic databases covering biomedical literature between 1990 and 2006. In 2010, Smartt updated this systematic review and included all relevant evidence that became available between 2007 and 2009.

5.5 The External Assessment Group undertook a systematic review of the evidence on cost effectiveness for the 4 tests. Genomic Health (Oncotype DX) submitted an economic model and Clarient submitted a report detailing an economic analysis of Mammostrat. The External Assessment Group constructed a de novo economic model. The outcomes of interest for the economic evaluation were the morbidity and mortality associated with invasive breast cancer and its treatment. These included survival and health-related quality of life, including the impact of adverse events associated with chemotherapy. The de novo economic model followed a linked evidence approach in which intermediate outcomes (results of the tests) were linked to treatment outcomes and hence quality-adjusted life year (QALY) gains. Costs and QALYs were assigned to each of the 4 tests and the comparator.

5.6 The population identified in the scope for this evaluation included assessment of the gene expression profiling and expanded immunohistochemistry tests in men with breast cancer if data were available. No such data that would allow the evaluation of these technologies in men were identified in the systematic review.

Clinical effectiveness

5.7 The terms analytical validity, clinical validity and clinical utility, used in this section, are defined in section 5.2.

5.8 Much of the clinical evidence was related to the Oncotype DX and MammaPrint tests because these tests are much further along the validation pathway than IHC4 and Mammostrat. The highest-quality evidence was reported for Oncotype DX, although limitations or gaps in the clinical data were identified for all tests. Most studies, for all tests, were retrospective in design, analysing archived tumour samples from a cohort of patients with documented information on patient characteristics and outcomes. Retrospective analyses are associated with increased bias compared with prospective randomised controlled trials. Some of the studies involved a prospective analysis of retrospective archived material from a previous randomised controlled trial. Potential issues still remain, including the effects of confounding and the possible incompleteness of some biological specimens.

5.9 Study populations were generally heterogeneous, although most of the evidence on Oncotype DX came from oestrogen receptor positive (ER+), lymph node negative (LN−) populations. Some studies included a small number of participants. Studies including larger sample sizes, in excess of 1000 samples, were available for Oncotype DX, Mammostrat and IHC4. Follow-up was short or not reported in a number of studies. Five studies were specific to a UK population, including 3 for Oncotype DX, 1 for IHC4 and 1 for Mammostrat.

MammaPrint

5.10 A range of studies provided evidence on the prognostic ability of MammaPrint in heterogeneous populations. However, the previous systematic reviews indicated that evidence relating to the clinical validity of MammaPrint was not always conclusive nor supported the prognostic value of the test. Four studies suggested that the test could predict prognosis, 1 study of prognostic utility did not reach statistical significance and in another the methods and results were at variance with other studies. In terms of clinical utility, the previous reviews

© NICE 2013. All rights reserved. Last modified September 2013

identified 1 prospective observational study (Bueno-de-Mesquita et al. [2007], also known as the RASTER study) demonstrating that MammaPrint had an impact on clinical decision-making when used in addition to current practice in the Netherlands (Dutch Institute for Healthcare Improvement [CBO] guidelines). Adjuvant systemic treatment was advised less often when Dutch CBO guidelines were used compared with use of MammaPrint. Therefore, Bueno-de-Mesquita et al. (2007) reported that the addition of MammaPrint to the standard Dutch clinical assessment of risk (modified by patient preference) in a cohort of 427 patients increased the number of patients receiving adjuvant systemic therapy by 20 (5%). At the time of the previous systematic review, follow-up was not long enough to provide evidence of its effect on clinical end points such as distant metastasis-free survival or its utility in predicting treatment benefit; however, follow-up data at 5 years have recently been published in the study by Drukker et al. (2013). The study reported, among other outcomes, that in the group of patients classified as being at low risk with MammaPrint and at high risk with Adjuvant! Online (of whom 76% had not received adjuvant chemotherapy), the 5-year distant recurrence-free interval was 98.4%. The previous systematic reviews recommended that further evidence from randomised controlled trials was needed in addition to robust evidence on the prediction of benefit from chemotherapy.

5.11 The External Assessment Group identified 7 additional, non-UK-based, studies of MammaPrint. Of these 7 studies, 4 on the clinical validity of MammaPrint demonstrated that the MammaPrint score is a strong independent prognostic factor, and may provide additional value to standard clinicopathological measures. A mix of evidence exists for outcomes at 5 and 10 years. The population in all these studies was relatively small. One of the studies was of a Japanese population, and follow-up was limited to only 5 years in 2 of the studies. For example, Mook et al. (2010) showed that in 148 women the distant metastasis-free survival at 5 years was 93% in the low-risk group and 72% in the high-risk group with an associated hazard ratio (HR) of 4.6 (95% confidence interval [CI] 1.8 to 12.0, p=0.001). The External Assessment Group did not identify any prospective studies of the impact of MammaPrint on long-term outcomes such as overall survival, but the prospective observational RASTER study published 5-year follow-up data after the External Assessment Group completed its assessment, and this was discussed by the Committee

© NICE 2013. All rights reserved. Last modified September 2013

(see section 6.13). Six studies with data on the clinical utility of MammaPrint were identified by the External Assessment Group. Five studies reported use of MammaPrint to reclassify patients into high- and low-risk groups and compared this with the risk assigned according to current local guidance. They reported a high level of discordance between MammaPrint and current classification, although these studies did not demonstrate how this would impact on treatment decisions. For example, Bueno-de-Mesquita et al. (2009) compared MammaPrint risk categories and risk assessment based on Adjuvant! Online, St Gallen guidelines, NPI and Dutch CBO guidelines (2004). Discordance between MammaPrint and the other risk assessment measures was 38%, 41%, 26%, and 30% respectively. One study reported that the use of MammaPrint would result in altered treatment advice for 40% of patients based on the assumption that all patients classified as high risk would receive chemotherapy and patients classified as low risk would not receive chemotherapy. Because the study was retrospective, altered treatment advice assumed in the analysis represented potential changes and not actual changes from using the test in clinical practice.

5.12 A study of the benefit of chemotherapy according to risk group stratification by MammaPrint was identified (Knauer et al. 2010) but was omitted from the systematic review because it was based on a pooled analysis of 6 primary studies. The External Assessment Group did not include the pooled analysis in the systematic review to avoid double counting of studies already included in the review. In addition, it did not consider the findings of the pooled analysis to be robust because the authors did not reanalyse the tumour samples, it is unclear how individual patient data were combined, and there were potential issues with the statistical analyses performed (for example, although median follow-up was 7.1 years the data were arbitrarily truncated at 5 years).

5.13 Robust evidence of clinical utility is not available for MammaPrint so it is not yet clear whether using the test will improve the use of adjuvant chemotherapy in the management of breast cancer in the UK. In summary, most studies of MammaPrint were retrospective in design, used small sample sizes and had heterogeneous patient populations and some studies included only pre-menopausal women. Moreover, no studies were conducted in the UK. The evidence for MammaPrint is based on the use of the test with fresh samples. It

© NICE 2013. All rights reserved. Last modified September 2013

is not clear whether this evidence would apply if the test were used on formalin-fixed paraffin-embedded samples. Overall, the External Assessment Group considered that further robust evidence on the clinical validity and clinical utility of the test would be helpful.

Oncotype DX

5.14 Oncotype DX was reported to be furthest along the validation pathway by previous systematic reviews. In terms of clinical validity, these reviews reported evidence that the Oncotype DX recurrence score was significantly correlated with disease-free survival and overall survival. Furthermore, the recurrence score was shown to be a better predictor of distant recurrence at 10 years than traditional clinicopathological predictors. The evidence on clinical utility was limited. One study (Paik et al. 2006) demonstrated a significantly increased benefit from the use of chemotherapy in the Oncotype DX high-risk group compared with the low-risk group, although the review highlighted that the study may have potential flaws. The study indicated that this benefit difference was caused by the better prognosis without chemotherapy (and hence the reduced absolute benefit these patients would receive) and the decreased relative benefit of chemotherapy in the lower-risk groups. The specific cancers in the low-risk groups were less likely to respond to chemotherapy, independent of actual survival probability. Key gaps were identified in the evidence base related to the extent to which the test added to the management of breast cancer and the proportion of patients who would benefit from the test. The previous systematic reviews indicated that prospective confirmation of the clinical utility of Oncotype DX was needed.

5.15 The External Assessment Group identified 12 additional studies of Oncotype DX. Further larger studies now support the prognostic ability of Oncotype DX. One large-scale UK study in post-menopausal women with ER+, LN− early breast cancer found that an increase in risk score was significantly associated with an increased risk of distant recurrence. Furthermore, the evidence base has been extended to include the LN+ population. The External Assessment Group did not identify any prospective studies of the impact of Oncotype DX on long-term outcomes such as overall survival. Four studies were identified that presented further evidence on the impact of Oncotype DX on clinical decision-making. These indicated that the use of Oncotype DX leads to changes in

© NICE 2013. All rights reserved. Last modified September 2013

treatment decisions for between 32% and 38% of patients. However, only 1 of these studies was performed in the UK and limitations in relation to the generalisability of the study were identified. In addition, the study only included a small sample of patients (interim results on 106 patients were available for the systematic review, the dataset for 142 patients was available for and used in the External Assessment Group's cost-effectiveness analysis). Four recent publications reported evidence that Oncotype DX predicts benefit from chemotherapy. However, only 1 of these studies on an LN+ population (Albain et al. 2010) presented new data. The other 3 publications (Tang et al. 2011, Mamounas et al. 2010 and Tang et al. 2010) reported the same trial data as Paik et al. (2006). The first evidence of improvements in quality of life and reduced patient anxiety as a result of using Oncotype DX have been reported, but the studies had small sample sizes (for example, Lo et al. [2010] included 89 patients). In summary, Oncotype DX is considered to have the most robust evidence base of the tests reviewed in this guidance, with data on the analytical validity, clinical validity and clinical utility of the test. The studies varied considerably in their size, design and patient populations. Many of the Oncotype DX studies were small and retrospective. A small number of studies were conducted in the UK. The External Assessment Group considered that further robust evidence on the clinical utility of the test would be helpful.

IHC4

5.16 No studies on analytical validity of IHC4 (based on ER, progesterone receptor [PR], human epidermal growth factor receptor 2 [HER2] and Ki-67 in addition to classical clinical and pathological variables combined using an algorithm) were identified. Of the 4 individual tests that make up IHC4, 2 (ER and HER2) are commonly measured in the NHS. However, the quantitative assessment of ER needed for IHC4 calculations is not routinely performed. Outstanding issues around the reproducibility of detecting Ki-67 also exist. This is noteworthy because the test is designed for local use and different local processing methods may potentially lead to different results. The External Assessment Group identified 1 study on the clinical validity of IHC4 (Cuzick, 2011), which reports that the IHC4 score is a highly significant predictor of distant recurrence. The authors validated the test in a cohort of 786 patients with ER+ cancer treated in the UK, and demonstrated that the IHC4 score was highly significantly predictive of outcome, with a hazard ratio of 4.8 (95% CI

© NICE 2013. All rights reserved. Last modified September 2013

2.2 to 10.2) for a change from the 25th to 75th percentile in a univariate analysis. This study also reported evidence comparing IHC4 against Oncotype DX. The study was rated as high quality. The External Assessment Group did not identify any prospective studies of the impact of IHC4 on long-term outcomes such as overall survival. It did not identify any published evidence on the clinical utility of IHC4 in terms of its ability to change treatment decisions or its ability to predict chemotherapy benefit. In summary, the External Assessment Group considered that the evidence base for IHC4 is currently limited to clinical validity (prognostic ability), although this evidence is considered to be relatively robust, and further evidence would be helpful on analytical validity and clinical utility.

Mammostrat

5.17 The External Assessment Group did not identify any specific studies on the analytical validity of Mammostrat, although some limited evidence on analytical validity was reported in studies of clinical validity and clinical utility. Three studies were identified that provided data to support the use of Mammostrat as an independent prognostic tool for women with ER+, tamoxifen-treated breast cancer. Although the evidence base for Mammostrat is at present relatively limited, these studies included a large sample size, appeared to be of reasonable quality, and 1 study provided data from a UK setting. The External Assessment Group did not identify any prospective studies of the impact of Mammostrat on long-term outcomes such as overall survival. In addition, clinical utility data on Mammostrat (from 1 study) suggest that the low- and high-risk groups benefit from chemotherapy, but not the intermediate-risk group. There was no published evidence on reclassification of risk groups compared with conventional means of risk classification, and no evidence on the impact of the test on clinical decision-making. Overall, the External Assessment Group considered that further evidence of analytical validity and clinical utility would be helpful.

Economic analysis

5.18 Four studies were identified as meeting the inclusion criteria of the systematic review of cost-effectiveness evidence (2 for MammaPrint and 2 for Oncotype

© NICE 2013. All rights reserved. Last modified September 2013

DX). None were conducted in England. Genomic Health and Clarient also submitted economic analyses on the cost effectiveness of Oncotype DX and Mammostrat in England respectively. Several issues were highlighted in the critique of these analyses, which needed further consideration. These included assumptions about: the baseline level of chemotherapy in clinical practice; the risk of distant recurrence; patients who would be offered the test; the proportion of patients who would be offered chemotherapy after reclassification with the new test; the cost of chemotherapy and therapy used to prevent or treat associated adverse events.

5.19 The External Assessment Group constructed a de novo economic model to specifically address the decision problem for this evaluation and to estimate the cost effectiveness of the 4 tests in England.

5.20 The population assessed in the economic model was women with ER+, LN−, HER2− early breast cancer up to 75 years old at diagnosis. One analysis assumed that all women in the group received the new tests. However, the External Assessment Group's clinical specialists suggested that the new tests may be targeted at a subgroup of this population – those at intermediate risk of distant recurrence for whom the decision about whether or not to give chemotherapy is most uncertain. A subgroup analysis was performed that assumed that the new test was given only to women with an NPI score above 3.4 (used as a proxy for those women at intermediate risk of distant recurrence), based on the assumption that most women at low risk (with an NPI score below 3.4) would not be considered for chemotherapy and that there would not be many women at high risk (with an NPI score of above 5.4) within the population considered.

Clinical outcomes

5.21 Modelling was used to estimate clinical outcomes. All women in the model were assumed to be treated with endocrine therapy. A state transition model was used to simulate breast cancer outcomes for patients treated with endocrine therapy alone or with the addition of chemotherapy. Outcomes associated with breast cancer were simulated using multiple health states including recurrence-free survival, recurrence (distant and local), adverse events from chemotherapy, and death.

© NICE 2013. All rights reserved. Last modified September 2013

Costs

5.22 The costs included in the economic model were the costs of the different tests, treatment costs (endocrine therapy and chemotherapy), costs of short-term and long-term adverse events associated with chemotherapy (including the secondary prevention of short-term adverse events), costs associated with managing distant recurrence, local recurrence and terminal care.

5.23 The cost of the MammaPrint test is £2675 (this cost was used in the economic model). The Oncotype DX test costs £2580 (this cost was used in the original economic analysis, but a revised cost was used for the economic analysis conducted for the confidential revised price). IHC4 was estimated to cost £100–£200 (£150 was used in the economic model) for quantitative analysis of ER (which may need additional time compared with traditional assessment of ER status), and assessment of PR and Ki-67 (which are not routinely collected) and running the algorithm (it was assumed that HER2 would be measured as part of standard practice). The Mammostrat test has an indicative cost between £1120 and £1620 (£1135 was used in the economic model).

Cost effectiveness

5.24 The primary analysis compared current clinical practice with treatment guided by Oncotype DX and IHC4. The systematic review of the evidence indicated most evidence for Oncotype DX compared with the other tests, and that the evidence base for Oncotype DX, in particular in relation to prognostic ability, was reasonably sound. There was less evidence for IHC4, but there was evidence relating to the performance of IHC4 compared with Oncotype DX. This evidence, with some additional assumptions when compared with the analysis of Oncotype DX, was used to model the cost effectiveness of IHC4. Additional assumptions include the reproducibility of the test and the use of risk groups as opposed to a continuous risk score. There was no evidence on the ability of IHC4 to predict benefit from chemotherapy; in the IHC4 analysis, the predicted benefit of chemotherapy was applied according to the Oncotype DX risk classification.

5.25 In addition to the primary economic analysis, further economic analyses were undertaken for Mammostrat and MammaPrint. These additional analyses were

© NICE 2013. All rights reserved. Last modified September 2013

deemed exploratory by the External Assessment Group because there are significant limitations in the evidence base and the generalisability of the data to practice in England. Only data from studies conducted in the USA (Mammostrat) and The Netherlands (MammaPrint) were available to estimate the reclassification of patients using the new test. There was concern whether these data are generalisable to England and there was also uncertainty in the data. There were no studies showing the impact of these tests on the management of breast cancer in the England. In addition, the External Assessment Group reported considerable uncertainty in the data used to estimate the predicted benefit of chemotherapy by MammaPrint risk groups.

5.26 All analyses assumed that the new tests were used in addition to current practice (for IHC4 it was assumed that quantitative analysis of ER [which may need additional time compared with traditional assessment of ER status], PR and Ki-67 is carried out in addition to current practice and data combined in an algorithm). Full details of the results can be found in section 5.6 of the diagnostics assessment report. A brief summary of the key results (including incremental cost-effectiveness ratios [ICERs]) of the base-case analysis and sensitivity analyses is presented below. Results of the 3 analyses (Oncotype DX and IHC4; Mammostrat; MammaPrint) cannot be directly compared because the data came from different studies with different patient characteristics and methodologies, and the basis for each model therefore varies significantly.

5.27 The base-case analysis modelled a hypothetical cohort of 1000 women over a lifetime horizon (100 years was used as the upper age limit). Two analyses are presented. In the first the tests were used for all women with ER+, LN−, HER2− early breast cancer aged up to and including 75 years. In the second the tests were used only for women with ER+, LN−, HER2− early breast cancer up to and including 75 years with an NPI score above 3.4 (used as a proxy for those women at intermediate risk of distant recurrence). Results are presented on a per patient basis and any differences in expected values are a result of rounding error.

© NICE 2013. All rights reserved. Last modified September 2013

Oncotype DX and IHC4

5.28 **Tests used for all women with ER+, LN−, HER2− early breast cancer and Oncotype DX is assessed at the list price of £2580.** In the primary economic analysis comparing Oncotype DX and IHC4 with current practice, the proportions of patients receiving chemotherapy were 19.11%, 9.57% and 14.42% respectively. The model predicted that there would be 64, 71 and 76 distant recurrences when using Oncotype DX, IHC4 or current practice respectively. Total costs and QALYs, assuming predictive benefits (that is, benefits from identifying who will benefit most from chemotherapy) based on Paik et al. (2006), are summarised in table 1.

Table 1 Per-patient costs, QALYs and ICERs in the primary economic analysis (Oncotype DX and IHC4 compared with current practice)[a]

	Mean cost (£)	Mean QALYs	ICER – compared with current practice
Oncotype DX	£9094	13.54	£26,940[b]
IHC4	£6340	13.49	Dominant
Current practice	£6519	13.44	

Abbreviations: ICER, incremental cost-effectiveness ratio; QALY, quality-adjusted life year.

[a] The analysis assumed the tests are used for all women with ER+, LN−, HER2− early breast cancer in England. Predictive benefit was based on Paik et al. (2006) and is based on the list price of Oncotype DX.

[b] Rounding error contributes to the difference from expected value.

5.29 Compared with current practice, Oncotype DX was associated with an incremental cost of £2575 and incremental QALYs of 0.1, yielding an ICER of £26,940 per QALY gained. IHC4 was £179 cheaper than current practice (cost saving), with incremental QALYs of 0.05 and was predicted to be dominant (that is, provide more QALYs at a lower cost) compared with current clinical practice. Oncotype DX, IHC4 and current practice were also compared using incremental analysis; that is, the least effective strategy was compared with the next least effective strategy that was neither dominated nor extendedly dominated. The cost-effectiveness acceptability curve showed that the

© NICE 2013. All rights reserved. Last modified September 2013

probability of IHC4 being cost effective (when compared with current practice) was almost 100% if the maximum acceptable ICER was £20,000 per QALY gained. At the same maximum acceptable ICER, the probability of Oncotype DX being cost effective, when compared with current practice only, was 12.4%.

5.30 Tests used for women with ER+, LN−, HER2− early breast cancer and an NPI score above 3.4, and Oncotype DX is assessed at the list price of £2580. In the primary economic analysis the proportion of these patients predicted to receive chemotherapy was 34.72%, 26.31% and 33.60% with Oncotype DX, IHC4 and current practice respectively. The model predicted that there would be 117, 129 and 144 distant recurrences when using Oncotype DX, IHC4 or current practice respectively. Total costs and QALYs, assuming predictive benefits based on Paik et al. (2006), are summarised in table 2.

Table 2 Per patient costs, QALYs and ICERs in the primary economic analysis (Oncotype DX and IHC4 compared with current practice)[a]

	Mean cost (£)	Mean QALYs	ICER – compared with current practice
Oncotype DX	£10,911	13.06	£9007[b]
IHC4	£8318	12.97	Dominant
Current practice	£8816	12.83	

Abbreviations: ICER, incremental cost-effectiveness ratio; QALY, quality-adjusted life year.

[a] The analysis assumed the tests are used for women with ER+, LN−, HER2− early breast cancer and an NPI score above 3.4 in England. Predictive benefit was based on Paik et al. (2006) and is based on the list price of Oncotype DX.

[b] Rounding error contributes to the difference from expected value.

5.31 Compared with current practice, Oncotype DX was associated with an incremental cost of £2095 and incremental QALYs of 0.23, which resulted in an ICER of £9007 per QALY gained. IHC4 was £498 cheaper than current practice (cost saving), with incremental QALYs of 0.14 and was predicted to be dominant (that is, provide more QALYs at a lower cost) compared with current clinical practice. Oncotype DX, IHC4 and current practice were also compared using incremental analysis; that is, the least effective strategy was compared

© NICE 2013. All rights reserved. Last modified September 2013

with the next least effective strategy that was neither dominated nor extendedly dominated. The cost-effectiveness acceptability curve showed that the probability of IHC4 being cost effective (when compared with current practice) was almost 100% if the maximum acceptable ICER was £20,000 per QALY gained. At the same threshold, the probability of Oncotype DX being cost effective, when compared with current practice only, was 91.6%.

5.32 **Sensitivity analyses (univariate)**. A range of univariate sensitivity analyses were undertaken to explore the impact of varying the main model parameters. Analyses of varying the assumptions underlying the structure of the model were also performed. The ICERs for Oncotype DX compared with current clinical practice, for all women with ER+, LN−, HER2− early breast cancer and those with an NPI above 3.4, were sensitive (defined as changes in the ICER by 10% or more) to some of the assumptions made in the model. These included the time horizon modelled, the starting age of the cohort, the risk of recurrence, the proportion of patients receiving chemotherapy after reclassification with the new test, the benefit of chemotherapy in the different risk groups and the distribution of patients by NPI score. For example, the ICERs for Oncotype DX (compared with current practice) when offered to all women with ER+, LN−, HER2− early breast cancer were £91,300 (assuming 30% relative risk reduction from chemotherapy for all patients) per QALY gained and £64,900 (assuming 40% relative risk reduction from chemotherapy for all patients) per QALY gained. The ICERs for IHC4 compared with current clinical practice, for all women with ER+, LN−, HER2− early breast cancer and those with an NPI score above 3.4, were sensitive to more assumptions (such as the time spent in the distant recurrence health state, the proportion of patients receiving chemotherapy under current practice and the cost of chemotherapy), but IHC4 remained dominant compared with current practice (that is, it provided more QALYs at a lower cost) except when the cost of IHC4 was set at £400 (the resulting ICER was £1557 per QALY gained).

5.33 Following the first consultation, the manufacturer of Oncotype DX submitted a proposal to make it easier for the NHS to access the technology. The proposal makes Oncotype DX available at a revised price. The proposed price is commercial in confidence. The proposal is made for patients at an intermediate risk of distant recurrence, defined as an NPI score above 3.4 in this guidance.

© NICE 2013. All rights reserved. Last modified September 2013

An External Assessment Group analysis of the proposal, using the proposal price and the assumption that Oncotype DX is validated as a prognostic tool but does not predict the benefit patients will get from chemotherapy, yielded an ICER of £22,600 per QALY gained compared with current clinical practice for patients with an NPI score above 3.4.

Mammostrat (exploratory analysis)

5.34 **Test used for all women with ER+, LN−, HER2− early breast cancer.** The proportion of patients receiving chemotherapy increased with the use of Mammostrat when compared with current practice (21.16% and 14.42% respectively). Current practice was associated with a mean cost of £7699 and mean QALYs of 12.86. Mammostrat was associated with a mean cost of £9040 and mean QALYs of 12.91. The ICER for Mammostrat was estimated to be £26,598 per QALY gained. However there were significant uncertainties and limitations associated with this analysis. These included uncertainty about the generalisability of the risk reclassification data to a UK population of patients with ER+, LN−, HER2− breast cancer, and the lack of evidence on the impact of the test on decision-making. In addition, the robustness of evidence on the predictive ability of the test is uncertain – clinical utility data from 1 study suggest that the low- and high-risk groups benefit from chemotherapy, but not the intermediate-risk group. The cost-effectiveness acceptability curve showed a 36.0% probability of Mammostrat being cost effective if the maximum acceptable ICER is £20,000.

5.35 **Test used for women with ER+, LN−, HER2− early breast cancer and an NPI score above 3.4**. The proportion of patients receiving chemotherapy increased slightly with the use of Mammostrat when compared with current practice (34.27% and 33.60% respectively). Current practice was associated with a mean cost of £9717 and mean QALYs of 12.34. Mammostrat was associated with a mean cost of £10,985 and mean QALYs of 12.29. Mammostrat was shown to be dominated by current practice. The cost-effectiveness acceptability curve showed an 18.0% probability of Mammostrat being cost effective if the maximum acceptable ICER is £20,000.

5.36 **Sensitivity analyses (univariate).** A range of univariate sensitivity analyses were undertaken to explore the impact of varying model parameters. When

© NICE 2013. All rights reserved. Last modified September 2013

offering the test to all women with ER+, LN−, HER2− early breast cancer the ICER was very sensitive to the proportion of patients who would receive chemotherapy based on the test result. The ICER ranged between £18,879 per QALY gained to being dominated, when using the confidence intervals from the Ross et al. (2008) study for the predicted benefit of chemotherapy in terms of the reduction of distant recurrence. The ICER was not sensitive to the assumptions about utility values, management costs and the time spent in the recurrence health state. Mammostrat remained dominated under the assumptions examined in the sensitivity analysis when the test was offered to women with ER+, LN−, HER2− early breast cancer and an NPI score above 3.4.

MammaPrint (exploratory analysis)

5.37 **Test used for all women with ER+, LN−, HER2− early breast cancer.** The proportion of patients receiving chemotherapy increased with the use of MammaPrint when compared with current practice (44.18% and 14.42% respectively). Current practice was associated with mean costs of between £6408 and £6629, and mean QALYs of between 13.39 and 13.49. MammaPrint was associated with mean costs of between £10,017 and £10,748 and mean QALYs of between 13.47 and 13.78. Because of uncertainty around the evidence on the benefit of chemotherapy for the MammaPrint risk groups, the results for MammaPrint were presented as a range (based on the confidence interval for the benefit of chemotherapy). The ICER was estimated to be between £12,240 and £53,058 per QALY gained. Additional uncertainties include the lack of UK data in a relevant population (patients with ER+, LN−, HER2− breast cancer; particularly in relation to risk reclassification compared with UK practice), the impact of the test on clinical decision-making in the UK and reliance on data mainly from pre-menopausal populations.

5.38 **Test used for women with ER+, LN−, HER2− early breast cancer and an NPI score above 3.4**. The proportion of patients receiving chemotherapy increased with the use of MammaPrint when compared with current practice (90.31% and 33.60% respectively). Current practice was associated with mean costs of between £8281 and £8872 and mean QALYs of between 12.81 and 13.07. MammaPrint was associated with mean costs of between £12,278 and

© NICE 2013. All rights reserved. Last modified September 2013

£14,014 and mean QALYs of between 12.99 and 13.73. Because of uncertainty around the evidence on the benefit of chemotherapy for the MammaPrint risk groups, the results for MammaPrint were presented as a range (based on the confidence interval for the benefit of chemotherapy). The ICER for MammaPrint was estimated to be between £6053 and £29,569 per QALY gained. Additional uncertainties include the lack of UK data and the reliance on data mainly from pre-menopausal populations.

5.39 **Sensitivity analyses (univariate and multivariate)**. Given the uncertainty in the base-case analysis a limited number of sensitivity analyses were undertaken. Univariate analyses included: assuming no additional cost to the NHS for the use of fresh tissue samples and that 5% of patients classified as good prognosis and 95% of patients classified as poor prognosis received chemotherapy. A multivariate sensitivity analysis explored different values for the benefit of chemotherapy in terms of reduction in the risk of distant recurrence, assuming MammaPrint was used in all women with ER+, LN−, HER2− early breast cancer.

6 Considerations

6.1 The Diagnostics Advisory Committee discussed the focus of the evaluation and the evidence available for the 4 tests. It noted that gene expression profiling and immunohistochemistry tests other than those included in this evaluation are being developed. The Committee also noted that at present, the level and quality of the available evidence varies for the 4 tests. In particular, evidence on the tests' ability to guide clinical decisions on the use of chemotherapy in England and to predict response to chemotherapy in women with early breast cancer was limited. The External Assessment Group's economic model for women with oestrogen receptor positive (ER+), lymph node negative (LN−) or human epidermal growth factor receptor 2 negative (HER2−) early breast cancer was used by the Committee when considering the likely cost effectiveness of the 4 tests. The Committee considered that the most appropriate use of these tests is in women for whom the decision to offer chemotherapy is uncertain, that is, women at intermediate risk of distant recurrence. It therefore considered that the subgroup analyses of women with a Nottingham Prognostic Index (NPI) score above 3.4 were the most relevant, based on the likelihood that there would not be many women with an NPI score of above 5.4 within the target population.

6.2 The Committee acknowledged the emotional and psychological strain for patients with breast cancer when considering therapy, in particular, chemotherapy and its associated adverse events. The Committee noted that this is likely to be significant in patients for whom the decision about whether or not to have chemotherapy is difficult after receiving the results of current tools used in the NHS (especially patients deemed to be at intermediate risk). The Committee also noted that tools used by the NHS to assess the suitability of patients with breast cancer for adjuvant chemotherapy vary across England. The Committee concluded that any tests that can help to alleviate emotional and psychological strain and promote consistency of practice within the NHS are likely to be appreciated by patients and clinicians alike.

6.3 The Committee discussed the generalisability of the data to men. The Committee acknowledged that breast cancer is not only observed in women and that men make up a small proportion of patients with breast cancer. The

© NICE 2013. All rights reserved. Last modified September 2013

Committee noted that all the clinical and economic evidence had been based on trials with women; however, experts on the Committee stated that even though there are some subtle gender-specific differences in the pathobiology of breast cancer, the general subtypes are identical in men and women. Therefore, in clinical practice men would be treated in the same way as women. The Committee therefore concluded that the recommendations in this guidance should also apply to men.

6.4 The Committee discussed the evidence base for Oncotype DX and concluded that, in general, it was the most developed of the 4 tests in the evaluation. The Committee discussed the analytical validity of Oncotype DX. The Committee noted that no new evidence was identified in the External Assessment Group review, but that evidence was identified in the previous systematic review (Marchionni et al. 2008) that showed reasonable within-laboratory replicability. The Committee also noted that the test is processed centrally by the manufacturer in the USA and the laboratory is CLIA (Clinical Laboratory Improvement Amendments) certified. Given the above, the Committee was satisfied with the analytical validity of the test. The Committee discussed the prognostic ability (clinical validity) of Oncotype DX. Experts on the Committee pointed out and the Committee agreed that the prognostic ability (the ability to predict the risk of distant recurrence) of Oncotype DX had been well validated. The Committee also considered a study by Sgroi et al. reported in abstract form at the San Antonio Breast Cancer Symposium 2012, which assessed the prognostic value of Oncotype DX (and IHC4) over and above standard clinical variables. The Committee noted that the abstract shows that Oncotype DX does not provide prognostic information for late distant metastasis. The Committee considered that these new data raise potential uncertainty around the long-term benefits of Oncotype DX, but judged that the relatively extensive evidence base supporting the prognostic ability of the test to be satisfactory at this time. The Committee therefore concluded that the prognostic ability of Oncotype DX was supported by robust evidence in the early breast cancer population.

6.5 The Committee then discussed the clinical utility of Oncotype DX. It heard from the External Assessment Group that a key aspect of clinical utility is the ability of a test to accurately predict those patients who will benefit most from

© NICE 2013. All rights reserved. Last modified September 2013

chemotherapy. The Committee therefore considered whether gains from chemotherapy could differ between patients with different prognoses (that is, patients in different risk groups). Experts on the Committee pointed to data from recent meta-analyses that showed proportional gains from chemotherapy were generally constant across clinical parameters such as tumour diameter and ER status (used to help determine a patient's prognosis). However, these constant proportional gains meant that those with a good prognosis would receive less absolute benefit from chemotherapy than those with a poor prognosis. Furthermore, the possibility that chemotherapy might be more effective both proportionally and absolutely in patients identified by Oncotype DX, given that the test provides information about the biological features of the tumour, was discussed. The possibility that tumours with the genomic characteristics identified by Oncotype DX might be more susceptible to chemotherapy was also explored. The evidence on the predicted benefit of chemotherapy (reduction in the risk of distant recurrence) for women receiving chemotherapy in addition to endocrine therapy compared with endocrine therapy alone was discussed. The Committee heard that data were available that suggest that Oncotype DX can predict the relative benefit of chemotherapy and that the effectiveness of chemotherapy varies depending on the classification of patients by the Oncotype DX test in LN− patients (Paik et al. 2006). These data indicated that women in lower risk groups benefit proportionally less from chemotherapy than those in higher risk groups (see section 5.14). The Committee considered that the Paik study was limited by its design, the sample sizes of individual risk groups, the use of some results from the training dataset (tamoxifen-treated patients of the NSABP B-20 trial) in the study dataset, the applicability of the study population (a younger population that includes patients with HER2+ breast cancer) to the population considered in this guidance, and the fact that the treatments (endocrine therapy and chemotherapy) used are different to those currently used in the NHS. In addition, the Committee considered that the relative benefit from chemotherapy by risk group was unclear. The Committee concluded that the evidence implying a predicted differential relative benefit of chemotherapy according to Oncotype DX risk group in LN− patients (Paik et al. 2006) was not robust. The Committee also reviewed evidence implying a predicted differential relative benefit of chemotherapy according to Oncotype DX risk group in LN+ patients (Albain et al. 2010) and data from the neoadjuvant setting. The

© NICE 2013. All rights reserved. Last modified September 2013

Committee concluded that these data were not robust enough to support the test's ability to predict the benefit of chemotherapy. In the absence of robust data the Committee concluded that equal benefit of chemotherapy should be assumed across all Oncotype DX risk groups. Therefore, although the Committee considered that adequate evidence supported the prognostic ability of Oncotype DX (that is, its ability to predict the risk of distant recurrence, see section 6.4), it concluded that it was not confident in the ability of Oncotype DX to predict benefit from chemotherapy.

6.6 The Committee discussed the cost effectiveness of Oncotype DX based on the original price proposed by the manufacturer (list price). The Committee considered that the incremental cost-effectiveness ratios (ICERs) from the base-case analysis of Oncotype DX were not the most appropriate for decision-making purposes because of the assumption of a predicted differential relative benefit of chemotherapy according to Oncotype DX risk group. The Committee discussed the ICERs presented in the sensitivity analysis that assumed equal benefit of chemotherapy across all Oncotype DX risk groups (at a level of either 30% or 40% relative risk reduction from chemotherapy). The Committee noted the ICERs for Oncotype DX (compared with current practice) when offered to all women with ER+, LN−, HER2− early breast cancer were £91,300 (30% relative risk reduction from chemotherapy) per quality-adjusted life year (QALY) gained and £64,900 (40% relative risk reduction from chemotherapy) per QALY gained. The Committee considered the ICERs to be too high to recommend Oncotype DX for use in the NHS for all women with ER+, LN−, HER2− early breast cancer. The Committee considered that the overall benefit of chemotherapy was likely to be closer to 27% relative risk reduction from chemotherapy across all Oncotype DX risk groups (EBCTCG overviews 2005, 2011). The Committee noted that there are potential differences in the population included in the EBCTCG review compared with the population in the economic analysis and that the outcome measures differed. Without data specific to the population under consideration, the Committee considered the EBCTCG figure to be the most appropriate for use at this time. The Committee concluded that the most plausible ICER, based on the evidence presented, was likely to exceed £91,300 for all women with ER+, LN−, HER2- early breast cancer. Therefore, based on the original

© NICE 2013. All rights reserved. Last modified September 2013

proposed price (list price), Oncotype DX would not be a cost-effective use of NHS resources in this group.

6.7 The Committee then considered a proposal submitted by the manufacturer of Oncotype DX. The proposal makes Oncotype DX available to the NHS at a revised price for those people assessed as being at intermediate risk. The proposed price is commercial in confidence. NICE advised the Committee, and the Committee agreed, that the access proposal appeared workable and efficient, and did not appear to constitute an excessive administrative burden on the NHS. The Committee went on to discuss the impact of the proposal on the cost effectiveness of Oncotype DX in people assessed as being at intermediate risk when it was assumed that Oncotype DX was able to predict a patient's prognosis but not the benefit of chemotherapy (relative risk reduction of distant recurrence from chemotherapy). The Committee accepted an analysis performed by the External Assessment Group, which showed that the ICER for Oncotype DX (compared with current practice) in this group of patients was £22,600 per QALY gained, assuming prognostic benefits of the test but no predictive effect. The Committee also noted the ICER could be significantly lower if Oncotype DX was shown to predict the benefit of chemotherapy by robust evidence from future research. The Committee noted that an NPI score above 3.4 was used in the analysis as a mechanism for identifying patients at intermediate risk, but also noted that other methods for determining the risk group were available and in use in the NHS. The Committee believed that the subgroup analysis of people with an NPI score above 3.4 was likely to be a reasonable approximation for people at intermediate risk generally. Therefore, given the strength of the evidence on the prognostic ability of the test (and evidence of analytical validity), the Committee concluded that Oncotype DX for use in people at intermediate risk of distant recurrence, when the decision to prescribe chemotherapy remains unclear, would represent a cost-effective use of NHS resources if acquired at the confidential revised price offered by the manufacturer.

6.8 The Committee discussed the need for further robust evidence to demonstrate the ability of Oncotype DX to identify patients who will benefit most from chemotherapy (see section 6.5). The Committee considered that further information on the clinical utility of the test is warranted. This should comprise

© NICE 2013. All rights reserved. Last modified September 2013

the development of robust evidence on the impact of Oncotype DX on clinical decision-making in England. The Committee noted that the Oncotype DX score may be combined with existing clinicopathological variables used informally by physicians at the local level, or more formally using a pre-specified algorithm. These 2 approaches should be kept in mind for any future research on the impact of Oncotype DX on clinical decision-making in England. The Committee noted that a decision-impact study in Bristol is near completion. Research should also address the ability of the test to predict the benefit of chemotherapy. The Committee noted there is an ongoing prospective trial (TAILORx) that will provide further information on the benefit of chemotherapy in women classified as intermediate risk by Oncotype DX. As the patient population included in TAILORx is from North America, the Committee encouraged the collection of data on Oncotype DX when used in the NHS in England (see section 7). The Committee was mindful that the extra value of the tests when used in addition to current clinical practice has been shown by the model constructed by the External Assessment Group, and that the use of Oncotype DX in the NHS in England represents an opportunity to collect further data on this. The Committee concluded that multicentre audit should be a priority for further investigation.

6.9 The Committee discussed the evidence available on the analytical validity of IHC4. It noted the test was at a comparatively early stage of development. In particular, it was noted that although there are data on the reliability and reproducibility of the measurement of ER, progesterone receptor (PR) and HER2 markers, data were lacking on the reliability and reproducibility of the Ki-67 marker measurement. The Committee heard that ER, PR and HER2 have an established UK National External Quality Assessment Scheme (NEQAS), and that a study was published recently on the reproducibility of Ki-67 and a UK NEQAS was being investigated for the marker. The Committee noted however that quantitative assessments of ER, PR and Ki-67 (not routinely reported in the NHS) should be appropriately considered in the NEQAS if not already done so. The Committee considered that data are needed on the reproducibility and reliability (analytical validity) of the complete IHC4 test (an algorithm combining 4 markers and classical clinical and pathological variables). This is particularly important as the test is designed for local processing in NHS laboratories. An additional study on quality assurance

© NICE 2013. All rights reserved. Last modified September 2013

was also considered by the Committee. This was a small preliminary study that did not materially change the results of the External Assessment Group analysis. The Committee concluded that the lack of data on analytical reliability meant that it was not possible to make a recommendation for general use of the IHC4 test at this time.

6.10 The Committee then discussed the clinical validity and clinical utility of IHC4. It noted that only 1 study was available on the clinical validity of the test. The Committee discussed the separate cohort of 786 patients used for external validation of the test in this study and concluded that it was not fully representative of the population of interest in this assessment because approximately 50% of patients did not receive 5 years of endocrine therapy. The Committee also noted that the External Assessment Group review did not identify any data on the clinical utility of IHC4. An additional study on how the test classifies patients by risk group compared with the NPI and Adjuvant! Online was also considered by the Committee. Although encouraging, this was a small preliminary study that did not provide an indication of how management decisions would actually change and did not materially change the results of the External Assessment Group analysis. The Committee also noted the recent availability of further data on IHC4 in the large TEAM study. The Committee considered that the general uncertainty in the clinical effectiveness evidence for IHC4 limited the validity of the economic analysis. It concluded that robust data on how the test might be used in the NHS in England (a continuous risk score, defined risk groups or both) and the impact of the test on clinical decision-making are needed. The Committee also indicated that data on the benefit of chemotherapy according to IHC4 score (or defined risk groups) would be useful. Although IHC4 was found to dominate current practice in the base-case economic analysis when offered to all women with ER+, LN−, HER2−early breast cancer and in a subgroup of women with an NPI score above 3.4, in addition to most of the sensitivity analyses, the Committee concluded that the uncertainty in the estimates of the clinical effectiveness of the test was too great to recommend adoption at this time. The Committee considered that further evidence was needed before the test could be adopted for general use by the NHS. Given the estimated low cost of the test and the modelling results that showed it has the potential to dominate current practice, the Committee considered it prudent to recommend the use of

© NICE 2013. All rights reserved. Last modified September 2013

IHC4 for research in the NHS to collect information on the analytical validity, and hence, clinical validity and clinical utility of the test (see section 7).

6.11 The Committee discussed the clinical evidence and the uncertainty in the estimates of the cost effectiveness of Mammostrat (because of uncertainty in the clinical evidence underpinning the economic analysis). The Committee noted there were limited published data on the analytical validity of the test. It went on to discuss the clinical validity of the test, and considered the results of the economic analysis to be limited because the risk reclassification data (provided in confidence) derived from a small subset of women included in the study by Ring et al. (2006; US cohort) demonstrated some inconsistencies and were not sufficiently robust in demonstrating the ability of the test to predict which women were at low, intermediate or high risk in the subgroup of women with an NPI score above 3.4. The Committee noted the recent availability of data on the clinical validity of Mammostrat in the TEAM study. The Committee considered that this study provides additional supportive data for a large UK population on the prognostic ability of the test and expands the evidence base to patients treated with aromatase inhibitors, rather than tamoxifen. Although further supportive data are available on the clinical validity of the test, the Committee considered that the economic analysis was also limited because there was uncertainty about the clinical utility of the test; in particular no evidence exists on how the test would affect clinical decision-making in England, and because of the discordant results (Ross et al. 2008) on the benefit of chemotherapy (only the low- and high-risk groups benefitted from chemotherapy but not the intermediate-risk group). Overall, although a limited number of studies have been conducted, the Committee was encouraged by the large sample sizes of the studies showing that Mammostrat can act as an independent prognostic tool. In particular, the Committee noted that a significant portion of the prognostic evidence was generated using UK-based patients. However, the Committee felt that to fully understand the benefits of the test, further data are needed to demonstrate how the test reclassifies people's risk when compared with current practice in England, and to demonstrate the impact of Mammostrat on clinical decision-making in England. The Committee considered that the uncertainty in the clinical-effectiveness evidence for Mammostrat limited the validity of the economic analysis. Therefore, given the uncertainty in the clinical effectiveness of the test (in

© NICE 2013. All rights reserved. Last modified September 2013

particular, the analytical validity and clinical utility), the Committee was unable to recommend the adoption of Mammostrat for general use in the NHS at this time and recommended the test for research use only. The Committee heard that there is an extensive ongoing research programme for this relatively new test.

6.12 The Committee discussed the clinical evidence and the uncertainty in the estimates of cost effectiveness of MammaPrint. The Committee noted that although the MammaPrint test was created using samples from an untreated breast cancer population, in particular with samples from patients who had not received endocrine therapy, data were available on the use of the test in patients treated with adjuvant endocrine therapy (for example, Kok et al. 2010). The Committee was not aware of evidence on the use of MammaPrint in UK clinical practice. The Committee noted that no new evidence was identified in the External Assessment Group's review on the analytical validity of the test, but that evidence had been identified in the previous systematic review by Marchionni et al. (2008). The Committee went on to consider the different sample types used by the test. The Committee was aware that the use of MammaPrint on formalin-fixed paraffin-embedded samples has been CE marked and that the manufacturer had submitted data to the Food and Drug Administration to demonstrate that the performance of MammaPrint in formalin-fixed paraffin-embedded samples is equivalent to that of fresh samples. The Committee discussed the clinical validity of the test and agreed with the External Assessment group that such evidence, although developing, is based on cohort studies of small sample sizes that have been conducted outside of England in a heterogeneous population of predominantly younger pre-menopausal women (younger women are more likely to be classified as having a poor prognosis using MammaPrint, which may overestimate the benefit of the test in the early breast cancer population as a whole). The Committee discussed the clinical utility of the test and noted that the risk reclassification data and the proportion of patients receiving chemotherapy were taken from studies of Dutch patients that included predominantly pre-menopausal women. Furthermore, the Committee agreed with the External Assessment Group that the impact of the test on decision-making in England had not been demonstrated and that the Knauer et al. study (2010) had considerable methodological limitations (see section 5.12), and therefore the

© NICE 2013. All rights reserved. Last modified September 2013

Committee considered that the clinical utility of MammaPrint had not been robustly demonstrated. The Committee considered that the uncertainty in the clinical-effectiveness evidence for MammaPrint limited the validity of the economic analysis.

6.13 The Committee also considered additional evidence on MammaPrint forwarded by the manufacturer, including the RASTER study (an updated analysis by Drukker et al. 2013), the IMPAKT 2012 working group statement and a summary of cost-effectiveness results based on NPI scores from 2 patient series data. However, the Committee agreed with the External Assessment Group, which concluded that this evidence did not materially change the results of the analysis. The Committee noted that the RASTER study provided prospective data on the additional prognostic value of MammaPrint when compared with Adjuvant! Online, in the form of an observational study of over 400 patients. However, the Committee considered that this study did not substantially reduce the uncertainty in clinical effectiveness because RASTER, similarly to other studies of MammaPrint, was conducted in the Netherlands in a younger population than that seen in England, with most patients younger than 55 years. The Committee also noted that treatment decisions were based on a range of factors, including the Dutch Institute for Healthcare Improvement (CBO) guidelines that are not used in England. In addition, the RASTER study included some patients with ER− (20%) or HER2+ (11% positive and 5% unknown) breast cancer. Using MammaPrint, these patients would be very likely to be categorised as having a poor prognosis and receive chemotherapy, which may lead to an overestimation of the benefit of the test in the population considered in this evaluation (ER+, LN− and HER2−). The Committee also considered the consensus statement by the IMPAKT 2012 working group and noted that it found the available evidence on the analytical validity and clinical validity of MammaPrint to be convincing. The Committee noted that the consensus statement did not summarise any new evidence not already included in the External Assessment Group's report. The Committee considered that the data on the clinical validity of the test were not generalisable to the population considered in this evaluation for the reasons already stated (that is, the data were from cohort studies of small sample sizes conducted outside England in a heterogeneous population of predominantly younger pre-menopausal women).

© NICE 2013. All rights reserved. Last modified September 2013

The Committee agreed with the External Assessment Group that the cost-effectiveness results based on NPI scores from 2 patient series lacked detailed descriptions of methodology, and so did not allow a clear assessment of the quality of the evaluation. Therefore, the Committee considered that the uncertainty in the clinical effectiveness data remained, and limited the validity of any economic analysis despite the additional evidence.

6.14 The Committee concluded that the uncertainty in the clinical effectiveness, in particular the clinical validity and clinical utility of the test, was too high to recommend the adoption of MammaPrint for general use in the NHS at this time and recommended the test for research only. The Committee noted that there is an ongoing prospective clinical trial (MINDACT) on the value of MammaPrint in predicting which patients would benefit from chemotherapy and that results from this trial may help to reduce the uncertainty about effectiveness.

6.15 The Committee expressed general concern over the lack of information on the impact of the use of gene expression profiling and expanded immunohistochemistry tests on clinical decision-making in England. It noted that some limited data on clinical decision-making in England were available for Oncotype DX, which were helpful in informing the assessment. The Committee requested further data on the ability of the tests to impact clinical decision-making. The applicable data forwarded by the manufacturers came from studies that were conducted outside England. The Committee agreed with the External Assessment Group that a lower baseline level of chemotherapy prescribing in England than in the USA or many other European countries increases the uncertainty in the generalisability of studies conducted outside England.

6.16 A potential equality issue was raised by the Committee, which was concerned about the lack of evidence on the use of the tests in women older than 75 years. The Committee accepted the evidence had been limited to women younger than 75 years; however, the recommendations in section 1 do not restrict access to the tests based on age of the patient. The Committee also discussed potential equality issues concerning the use of the new tests in men. The Committee heard that given the relatively low number of men with breast

© NICE 2013. All rights reserved. Last modified September 2013

cancer when compared with women, evidence on the performance of these tests in men was less likely to be generated. Experts on the Committee pointed out that breast cancer in men shared many characteristics with that seen in women and that both groups were treated similarly in clinical practice (see section 6.3). Therefore, the Committee felt it appropriate that the recommendations apply to both men and women.

© NICE 2013. All rights reserved. Last modified September 2013

7 Recommendations for further research

7.1 The following research is recommended in the context of people with oestrogen receptor positive (ER+), lymph node negative (LN−) or human epidermal growth factor receptor 2 negative (HER2−) early breast cancer.

7.2 **MammaPrint:** research is recommended on the clinical validity of the test in people that are representative of the population in England. In particular, information on how the test reclassifies people when compared with current practice in England and their risk of distant recurrence would be useful. Research into the clinical utility of the test is also recommended; in particular, evidence of the impact of the test on clinical decision-making in England and robust data on its ability to predict the benefit of chemotherapy.

7.3 **Oncotype DX:** research is recommended on the clinical utility of the test, including robust evidence on the impact of Oncotype DX on clinical decision-making in England (containing consideration of informal approaches compared with a formal algorithm for combining the Oncotype DX score with clinicopathological variables) and its ability to predict the benefit of chemotherapy. As part of the adoption of Oncotype DX by the NHS, the Committee encourages the collection of clinical utility and any other useful data by the health system, potentially by a multicentre audit.

7.4 The Committee noted that the MINDACT study is being conducted on MammaPrint and the TAILORx study is being conducted on Oncotype DX. The Committee encourages the availability of data showing the risk of distant recurrence of patients in these trials using tools representative of current practice adopted by the NHS (for example, Nottingham Prognostic Index [NPI] and Adjuvant! Online). Researchers should be mindful of the evolving breast cancer practice in England. For example, the emergence of the PREDICT tool; although a new tool at present, this may be more widely used in the future.

7.5 **IHC4:** research into the analytical validity (reliability and reproducibility) of the complete IHC4 test is recommended (an algorithm combining 4 markers and classical clinical and pathological variables), particularly within the NHS and when performed in local laboratories. Studies to confirm the prognostic ability

© NICE 2013. All rights reserved. Last modified September 2013

and to determine the impact of IHC4 on clinical decision-making in England and, ideally, to predict the benefit of chemotherapy are recommended.

7.6 **Mammostrat:** research on the analytical validity (reliability and reproducibility) of the test is recommended. Research on the clinical utility of the test is also recommended. In particular, evidence of how the test reclassifies people's risk when compared with current practice in England, evidence on the impact of Mammostrat on clinical decision-making in England, and its ability to predict the benefit of chemotherapy.

© NICE 2013. All rights reserved. Last modified September 2013

8 Implementation

8.1 NICE will support this guidance with a range of activities to promote the recommendations for further research. This will include incorporating the research recommendations in section 7 into the NICE guidance research recommendations database (available on the NICE website at www.nice.org.uk) and highlighting these recommendations to public research bodies. The research proposed will also be put forward to NICE's Medical Technologies Evaluation Programme research facilitation team for consideration of the development of specific research protocols.

8.2 The manufacturer has offered Oncotype DX to the NHS under a proposal (December 2012) that makes Oncotype DX available to the NHS at a revised price. The proposal price is commercial-in-confidence. It is the responsibility of the manufacturer to communicate details of the proposal to the relevant NHS organisations. Any enquiries from NHS organisations about the access proposal should be directed to Genomic Health UK at NHSOncotype@genomichealth.com or 020 3031 8087.

© NICE 2013. All rights reserved. Last modified September 2013

10 Review

NICE updates the literature search at least every 3 years to ensure that relevant new evidence is identified. NICE will contact product sponsors and other stakeholders about issues that may affect the value of the diagnostic technologies. NICE may review and update diagnostics guidance at any time if significant new evidence becomes available.

11 Diagnostics Advisory Committee members and NICE project team

Diagnostics Advisory Committee

The Diagnostics Advisory Committee is an independent committee consisting of 22 standing members and additional specialist members. During this assessment the membership of the Diagnostics Advisory Committee changed as some members reached the end of their terms and others were appointed in their place. A full list of the Committee members who participated in this assessment appears below.

Standing Committee members

Dr Trevor Cole
Consultant Clinical and Cancer Geneticist, Birmingham Women's Hospital

Professor Paul Collinson
Consultant Chemical Pathologist and Professor of Cardiovascular Biomarkers, St George's Hospital

Dr Sue Crawford
General Practitioner (GP) Principal, Chillington Health Centre

Professor Ian Cree
Senior Clinical Advisor, National Institute for Health Research (NIHR) Evaluation Trials and Studies Coordinating Centre, University of Southampton

Professor Erika Denton
National Clinical Director for Imaging, Department of Health, Honorary Professor of Radiology, University of East Anglia and Norfolk and Norwich University Hospital

Dr Steve Edwards
Head of Health Technology Assessment, British Medical Journal (BMJ) Evidence Centre

Mr David Evans
Lay member

© NICE 2013. All rights reserved. Last modified September 2013

Dr Simon Fleming
Consultant in Clinical Biochemistry and Metabolic Medicine, Royal Cornwall Hospital

Professor Lisa Hall
Professor of Analytical Biotechnology, University of Cambridge

Professor Chris Hyde
Professor of Public Health and Clinical Epidemiology, Peninsula Technology Assessment Group (PenTAG)

Professor Noor Kalsheker
Professor of Clinical Chemistry, University of Nottingham

Dr Gail Norbury
Consultant Clinical Scientist, Guy's and St Thomas' NHS Foundation Trust

Dr Mark Kroese (Vice Chair)
Diagnostics Advisory Committee and Consultant in Public Health Medicine, PHG Foundation, Cambridge and UK Genetic Testing Network

Dr Peter Naylor
General Practitioner (GP), Chair Wirral Health Commissioning Consortia

Professor Adrian Newland (Chair)
Diagnostics Advisory Committee

Dr Richard Nicholas
Consultant Neurologist, Honorary Senior Lecturer, Heatherwood and Wexham Park Hospitals

Ms Margaret Ogden
Lay member

Mr Stuart Saw
Director of Finance, North East London and the City primary care trusts

© NICE 2013. All rights reserved. Last modified September 2013

Professor Mark Sculpher
Professor of Health Economics at the Centre for Health Economics, University of York

Dr Steve Thomas
Consultant Vascular and Cardiac Radiologist at Sheffield Teaching Hospitals Foundation Trust

Mr Paul Weinberger
Chief Executive Officer (CEO), Diasolve Ltd, London

Mr Christopher Wiltsher
Lay representative

Specialist Committee members

Professor Anthony Howell
Director of the Breakthrough Breast Cancer Research

Mr Simon Pain
Consultant Breast and Endocrine Surgeon, Department of General Surgery, Norfolk and Norwich University Hospital

Mrs Ursula Van Mann
Lay member

Mrs Carole Farrell
Nurse Clinician, The Christie NHS Foundation Trust

Professor Louise Jones
Consultant Clinical Scientist, Barts and the London NHS Trust

NICE project team

Each diagnostics assessment is assigned to a team consisting of a Technical Analyst (who acts as the topic lead), Technical Advisers and Project Managers.

© NICE 2013. All rights reserved. Last modified September 2013

Gurleen Jhuti
Topic Lead

Hanan Bell and Pall Jonsson
Technical Advisers

Jackson Lynn and Robert Fernley
Project Managers

12 Sources of evidence considered by the Committee

The diagnostics assessment report was prepared by the School of Health and Related Research (ScHARR).

- Ward S, Scope A, Rachid R et al. Gene expression profiling and expanded immunohistochemistry tests to guide the use of adjuvant chemotherapy in breast cancer management, October 2011.

Registered stakeholders

The following organisations accepted the invitation to participate in this assessment as stakeholders. They were invited to attend the scoping workshop and to comment on the diagnostics assessment report and the diagnostics consultation document.

Manufacturers/sponsors:

The technologies under consideration

- Agendia Bvd (MammaPrint)
- Clarient (Mammostrat)
- Genomic Health (Oncotype DX)
- Royal Marsden Hospital and Queen Mary University London – academic sponsor (IHC4)

Comparator technologies

- None

Other

- ARUP Laboratories
- Ipsogen
- Nottingham University
- Randox Laboratories

© NICE 2013. All rights reserved. Last modified September 2013

- Roche Diagnostics

Professional/specialist and patient/carer groups:

- BHR University NHS Trust
- Breakthrough Breast Cancer
- Bupa
- Cambridge University Hospital
- Cherry Lodge Cancer Care
- Mersey and Cheshire Cancer Network
- Royal College of Physicians
- Southport and Ormskirk Hospital NHS Trust
- The Royal College of Pathologists
- University College London Hospitals NHS Foundation Trust
- University Hospital of South Manchester

About this guidance

NICE diagnostics technologies guidance is designed to help the NHS adopt efficient and cost-effective medical diagnostic technologies more rapidly and consistently.

The programme concentrates on pathological tests, imaging, endoscopy and physiological measurement, since these represent most of the investigations performed on patients. The types of products that might be included are medical diagnostic technologies that give greater independence to patients, and diagnostic devices or tests used to detect or monitor medical conditions. Diagnostic technologies may be used for various purposes: diagnosis, clinical monitoring, screening, treatment triage, assessing stages of disease progression, and risk stratification.

This guidance was developed using the NICE diagnostic technologies guidance process.

We have produced a summary for patients and carers. Tools to help you put the guidance into practice and information about the evidence it is based on are also available.

Your responsibility
This guidance represents the view of NICE, which was arrived at after careful consideration of the evidence available. Healthcare professionals are expected to take it fully into account when exercising their clinical judgement. However, the guidance does not override the individual responsibility of healthcare professionals to make decisions appropriate to the circumstances of the individual patient, in consultation with the patient and/or guardian or carer.

Implementation of this guidance is the responsibility of local commissioners and/or providers. Commissioners and providers are reminded that it is their responsibility to implement the guidance, in their local context, in light of their duties to have due regard to the need to eliminate unlawful discrimination, advance equality of opportunity, and foster good relations. Nothing in this guidance should be interpreted in a way which would be inconsistent with compliance with those duties.

81471	X-linked intellectual disability (XLID) (eg, syndromic and non-syndromic XLID); duplication/deletion gene analysis, must include analysis of at least 60 genes, including ARX, ATRX, CDKL5, FGD1, FMR1, HUWE1, IL1RAPL, KDM5C, L1CAM, MECP2, MED12, MID1, OCRL,		X					

2015 Genetic Testing CPT code review

81410-81411

1) Aortic dysfunction or dilation (eg, Marfan syndrome, Loeys Dietz syndrome, Ehler Danlos syndrome type IV, arterial tortuosity syndrome); genomic sequence analysis pane
2) Used for diagnosing both symptomatic patients and asymptomatic family members
3) **American College of Medical Genetics (2012)–**evaluation of a patient with possible Marfan's Syndrome
    a. Consider *FBN1* gene sequencing
    b. Searching for mutations in *FBN1*continues to have a circumscribed role in the diagnosis of equivocal cases. Said differently, MFS remains, by and large, a clinical diagnosis.
    c. Does not address screening asymptomatic family members
4) **American College of Cardiology/American Heart Association (2010)** guidelines for diagnosis and management of patients with thoracic aortic disease
    a. Test for genes associated with aortic aneurysm and/or dissection in patients and family members (*FBN1, TGFBR1, TGFBR2,COL3A1, ACTA2, MYH11*)
    b. Use test results to limit aortic imaging to relatives with the genetic mutation. *(LOE: C)*

1) **Canadian Cardiovascular Society (2014)** opinion
    a. We recommend clinical and genetic screening for suspected Marfan syndrome to clarify the nature of the disease and provide a basis for individual counselling (Strong Recommendation, High-Quality Evidence).
    b. Affects monitoring—recommend echocardiographic screening at diagnosis to measure aortic root and ascending aorta diameters, and repeated 6 months thereafter to determine rate of progression. If aortic diameters remain stable, annual imaging is recommended. (Strong Recommendation, High-Quality Evidence).
2) Recommendation:
    a. **Diagnostic** List

81415-81417

1) Exome testing
2) The human exome comprises only 1–2% of the whole genome, it is this portion that codes for proteins, and was thought to contain 85% of all pathogenic mutations causing Mendelian disorders. The exome can be sequenced in only 48 h at roughly a third of the cost, with far fewer data to store and analyse compared to whole genome testing
3) GAP comments:

   a. May find other genetic mutations that do not address the specific reason for the tests (i.e. BRCA1 mutation, etc.); therefore, need careful genetic counseling prior to testing
   b. Used when there are multiple anomalies in a child, or when other specific testing has not found a diagnosis. 20-30% chance of finding a genetic cause for a syndrome or developmental delay in a population of children who already had non-revealing testing
   c. Cost is about $5000 for a test, may be cost effective rather than doing a series of single gene tests
   d. Recommended change to non-prenatal genetic testing guideline: "A genetic counseling/geneticist visit is required prior to ordering test."
   e. From Cary Harding: Regarding 81417: If any validation of an exome result is necessary, that should be done by another method rather than repeating an exome analysis

4) OHP medical director feedback:
   a. My main concerns are these: it appears that there is a great likelihood of identifying lots of "noise" mutations—things that may or may not have anything to do with the actual problem at hand…many [of the] genetic syndromes don't have any specific treatments that improve their outcome, so it might not alter treatment. It is possible that health monitoring might be changed, because we are basically screening for any genetic mutation. Depending on whether a specific diagnosis is reached, prognosis may change; further testing of parents would probably be needed to answer questions regarding family risk. So an argument could be made that it meets guideline D1, although it really is not clear.
   b. I would need CLEAR documentation how the genetic consultant believes the testing will treat the member. I do get provider feedback with a confirmed diagnosis would allow health plan benefits for the member otherwise not received and this is a majority of our current requests. Our CCO rarely approves this request on the basis it appears to be an investigation and is not assisting on a treatment plan.
   c. Until mutations are better known and we know which ones truly would materially benefit treatment/outcome, I concur testing would be investigational and hence not be covered by OHP plan. There also is the ethics concern raised…of uncovering incidental mutations that may be alarming to members and/or their blood relatives with uncertainty in what it means and whether any prophylactic treatment is indicated. I recommend testing be focused based on strong scientific findings for which recommendations include well-reasoned consideration risks vs. benefits.
5) Other expert input (Alison Adams Martinez, Ph.D**.,** Geneticist Oklahoma Health Care Authority)
   a. The published policies of most private payers indicate that they do not cover WES. However, once you get past testing more than 2-3 whole genes, it actually becomes more cost effective to do the WES up front and prevent the parade of single-gene test requests. So, I felt that the literature/other policies would support

us if we wanted to take a hardline stance against covering WES, but at the same time we could justify covering it in cases where the member's clinical features would make them eligible for genetic testing of multiple genes…we agreed that we would reimburse for WES in select cases…[but] if we got too many claims that we would have to revisit the decision and not cover it at all. So far, we have paid for maybe 10 WES claims over the past year. In all cases, they met the criteria outlined by the ACMG. We've paid between $5-7K per WES claim

6) Evidence
    - **a. TEC 2013**
        - i. Has an algorithm indicating when testing may be indicated
        - ii. Diagnostic yield 10-50%
        - iii. Concern for many mutations found that have no or unknown clinical significance or are unrelated to the reason for testing
        - iv. Medical management decisions, including initiation of new treatment or discontinuing inappropriate treatment, may result for only a subset of those diagnosed.
        - v. Reproductive decisions for parents considering an additional pregnancy may be informed by determining the mode of inheritance.
        - vi. Appropriate use of exome sequencing requires considerable genetic, clinical, and genetic counseling expertise.
7) Other coverage policies
    - **a. Aetna 2014**
        - i. Exome testing is experimental
    - **b. Anthem BCBS 2014**
        - i. Diagnostic genetic testing using panels of genes (with or without next generation sequencing), including but not limited to whole genome and whole exome sequencing, is considered **investigational and not medically necessary** unless all components of the panel have been determined to be medically necessary based on the criteria above. .
8) Recommendations:
    - a. 81415, 81416 (whole exome testing, sequence analysis and comparator genome sequencing): **Diagnostic List**
    - b. 81417 (re-evaluation): **Non-covered List**
        - i. Note: exclusion of 81417 was based on expert testimony that was not reviewed by the entire GAP.
    - c. See changes to the non-prenatal genetic testing guideline
        - i. Requirement for genetic consultation prior to covering test (81415, 81416)
        - ii. Statement that 81417 is non-covered

81425-81427

1) Genome testing
2) Sequencing of an entire human genome to test for genetic mutations. The human genome can now be sequenced in 2 weeks for approximately £4000 (€4700, US$6200) in many laboratories.

3) GAP comments: "not ready for clinical prime time"; "premature for use in clinical practice"; "need for data/experience." Decision was to delay coverage until more research has been done to clarify the role of these tests in clinical practice
4) Recommendation: **Non-covered List**
    a. Notation made in the non-prenatal genetic testing guideline

81430-81431

1) 81430: Hearing loss (eg, nonsyndromic hearing loss, Usher syndrome, Pendred syndrome); genomic sequence analysis panel, must include sequencing of at least 60 genes, including CDH23, CLRN1, GJB2, GPR98, MTRNR1, MYO7A, MYO15A, PCDH15, OTOF, SLC26A4, TMC1, TMPRSS3
2) 81431: Hearing loss (eg, nonsyndromic hearing loss, Usher syndrome, Pendred syndrome); duplication/deletion analysis panel, must include copy number analyses for STRC and DFNB1 deletions in GJB2 and GJB6 genes
3) Similar code placement:
    a. GJB2 and GJB6 gene analysis assays for nonsyndromic hearing loss are on the diagnostic list (81252, 81253)
4) **American College of Medical Genetics 2014,** guideline for evaluation of hearing loss
    a. If nonsyndromic hearing loss is suspected, consider single-gene tests such as *GJB2* and *GJB6*, gene panel tests, or NGS testing based on history and findings
5) GAP comments: Start with the two most likely tests, if normal, use panels. GJB2 and 6 tests find about 50% of genetic problems. GJB2/6 testing costs $500, panels $3-5,000
    a. Recommend adding clause to guideline: GJB2 and GJB6 need to be tested first and be negative in non-syndromic patients prior to panel being covered
6) Recommendation—**Diagnostic List**
    a. See recommended changes to the non-prenatal genetic testing guideline

81435, 81436

1) 81435-6: Hereditary colon cancer syndromes (eg, Lynch syndrome, familial adenomatosis polyposis); duplication/deletion gene analysis panel, must include analysis of at least 7 genes, including APC, CHEK2, MLH1, MSH2, MSH6, MUTYH, and PMS2
2) Similar Prioritized List placements:
    a. Testing for Lynch syndrome (hereditary nonpolyposis colon cancer) (CPT 81292-81300) with a guideline
        i. MLH1, MSH2, MSH6 individual gene tests (81292-81300)
            1. Current MLH1 tests include full sequence analysis, known familial variants, and duplication/deletion variants (81292-81294)
        ii. PMS2 individual gene tests (81317-81319)

3) **National Comprehensive Cancer Network (NCCN) 2014** screening guideline for colon cancer
    a. Recommends screening for MLH1, MSH2, MSH6, FMS2 and EPCAM for high risk family members
    b. Test results change screening frequency and age to begin screening for affected persons
4) Recommendation: **Diagnostic** List
    a. See recommended changes to the Non-Prenatal Genetic Testing Guideline

81440, 81460, 81465

1) Mitochondrial genome testing
2) Mutations of mitochondrial DNA can lead to a number of illnesses including exercise intolerance and Kearns-Sayre syndrome (KSS). Some evidence suggests that they might be major contributors to the aging process and age-associated pathologies. Recently a mutation in mtDNA has been used to help diagnose prostate cancer in patients with negative prostate biopsy.
3) Evidence
    a. **Falk 2010**, review of mitochondrial disease
        i. Recommends whole mitochondrial DNA genome sequencing when a strong suspicion exists based on the symptom constellation and family history.
        ii. Panel testing of approximately a dozen "common" mtDNA point mutations that cause well-characterized disorders…has historical significance but current utility primarily in adults. Indeed, the high cost of such limited point mutation panel testing currently approximates that of sequencing the entire 16,569 basepair mitochondrial DNA genome…it is typically more cost-efficient and ultimately informative to complete whole mitochondrial DNA genome sequence analysis to evaluate individuals (particularly children) with strong maternal pedigrees
        iii. It is important to realize that mtDNA may harbor other genetic abnormalities that are not detectable by whole genome sequence analysis.
4) GAP comments: "May avoid muscle biopsy or other diagnostic studies." Dr. Cary Harding, a metabolic specialist, thought this test was appropriate in certain clinical situations. He recommended putting in a guideline requiring a genetics or metabolic consult prior to ordering the test.
5) Recommendation: **Diagnostic List**
    a. See recommended changes to the Non-Prenatal Genetic Testing Guideline
        i. Requires genetic or metabolic consult prior to ordering test

81470, 81471

1) X-linked intellectual disability (XLID) (eg, syndromic and non-syndromic XLID); genomic sequence analysis panel

2) Refers to forms of intellectual disability which are specifically associated with X-linked recessive inheritance. As with most X-linked disorders, males are more heavily affected than females. Females with one affected X chromosome and one normal X chromosome tend to have milder symptoms. Unlike many other types of intellectual disability, the genetics of these conditions are relatively well understood. It has been estimated there are ~200 genes involved in this syndrome; of these ~100 have been identified. X-linked intellectual disability accounts for ~16% of all cases of intellectual disability in males.
3) The panel testing would include multiple of these known genes
4) Similar code coverage:
    a. CPT 81243, 81244 (Fragile X genetic testing) is covered with the following notation in the genetic testing guideline:
        i. "for individuals with intellectual disability/developmental delay. Although the yield of Fragile X is 3.5-10%, this is included because of additional reproductive implications."
5) GAC input: do not cover. The labs consulted on this question report a pick up rate for significant mutations is quite low, <5%
6) Recommendation: **Non-covered List**
    a. Notation made in the non-prenatal genetic testing guideline

GAC Recommended Changes to the Diagnostic Guideline D1, Non-Prenatal Genetic Testing Guideline
October 16, 2014

Issues:

1) The Non-Prenatal Genetic Testing Algorithm has modifications suggested by the Genetics Advisory Committee. These suggestions have arisen out of the review of the 2015 CPT codes regarding specific genetic tests.

Recommendations:

1) Adopt the amended Diagnostic Guideline 1 as below

DIAGNOSTIC GUIDELINE D1, NON-PRENATAL GENETIC TESTING GUIDELINE

Coverage of genetic testing in a non-prenatal setting shall be determined by the algorithm shown in Figure C.1 unless otherwise specified below.

A) Related to genetic testing for patients with breast/ovarian and colon/endometrial cancer or other related cancers suspected to be hereditary, or patients at increased risk to due to family history.
   1) Services are provided according to the Comprehensive Cancer Network Guidelines.
      a) Lynch syndrome (hereditary colorectal and endometrial cancer, and other
      a) cancers associated with Lynch syndrome) services (CPT 81288, 81292-81300, 81317-81319, 81435, 81436) and familial adenomatous polyposis (FAP) services (CPT 81201-81203) should be provided as defined by the NCCN Clinical Practice Guidelines in Oncology. ~~Colorectal Cancer Screening~~ Genetic/Familial High-Risk Assessment: Colorectal. V.2.2014 ~~V.1.2013~~ (~~5/13/13~~ 5/19/14). ***www.nccn.org***
      b) BRCA1/BRCA2 testing services (CPT 81211-81217) for women without a personal history of breast, ovarian and other associated cancers should be provided to high risk women as defined ~~in Guideline Note 3 or as otherwise defined~~ by the US Preventive Services Task Force or according to the NCCN Clinical Practice Guidelines in Oncology. Genetic/Familial High-Risk Assessment: Breast and Ovarian. V.2.2014 (9/23/14). ***www.nccn.org***..
      c) BRCA1/BRCA2 testing services (CPT 81211-81217) for women with a personal history of breast, ovarian and other associated cancers and for men with breast cancer should be provided according to the NCCN Clinical Practice Guidelines in Oncology. Genetic/Familial High-Risk Assessment: Breast and Ovarian. V.2.2014 (9/23/14) ~~V.1.2011 (4/7/11).~~ ***www.nccn.org***
      d) PTEN (Cowden syndrome) services (CPT 81321-81323) should be provided as defined by the NCCN Clinical Practice Guidelines in Oncology. Colorectal Screening. V.1.2013 (5/13/13). ***www.nccn.org.***
   2) Genetic counseling should precede genetic testing for hereditary cancer whenever possible.
      a) Pre and post-test genetic counseling should be covered when provided by a suitably trained health professional with expertise and experience in cancer genetics
         i) "Suitably trained" is defined as board certified or active candidate status from the American Board of Medical Genetics, American Board of Genetic Counseling, or Genetic Nursing Credentialing Commission.
      b) If timely pre-test genetic counseling is not possible for time-sensitive cases, appropriate genetic testing accompanied by pre- and post- test informed consent and post-test disclosure performed by a board-certified physician with experience in cancer genetics should be covered.
         i) Post-test genetic counseling should be performed as soon as is practical.
   3) If the mutation in the family is known, only the test for that mutation is covered. For example, if a mutation for BRCA 1 has been identified in a family, a single site mutation analysis for that mutation is covered (CPT 81215), while a full sequence BRCA 1 and 2 (CPT 81211) analyses is not. There is one exception, for individuals of Ashkenazi Jewish ancestry with a known mutation in the family, the panel for Ashkenazi Jewish BRCA mutations is covered (CPT 81212).
   4) Costs for rush genetic testing for hereditary breast/ovarian and colon/endometrial cancer is not covered.

B) Related to diagnostic evaluation of individuals with intellectual disability (defined as a full scale or verbal IQ < 70 in an individual > age 5), developmental delay (defined as a cognitive index <70

on a standardized test appropriate for children < 5 years of age), Autism Spectrum Disorder, or multiple congenital anomalies:

1) CPT 81228, Cytogenomic constitutional microarray analysis for copy number variants for chromosomal abnormalities: Cover for diagnostic evaluation of individuals with intellectual disability/developmental delay; multiple congenital anomalies; or, Autism Spectrum Disorder accompanied by at least one of the following: dysmorphic features including macro or microcephaly, congenital anomalies, or intellectual disability/developmental delay in addition to those required to diagnose Autism Spectrum Disorder. In 2012, this test may also be billed using one of CPT 88384-88386, or stacking CPTs 83890-83915.
2) CPT 81229, Cytogenomic constitutional microarray analysis for copy number variants for chromosomal abnormalities; plus cytogenetic constitutional microarray analysis for single nucleotide polymorphism (SNP) variants for chromosomal abnormalities: Cover for diagnostic evaluation of individuals with intellectual disability/developmental delay; multiple congenital anomalies; or, Autism Spectrum Disorder accompanied by at least one of the following: dysmorphic features including macro or microcephaly, congenital anomalies, or intellectual disability/developmental delay in addition to those required to diagnose Autism Spectrum Disorder; only if (a) consanguinity and recessive disease is suspected, or (b) uniparental disomy is suspected, or (c) another mechanism is suspected that is not detected by the copy number variant test alone. In 2012, this test may also be billed using one of CPT 88384-88386, or stacking CPTs 83890-83915.
3) CPT 81243, 81244, Fragile X genetic testing is covered for individuals with intellectual disability/developmental delay. Although the yield of Fragile X is 3.5-10%, this is included because of additional reproductive implications.
4) A visit with the appropriate specialist (often genetics, developmental pediatrics, or child neurology), including physical exam, medical history, and family history is covered. Physical exam, medical history, and family history by the appropriate specialist, prior to any genetic testing is often the most cost-effective strategy and is encouraged.

C) Related to other tests with specific CPT codes:
1) The following tests are not covered:
   a) CPT 81225, CYP2C9 (cytochrome P450, family 2, subfamily C, polypeptide 9) (eg, drug metabolism), gene analysis, common variants (eg, *2, *3, *5, *6)
   b) CPT 81226, CYP2D6 (cytochrome P450, family 2, subfamily D, polypeptide 6) (eg, drug metabolism), gene analysis, common variants (eg, *2, *3, *4, *5, *6, *9, *10, *17, *19, *29, *35, *41, *1XN, *2XN, *4XN).
   c) CPT 81227, CYP2C9 (cytochrome P450, family 2, subfamily C, polypeptide 9) (eg, drug metabolism), gene analysis, common variants (eg, *2, *3, *5, *6)
   d) CPT 81287, MGMT (O-6-methylguanine-DNA methyltransferase) (eg, glioblastoma multiforme), methylation analysis
   e) CPT 81291, MTHFR (5,10-methylenetetrahydrofolate reductase) (eg, hereditary hypercoagulability) gene analysis, common variants (eg, 677T, 1298C)
   f) CPT 81330, SMPD1(sphingomyelin phosphodiesterase 1, acid lysosomal) (eg, Niemann-Pick disease, Type A) gene analysis, common variants (eg, R496L, L302P, fsP330)
   g) CPT 81350, UGT1A1 (UDP glucuronosyltransferase 1 family, polypeptide A1) (eg, irinotecan metabolism), gene analysis, common variants (eg, *28, *36, *37)
   h) CPT 81355, VKORC1 (vitamin K epoxide reductase complex, subunit 1) (eg, warfarin metabolism), gene analysis, common variants (eg, -1639/3673)
   i) CPT 81417, re-evaluation of whole exome sequencing
   j) CPT 81425-81427, Genome sequence analysis
   k) CPT 81470, 81471, X-linked intellectual disability (XLID) genomic sequence panels
   l) CPT 81504, Oncology (tissue of origin), microarray gene expression profiling of > 2000 genes, utilizing formalin-fixed paraffin-embedded tissue, algorithm reported as tissue similarity scores
2) The following tests are covered only if they meet the criteria for the Non-Prenatal Genetic Testing Algorithm AND the specified situations:
   a) CPT 81205, BCKDHB (branched-chain keto acid dehydrogenase E1, beta polypeptide) (eg, Maple syrup urine disease) gene analysis, common variants (eg, R183P, G278S,

E422X): Cover only when the newborn screening test is abnormal and serum amino acids are normal

b) Diagnostic testing for cystic fibrosis (CF)
   i) CFTR, cystic fibrosis transmembrane conductance regulator tests. CPT 81220, 81223, 81222: For infants with a positive newborn screen for cystic fibrosis or who are symptomatic for cystic fibrosis, or for clients that have previously been diagnosed with cystic fibrosis but have not had genetic testing, CFTR gene analysis of a panel containing at least the mutations recommended by the American College of Medical Genetics* (CPT 81220) is covered. If two mutations are not identified, CFTR full gene sequencing (CPT 81223) is covered. If two mutations are still not identified, duplication/deletion testing (CPT 81222) is covered. These tests may be ordered as reflex testing on the same specimen.
c) Carrier testing for cystic fibrosis
   i) CFTR gene analysis of a panel containing at least the mutations recommended by the American College of Medical Genetics* (CPT 81220) is covered.
d) CPT 81240. F2 (prothrombin, coagulation factor II) (eg, hereditary hypercoagulability) gene analysis, 20210G>A variant: Factor 2 20210G>A testing should not be covered for adults with idiopathic venous thromoboembolism; for asymptomatic family members of patients with venous thromboembolism and a Factor V Leiden or Prothrombin 20210G>A mutation; or for determining the etiology of recurrent fetal loss or placental abruption.
e) CPT 81241. F5 (coagulation Factor V) (eg, hereditary hypercoagulability) gene analysis, Leiden variant: Factor V Leiden testing should not be covered for: adults with idiopathic venous thromoboembolism; for asymptomatic family members of patients with venous thromboembolism and a Factor V Leiden or Prothrombin 20210G>A mutation; or for determining the etiology of recurrent fetal loss or placental abruption.
f) CPT 81256, HFE (hemochromatosis) (eg, hereditary hemochromatosis) gene analysis, common variants (eg, C282Y, H63D): Covered for diagnostic testing of patients with elevated transferrin saturation or ferritin levels. Covered for predictive testing ONLY when a first degree family member has treatable iron overload from HFE.
g) CPT 81332 SERPINA1 (serpin peptidase inhibitor, clade A, alpha-1 antiproteinase, antitrypsin, member 1) (eg, alpha-1-antitrypsin deficiency), gene analysis, common variants (eg, *S and *Z): The alpha-1-antitrypsin protein level should be the first line test for a suspected diagnosis of AAT deficiency in symptomatic individuals with unexplained liver disease or obstructive lung disease that is not asthma or in a middle age individual with unexplained dyspnea. Generic testing or the anpha-1 phenotype test is appropriate is the protein test is abnormal or borderline. The genetic test is appropriate for siblings of people with AAT deficiency regardless of the AAT protein test results.
h) CPT 81415-81417, exome testing: A genetic counseling/geneticist consultation is required prior to ordering test
i) CPT 81430-81431, Hearing loss (eg, nonsyndromic hearing loss, Usher syndrome, Pendred syndrome); genomic sequence analysis panel: Testing for mutations in GJB2 and GJB6 need to be done first and be negative in non-syndromic patients prior to panel testing.
j) CPT 81440, 81460, 81465, mitochondrial genome testing: A genetic counseling/geneticist or metabolic consultation is required prior to ordering test.

3) Do not cover a more expensive genetic test (generally one with a wider scope or more detailed testing) if a cheaper (smaller scope) test is available and has, in this clinical context, a substantially similar sensitivity. For example, do not cover CFTR gene sequencing as the first test in a person of Northern European Caucasian ancestry because the gene panels are less expensive and provide substantially similar sensitivity in that context.

ACMG PRACTICE GUIDELINES | Genetics inMedicine

Evaluation of the adolescent or adult with some features of Marfan syndrome

Reed E. Pyeritz, MD, PhD;[1] for the Professional Practice and Guidelines Committee, ACMG

Disclaimer: ACMG standards and guidelines are designed primarily as an educational resource for medical geneticists and other health care providers to help them provide quality medical genetic services. Adherence to these standards and guidelines does not necessarily ensure a successful medical outcome. These standards and guidelines should not be considered inclusive of all proper procedures and tests or exclusive of other procedures and tests that are reasonably directed to obtaining the same results. In determining the propriety of any specific procedure or test, the geneticists should apply their own professional judgment to the specific clinical circumstances presented by the individual patient or specimen. It may be prudent, however, to document in the patient's record the rationale for any significant deviation from these standards and guidelines.

Individuals who are suspected of having Marfan syndrome are often referred to a medical geneticist for further evaluation and diagnosis. However, there are a number of conditions that share physical manifestations with those of Marfan syndrome; therefore, an approach to diagnosis and evaluation is crucial to the proper long-term follow-up of these individuals. This practice guideline provides guidance for the approach to this cadre of individuals.

Genet Med 2012:14(1):171–177

Key Words: aortic aneurysm; aortic dissection; fibrillin; Loeys–Dietz syndrome; marfanoid

INTRODUCTION

A common reason for referral to cardiologists and medical geneticists is the tall, lanky individual who wants clearance for physical activities or who has vague complaints of discomfort in the back, chest, or joints. Obviously, concern for Marfan syndrome (MFS) is appropriate, but frequently the diagnosis cannot be established by the original "Ghent Criteria."[1] The specialist often wonders whether or how to label such an individual, whether further testing (such as computed tomography (CT) of the spine) or molecular genetic testing is necessary, and whether to recommend follow-up evaluation. New diagnostic criteria for MFS have been published recently.[2] A practice guideline that addresses these issues in the context of the new criteria will assist a variety of clinicians in dealing more appropriately with such patients and reduce instances of overly restricting people who do not have MFS or inappropriately reassuring those who do.

The following list of disorders (with OMIM numbers in parentheses) presents considerable diagnostic challenges because of shared features, overlapping phenotypes, similar inheritance patterns, and, at least for some, causation by mutations in the same gene, *FBN1*.

- MFS (154700)
- Ehlers–Danlos syndrome, hypermobile type (EDS) (130020)
- Familial thoracic aortic aneurysm and dissection (reviewed in 607086)
- Loeys–Dietz syndrome (LDS) and other disorders of TGFβ receptors (reviewed in 609192)
- Congenital contractural arachnodactyly (CCA) (121050)
- MASS phenotype (604308)
- Familial arterial tortuosity syndrome (208050)
- Familial mitral valve prolapse (MVP) (157700)
- Familial ectopia lentis (129600)
- Bicuspid aortic valve sequence (109730)
- Familial tall stature
- Familial pectus excavatum (169300)
- Familial scoliosis (181800)
- Stickler syndrome (108300)

Diagnostic criteria for these related disorders are based entirely on expert opinion, but rarely have groups of experts collaborated on refining their ideas.[1,3] The entire field suffers from the lack of any systematic attempt to apply rigorous methodology to categorization. The focus of what follows is the evaluation for the MFS. Comments about the other disorders are included as an appendix.

Medical geneticists, cardiologists, and sports medicine physicians, among others, are frequently consulted about tall, thin children and adolescents out of concern for MFS. The main reason that primary-care providers are interested in ruling MFS in or out is the risk of progressive aortic dilatation and aortic dissection, particularly related to physical activity. In this regard, if the echocardiogram shows an aortic root dimension within the normal range for body surface area,[4] in almost all of the disorders to be considered, the risk of aortic dissection is very low. The one exception is LDS[5] and other phenotypes

[1]Perelman School of Medicine, University of Pennsylvania, Philadelphia, Pennsylvania, USA. Correspondence: Reed E. Pyeritz (reed.pyeritz@uphs.upenn.edu)

Submitted 24 October 2011; accepted 25 October 2011; advance online publication 5 January 2012. doi:10.1038/gim.2011.48

associated with mutations in *TGFBR1* and *TGFBR2*,[6] in some of which both the aorta and its major branches dissect in the absence of much, if any, dilatation. Thus, the echocardiogram is an essential test whenever any of these conditions is considered seriously and whenever concerns about modulating physical activity are raised. Likewise, a slit-lamp examination, with the pupils fully dilated, is essential to exclude ectopia lentis; when MFS is seriously suspected, this test should be performed by an ophthalmologist comfortable with the ocular features of MFS.

Because all of the conditions listed above (except arterial tortuosity syndrome, which is recessive) can be inherited as autosomal dominant traits, the family history is a crucial component of any diagnostic matrix. Historical information may suffice, but usually more detail is needed in the form of medical and autopsy records. Frequently, a grandparent dies of an "aneurysm" and the family does not know what vessel or what region of the aorta was involved. More so in the past than now, a relative who died of an ascending aortic dissection and had a postmortem examination that showed "cystic medical necrosis" was automatically said to have had MFS, even in the absence of any other physical features of that condition. Personally examining the sibs and parents of a child in whom MFS is suspected is at least as important as obtaining a complete family history. Many of the helpful diagnostic features, such as scoliosis, striae atrophicae, disproportionate stature, MVP, and aortic root dilatation are clinically silent and may not be apparent to the relative and those close to him or her.

Almost all of the conditions listed above are "syndromes," in that multiple features are required to establish the diagnosis. For those conditions caused by a mutation in a single gene, the syndromic features are pleiotropic manifestations of the mutation and the pathogenetic mechanisms that derive from it. However, a number of important caveats affect this interpretation. First, virtually all of the features are age dependent; when examining a young relative, usually fewer features will be evident than in older relatives. Second, all genetic syndromes show variable expression beyond age dependency, for reasons that are poorly understood. Third, many of the features of these conditions also occur "sporadically" in the general population for both genetic and nongenetic reasons. Examples are nearsightedness, tall stature, pectus excavatum, scoliosis, joint hypermobility, and MVP. Fourth, many of these same features are more likely to occur among relatives because of polygenic contributions to pathogenesis. Occasional families will show such frequent occurrence of one of these features that Mendelian inheritance is inferred; this led to some of the diagnoses listed above, although with rare exceptions the causative locus has not been identified. Examples are familial forms of pectus excavatum, scoliosis, tall stature, and what the rheumatologists term "familial benign joint hypermobility," which is distinguished from forms of EDS by an absence of involvement of the skin.

The frequency of specific features in the general population contributes to their importance as diagnostic criteria in a Bayesian sense. For example, lumbosacral dural ectasia occurs in very few conditions besides MFS and LDS and almost never in the absence of some systemic disorder. This prompted the inclusion of dural ectasia as a "major criterion" for the diagnosis of MFS in the Ghent scheme.[1] Similar reasoning was used to so distinguish ectopia lentis, aortic dissection, and aortic dilatation. But it is important to emphasize again that these decisions were based on expert opinion and are just beginning to be subjected to formal scrutiny. If the diagnosis of MFS is clear in a patient who has no back or radicular pain, then there is almost no need to image the lower spine. On the other hand, if the diagnosis of MFS hangs on whether dural ectasia is present, then the effort, expense, and radiation (if a CT scan is done) of imaging are warranted. The severity of dural ectasia is clearly age dependent, but no cross-sectional survey of a pediatric population has been performed to determine when radiographic features appear. In the new diagnostic criteria for MFS, the presence or absence of dural ectasia has been reduced in importance.

Some of the diagnoses are ones of exclusion. For example, a family history of aortic aneurysms and mild thoracic-cage abnormalities, with no one meeting criteria for MFS, warrants a label of familial aortic aneurysm (although that implies little about etiology). Likewise, a family history of MVP and mild joint hypermobility, in the absence of features of MASS such as striae, thoracic-cage abnormalities, and myopia, warrants a label of familial MVP. Familial pectus, familial tall stature, and familial ectopia lentis fall into this group. Occasionally, long-term follow-up of patients or introduction of relatives with a wider spectrum of features may prompt reevaluation of the initial diagnosis. This has happened rather often with familial ectopia lentis due to mutations in *FBN1*.

Because echocardiography is an expensive, if benign, test, physicians often wonder whether to rescreen and at what interval. Certainly in MFS, a maximum interval is annually; the larger the aortic root diameter, the more frequently the test should be performed. This holds for familial aortic aneurysm, bicuspid aortic valve with aneurysm, and LDS. For the tall, lanky adolescent with flat feet and myopia, if the family history is unremarkable and the initial echocardiogram is completely normal, the study might be repeated only if cardiovascular symptoms arise. A great many patients fall somewhere in between, and repeating an echocardiogram every 2 to 3 years, or whenever a major increase in physical exertion is planned, seems reasonable. Interestingly, patients followed by cardiologists tend to have echocardiograms more frequently.

Anyone with moderate or severe aortic root dilation and/or a *TGFBR1* or *-2* mutation should be taught the signs and symptoms of aortic dissection and should consider wearing a medical alert bracelet.

EVALUATION FOR MFS

MFS is characterized by autosomal dominant inheritance of features in the skeletal, ocular, cardiovascular, and pulmonary

systems, along with muscular and adipose hypoplasia, dural ectasia, and hernias.[7] As individuals with MFS live longer with aggressive and prophylactic management of their cardiovascular disease, additional features are emerging, such as renal and hepatic cysts.[8] Because about one-third of patients have parents unaffected by MFS, more features are required in them to be certain of the diagnosis. Mutations in *FBN1*, the gene that encodes the large glycoprotein, fibrillin-1, cause MFS, but also cause many of the related conditions. Conversely, conditions that have been confused with MFS, such as CCA and LDS, are due to mutations in genes that encode either related proteins (e.g., fibrillin-2) or proteins involved in pathogenesis of common features (e.g., TGFβ receptors). There is no case of classic, bona fide MFS due to mutations in a gene other than *FBN1*. However, current clinical molecular testing of *FBN1* successfully detects mutations in such unequivocal patients in only about 90–95% of cases.[9] For all of these reasons, searching for mutations in *FBN1* continues to have a circumscribed role in the diagnosis of equivocal cases. Said differently, MFS remains, by and large, a clinical diagnosis.

Diagnostic criteria

If there is no family history of MFS, then the subject has the condition under any of the following four situations:

A dilated aortic root (defined as greater than or equal to two standard deviations above the mean for age, sex, and body surface area, i.e., a *Z*-score of > +2) and ectopia lentis
A dilated aortic root and a mutation in *FBN1* that is clearly pathologic
A dilated aortic root and multiple systemic features (see below) or
Ectopia lentis and a mutation in *FBN1* that has previously been associated with aortic disease

If there is a positive family history of MFS (independently ascertained with these criteria), then the subject has the condition under any of the following three situations:

Ectopia lentis
Multiple systemic features (see below) or
A dilated aortic root (if over 20 years, greater than two standard deviations; if younger than 20, greater than three standard deviations)

The scoring system for systemic features involves the following:

Wrist AND thumb sign = 3 (wrist OR thumb sign = 1)
Pectus carinatum deformity = 2 (pectus excavatum or chest asymmetry = 1)
Hindfoot deformity = 2 (plain pes planus = 1)
Pneumothorax = 2
Dural ectasia = 2
Protrusio acetabuli = 2
Reduced upper-to-lower segment ratio AND increased arm/height AND no severe scoliosis = 1
Scoliosis or thoracolumbar kyphosis = 1
Reduced elbow extension = 1
Facial features (three of five including dolichocephaly, enophthalmos, downslanting palpebral fissures, malar hypoplasia, and retrognathia) = 1
Skin striae = 1
Myopia >3 diopters = 1
Mitral valve prolapse (all types) = 1
Maximum total: 20 points; score of 7 or more indicates systemic involvement

Diagnostic evaluation

1. Physical exam
2. Family history
3. Echocardiogram
4. Dilated eye exam
5. Consider CT or magnetic resonance imaging for evidence of lumbosacral dural ectasia and protrusion acetabulae
6. Consider *FBN1* gene sequencing

Management

Cardiovascular: (recommend management by a skilled cardiologist)

A. Aortic root dilation and/or diagnostic criteria met for MFS:

Annual echocardiogram for root diameter <4.5 cm in an adult and rate of increase <0.5 cm/year

β-Blocker therapy.[10] A randomized controlled trial of losartan versus atenolol is under way, but the results are potentially not available until 2013–14.[11] The final *N* of 604 subjects was reached at the end of January 2011.

Echocardiogram every 6 months if diameter is >2 SD in an adult or rate of increase in size is >0.5 cm/year

Surgical repair for measurements >4.5 cm, rate of increase in size >1 cm/year, or progressive aortic regurgitation

Magnetic resonance angiography or CT of the entire aorta starting in young adulthood. Repeat annually if there is a history of aortic root replacement or dissection, less frequently if not

B. Normal aortic root size with systemic involvement of another system with a positive family/genetic history:

Annual echocardiogram

C. Normal aortic root size with systemic involvement with a negative family/genetic history:

Repeat echocardiogram every 2 to 3 years until adult height is reached. Then repeat if symptomatic or when a major increase in physical activity is planned. The diameter of the aortic root is slightly larger in men than women of the same body size and, in both sexes, increases very slightly and gradually in normal individuals with age, but should not exceed the general upper limit of normal of 40–42 mm, even in tall individuals.

APPENDIX

EDS HYPERMOBILE TYPE

Joint hypermobility in this condition may mimic that in MFS. The skin may be mildly hyperextensible whereas it rarely is in MFS. Aortic root dilation, usually mild, occurs in one-quarter to one-third of individuals with EDS classic and hypermobility types.[12] There is not thought to be a risk of dissection without significant aortic root dilatation. Long-term prognosis is not known. Other features include joint laxity, easy bruising, functional bowel disorders, osteoporosis, and chronic pain.

Diagnostic criteria

Diagnosis is based on clinical evaluation and family history. A small subset of individuals with the hypermobile form of EDS have an insertion or deletion in the *TNXB* gene.

Major diagnostic criteria[13]

All of the following criteria should be met to establish a diagnosis of EDS, hypermobility type:

1. Joint hypermobility confirmed by a score of 5 or more on the 9-point Beighton scale:[14]
   - Passive dorsiflexion of each fifth finger >90 degrees (1 point each side)
   - Passive apposition of each thumb to the flexor surface of the forearm (1 point each side)
   - Hyperextension of each elbow >10 degrees (1 point each side)
   - Hyperextension of each knee >10 degrees (1 point each side)
   - Place palms flat on the floor when bending over with knees fully extended (1 point)
2. Soft or velvety skin with normal or slightly increased extensibility
3. Absence of skin or soft tissue fragility (suggestive of other EDS subtypes)

Minor diagnostic criteria

These criteria are supportive but not sufficient to establish the diagnosis.

1. Autosomal dominant family history of similar features without skin abnormalities
2. Recurrent joint dislocation or subluxation
3. Chronic joint or limb pain
4. Easy bruising
5. Functional bowel disorders (functional gastritis, irritable bowel syndrome)
6. Neurally mediated hypotension or postural orthostatic tachycardia
7. High, narrow palate
8. Dental crowding

Diagnostic evaluation

1. Physical exam
2. Family history
3. Echocardiogram to evaluate for aortic root dilatation
4. Dilated eye exam (to exclude MFS)

Management

Cardiovascular: (recommend management by a skilled cardiologist)

A. Normal aortic root size:

Repeat echocardiogram every 2–3 years until adult height reached. If no dilatation present, repeat echocardiogram if cardiovascular symptoms develop or when a major increase in physical activity is planned. If dilatation present, follow as described in the next section.

B. Aortic root dilation:

Echocardiogram every 6 months if diameter is >4.5 cm in an adult or rate of increase in size is >0.5 cm/year. Annual echocardiogram for root diameter <4.5 cm in an adult and rate of increase is <0.5 cm/year

C. Bone Density:

Encourage calcium and vitamin D supplementation
Low-impact weight-bearing exercise
Order DXA scan for height loss greater than one inch

D. Gastrointestinal:

Gastritis and reflux may require a proton pump inhibitor, H-2 blocker, and sucralfate.
Delayed gastric emptying may require a promotility agent
Irritable bowel is treated with antispasmodics, antidiarrheals, and laxatives as needed

E. Musculoskeletal:

Low-resistance exercise is recommended to improve joint stability by increasing muscle tone. Physical therapy for myofascial release is often necessary to facilitate participation in low-resistance exercise. A pain management specialist is a crucial participant in the care of a patient with EDS hypermobile type with chronic pain. Due to a general decrease in the degree of stabilization and pain reduction and the duration of improvement as compared with those without EDS hypermobile type, orthopedic surgery should be delayed, if possible, in favor of physical therapy and bracing.
Vitamin C is a cofactor for cross-linking of collagen fibrils and may improve hypermobility

FAMILIAL THORACIC AORTIC ANEURYSM AND DISSECTION (FAA)

Some families show an autosomal dominant predisposition to developing aneurysms in the thoracic aorta whereas others develop dilatation anywhere in the aorta. The larger the dilatation, the greater the risk of dissection. In other families, a risk of dissection exists with minimal or no dilatation. Several genetic

loci have been mapped in families with aortic aneurysm, but most of the genes are yet to be identified. *TGFBR2* mutations have been reported in a few families. Two splicing and one missense mutation in the *MYH11* gene have been described in two families with FAA and patent ductus arteriosus.[15] Occasionally, patients with aortic aneurysm will have deformity of the thoracic cage (scoliosis, pectus excavatum). These skeletal changes are also seen in people with bicuspid aortic valve sequence, which raises the question of whether patients with only ascending aortic aneurysms are simply failing to express the bicuspid valve.

Diagnostic evaluation[16]

1. Physical examination
2. Family history
3. Echocardiogram
4. Dilated eye exam (to exclude MFS)
5. Consider gene sequencing
6. Imaging of the vasculature, including the cerebral vasculature, for those with a genetic mutation that predisposes to diffuse arteriopathy

Diagnostic criteria

Autosomal dominant family history of dilation or dissection of the aortic root, ascending aorta, or descending aorta in the absence of major criteria for the diagnosis of MFS or another connective tissue disorder.

Management (recommend management by a skilled cardiologist)

Aortic dissection is rare in early childhood, but aortic dilation may be present. In most adults, the risk of aortic dissection or rupture becomes significant at diameters >5.0 cm. However, mutations in some genes (*TGFBR1* and *-2*) predispose to dissection at smaller and even normal aortic diameters. Persons with mutations in *MYH11, SMAD3,* and *ACTA2* should be considered for repair with a diameter between 4.5–5.0 cm.

Annual echocardiograms for individuals with small aortic dimensions and slow rate of increase of the dilation in the absence of a *TGFBR* mutation

Echocardiograms at least every 6 months if the root exceeds 4.5 cm in an adult, the rate of aortic growth exceeds 0.5 cm/year, or significant aortic regurgitation occurs.

Imaging of the entire aorta every 2–3 years

β-blockade for aortic root dilation. No randomized controlled trial of angiotensin receptor blockade is planned.

Prophylactic surgical repair if the rate of dilation approaches 1 cm/year, if there is progression of aortic regurgitation, if the diameter approaches 5 cm in those with a mutation known to predispose to earlier dissection, when the diameter is 5.0 cm in those with bicuspid aortic valve, and for a diameter of 5.0–5.5 cm for all others.

LDS

The features include characteristic facial features, craniosynostosis, bifid uvula or cleft palate, tortuosity of the aorta and its branches, aortic dilatation and dissection, and joint hypermobility.[5] Patients have had mutations in one or another of the receptors for TGFβ. When this condition is suspected, echocardiography must be augmented by a CT or magnetic resonance angiogram of the thorax, abdomen, and pelvis. Because dissection tends to occur at smaller aortic diameters than in MFS, earlier prophylactic aortic root repair is indicated. A variant of LDS strongly resembles the vascular form of Ehlers–Danlos syndrome, especially in terms of thin skin.

Diagnostic evaluation

1. Physical exam
2. Family history
3. Echocardiogram
4. Dilated eye exam (to exclude MFS)
5. Magnetic resonance angiography of the head, neck, thorax, abdomen, and pelvis
6. *TGFBR1* and *TGFBR2* gene sequencing

Diagnostic criteria

In a patient found to have consistent facial features, bifid uvula, and arterial tortuosity, the diagnosis can be confirmed with *TGFBR* testing. Tortuosity can sometimes be isolated (e.g., found only in the head and neck), requiring the magnetic resonance angiography of the head, neck, thorax, abdomen, and pelvis for a complete evaluation.

Management (recommend management by a skilled cardiologist)

Craniosynostosis is treated in the standard manners

Annual echocardiogram if no aortic root dilation

Echocardiogram at least every 6 months if aortic root dilation is detected

Annual magnetic resonance angiography of the head, neck, thorax, abdomen, and pelvis

β-blockade. There is no randomized controlled trial of angiotensin receptor blockade under way.

Aortic dilation and dissection in childhood is a feature of LDS, but not for all patients with a mutation in *TGFBR1* or *TGFBR2*. There is a low threshold for prophylactic aortic grafting in LDS. If the progression is rapid, aortic root replacement is recommended at 2.0 cm.[17]

CCA, BEALS SYNDROME

This condition shows congenital contractures of the elongated digits, elbows, and knees that can improve with physical therapy. Scoliosis develops during childhood and can become severe. The helix of the ear shows overfolding. There is no ectopia lentis. There is a Marfan-like habitus. Originally, the cardiovascular system was said to be unaffected, but first MVP and more recently aortic dilatation have been described. Every patient thought to have CCA should have echocardiography, perhaps on a regular basis, at least during childhood and adolescence. Congenital contractures, typically of the digits and

elbows, also occur in MFS. Some "crumpling" of the ear is also not uncommon in the general population. Therefore, diagnosis of CCA can be difficult. The role of examining the *FBN2* locus for mutations is unclear.

Diagnostic evaluation

1. Physical exam
2. Family history
3. Echocardiogram
4. Dilated eye exam (to exclude MFS)
5. Consider *FBN2* gene sequencing

Diagnostic criteria

Individuals with CCA typically have a marfanoid habitus; flexion contractures of multiple joints including elbows, hips, knees, and fingers; kyphoscoliosis; muscular hypoplasia; and abnormal pinnae ("crumpled" outer helices).[18]

Management

Physical therapy for joint manifestations and surgical release of severe contractures

Bracing and/or surgical correction of kyphoscoliosis

Echocardiogram every 2 years until adult height reached. If no dilation present, repeat if symptomatic or when a major increase in physical activity is planned.

Annual evaluation by physical exam for scoliosis until adult height reached

Aortic root dilation is treated as described above MFS

MASS PHENOTYPE

The acronym stands for mitral valve prolapse and myopia, an aortic root that may be at the upper limits of normal in caliber, striae atrophicae, and skeletal features reminiscent of, but less severe than, MFS.[19] A few patients designated as having MASS have had mutations in *FBN1*, but most do not. This condition is termed a "phenotype" because there are undoubtedly multiple causes. Importantly, almost all patients diagnosed as having MASS over a decade showed no progressive aortic root dilatation or aortic dissection (Pyeritz unpublished).

This diagnosis cannot be made with certainty in the absence of a multigenerational family history documenting no progression of aortic root dilation. Therefore, a child who appears to have the MASS phenotype without a family history should be followed as described above for MFS.

FAMILIAL ARTERIAL TORTUOSITY SYNDROME

This condition was first described as a severe condition of infancy. Recently, a pleiotropic condition of adults that shows autosomal recessive inheritance was described.[6] Patients have marked tortuosity of the aorta and its branches, and there is a predisposition to dissection. They also have telangiectases of the cheeks, lax skin, high palate, and joint laxity. When this condition is suspected, echocardiography must be augmented by a CT or magnetic resonance angiogram of the thorax, abdomen, and pelvis. Mutations in a nuclear glucose transporter encoded by the *SLC2A10* gene have been found.[20]

Monitoring guidelines are the same as those described above for LDS.

MVP

In some families, MVP occurs as an autosomal dominant trait, either isolated or in association with an asthenic habitus. Because the pathogenesis of MVP is varied, the valvular abnormality is seen in a number of other hereditary syndromes, including dilated cardiomyopathy, myotonic dystrophy, fragile-X syndrome, and some in this Appendix, including MASS, various EDS types, bicuspid aortic valve, and Stickler syndrome.

A child with MVP and an asthenic habitus should have aortic root measurements taken when MVP monitoring echocardiograms are done. If dilation of the aortic root is found, the child should be followed as described above for MFS.

FAMILIAL ECTOPIA LENTIS

Some families show variable skeletal manifestations of MFS along with ectopia lentis. Initially, these cases were said not to have aortic dilatation, but subsequently some have developed this feature and are more appropriately said to have MFS. Mutations near the 3′-end of *FBN1* have been associated with this autosomal dominant condition. If ectopia lentis and 3′ mutation are observed, follow the cardiovascular system as described above for MFS.

BICUSPID AORTIC VALVE SEQUENCE

Left-sided flow defects show more familial predisposition than any other general class of congenital heart disease other than conotruncal defects. The causes are unknown, but a defect of the neural crest is suspected. The features that show variable expression in families with this sequence are congenital bicuspid aortic valve, dilatation of the ascending aorta (not usually the sinuses of Valsalva), aortic coarctation, MVP, and thoracic-cage deformity. Heterozygosity for mutations in *NOTCH1* has been reported in a few families and in 4% of sporadic cases of bicuspid aortic valve.[21]

FAMILIAL TALL STATURE

One family distinguished by pectus excavatum and tall stature in the proband and tall stature in the relatives had a mutation in *FBN1*. No one had cardiovascular problems. There has been no systematic survey of disproportionately tall individuals for other features of MFS or mutations in *FBN1*.

FAMILIAL PECTUS EXCAVATUM

Pectus excavatum occurs as an autosomal dominant trait in occasional families. The literature is silent on whether pectus carinatum or combined anterior chest defects also occur, probably because ascertainment has typically been through surgeons consulted to repair the excavatum defects. There has been no systematic survey for other features of MFS or mutations in *FBN1*.

FAMILIAL SCOLIOSIS

"Idiopathic" scoliosis clearly shows familial predispositions.[22,23] There has been no systematic survey for other features of MFS or mutations in *FBN1*.

STICKLER SYNDROME

Occasionally, the person with Stickler syndrome will be considered initially as having MFS or another connective tissue disorder. The features that overlap include retrognathia, high-grade myopia and retinal detachment, and MVP.

DISCLOSURE

The author declares no conflict of interest.

1. Introduction

The term “thoracic aortic disease” encompasses a broad range of degenerative, structural, acquired, genetic-based, and traumatic disease states and presentations. According to the Centers for Disease Control and Prevention death certificate data, diseases of the aorta and its branches account for 43 000 to 47 000 deaths annually in the United States. The precise number of deaths attributable to thoracic aortic diseases is unclear. However, autopsy studies suggest that the presentation of thoracic aortic disease is often death due to aortic dissection (AoD) and rupture, and these deaths account for twice as

many deaths as attributed to ruptured abdominal aortic aneurysms (AAAs). This guideline includes diseases involving any or all parts of the thoracic aorta with the exception of aortic valve diseases and includes the abdominal aorta when contiguous thoracic aortic diseases are present.

Table 1. Applying Classification of Recommendations and Level of Evidence

ESTIMATE OF CERTAINTY (PRECISION) OF TREATMENT EFFECT	SIZE OF TREATMENT EFFECT	
	CLASS I *Benefit >>> Risk* Procedure/Treatment SHOULD be performed/ administered	**CLASS IIA** *Benefit >> Risk* *Additional studies with focused objectives needed* IT IS REASONABLE to perform procedure/administer treatment
LEVEL A Multiple populations evaluated* Data derived from multiple randomized clinical trials or meta-analyses	■ Recommendation that procedure or treatment is useful/effective ■ Sufficient evidence from multiple randomized trials or meta-analyses	■ Recommendation in favor of treatment or procedure being useful/effective ■ Some conflicting evidence from multiple randomized trials or meta-analyses
LEVEL B Limited populations evaluated* Data derived from a single randomized trial or nonrandomized studies	■ Recommendation that procedure or treatment is useful/effective ■ Limited evidence from single randomized trial or nonrandomized studies	■ Recommendation in favor of treatment or procedure being useful/effective ■ Some conflicting evidence from single randomized trial or nonrandomized studies
LEVEL C Very limited populations evaluated* Only consensus opinion of experts, case studies, or standard of care	■ Recommendation that procedure or treatment is useful/effective ■ Only expert opinion, case studies, or standard of care	■ Recommendation in favor of treatment or procedure being useful/effective ■ Only diverging expert opinion, case studies, or standard of care
Suggested phrases for writing recommendations†	should is recommended is indicated is useful/effective/beneficial	is reasonable can be useful/effective/beneficial is probably recommended or indicated

Class IIb *Benefit ≥ Risk* *Additional studies with broad objectives needed; additional registry data would be helpful* Procedure/Treatment MAY BE CONSIDERED	Class III *Risk ≥ Benefit* Procedure/Treatment should NOT be performed/administered SINCE IT IS NOT HELPFUL AND MAY BE HARMFUL
■ Recommendation's usefulness/efficacy less well established ■ Greater conflicting evidence from multiple randomized trials or meta-analyses	■ Recommendation that procedure or treatment is not useful/effective and may be harmful ■ Sufficient evidence from multiple randomized trials or meta-analyses
■ Recommendation's usefulness/efficacy less well established ■ Greater conflicting evidence from single randomized trial or nonrandomized studies	■ Recommendation that procedure or treatment is not useful/effective and may be harmful ■ Limited evidence from single randomized trial or nonrandomized studies
■ Recommendation's usefulness/efficacy less well established ■ Only diverging expert opinion, case studies, or standard of care	■ Recommendation that procedure or treatment is not useful/effective and may be harmful ■ Only expert opinion, case studies, or standard of care
may/might be considered may/might be reasonable usefulness/effectiveness is unknown /unclear/uncertain or not well established	is not recommended is not indicated should not is not useful/effective/beneficial may be harmful

* Data available from clinical trials or registries about the usefulness/efficacy in different subpopulations, such as sex, age, history of diabetes, history of prior myocardial infarction, history of heart failure, and prior aspirin use. A recommendation with Level of Evidence B or C does not imply that the recommendation is weak. Many important clinical questions addressed in the guidelines do not lend themselves to clinical trials. Even though randomized trials are not available, there may be a very clear clinical consensus that a particular test or therapy is useful or effective.

† In 2003, the ACCF/AHA Task Force on Practice Guidelines developed a list of suggested phrases to use when writing recommendations. All guideline recommendations have been written in full sentences that express a complete thought, such that a recommendation, even if separated and presented apart from the rest of the document (including headings above sets of recommendations), would still convey the full intent of the recommendation. It is hoped that this will increase readers' comprehension of the guidelines and will allow queries at the individual recommendation level.

2. Critical Issues

As the writing committee developed this guideline, several critical issues emerged:

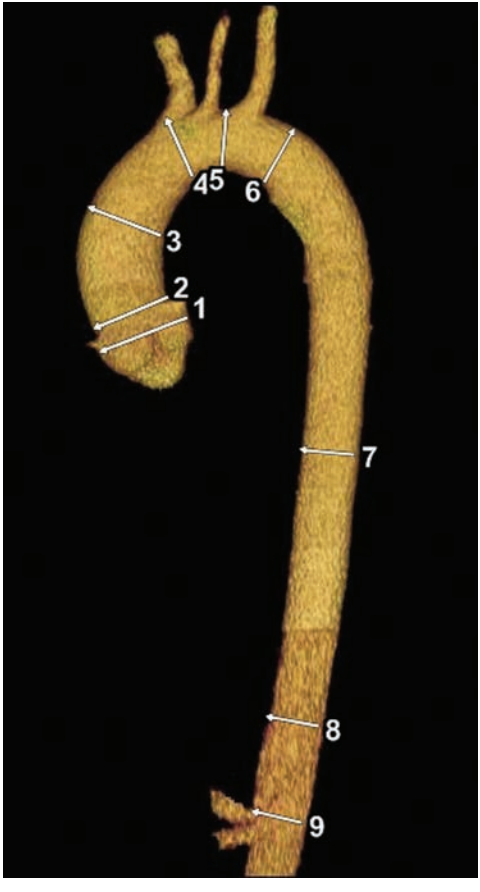
- Thoracic aortic diseases are usually asymptomatic and not easily detectable until an acute and often catastrophic complication occurs. Imaging of the thoracic aorta with computed tomographic imaging (CT), magnetic resonance imaging (MR), or in some cases, echocardiographic examination is the only method to detect thoracic aortic diseases
- Radiologic imaging technologies have improved in terms of accuracy of detection of thoracic aortic disease. However risks associated with repeated radiation exposure, as well as contrast medium–related toxicity have also been recognized. The writing committee therefore formulated recommendations on a standard reporting format (Section 3) as well as surveillance schedules (Section 21).
- Imaging for asymptomatic patients at high risk based on history or associated disease is expensive and not always covered by payers.
- For many thoracic aortic diseases, results of treatment for stable, often asymptomatic, but high-risk conditions are far better than the results of treatment required for acute and often catastrophic disease presentations. Thus, the identification and treatment of patients at risk for acute and

catastrophic disease presentations (eg, thoracic AoD and thoracic aneurysm rupture) prior to such an occurrence are paramount to eliminating the high morbidity and mortality associated with acute presentations.

■ Patients with acute AoD are subject to missed or delayed detection of this catastrophic disease state. Many present with atypical symptoms and findings, making diagnosis even more difficult. Awareness of the varied and complex nature of thoracic aortic disease presentations has been lacking, especially for acute AoD. Risk factors and clinical presentation clues are noted in Section 7. The collaboration of multiple medical specialties for this guideline will provide opportunities to raise the level of awareness among all medical specialties.

■ There is rapidly accumulating evidence that genetic alterations or mutations predispose some individuals to aortic diseases (see Sections 4-6). Therefore, identification of the genetic alterations leading to these aortic diseases has the potential for early identification of individuals at risk. In addition, biochemical abnormalities involved in the progression of aortic disease are being identified through studies of patients' aortic samples and animal models of the disease. The biochemical alterations identified in the aortic tissue have the potential to serve as biomarkers for aortic disease. Understanding the molecular pathogenesis may lead to targeted therapy to prevent aortic disease. Medical and gene-based treatments are beginning to show promise for reducing or delaying catastrophic complications of thoracic aortic diseases.

Figure 1. Normal Anatomy of the Thoracoabdominal Aorta.



Anatomic Location	
1.	Aortic sinuses of Valsalva
2.	Sinotubular junction
3.	Mid ascending aorta (midpoint in length between Nos. 2 and 4)
4.	Proximal aortic arch (aorta at the origin of the innominate artery)
5.	Mid aortic arch (between left common carotid and subclavian arteries)
6.	Proximal descending thoracic aorta (begins at the isthmus, approximately 2 cm distal to left subclavian artery)
7.	Mid descending aorta (midpoint in length between Nos. 6 and 8)
8.	Aorta at diaphragm (2 cm above the celiac axis origin)
9.	Abdominal aorta at the celiac axis origin

Normal anatomy of the thoracoabdominal aorta with standard anatomic landmarks for reporting aortic diameter as illustrated on a volume-rendered CT image of the thoracic aorta. CT indicates computed tomographic imaging.

3. Recommendations for Aortic Imaging Techniques to Determine the Presence and Progression of Thoracic Aortic Disease

Class I

1. Measurements of aortic diameter should be taken at reproducible anatomic landmarks, perpendicular to the axis of blood flow, and reported in a clear and consistent format. *(LOE: C)*

2. For measurements taken by computed tomographic imaging or magnetic resonance imaging, the external diameter should be measured perpendicular to the axis of blood flow. For aortic root measurements, the widest diameter, typically at the mid-sinus level, should be used. *(LOE: C)*

3. For measurements taken by echocardiography, the internal diameter should be measured perpendicular to the axis of blood flow. For aortic root measurements the widest diameter, typically at the mid-sinus level, should be used. *(LOE: C)*

4. Abnormalities of aortic morphology should be recognized and reported separately even when aortic diameters are within normal limits. *(LOE: C)*

5. The finding of aortic dissection, aneurysm, traumatic injury and/or aortic rupture should be immediately communicated to the referring physician. *(LOE: C)*

6. Techniques to minimize episodic and cumulative radiation exposure should be utilized whenever possible. *(LOE: B)*

Class IIa

1. If clinical information is available, it can be useful to relate aortic diameter to the patient's age and body size. *(LOE: C)*

Table 2. Essential Elements of Aortic Imaging Reports

1. The location at which the aorta is abnormal.
2. The maximum diameter of any dilatation, measured from the external wall of the aorta, perpendicular to the axis of flow, and the length of the aorta that is abnormal.
3. For patients with presumed or documented genetic syndromes at risk for aortic root disease measurements of aortic valve, sinuses of Valsalva, sinotubular junction, and ascending aorta.
4. The presence of internal filling defects consistent with thrombus or atheroma.
5. The presence of IMH, PAU, and calcification.
6. Extension of aortic abnormality into branch vessels, including dissection and aneurysm, and secondary evidence of end-organ injury (eg, renal or bowel hypoperfusion
7. Evidence of aortic rupture, including periaortic and mediastinal hematoma, pericardial and pleural fluid, and contrast extravasation from the aortic lumen.
8. When a prior examination is available, direct image to image comparison to determine if there has been any increase in diameter.

IMH indicates intramural hematoma; and PAU, penetrating atherosclerotic ulcer.

Table 3. Normal Adult Thoracic Aortic Diameters

Thoracic Aorta	Range of Reported Mean (cm)	Reported SD (cm)	Assessment Method
Root (female)	3.50 to 3.72	0.38	CT
Root (male)	3.63 to 3.91	0.38	CT
Ascending (female, male)	2.86	NA	CXR
Mid-descending (female)	2.45 to 2.64	0.31	CT
Mid-descending (male)	2.39 to 2.98	0.31	CT
Diaphragmatic (female)	2.40 to 2.44	0.32	CT
Diaphragmatic (male)	2.43 to 2.69	0.27 to 0.40	CT, arteriography

CT indicates computed tomographic imaging; CXR, chest x-ray; and NA, not applicable.

Reprinted with permission from Johnston KW, Rutherford RB, Tilson MD, et al. Suggested standards for reporting on arterial aneurysms. Subcommittee on Reporting Standards for Arterial Aneurysms, Ad Hoc Committee on Reporting Standards, Society for Vascular Surgery and North American Chapter, International Society for Cardiovascular Surgery. J Vasc Surg. 1991;13:452–8.

4. Recommendations for Genetic Syndromes

Class I

1. An echocardiogram is recommended at the time of diagnosis of Marfan syndrome to determine the aortic root and ascending aortic diameters and 6 months thereafter to determine the rate of enlargement of the aorta. *(LOE: C)*

2. Annual imaging is recommended for patients with Marfan syndrome if stability of the aortic diameter is documented. If the maximal aortic diameter is 4.5 cm or greater, or if the aortic diameter shows significant growth from baseline, more frequent imaging should be considered. *(LOE: C)*

3. Patients with Loeys-Dietz syndrome or a confirmed genetic mutation known to predispose to aortic aneurysms and aortic dissections *(TGFBR1, TGFBR2, FBN1, ACTA2,* or *MYH11)* should undergo complete aortic imaging at initial diagnosis and 6 months thereafter to establish if enlargement is occurring. *(LOE: C)*

4. Patients with Loeys-Dietz syndrome should have yearly magnetic resonance imaging from the cerebrovascular circulation to the pelvis. *(LOE: B)*

5. Patients with Turner syndrome should undergo imaging of the heart and aorta for evidence of bicuspid aortic valve, coarctation of the aorta, or dilatation of the ascending thoracic aorta. If initial imaging is normal and there are no risk factors for aortic dissection, repeat imaging should be performed every 5 to 10 years or if otherwise clinically indicated. If abnormalities exist, annual imaging or follow-up imaging should be done. *(LOE: C)*

Class IIa

1. It is reasonable to consider surgical repair of the aorta in all adult patients with Loeys-Dietz syndrome or a confirmed *TGFBR1* or *TGFBR2* mutation and an aortic diameter of 4.2 cm or greater by transesophageal echocardiogram (internal diameter) or 4.4 to 4.6 cm or greater by computed tomographic imaging and/or magnetic resonance imaging (external diameter). *(LOE: C)*

2. For women with Marfan syndrome contemplating pregnancy, it is reasonable to prophylactically replace the aortic root and ascending aorta if the diameter exceeds 4.0 cm. *(LOE: C)*

3. If the maximal cross-sectional area in square centimeters of the ascending aorta or root divided by the patient's height in meters exceeds a ratio of 10, surgical repair is reasonable because shorter patients have dissection at a smaller size and 15% of patients with Marfan syndrome have dissection at a size smaller than 5.0 cm. *(LOE: C)*

Class IIb

1. In patients with Turner syndrome with additional risk factors, including bicuspid aortic valve, coarctation of the aorta, and/or hypertension, and in patients who attempt to become pregnant or who become pregnant, it may be reasonable to perform imaging of the heart and aorta to help determine the risk of aortic dissection. *(LOE: C)*

Table 4. Gene Defects Associated With Familial Thoracic Aortic Aneurysm and Dissection

Defective Gene Leading to Familial Thoracic Aortic Aneurysms and Dissection	Contribution to Familial Thoracic Aortic Aneurysms and Dissection	Associated Clinical Features	Comments on Aortic Disease
TGFBR2 mutations	4%	Thin, translucent skin Arterial or aortic tortuosity Aneurysm of arteries	Multiple aortic dissections documented at aortic diameters <5.0 cm
MYH11 mutations	1%	Patent ductus arteriosus	Patient with documented dissection at 4.5 cm
ACTA2 mutations	14%	Livedo reticularis Iris flocculi Patent ductus arteriosus Bicuspid aortic valve	Two of 13 patients with documented dissections <5.0 cm

ACTA2 indicates actin, alpha 2, smooth muscle aorta; *MYH11*, smooth muscle specific beta-myosin heavy chain; and *TGFBR2*, transforming growth factor-beta receptor type II.

Table 5. Genetic Syndromes Associated With Thoracic Aortic Aneurysm

Genetic Syndrome	Common Clinical Features	Genetic Defect
Marfan syndrome	Skeletal features (see text) Ectopia lentis Dural ectasia	*FBN1* mutations*
Loeys-Dietz syndrome	Bifid uvula or cleft palate Arterial tortuosity Hypertelorism Skeletal features similar to MFS Craniosynostosis Aneurysms and dissections of other arteries	*TGFBR2* or *TGFBR1* mutations
Ehlers-Danlos syndrome, vascular form	Thin, translucent skin Gastrointestinal rupture Rupture of the gravid uterus Rupture of medium-sized to large arteries	*COL3A1* mutations
Turner syndrome	Short stature Primary amenorrhea Bicuspid aortic valve Aortic coarctation Webbed neck, low-set ears, low hairline, broad chest	45,X karyotype

* The defective gene at a second locus for MFS is TGFBR2 but the clinical phenotype as MFS is debated.

AoD indicates aortic dissection; *COL3A1*, type III collagen; CT, computed tomographic imaging; *FBN1*, fibrillin 1; MFS, Marfan syndrome; MR, magnetic resonance imaging; TEE, transesophageal echocardiogram; *TGFBR1*, transforming growth factor-beta receptor type I; and *TGFBR2*, transforming growth factor-beta receptor type II.

and Dissection

Diagnostic Test	Comments on Aortic Disease
Ghent diagnostic criteria DNA for sequencing	Surgical repair when the aorta reaches 5.0 cm unless there is a family history of AoD at <5.0 cm, a rapidly expanding aneurysm or presence or significant aortic valve regurgitation
DNA for sequencing	Surgical repair recommended at an aortic diameter of ≥4.2 cm by TEE (internal diameter) or 4.4 to ≥4.6 cm by CT and/or MR (external diameter)
DNA for sequencing Dermal fibroblasts for analysis of type III collagen	Surgical repair is complicated by friable tissues Noninvasive imaging recommended
Blood (cells) for karyotype analysis	AoD risk is increased in patients with bicuspid aortic valve, aortic coarctation, hypertension, or pregnancy

5. Recommendations for Familial Thoracic Aortic Aneurysms and Dissections

Class I

1. Aortic imaging is recommended for first-degree relatives of patients with thoracic aortic aneurysm and/or dissection to identify those with asymptomatic disease. *(LOE: B)*

2. If the mutant gene (*FBN1, TGFBR1, TGFBR2, COL3A1, ACTA2, MYH11*) associated with aortic aneurysm and/or dissection is identified in a patient, first-degree relatives should undergo counseling and testing. Then, only the relatives with the genetic mutation should undergo aortic imaging. *(LOE: C)*

Class IIa

1. If one or more first-degree relatives of a patient with known thoracic aortic aneurysm and/or dissection are found to have thoracic aortic dilatation, aneurysm, or dissection, then imaging of second-degree relatives is reasonable. *(LOE: B)*

2. Sequencing of the *ACTA2* gene is reasonable in patients with a family history of thoracic aortic aneurysms and/or dissections to determine if *ACTA2* mutations are responsible for the inherited predisposition. *(LOE: B)*

Class IIb

1. Sequencing of other genes known to cause familial thoracic aortic aneurysms and/or dissection (*TGFBR1, TGFBR2, MYH11*) may be considered in patients with a family history and clinical features associated with mutations in these genes. *(LOE: B)*

2. If one or more first-degree relatives of a patient with known thoracic aortic aneurysm and/or dissection are found to have thoracic aortic dilatation, aneurysm, or dissection, then referral to a geneticist may be considered. *(LOE: C)*

6. Recommendations for Bicuspid Aortic Valve and Associated Congenital Variants in Adults

Class I

1. First-degree relatives of patients with a bicuspid aortic valve, premature onset of thoracic aortic disease with minimal risk factors, and/or a familial form of thoracic aortic aneurysm and dissection should be evaluated for the presence of a bicuspid aortic valve and asymptomatic thoracic aortic disease. *(LOE: C)*

2. All patients with a bicuspid aortic valve should have both the aortic root and ascending thoracic aorta evaluated for evidence of aortic dilatation. *(LOE: B)*

7. Recommendations for Estimation of Pretest Risk of Thoracic Aortic Dissection

Class I

1. Providers should routinely evaluate any patient presenting with complaints that may represent acute thoracic aortic dissection to establish a pretest risk of disease that can then be used to guide diagnostic decisions. This process should include specific questions about medical history, family history, and pain features as well as a focused examination to identify findings that are associated with aortic dissection, including:

a. High-risk conditions and historical features *(LOE: B)*:

- Marfan syndrome, Loeys-Dietz syndrome, vascular Ehlers-Danlos syndrome, Turner syndrome, or other connective tissue disease.
- Patients with mutations in genes known to predispose to thoracic aortic aneurysms and dissection, such as *FBN1, TGFBR1, TGFBR2, ACTA2,* and *MYH11*.
- Family history of aortic dissection or thoracic aortic aneurysm.
- Known aortic valve disease.
- Recent aortic manipulation (surgical or catheter-based).
- Known thoracic aortic aneurysm.

b. High-risk chest, back or abdominal pain features *(LOE: B)*:
   - Pain that is abrupt or instantaneous in onset.
   - Pain that is severe in intensity.
   - Pain that has a ripping, tearing, stabbing, or sharp quality.

c. High-risk examination features *(LOE: B)*:
   - Pulse deficit.
   - Systolic blood pressure limb differential greater than 20 mm Hg.
   - Focal neurologic deficit.
   - Murmur of aortic regurgitation (new).

2. Patients presenting with sudden onset of severe chest, back and/or abdominal pain, particularly those less than 40 years of age, should be questioned about a history and examined for physical features of Marfan syndrome, Loeys-Dietz syndrome, vascular Ehlers-Danlos syndrome, Turner syndrome, or other connective tissue disorder associated with thoracic aortic disease. (LOE: B)

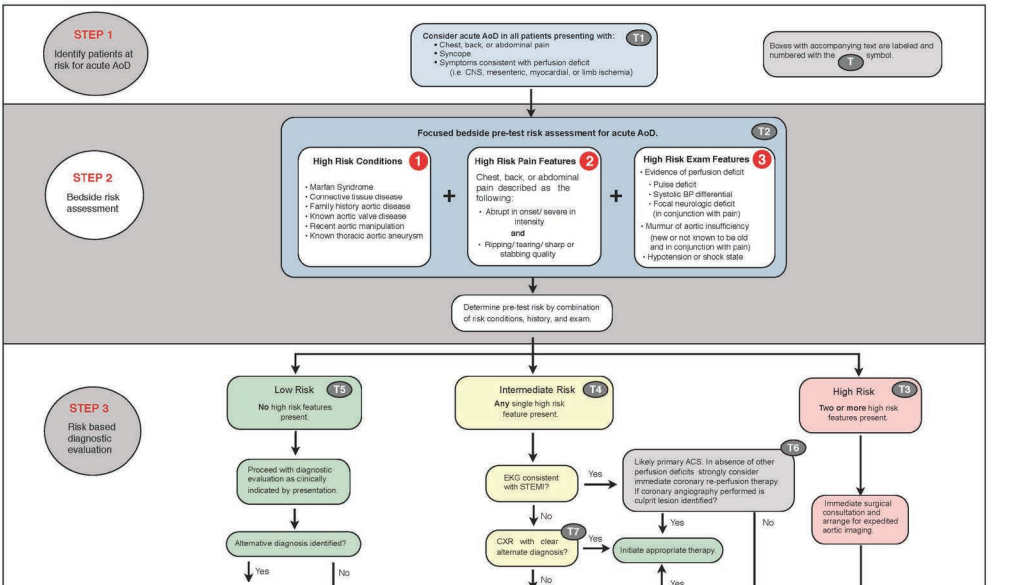
3. Patients presenting with sudden onset of severe chest, back, and/or abdominal pain should be questioned about a history of aortic pathology in immediate family members as there is a strong familial component to acute thoracic aortic disease. *(LOE: B)*

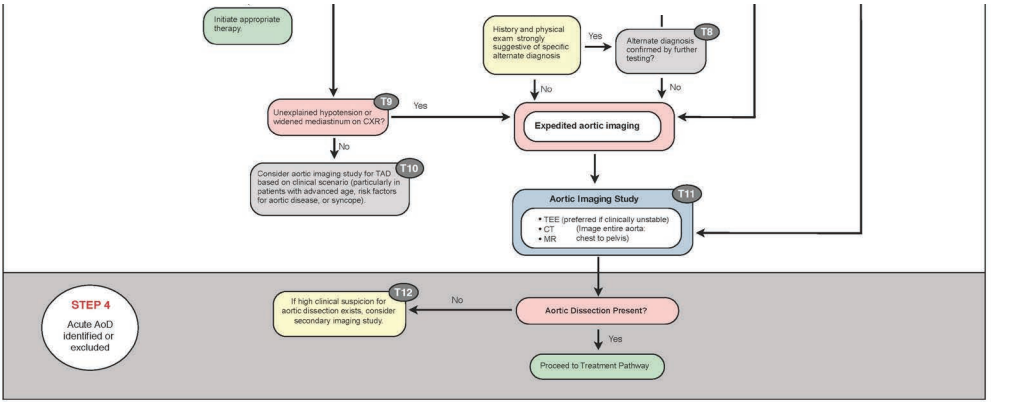
4. Patients presenting with sudden onset of severe chest, back and/or abdominal pain should be questioned about recent aortic manipulation (surgical or catheter-based) or a known history of aortic valvular disease, as these factors predispose to acute aortic dissection. *(LOE: C)*

5. In patients with suspected or confirmed aortic dissection who have experienced a syncopal episode, a focused examination should be performed to identify associated neurologic injury or the presence of pericardial tamponade. *(LOE: C)*

6. All patients presenting with acute neurologic complaints should be questioned about the presence of chest, back, and/or abdominal pain and checked for peripheral pulse deficits as patients with dissection-related neurologic pathology are less likely to report thoracic pain than the typical aortic dissection patient. *(LOE: C)*

Figure 2. AoD Evaluation Pathway.



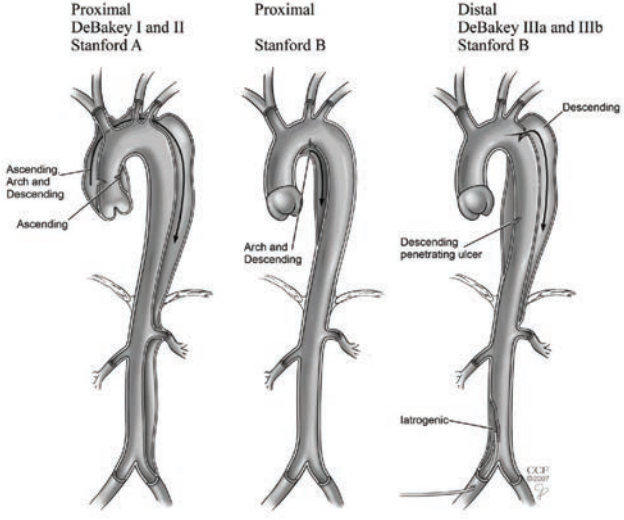


ACS indicates acute coronary syndrome; AoD, aortic dissection; BP, blood pressure; CNS, central nervous system; CT, computed tomographic imaging; CXR, chest x-ray; EKG, electrocardiogram; MR, magnetic resonance imaging; STEMI, ST-elevated myocardial infarction; TAD; thoracic aortic disease; and TEE, transesophageal echocardiogram.

Table 6. Risk Factors for Development of Thoracic Aortic Dissection

Conditions Associated With Increased Aortic Wall Stress
Hypertension, particularly if uncontrolled
Pheochromocytoma
Cocaine or other stimulant use
Weight lifting or other Valsalva maneuver
Trauma
Deceleration or torsional injury (eg, motor vehicle crash, fall)
Coarctation of the aorta
Conditions Associated With Aortic Media Abnormalities
Genetic
Marfan syndrome
Ehlers-Danlos syndrome, vascular form
Bicuspid aortic valve (including prior aortic valve replacement)
Turner syndrome
Loeys-Dietz syndrome
Familial thoracic aortic aneurysm and dissection syndrome
Inflammatory vasculitides
Takayasu arteritis
Giant cell arteritis
Behçet arteritis
Other
Pregnancy
Polycystic kidney disease
Chronic corticosteroid or immunosuppression agent administration
Infections involving the aortic wall either from bacteremia or extension of adjacent infection

Figure 3. Aortic Dissection Classification: DeBakey and Stanford Classifications.



Reprinted with permission from the Cleveland Clinic Foundation.

8. Initial Evaluation and Management of Acute Thoracic Aortic Disease

8.1. Recommendations for Screening Tests

Class I

1. An electrocardiogram should be obtained on all patients who present with symptoms that may represent acute thoracic aortic dissection.

a. Given the relative infrequency of dissection-related coronary artery occlusion, the presence of ST-segment elevation suggestive of myocardial infarction should be treated as a primary cardiac event without delay for definitive aortic imaging unless the patient is at high risk for aortic dissection. *(LOE: B)*

2. The role of chest x-ray in the evaluation of possible thoracic aortic disease should be directed by the patient's pretest risk of disease as follows.

a. Intermediate risk: Chest x-ray should be performed on all intermediate-risk patients, as it may establish a clear alternate diagnosis that will obviate the need for definitive aortic imaging. *(LOE: C)*

b. Low risk: Chest x-ray should be performed on all low-risk patients, as it may either establish an alternative diagnosis or demonstrate findings that are suggestive of thoracic aortic disease, indicating the need for urgent definitive aortic imaging. *(LOE: C)*

3. Urgent and definitive imaging of the aorta using transesophageal echocardiogram, computed tomographic imaging, or magnetic resonance imaging is recommended to identify or exclude thoracic aortic dissection in patients at high risk for the disease by initial screening. *(LOE: B)*

Class III

1. A negative chest x-ray should not delay definitive aortic imaging in patients determined to be high risk for aortic dissection by initial screening. *(LOE: C)*

8.2. Recommendations for Diagnostic Imaging Studies

Class I

1. Selection of a specific imaging modality to identify or exclude aortic dissection should be based on patient variables and institutional capabilities, including immediate availability. *(LOE: C)*

2. If a high clinical suspicion exists for acute aortic dissection but initial aortic imaging is negative, a second imaging study should be obtained. *(LOE: C)*

8.3. Recommendations for Initial Management (see Figure 4)

Class I

1. Initial management of thoracic aortic dissection should be directed at decreasing aortic wall stress by controlling heart rate and blood pressure as follows:

a. In the absence of contraindications, intravenous beta blockade should be initiated and titrated to a target heart rate of 60 beats per minute or less. *(LOE: C)*

b. In patients with clear contraindications to beta blockade, nondihydropyridine calcium channel–blocking agents should be utilized as an alternative for rate control. *(LOE: C)*

c. If systolic blood pressures remain greater than 120 mm Hg after adequate heart rate control has been obtained, then angiotensin-converting enzyme inhibitors and/or other vasodilators should be administered intravenously to further reduce blood pressure that maintains adequate end-organ perfusion. *(LOE: C)*

d. Beta blockers should be used cautiously in the setting of acute aortic regurgitation because they will block the compensatory tachycardia. *(LOE: C)*

Class III

1. Vasodilator therapy should not be initiated prior to rate control so as to avoid associated reflex tachycardia that may increase aortic wall stress, leading to propagation or expansion of a thoracic aortic dissection. *(LOE: C)*

8.4. Recommendations for Definitive Management (see Figures 3 and 5)

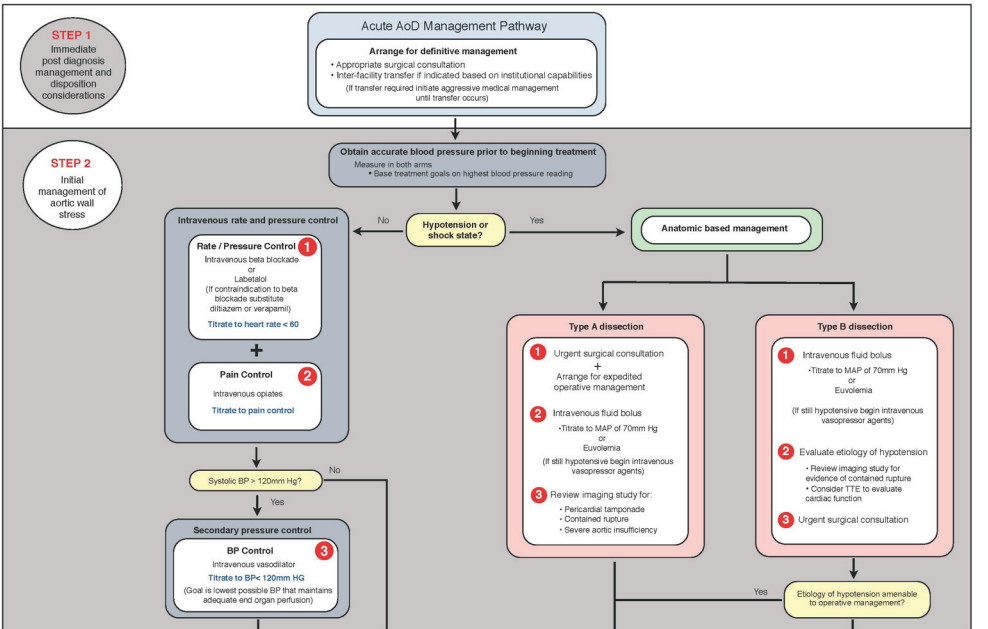
Class I

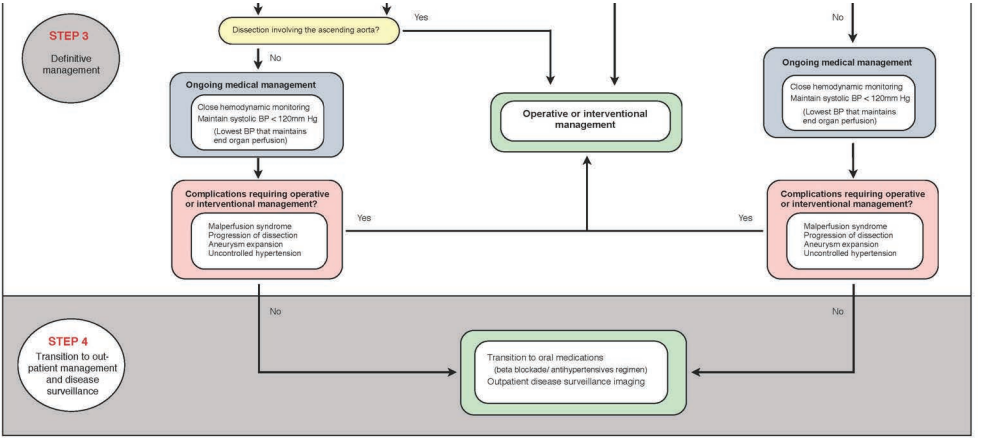
1. Urgent surgical consultation should be obtained for all patients diagnosed with thoracic aortic dissection regardless of the anatomic location (ascending versus descending) as soon as the diagnosis is made or highly suspected. *(LOE: C)*

2. Acute thoracic aortic dissection involving the ascending aorta should be urgently evaluated for emergent surgical repair because of the high risk of associated life-threatening complications such as rupture. *(LOE: B)*

3. Acute thoracic aortic dissection involving the descending aorta should be managed medically unless life-threatening complications develop (ie, malperfusion syndrome, progression of dissection, enlarging aneurysm, inability to control blood pressure or symptoms). *(LOE: B)*

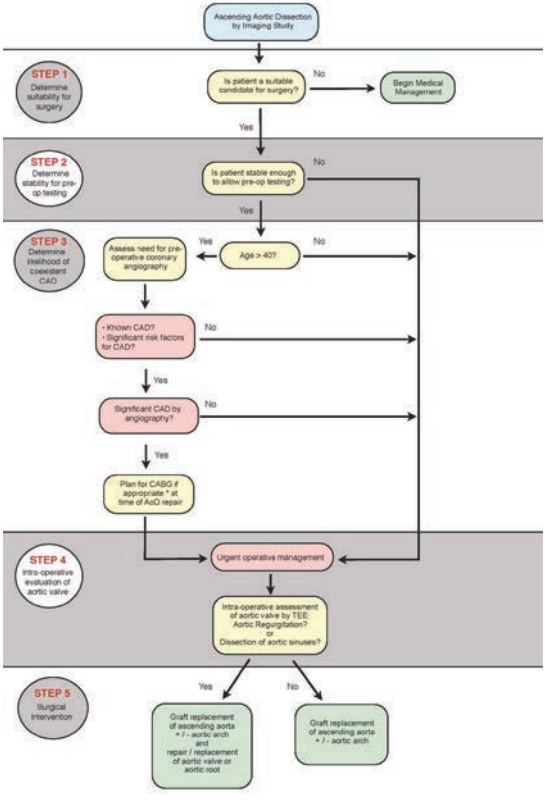
Figure 4. Acute AoD Management Pathway.





AoD indicates aortic dissection; BP, blood pressure; MAP, mean arterial pressure; and TTE, transthoracic echocardiogram.

Figure 5. Acute Surgical Management Pathway for AoD.



*Addition of 'if appropriate' based on Patel MR, Dehmer GJ, Hirshfeld JW, et al. ACCF/SCAI/STS/AATS/AHA/ASNC 2009 Appropriateness Criteria for Coronary Revascularization. J Am Coll Cardiol. 2009;53:530–53.

AoD indicates aortic dissection; CABG, coronary artery bypass graft surgery; CAD, coronary artery disease; TAD, thoracic aortic disease; and TEE, transesophageal echocardiogram.

9. Recommendation for Surgical Intervention for Acute Thoracic Aortic Dissection

Class I

1. For patients with ascending thoracic aortic dissection, all aneurysmal aorta and the proximal extent of the dissection should be resected. A partially dissected aortic root may be repaired with aortic valve resuspension. Extensive dissection of the aortic root should be treated with aortic root replacement with a composite graft or with a valve sparing root replacement. If a DeBakey Type II dissection is present, the entire dissected aorta should be replaced. *(LOE: C)*

10. Recommendation for Intramural Hematoma Without Intimal Defect

Class IIa

1. It is reasonable to treat intramural hematoma similar to aortic dissection in the corresponding segment of the aorta. *(LOE: C)*

11. Recommendation for History and Physical Examination for Thoracic Aortic Disease

Class I

1. For patients presenting with a history of acute cardiac and noncardiac symptoms associated with a significant likelihood of thoracic aortic disease, the clinician should perform a focused physical examination, including a careful and complete search for arterial perfusion differentials in both upper and lower extremities, evidence of visceral ischemia, focal neurologic deficits, a murmur of aortic regurgitation, bruits, and findings compatible with possible cardiac tamponade. *(LOE: C)*

12. Recommendation for Medical Treatment of Patients With Thoracic Aortic Diseases

Class I

1. Stringent control of hypertension, lipid profile optimization, smoking cessation, and other atherosclerosis risk-reduction measures should be instituted for patients with small aneurysms not requiring surgery, as well as for patients who are not considered surgical or stent graft candidates. *(LOE: C)*

12.1. Recommendations for Blood Pressure Control

Class I

1. Antihypertensive therapy should be administered to hypertensive patients with thoracic aortic diseases to achieve a goal of less than 140/90 mm Hg (patients without diabetes) or less than 130/80 mm Hg (patients with diabetes or chronic renal disease) to reduce the risk of stroke, myocardial infarction, heart failure, and cardiovascular death. *(LOE: B)*

2. Beta adrenergic–blocking drugs should be administered to all patients with Marfan syndrome and aortic aneurysm to reduce the rate of aortic dilatation unless contraindicated. *(LOE: B)*

Class IIa

1. For patients with thoracic aortic aneurysm, it is reasonable to reduce blood pressure with beta blockers and angiotensin-converting enzyme inhibitors or angiotensin receptor blockers to the lowest point patients can tolerate without adverse effects. *(LOE: B)*

2. An angiotensin receptor blocker (losartan) is reasonable for patients with Marfan syndrome, to reduce the rate of aortic dilatation unless contraindicated. *(LOE: B)*

13. Recommendations for Asymptomatic Patients With Ascending Aortic Aneurysm (see Figures 6 and 7)

Class I

1. Asymptomatic patients with degenerative thoracic aneurysm, chronic aortic dissection, intramural hematoma, penetrating atherosclerotic ulcer, mycotic aneurysm, or pseudoaneurysm, who are otherwise suitable candidates and for whom the ascending aorta or aortic sinus diameter is 5.5 cm or greater should be evaluated for surgical repair. *(LOE: C)*

2. Patients with Marfan syndrome or other genetically mediated disorders (vascular Ehlers-Danlos syndrome, Turner syndrome, bicuspid aortic valve, or familial thoracic aortic aneurysm and dissection) should undergo elective operation at smaller diameters (4.0 to 5.0 cm depending on the condition; see Section 4) to avoid acute dissection or rupture. *(LOE: C)*

3. Patients with a growth rate of more than 0.5 cm/y in an aorta that is less than 5.5 cm in diameter should be considered for operation. *(LOE: C)*

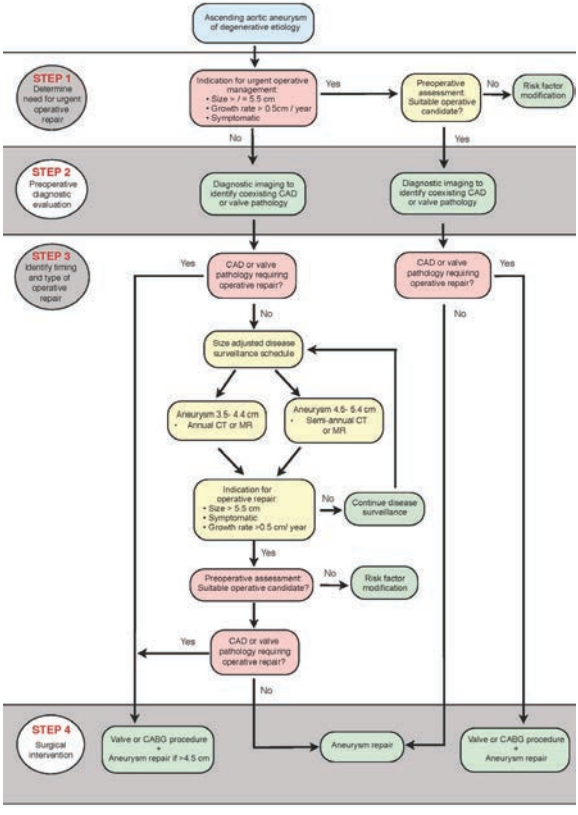
4. Patients undergoing aortic valve repair or replacement and who have an ascending aorta or aortic root of greater than 4.5 cm should be considered for concomitant repair of the aortic root or replacement of the ascending aorta. *(LOE: C)*

Class IIa

1. Elective aortic replacement is reasonable for patients with Marfan syndrome, other genetic diseases, or bicuspid aortic valves, when the ratio of maximal ascending or aortic root area ($\prod r^2$) in cm^2 divided by the patient's height in meters exceeds 10. *(LOE: C)*

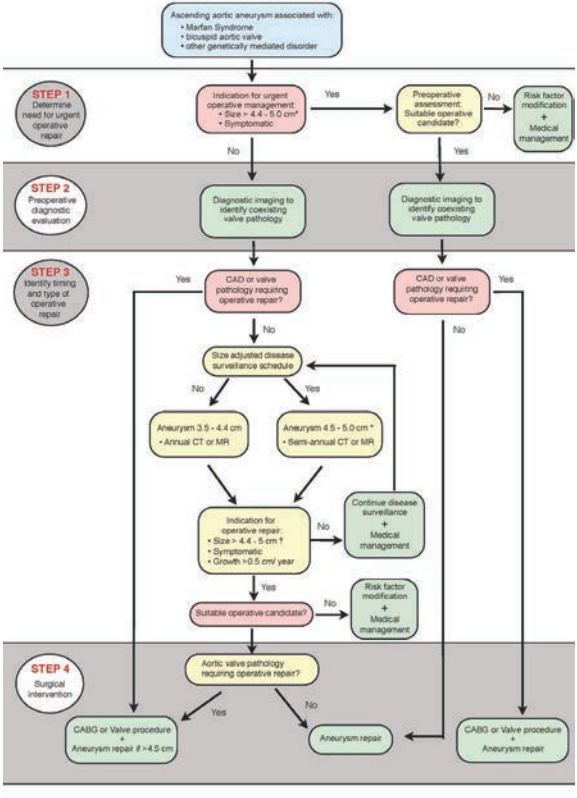
2. It is reasonable for patients with Loeys-Dietz syndrome or a confirmed *TGFBR1* or *TGFBR2* mutation to undergo aortic repair when the aortic diameter reaches 4.2 cm or greater by transesophageal echocardiogram (internal diameter) or 4.4 to 4.6 cm or greater by computed tomographic imaging and/or magnetic resonance imaging (external diameter). *(LOE: C)*

Figure 6. Ascending Aortic Aneurysm of Degenerative Etiology.



CABG indicates coronary artery bypass graft surgery; CAD, coronary artery disease; CT, computed tomographic imaging; and MR, magnetic resonance imaging.

Figure 7. Ascending Aortic Aneurysms Associated With Genetic Disorder.



*Depends on specific genetic condition. †See Recommendations for Asymptomatic Patients With Ascending Aortic Aneurysm (Section 13), and Recommendations for Bicuspid Aortic Valve and Associated Congenital Variants in Adults (Section 6). CABG indicates coronary artery bypass graft surgery; CAD, coronary artery disease; CT, computed tomographic imaging; and MR, magnetic resonance imaging.

14. Recommendation for Symptomatic Patients With Thoracic Aortic Aneurysm

Class I

1. Patients with symptoms suggestive of expansion of a thoracic aneurysm should be evaluated for prompt surgical intervention unless life expectancy from comorbid conditions is limited or quality of life is substantially impaired. *(LOE: C)*

15. Recommendations for Open Surgery for Ascending Aortic Aneurysm

Class I

1. Separate valve and ascending aortic replacement are recommended in patients without significant aortic root dilatation, in elderly patients, or in young patients with minimal dilatation who have aortic valve disease. *(LOE: C)*

2. Patients with Marfan, Loeys-Dietz, and Ehlers-Danlos syndromes and other patients with dilatation of the aortic root and sinuses of Valsalva should undergo excision of the sinuses in combination with a modified David reimplantation operation if technically feasible or, if not, root replacement with valved graft conduit. *(LOE: B)*

16. Recommendations for Aortic Arch Aneurysms

Class IIa

1. For thoracic aortic aneurysms also involving the proximal aortic arch, partial arch replacement together with ascending aorta repair using right subclavian/axillary artery inflow and hypothermic circulatory arrest is reasonable. *(LOE: B)*

2. Replacement of the entire aortic arch is reasonable for acute dissection when the arch is aneurysmal or there is extensive aortic arch destruction and leakage. *(LOE: B)*

3. Replacement of the entire aortic arch is reasonable for aneurysms of the entire arch, for chronic dissection when the arch is enlarged, and for distal arch aneurysms that also involve the proximal descending thoracic aorta, usually with the elephant trunk procedure. *(LOE: B)*

4. For patients with low operative risk in whom an isolated degenerative or atherosclerotic aneurysm of the aortic arch is present, operative treatment is reasonable for asymptomatic patients when the diameter of the arch exceeds 5.5 cm. *(LOE: B)*

5. For patients with isolated aortic arch aneurysms less than 4.0 cm in diameter, it is reasonable to reimage using computed tomographic imaging or magnetic resonance imaging, at 12-month intervals, to detect enlargement of the aneurysm. *(LOE: C)*

6. For patients with isolated aortic arch aneurysms 4.0 cm or greater in diameter, it is reasonable to reimage using computed tomographic imaging or magnetic resonance imaging, at 6-month intervals, to detect enlargement of the aneurysm. *(LOE: C)*

17. Recommendations for Descending Thoracic Aorta and Thoracoabdominal Aortic Aneurysms

Class I

1. For patients with chronic dissection, particularly if associated with a connective tissue disorder, but without significant comorbid disease, and a descending thoracic aortic diameter exceeding 5.5 cm, open repair is recommended. *(LOE: B)*

2. For patients with degenerative or traumatic aneurysms of the descending thoracic aorta exceeding 5.5 cm, saccular aneurysms, or postoperative pseudoaneurysms, endovascular stent grafting should be strongly considered when feasible. *(LOE: B)*

3. For patients with thoracoabdominal aneurysms, in whom endovascular stent graft options are limited and surgical morbidity is elevated, elective surgery is recommended if the aortic diameter exceeds 6.0 cm, or less if a connective tissue disorder such as Marfan or Loeys-Dietz syndrome is present. *(LOE: C)*

4. For patients with thoracoabdominal aneurysms and with end-organ ischemia or significant stenosis from atherosclerotic visceral artery disease, an additional revascularization procedure is recommended. *(LOE: B)*

Table 7. Summary of Society of Thoracic Surgeons Recommendations for Thoracic Stent Graft Insertion

Entity/Subgroup	Classification	Level of Evidence
Penetrating ulcer/intramural hematoma		
Asymptomatic	III	C
Symptomatic	IIa	C
Acute traumatic	I	B
Chronic traumatic	IIa	C
Acute Type B dissection		
Ischemia	I	A
No ischemia	IIb	C
Subacute dissection	IIb	B
Chronic dissection	IIb	B
Degenerative descending		
>5.5 cm, comorbidity	IIa	B
>5.5 cm, no comorbidity	IIb	C
<5.5 cm	III	C
Arch		
Reasonable open risk	III	A
Severe comorbidity	IIb	C
Thoracoabdominal/Severe comorbidity	IIb	C

18. Recommendations for Counseling and Management of Chronic Aortic Diseases in Pregnancy

Class I

1. Women with Marfan syndrome and aortic dilatation, as well as patients without Marfan syndrome who have known aortic disease, should be counseled about the risk of aortic dissection as well as the heritable nature of the disease prior to pregnancy. *(LOE: C)*

2. For pregnant women with known thoracic aortic dilatation or a familial or genetic predisposition for aortic dissection, strict blood pressure control, specifically to prevent Stage II hypertension, is recommended. *(LOE: C)*

3. For all pregnant women with known aortic root or ascending aortic dilatation, monthly or bimonthly echocardiographic measurements of the ascending aortic dimensions are recommended to detect aortic expansion until birth. *(LOE: C)*

4. For imaging of pregnant women with aortic arch, descending, or abdominal aortic dilatation, magnetic resonance imaging (without gadolinium) is recommended over computed tomographic imaging to avoid exposing both the mother and fetus to ionizing radiation. Transesophageal echocardiogram is an option for imaging of the thoracic aorta. (LOE: C)

5. Pregnant women with aortic aneurysms should be delivered where cardiothoracic surgery is available. *(LOE: C)*

Class IIa

1. Fetal delivery via cesarean section is reasonable for patients with significant aortic enlargement, dissection, or severe aortic valve regurgitation. *(LOE: C)*

Class IIb

1. If progressive aortic dilatation and/or advancing aortic valve regurgitation are documented, prophylactic surgery may be considered. *(LOE: C)*

19. Recommendations for Aortic Arch and Thoracic Aortic Atheroma and Atheroembolic Disease

Class IIa	**1.** Treatment with a statin is a reasonable option for patients with aortic arch atheroma to reduce the risk of stroke. *(LOE: C)*
Class IIb	**1.** Oral anticoagulation therapy with warfarin (INR 2.0 to 3.0) or antiplatelet therapy may be considered in stroke patients with aortic arch atheroma 4.0 mm or greater to prevent recurrent stroke. *(LOE: C)*

20. Periprocedural and Perioperative Management

20.1. Recommendations for Brain Protection During Ascending Aortic and Transverse Aortic Arch Surgery

Class I	**1.** A brain protection strategy to prevent stroke and preserve cognitive function should be a key element of the surgical, anesthetic, and perfusion techniques used to accomplish repairs of the ascending aorta and transverse aortic arch. *(LOE: B)*
Class IIa	**1.** Deep hypothermic circulatory arrest, selective antegrade brain perfusion, and retrograde brain perfusion are techniques that alone or in combination are reasonable to minimize brain injury during surgical repairs of the ascending aorta and transverse aortic arch. Institutional experience is an important factor in selecting these techniques. *(LOE: B)*

Class III	**1.** Perioperative brain hyperthermia is not recommended in repairs of the ascending aortic and transverse aortic arch as it is probably injurious to the brain. *(LOE: B)*

20.2. Recommendations for Spinal Cord Protection During Descending Aortic Open Surgical and Endovascular Repairs

Class I	**1.** Cerebrospinal fluid drainage is recommended as a spinal cord protective strategy in open and endovascular thoracic aortic repair for patients at high risk of spinal cord ischemic injury. *(LOE: B)*
Class IIa	**1.** Spinal cord perfusion pressure optimization using techniques, such as proximal aortic pressure maintenance and distal aortic perfusion, is reasonable as an integral part of the surgical, anesthetic, and perfusion strategy in open and endovascular thoracic aortic repair patients at high risk of spinal cord ischemic injury. Institutional experience is an important factor in selecting these techniques. *(LOE: B)* **2.** Moderate systemic hypothermia is reasonable for protection of the spinal cord during open repairs of the descending thoracic aorta. *(LOE: B)*

Class IIb

1. Adjunctive techniques to increase the tolerance of the spinal cord to impaired perfusion may be considered during open and endovascular thoracic aortic repair for patients at high risk of spinal cord injury. These include distal perfusion, epidural irrigation with hypothermic solutions, high-dose systemic glucocorticoids, osmotic diuresis with mannitol, intrathecal papaverine, and cellular metabolic suppression with anesthetic agents. *(LOE: B)*

2. Neurophysiological monitoring of the spinal cord (somatosensory evoked potentials or motor evoked potentials) may be considered as a strategy to detect spinal cord ischemia and to guide reimplantation of intercostal arteries and/or hemodynamic optimization to prevent or treat spinal cord ischemia. *(LOE: B)*

21. Recommendations for Surveillance of Thoracic Aortic Disease or Previously Repaired Patients

Class IIa

1. Computed tomographic imaging or magnetic resonance imaging of the thoracic aorta is reasonable after a Type A or B aortic dissection or after prophylactic repair of the aortic root/ascending aorta. *(LOE: C)*

2. Computed tomographic imaging or magnetic resonance imaging of the aorta is reasonable at 1, 3, 6, and 12 months postdissection and, if stable, annually thereafter so that any threatening enlargement can be detected in a timely fashion. *(LOE: C)*

3. When following patients with imaging, utilization of the same modality at the same institution is reasonable, so that similar images of matching anatomic segments can be compared side by side. *(LOE: C)*

4. If a thoracic aortic aneurysm is only moderate in size and remains relatively stable over time, magnetic resonance imaging instead of computed tomographic imaging is reasonable to minimize the patient's radiation exposure. *(LOE: C)*

5. Surveillance imaging similar to classic aortic dissection is reasonable in patients with intramural hematoma. *(LOE: C)*

Table 8. Suggested Follow-up of Aortic Pathologies After Repair or Treatment

Pathology	Interval	Study
Acute dissection	Before discharge, 1 mo, 6 mo, yearly	CT or MR, chest plus abdomen TTE
Chronic dissection	Before discharge, 1 y, 2 to 3 y	CT or MR, chest plus abdomen TTE
Aortic root repair	Before discharge, yearly	TTE
AVR plus ascending	Before discharge, yearly	TTE
Aortic arch	Before discharge, 1 y, 2 to 3 y	CT or MR, chest plus abdomen
Thoracic aortic stent	Before discharge, 1 mo, 2 mo, 6 mo, yearly Or 30 days*	CXR, CT, chest plus abdomen
Acute IMH/PAU	Before discharge, 1 mo, 3 mo, 6 mo, yearly	CT or MR, chest plus abdomen

*US Food and Drug Administration stent graft studies usually required before discharge or at 30-day CT scan to detect endovascular leaks. If there is concern about a leak, a predischarge study is recommended; however, the risk of renal injury should be borne in mind. All patients should be receiving beta blockers after surgery or medically managed aortic dissection, if tolerated. Adapted from Erbel R, Alfonso F, Boileau C, et al. Diagnosis and management of aortic dissection. Eur Heart J. 2001;22:1642–81.

AVR indicates aortic valve replacement; CT, computed tomographic imaging; CXR, chest X-ray; IMH, intramural hematoma; MR, magnetic resonance imaging; PAU, penetrating atherosclerotic ulcer; and TTE, transthoracic echocardiography.

22. Recommendation for Employment and Lifestyle in Patients With Thoracic Aortic Disease

Class IIa

1. For patients with a current thoracic aortic aneurysm or dissection, or previously repaired aortic dissection, employment and lifestyle restrictions are reasonable, including the avoidance of strenuous lifting, pushing or straining that would require a Valsalva maneuver. *(LOE: C)*

Canadian Journal of Cardiology 30 (2014) 577–589

Position Statement

Canadian Cardiovascular Society Position Statement on the Management of Thoracic Aortic Disease

ABSTRACT

This Canadian Cardiovascular Society position statement aims to provide succinct perspectives on key issues in the management of thoracic aortic disease (TAD). This document is not a comprehensive overview of TAD and important elements of the epidemiology, presentation, diagnosis, and management of acute aortic syndromes are deliberately not discussed; readers are referred to the 2010 guidelines published by the American Heart Association, American College of Cardiology, American Association for Thoracic Surgery, and other stakeholders. Rather, this document is a practical guide for clinicians managing adult patients with TAD. Topics covered include size thresholds for surgical intervention, emerging thera-

RÉSUMÉ

Cet énoncé de position de la Société canadienne de cardiologie a pour but de donner des perspectives succinctes sur les aspects clés de la prise en charge de la maladie de l'aorte thoracique (MAT). Ce document n'est pas un aperçu complet de la MAT, et les éléments importants de l'épidémiologie, du tableau clinique, du diagnostic et de la prise en charge des syndromes aortiques aigus ne sont délibérément pas discutés; les lecteurs sont invités à consulter les lignes directrices de 2010 publiées par l'American Heart Association, l'American College of Cardiology, l'American Association for Thoracic Surgery et les autres parties prenantes. Ce document est plutôt un guide pratique pour les cliniciens

Thoracic Aortic Aneurysm

Size thresholds for elective thoracic aortic intervention

Thoracic aortic aneurysms are largely asymptomatic until a sudden and catastrophic event, including aortic rupture or dissection, occurs, and is rapidly fatal in a large proportion of patients.[1,2] Elective intervention on the thoracic aorta carries a much lower risk of mortality and morbidity, and prophylactic aortic surgery can be life-saving.

The decision to perform aortic intervention is a balance between risks of natural history of the disease vs the risk of the surgical intervention itself, and any additional long-term risks

This statement was developed following a thorough consideration of medical literature and the best available evidence and clinical experience. It represents the consensus of a Canadian panel comprised of multidisciplinary experts on this topic with a mandate to formulate disease-specific recommendations. These recommendations are aimed to provide a reasonable and practical approach to care for specialists and allied health professionals obliged with the duty of bestowing optimal care to patients and families, and can be subject to change as scientific knowledge and technology advance and as practice patterns evolve. The statement is not intended to be a substitute for physicians using their individual judgement in managing clinical care in consultation with the patient, with appropriate regard to all the individual circumstances of the patient, diagnostic and treatment options available and available resources. Adherence to these recommendations will not necessarily produce successful outcomes in every case.

Special Report: Exome Sequencing for Clinical Diagnosis of Patients with Suspected Genetic Disorders

Assessment Program
Volume 28, No. 3
August 2013

Executive Summary

Background

There are different clinical diagnostic scenarios for which traditional Sanger DNA sequencing technology is clinically available. Its success as a diagnostic tool depends on the accuracy and completeness of the differential diagnosis, as well as the number and locations of mutations responsible for the observed disease. Single-gene disorders are diseases that result from a mutation in one gene that has a large effect on phenotype. A clinical focus of this Special Report is the scenario of an undiagnosed, suspected single-gene disorder that features multiple congenital anomalies. Disorders (often early developmental) that present with multiple anomalies suggest a genetic etiology. They are often clinically difficult to diagnose due to nonspecific presentation, potentially overlapping differential diagnoses (clinical heterogeneity) or a rare disorder, and lack of a clear diagnostic testing path. The search for a clinical diagnosis may result in a long (months to years) diagnostic odyssey comprising several specialist consults and many different individual molecular, cytogenetic and biochemical tests, as well as other types of diagnostic procedures. A relatively unbiased sequencing application that examines most genes without requiring prior knowledge of potential diagnoses would be advantageous.

Single-gene disorders are inherited in various patterns (e.g., autosomal dominant, autosomal recessive, X-linked) and are affected by penetrance (proportion of individuals with the disease-related mutation who have the disease phenotype at all) and by expressivity (variable phenotypes that can occur in different individuals with the same genetic mutation). Disorders arising from a mutation in a single gene may be caused by exactly the same mutation in all individuals with the condition, or may be caused by any one of many different mutations in the same gene (allelic heterogeneity). In contrast, a large proportion of heritable disorders are genetically heterogeneous; clinically indistinguishable or overlapping phenotypes may be caused by mutations in different genes (locus heterogeneity). The number of genes involved can range from just a few to hundreds. For many of these genetically heterogeneous disorders, the full complement of causal genes is not yet known.

Determining genetic causality for disease and establishing a molecular diagnosis in clinical practice is challenging; in recent years, molecular technologies have strikingly increased gene discovery and understanding the causes of single-gene disorders among patients with suspected, but previously undiagnosed, genetic disorders. The value of molecular diagnosis in these patients can be viewed from a clinical perspective similar to other diagnostic tests; it is also commonly addressed from perspectives of clinical and personal utility, as well as a societal view. A molecular diagnosis can: confirm a suspected or established clinical diagnosis; inform prognosis; aid in selecting treatment, surveillance or preventive options; reveal mode of inheritance; identify carrier/risk status of family members; and guide research regarding new therapy or patient management. Available guidelines are currently focused on molecular diagnosis, distinguishing among phenotypically overlapping possible conditions, and on referral for genetic consultation.

Clinical Policy Bulletin:
Genetic Testing
Number: 0140

Policy

Aetna considers genetic testing medically necessary to establish a molecular diagnosis of an inheritable disease when *all* of the following are met:

- The member displays clinical features, or is at direct risk of inheriting the mutation in question (pre-symptomatic); *and*
- The result of the test will directly impact the treatment being delivered to the member; *and*
- After history, physical examination, pedigree analysis, genetic counseling, and completion of conventional diagnostic studies, a definitive diagnosis remains uncertain, and one of the following diagnoses is suspected (this list is not all-inclusive):

Achondroplasia (FGFR3) Albinism Alpha-1 antitrypsin deficiency (SERPINA1) Alpha thalassemia/Hb Bart hydrops fetalis syndrome/HbH disease** (HBA1/HBA2, alpha globin 1 and alpha globulin 2) Angelman syndrome (GABRA, SNRPN Beta thalassemia** (beta globin) Bloom syndrome (BLM) CADASIL (see below) Canavan disease (ASPA (aspartoacylase A)) Charcot-Marie Tooth disease (PMP-22) Classical lissencephaly Congenital adrenal hyperplasia/21 hydroxylase deficiency (CYP21A2)* Congenital amegakaryocytic thrombocytopenia Congenital central hypoventilation syndrome (PHOX2B) Congenital muscular dystrophy type 1C (MDC1C) (FKRP (Fukutin related protein)) Crouzon syndrome (FGFR2, FGFR3) Cystic fibrosis (CFTR) (see below) Dentatorubral-pallidoluysian atrophy Duchenne/Becker muscular dystrophy (dystrophin) Dysferlin myopathy Ehlers-Danlos syndrome Emery-Dreifuss muscular dystrophy (EDMD1, 2, and 3) Fabry disease	Hereditary polyposis coli (APC) Hereditary spastic paraplegia 3 (SPG3A) and 4 (SPG4, SPAST) Huntington's disease (HTT, HD (Huntington)) Hypochondroplasia (FGFR3) Hypertrophic cardiomyopathy (see below) Jackson-Weiss syndrome (FGFR2)Kallmann syndrome (FGFR1) Kennedy disease (SBMA) Leber hereditary optic neuropathy (LHON) Leigh Syndrome and NARP (neurogenic muscle weakness, ataxia, and retinitis pigmentosa) Long QT syndrome (see below) Limb girdle muscular dystrophy (LGMD1, LGMD2) (FKRP (Fukutin related protein)) Malignant hyperthermia (RYR1) Maple syrup urine disease (branched-chain keto acid dehydrogenase E1) Marfan's syndrome (TGFBR1, TGFBR2) McArdle's disease Medium chain acyl coA dehydrogenase deficiency (ACADM) Medullary thyroid carcinoma MELAS (mitochondrial encephalomyopathy with lactic acidosis and stroke-like episodes) (MTTL1, tRNAleu) Mucolipidosis type IV (MCOLN1, mucolipin 1) Mucopolysaccharidoses type 1 (MPS-1)

Additional Information
Clinical Policy Bulletin Notes

Factor V Leiden mutation (F5 (Factor V))	Muenke syndrome (FGFR3)
Factor XIII deficiency, congenital (F13 (Factor XIII beta globulin))	Multiple endocrine neoplasia type 1
Familial adenomatous polyposis coli (APC) (see below)	Muscle-Eye-Brain disease (POMGNT1)
Familial dysautonomia (IKBKAP)	MYH-associated polyposis (MYH) (see below)
Familial hypocalciuric hypercalcemia (see below)	Myoclonic epilepsy (MERRF) (MTTK (tRNAlys))
Familial Mediterranean fever (MEFV)	Myotonic dystrophy (DMPK, ZNF-9)
Fanconi anemia (FANCC, FANCD)	Neimann-Pick disease, type A (SMPD1, sphingomyelin phosphodiesterase)
Facioscapulohumeral muscular dystrophy (FSHMD1A)	Nephrotic syndrome, congenital (NPHS1, NPHS2)
Fragile X syndrome, FRAXA (FMR1) (see below)	Neurofibromatosis type 1 (NF1, neurofibromin)
Friedreich's ataxia (FRDA (frataxin))	Neurofibromatosis type 2 (Merlin)
Galactosemia (GALT)	Neutropenia, congenital cyclic
Gaucher disease (GBA (acid beta glucosidase))	Phenylketonuria (PAH)
Gitelman's syndrome	Pfeiffer syndrome (FGFR1)
Hemoglobin E thalassemia **	Prader-Willi-Angelman syndrome (SNRPN, GABRA5, NIPA1, UBE3A, ANCR, GABRA)
Hemoglobin S and/or C **	Primary dystonia (TOR1A (DYT1))
Hemophilia A/VWF (F8 (Factor VIII))	Prothrombin (F2 (Factor II, 20210G> A mutation))
Hemophilia B (F9 (Factor IX))	Pyruvate kinase deficiency (PKD)
Hereditary amyloidosis (TTR variants)	Retinoblastoma (Rh)
Hereditary deafness (GJB2 (Connexin-26, Connexin-32))	Rett syndrome (FOXG1, MECP2)
Hereditary hemorrhagic telangiectasia (HHT)	Saethre-Chotzen syndrome (TWIST, FGFR2)
Hereditary hemochromatosis (HFE) (see below)	SHOX-related short stature (see below)
Hereditary leiomyomatosis and renal cell cancer (HLRCC) syndrome (fumarate hydratase (FH) gene)	Smith-Lemli-Opitz syndrome
Hereditary neuropathy with liability to pressure palsies (HNPP)	Spinal muscular atrophy (SMN1, SMN2)
Hereditary non-polyposis colorectal cancer (HNPCC) (MLH1, MSH2, MSH6. MSI) (see below)	Spinocerebellar ataxia (SCA types 1, 2, 3 (MJD), 6 (CACNA1A), 7, 8, 10, 17 and DRPLA)
Hereditary pancreatitis (PRSS1) (see below)	Tay-Sachs disease (HEXA (hexosaminidase A))
Hereditary paraganglioma (SDHD, SDHB)	Thanatophoric dysplasia (FGFR3)
	Von Gierke disease (G6PC, Glycogen storage disease, Type 1a)
	Von Hippel-Lindau syndrome (VHL)
	Walker-Warburg syndrome (POMGNT1)
	22q11 deletion syndromes (DCGR (CATCH-22))

* Medically necessary if results of the adrenocortical profile following cosyntropin stimulation test are equivocal or for purposes of genetic counseling.

** Electrophoresis is the appropriate initial laboratory test for individuals judged to be at-risk for a hemoglobin disorder.

In the absence of specific information regarding advances in the knowledge of mutation characteristics for a particular disorder, the current literature indicates that genetic tests for inherited disease need only be conducted once per lifetime of the member.

Note: Genetic testing of Aetna members is excluded from coverage under Aetna's benefit plans if the testing is performed primarily for the medical management of other family members who are not covered under an Aetna benefit plan. In these circumstances, the insurance carrier for the family members who are not covered by Aetna should be contacted regarding coverage of genetic testing. Occasionally, genetic testing of tissue samples from other family members who are not covered by Aetna may be required to provide the medical information necessary for the proper medical care of an Aetna member. Aetna covers genetic testing for heritable disorders in non-Aetna members when *all* of the following conditions are met:

- The information is needed to adequately assess risk in the Aetna member; *and*
- The information will be used in the immediate care plan of the Aetna member; *and*

The non-Aetna member's benefit plan, if any, will not cover the test (a copy of the denial letter*** from the non-Aetna member's benefit plan must be provided).

*** Aetna may also request a copy of the certificate of coverage from the non-member's health insurance plan if: (i) the denial letter from the non-member's insurance carrier fails to specify the basis for non-coverage; (ii) the denial is based on a specific plan exclusion; or (iii) the genetic test is denied by the non-member's insurance carrier as not medically necessary and the medical information provided to Aetna does not make clear why testing would not be of significant medical benefit to the non-member.

Medical Necessity Criteria for Specific Genetic Tests:

1. Adenosis polyposis coli (APC):

   Aetna considers adenosis polyposis coli (APC) genetic testing medically necessary for either of the following indications:

   1. Members with greater than 20 colonic polyps; *or*
   2. Members with 1st-degree relatives (i.e., siblings, parents, and offspring) diagnosed with familial adenomatous polyposis (FAP) or with a documented APC mutation. The specific APC mutation should be identified in the affected 1st-degree relative with FAP prior to testing the member, if feasible. Full sequence APC genetic testing is considered medically necessary only when it is not possible to determine the family mutation first.

   Aetna considers APC genetic testing experimental and investigational for all other indications (e.g., desmoid tumor) because its effectiveness for indications other than the ones listed above has not been established.

2. CADASIL:

   Aetna considers DNA testing for CADASIL medically necessary for *either* of the following indications:

   1. Pre-symptomatic individuals where there is a family history consistent with an autosomal dominant pattern of inheritance and there is a known mutation in an affected member of the family; *or*
   2. Symptomatic individuals who have a family history consistent with an autosomal dominant pattern of inheritance of this condition (clinical signs and symptoms of CADASIL include stroke, cognitive defects and/or dementia, migraine, and psychiatric disturbances).

   Aetna considers CADASIL genetic testing experimental and investigational for all other indications because its effectiveness for indications other than the ones listed above has not been established.

3. Catecholaminergic polymorphic ventricular tachycardia (CPVT):

   Aetna considers genetic testing for CPVT medically necessary for the following indications:

   1. Children or young adults (less than 40 years of age) with a 1st degree relative with a clinical diagnosis of CPVT, or a 1st or 2nd degree relative with a defined CPVT mutation; or
   2. Persons who display exercise- or emotion-induced PVT or ventricular fibrillation, occurring in a structurally normal heart.

4. Cystic fibrosis:

   Aetna considers genetic carrier testing for cystic fibrosis medically necessary for members in any of the following groups:

   1. Couples seeking prenatal care; *or*
   2. Couples who are planning a pregnancy; *or*
   3. Persons with a family history of cystic fibrosis; *or*
   4. Persons with a 1st degree relative identified as a cystic fibrosis carrier; *or*
   5. Reproductive partners of persons with cystic fibrosis.

   Aetna considers genetic carrier testing for cystic fibrosis experimental and investigational for all other indications because its effectiveness for indications other than the ones listed above has not been established.

   Aetna considers a core panel of 25 mutations that are recommended by the American College of Medical Genetics (ACMG) medically necessary for cystic fibrosis genetic testing. The standard CF transmembrane regulator (CFTR)mutation panel is as follows (Available at: http://www.acmg.net/):

ΔF508	ΔI507	G542X	G551D	W1282X	N1303K
R553X	621+1G→T	R117H	1717-1G→A	A455E	R560T
R1162X	G85E	R334W	R347P	711+1G→T	1898+1G→A
		3849+10kbC→	2789+5G→		

2184delA	1078delT	T	A	3659delC	I148T
3120+1G→ A					

Aetna considers experimental and investigational screening for cystic fibrosis mutations that extend beyond the standard mutation panel recommended by the ACMG.

5. Factor V Leiden:

   Aetna considers Factor V Leiden genetic testing medically necessary for members with *any* of the following indications:

   1. Age less than 50, any venous thrombosis; *or*
   2. Myocardial infarction in female smokers under age of 50; *or*
   3. Recurrent venous thrombosis; *or*
   4. Relatives of individuals with venous thrombosis under age of 50; *or*
   5. Venous thrombosis and a strong family history of thrombotic disease; *or*
   6. Venous thrombosis in pregnant women or women taking oral contraceptives; *or*
   7. Venous thrombosis in unusual sites (such as hepatic, mesenteric, and cerebral veins).

   Aetna considers Factor V Leiden genetic testing experimental and investigational for all other indications because its effectiveness for indications other than the ones listed above has not been established .

   Aetna considers Factor V HR2 allele DNA mutation analysis experimental and investigational because its effectiveness has not been established.

6. Familial nephrotic syndrome (NPHS1, NPHS2):

   1. Aetna considers genetic testing for an NPHS1 mutation medically necessary for children with congenital nephrotic syndrome (nephrotic syndrome appearing within the first month of life) who are of Finnish descent or who have a family history of congenital nephrotic syndrome. Genetic testing for NPHS1 mutations are considered experimental and investigational for screening other persons with nephrotic syndrome and for all other indications because its effectiveness for other indications other has not been established.
   2. Aetna considers genetic testing for an NPHS2 mutation medically necessary for children with steroid resistant nephrotic syndrome (SRNS) and for children who have a family history of SRNS. Genetic testing for NPHS2 is considered experimental and investigational for persons with steroid-responsive nephrotic syndrome and for all other indications because its effectiveness for indications other than the ones listed above has not been established.

   Aetna considers genetic testing for familial nephrotic syndrome experimental and investigational for all other indications.

7. Fragile X:

   Aetna considers genetic testing for fragile X syndrome medically necessary for members in any of the following risk categories where the results of the test will affect a member's clinical management or reproductive decisions:

   1. Individuals with mental retardation, developmental delay, or autism; *or*
   2. Individuals planning a pregnancy who have *either* of the following:

      1. A family history of fragile X syndrome, *or*
      2. A family history of undiagnosed mental retardation; *or*

   3. Fetuses of known carrier mothers. Prenatal testing of a fetus by amniocentesis or chorionic villus sampling is indicated following a positive Fragile X carrier test in the mother.

   Aetna considers Fragile X DNA testing medically necessary for members with a negative cytogenetic test for fragile X if they have any physical or behavioral characteristics of fragile X syndrome and have a family history of fragile X syndrome or undiagnosed mental retardation.

   Aetna considers Fragile X DNA testing medically necessary for members with a phenotype that is not typical for fragile X syndrome who have a cytogenetic test that is positive for fragile X.

   Aetna considers population-based fragile X syndrome screening of individuals who are not in any of the above-listed risk categories experimental and investigational because its effectiveness for indications other than the ones listed above has not been established.

8. Hereditary hemochromatosis:

   Aetna considers genetic testing for HFE gene mutations medically necessary for persons who meet all of the following criteria:

1. Member who has symptoms consistent with iron overload; and
2. Member who has 2 consecutive transferrin saturations of 45 % or more.

Aetna considers genetic testing for HFE gene mutations medically necessary for 1st degree relatives of persons homozygous for HFE gene mutations. Genetic testing for hereditary hemochromatosis is considered experimental and investigational for all other indications because its effectiveness for indications other than the ones listed above has not been established.

9. Hereditary non-polyposis colorectal cancer (HNPCC):

    1. Aetna considers genetic testing for HNPCC (MLH1, MSH2, MSH6, PMS2 sequence analysis) medically necessary for members who meet any one of the following criteria:

        1. Member meets Amsterdam II criteria or revised Bethesda guidelines (see appendix); *or*
        2. Member is diagnosed with endometrial cancer before age 50 years; *or*
        3. Member has a 1st- or 2nd-degree relative with a disease confirmed to be caused by a HNPCC mutation (genes MLH1, MSH2, MSH6, PMS2) upon testing of the 1st- or 2nd-degree relative.

    2. Aetna considers microsatellite instability (MSI) testing or immunohistochemical (IHC) analysis of tumors medically necessary as an initial test in persons with colorectal and/or endometrial cancer who meet the revised Bethesda criteria (see appendix) in order to identify those persons who should proceed with HNPCC mutation analysis.

    See also CPB 0516 - Colorectal Cancer Screening.

10. Hereditary pancreatitis (PRSS1):

    Aetna considers genetic testing for hereditary pancreatitis (PRSS1 mutation) medically necessary in symptomatic persons with any of the following indications:

    1. A family history of pancreatitis in a 1st-degree (parent, sibling, child) or 2nd-degree (aunt, uncle, grandparent) relative; *or*
    2. An unexplained episode of documented pancreatitis occurring in a child that has required hospitalization, and where there is significant concern that hereditary pancreatitis should be excluded; *or*
    3. Recurrent (2 or more separate, documented episodes with hyper-amylasemia) attacks of acute pancreatitis for which there is no explanation (anatomical anomalies, ampullary or main pancreatic strictures, trauma, viral infection, gallstones, alcohol, drugs, hyperlipidemia, etc.); *or*
    4. Unexplained (idiopathic) chronic pancreatitis.

    This policy is based upon guidelines from the Consensus Committees of the European Registry of Hereditary Pancreatic Diseases, the Midwest Multi-Center Pancreatic Study Group and the International Association of Pancreatology (Ellis et al, 2001).

    Aetna considers genetic testing for hereditary pancreatitis experimental and investigational for all other indications because its effectiveness for indications other than the ones listed above has not been established.

11. Long QT syndrome:

    Aetna considers genetic testing for long QT syndrome medically necessary for either of the following:

    1. Persons with a prolonged QT interval on resting electrocardiogram (a corrected QT interval (QTc) of 470 msec or more in males and 480 msec or more in females) without an identifiable external cause for QTc prolongation (such as heart failure, bradycardia, electrolyte imbalances, certain medications and other medical conditions); *or*
    2. Persons with 1st-degree relatives (siblings, parents, offspring) with a defined LQT mutation, or long QT syndrome in sudden death (1st or 2nd degree) close relatives.

    Aetna considers genetic testing for long QT syndrome experimental and investigational for all other indications because its effectiveness for indications other than the ones listed above has not been established.

12. Malignant Hyperthermia Susceptibility:

    Aetna considers genetic testing for malignant hyperthermia susceptibility (MHS) medically necessary for either of the following indications:

    1. screening clinically confirmed MHS patients for variants in the RYR1 gene that are considered causative for MH by the European Malignant Hyperthermia Group (EMHG) to facilitate predictive testing in at-risk relatives.
    2. screening at-risk relatives of patients with clinically confirmed MHS for a known familial variant in the RYR1 gene that is considered causative for MH by the EMHG.

    Aetna considers genetic testing for malignant hyperthermia susceptibility (MHS) experimental and investigational for all other indications.

Aetna considers genetic testing for central core disease (CCD) experimental and investigational because there is inadequate evidence in the peer-reviewed published literature regarding its effectiveness.

13. MYH-associated polyposis:

    Aetna considers testing for MYH mutations medically necessary for the following indications:

    1. Asymptomatic siblings of individuals with known MYH polyposis; *or*
    2. Individuals with personal history of adenomatous polyposis who have negative APC mutation testing and a negative family history for adenomatous polyposis; *or*
    3. Individuals with personal history of adenomatous polyposis whose family history is consistent with recessive inheritance (i.e., family history is positive only for sibling(s)).

    Aetna considers MYH mutations testing experimental and investigational for members of a polyposis family with clear autosomal dominant inheritance, or for any other indications because its effectiveness for indications other than the ones listed above has not been established.

14. Primary dystonia (DYT1):

    Aetna considers genetic testing for DYT1 medically necessary for the following indications:

    1. Parents of children with an established DYT1 mutation, for purposes of family planning; *or*
    2. Persons with onset of primary dystonia other than focal cranial-cervical dystonia after age 30 years who have a affected relative with early onset (before 30 years); *or*
    3. Persons with primary dystonia with onset before age 30 years.

    Aetna considers DYT-1 testing experimental and investigational for all other indications, including the following because its effectiveness for indications other than the ones listed above has not been established:

    1. Asymptomatic individuals (other than parents of affected children), including those with affected family members (genetic testing for dystonia (DYT-1) is not sufficient to make a diagnosis of dystonia unless clinical features show dystonia); *or*
    2. Persons with onset of symptoms after age 30 years who either have focal cranial-cervical dystonia; *or*
    3. Persons with onset of symptoms after age 30 years who have no affected relative with early onset dystonia.

    This policy is adapted from guidelines from the European Federation of Neurological Societies.

15. Spinal Muscular Atrophy

    Aetna considers genetic testing for spinal muscular atrophy (SMA) medically necessary for the following indications:

    1. the diagnosis of persons with hypotonia and muscle weakness who are suspected of having spinal muscular atrophy; or
    2. the identification of SMN1 deletion carriers in the families of persons with SMA; or
    3. the prenatal diagnosis or preimplantation genetic diagnosis of SMA in the pregnancy of two known carriers

    Aetna considers genetic testing for spinal muscular atrophy (SMA) experimental and investigational for the identification of SMN1 deletion carriers in the general population and for all other indications because there is inadequate evidence in the published peer-reviewed clinical literature regarding its effectiveness.

16. SHOX-related short stature:

    Aetna considers genetic testing for SHOX-related short stature medically necessary for children and adolescents with any of the following features:

    1. Above-average body mass index (BMI); *or*
    2. Cubitus valgus (increased carrying angle); *or*
    3. Dislocation of the ulna at the elbow; *or*
    4. Increased sitting height/height ratio; *or*
    5. Madelung deformity of the forearm; *or*
    6. Muscular hypertrophy; *or*
    7. Reduced arm span/height ratio; *or*
    8. Short or bowed forearm.

    Aetna considers genetic testing for SHOX-related short stature experimental and investigational for all other indications because its effectiveness for indications other than the ones listed above has not been established.

17. Hypertrophic cardiomyopathy (HCM):

    Aetna considers genetic testing for HCM medically necessary for individuals who are at-risk for development of HCM, defined as having a close (1st or 2nd degree) relative with established HCM, when there is a known pathogenic gene mutation present in an affected relative. Aetna considers genetic testing for HCM experimental and investigational for all

other indications because its effectiveness for indications other than the one listed above has not been established.

18. Thoracic aortic aneurysms and dissections (TAAD)

    Aetna considers genetic testing for thoracic aortic aneurysms and dissections (TAAD) medically necessary for asymptomatic blood relatives of persons with genetically confirmed TAAD. Genetic testing for thoracic aortic aneurysms and dissections (TAAD) is considered experimental and investigational for any other indication, including but not limited to patients clinically diagnosed with TAAD, with a positive family history of the disorder, and for whom a genetic syndrome has been excluded.

19. Arrhythmogenic Right Ventricular Dysplasia/Cardiomyopathy (ARVD/C)

    Genetic testing for Arrhythmogenic Right Ventricular Dysplasia/Cardiomyopathy (ARVD/C) is considered medically necessary for the following indications:

    1. Testing for sequence variants in the DSG2, DSP, and PKP2 genes in probands with ITF-confirmed ARVD/C to facilitate genetic screening for ARVD/C in at-risk relatives; or
    2. Testing for a known familial sequence variant in the DSG2, DSP, and PKP2 genes for at-risk relatives of probands with ITF-confirmed ARVD/C, who are either asymptomatic or have ARVD/C symptoms that fails to meet the ITF diagnostic criteria.

    Genetic testing for ARVD/C is considered experimental and investigational for all other indications.

20. Osteogenesis imperfecta

    Genetic testing for COL1A1 and COL1A2 gene sequencing in the management of osteogenesis imperfecta types I to IV, is considered medically necessary for the following indications:

    1. Genetic testing for sequence variants in COL1A1/2 to confirm the presence of mosaicism in the asymptomatic parent of a child with OI caused by sequence variants in COL1A1/2 for reproductive decision making purposes; or
    2. Preimplantation genetic diagnosis or prenatal diagnosis for sequence variants in COL1A1/2 in couples in which 1 or both members have OI caused by sequence variants in COL1A1/2.

    Genetic testing for COL1A1 and COL1A2 gene sequencing is considered experimental and investigational in any other circumstances, including, but not limited to:

    1. testing for sequence variants in COL1A1/2 to confirm diagnosis of OI when clinical and radiological examination and family history provide adequate information for diagnosis of OI.
    2. Genetic testing for sequence variants in COL1A1/2 for the diagnosis of OI when clinical and radiological examination and family history provide inadequate information for diagnosis of OI.
    3. Genetic testing for sequence variants in COL1A1/2 in children diagnosed with OI to aid in reproductive planning for unaffected couples seeking to have additional children.

    Genetic testing for COLA1A/2 is considered experimental and investigational for all other indications.

21. Neurofibromatosis

    Genetic testing for neurofibromatosis is considered medically necessary for persons who meet all of the following criteria:

    - Displays a sign of or has clinical features of the NF; and
    - Has a 50% risk of inheriting NF (pre-symptomatic); and
    - A definitive diagnosis remains uncertain despite a complete family/personal history, physical examination and conventional diagnostic studies; and
    - Confirmation of the diagnosis will impact treatment.

    Genetic testing for neurofibromatosis is considered experimental and investigational for all other indications.

22. Marfan syndrome

    Aetna considers genetic testing for Marfan syndrome (MFS) medically necessary for the following indications:

    1. the use of FBN1 gene testing to facilitate the diagnosis of Marfan syndrome in patients who do not fulfill the Ghent diagnostic criteria but have at least one major feature of the condition; or
    2. the use of Marfan syndrome gene testing in patients fulfilling the Ghent diagnostic criteria for the purpose of obtaining information for reproductive decision making or facilitating the diagnosis of Marfan syndrome in at-risk relatives; or.
    3. the use of Marfan syndrome gene testing in the evaluation of at-risk relatives of patients carrying known disease-causing variants; or
    4. the prenatal diagnosis or PGD of Marfan syndrome in the offspring of patients with known disease-causing variants.

    Genetic testing for Marfan syndrome (MFS) is considered experimental and investigational for any other indications, including but not limited to:

1. the use of FBN1 gene testing in the diagnostic evaluation of Marfan syndrome in patients exhibiting only minor features of the condition, according to the Ghent diagnostic criteria.
2. the use of TGFBR2 gene testing to facilitate the diagnosis of Marfan syndrome in patients testing negative for FBN1 gene variants
3. the use of TGFBR1 gene testing to facilitate the diagnosis of Marfan syndrome in patients testing negative for FBN1 and TGFBR2 gene variants.
4. the use of Marfan syndrome gene testing in patients fulfilling the Ghent diagnostic criteria who will not be using the information for reproductive decision making or facilitating the diagnosis of Marfan syndrome in at-risk relatives.

23. Cadherin-1 for hereditary diffuse gastric cancer

Cadherin-1 (e-cadherin, CDH1) for hereditary diffuse gastric cancer (HDGC) is considered medically necessary for persons who meet the following criteria:

1. Individuals with HDGC for the purpose of identifying a CDH1 gene sequence variant that may be used to screen at-risk first- and second-degree relatives; or
2. Presymptomatic testing of first- and second-degree at-risk relatives for a known familial variant in the CDH1 gene.

Cadherin 1 testing is considered experimental and investigational for confirming the clinical diagnosis of HDGC and for other indications because there is inadequate evidence in the peer-reviewed published clinical literature regarding its effectiveness.

24. Maturity Onset Diabetes of the Young (MODY)

Genetic testing for maturity-onset diabetes of the young (MODY) is considered medically necessary for the diagnosis of MODY2 or MODY3 in persons with hyperglycemia or non-insulin-dependent diabetes who have a family history of abnormal glucose metabolism in at least 2 consecutive generations, with the patient or ≥ 1 family members diagnosed before age 25.

Genetic testing for maturity-onset diabetes of the young (MODY) is considered experimental and investigational for all other indications.

25. Huntington disease

Aetna considers genetic testing for Huntington disease (HD) medically necessary for either of the following indications:

1. predictive testing for CAG repeat length in asymptomatic individuals from families in which there is a history of HD to define risk of transmission; or
2. prenatal testing for CAG repeat length in fetuses from families in which there is a history of HD.

Genetic testing for Huntington disease is considered experimental and investigational for indications other than those listed above.

26. Familial hypocalciuric hypercalcemia:

Aetna considers familial hypocalciuric hypercalcemia (FHH) medically necessary in any of the following:

1. Atypical cases where no family members are available for testing; *or*
2. Families with familial isolated hyperparathyroidism; *or*
3. Infants or children under 10 years of age in whom neonatal hyperparathyroidism, neonatal severe hyperparathyroidism, and FHH are the commonest causes of parathyroid hormone-dependent hypercalcemia; *or*
4. Individuals with overlap in the calcium/creatinine (Ca/Cr) clearance ratio, namely between 0.01 and 0.02; *or*
5. Individuals with the phenotype of FHH whose parents are both normocalcemic (i.e., FHH possibly caused by a de novo CaSR mutation).

27. PTEN Gene Testing

Based upon guidelines from the National Comprehensive Cancer Network, PTEN gene testing is considered medically necessary in individuals with a suspected or known clinical diagnosis of Cowden syndrome or Bannayan-Riley-Ruvalcaba syndrome (BRR), or a known family history of a PTEN mutation who meet any of the following criteria:

1. A relative with a known deleterious PTEN gene mutation; *or*
2. Personal history of any of the following:

    1. Bannayan RIley-Ruvalcaba syndrome; *or*
    2. Adult Lhermitte-Duclos disease (LDD); *or*
    3. Autism-spectrum disorder and macrocephaly; *or*
    4. At least 2 biopsy-proven trichilemmomas; *or*
    5. Macrocephaly plus one other major criteria*; *or*
    6. Three major criteria* without macrocephaly; *or*

7. One major and at least three minor criteria*; *or*
8. Four or more minor criteria*.

3. Family history of both of the following:

    1. At-risk relative (includes 1st-degree relative or more distant relatives if the 1st degree relative is unavailable or unwilling to be tested) with a clinical diagnosis of Cowden syndrome or BRR (no previous genetic testing); *and*
    2. One major or two minor criteria* in the at-risk relative.

* Criteria for PTEN genetic testing purposes are:

Major:

- Breast cancer
- Mucocutaneous lesions
    - One biopsy-proven trichilemmoma
    - Multiple palmoplantar keratoses
    - Multi-focal or extensive oral mucosal papillomatosis
    - Multiple cutaneous facial papules (often verrucous)
    - Macular pigmentation of glans penis
- Macrocephaly (97th percentile or greater; 58 cm in adult women, 60 cm in adult men)
- Endometrial cancer
- Non-medullary thyroid cancer
- Multiple GI hamartomas or ganglioneuromas

Minor:

- Other thyroid lesions (e.g., adenoma, nodule(s), goiter)
- Mental retardation (IQ < 75)
- Autism spectrum disorder
- Single gastrointestinal hamartoma or ganglioneuroma
- Fibrocystic disease of the breast
- Lipomas
- Fibromas
- Renal cell carcinoma
- Uterine fibroids.

1. Li-Fraumeni syndrome (TP53 gene)

    TP53 gene testing is considered medically necessary for individuals with a suspected or known clinical diagnosis of Li-Fraumeni syndrome (LFS) or Li-Fraumeni-Like syndrome, or a known family history of a TP53 mutation. Testing is considered medically necessary in individuals whose medical and/or family history is consistent with any of these:

    1. A relative with a known deleterious TP53 gene mutation; *or*
    2. A diagnosis of classic Li-Fraumeni syndrome, defined by all of the following:

        1. Diagnosis of sarcoma before the age of 45 years; *and*
        2. A parent, child, or full sibling diagnosed with cancer before the age of 45 years; *and*
        3. An additional 1st- or 2nd-degree relative in the same lineage with cancer diagnosed before age 45 years, or a sarcoma at any age; *or*

    3. Persons meeting Chompret criteria:

        1. Persons with a tumor from the LFS tumor spectrum (e.g., soft tissue sarcoma, osteosarcoma, brain tumor, breast cancer, adrenocortical carcinoma, leukemia, lung bronchoalveolar cancer) before age 46 years AND at least one first- or second-degree relative with any of the aforementioned cancers (other than breast cancer if the proband has breast cancer) before the age of 56 years or with multiple primaries at any age; *or*
        2. Persons with multiple tumors (except multiple breast tumors), two of which belong to the LFS tumor spectrum with the initial cancer occurring before the age of 46 years; *or*
        3. Individuals with adrenocortical carcinoma or choroid plexus carcinoma at any age of onset, regardless of family history; *or*

    4. A diagnosis of breast cancer before age 30 years with a negative BRCA1/2 test especially if there is a family history of sarcoma, brain tumor, or adrenocortical carcinoma.

    **** Cancers associated with Li-Fraumeni syndrome include but are not limited to premenopausal breast cancer,

bone and soft tissue sarcomas, acute leukemia, brain tumor, adrenocortical carcinoma, choroid plexus carcinoma, colon cancer, and early onset of other adenocarcinomas or other childhood cancers. Note that Ewing sarcoma is less likely to be related to Li-Fraumeni as compared to other sarcomas.

2. Peutz-Jeghers syndrome

Based on NCCN guidelines, STK11 (LKB1) gene testing may be considered for individuals with a suspected or known clinical diagnosis of Peutz-Jeghers syndrome, or a known family history of a STK11 (LKB1) mutation. Testing may be considered for individuals whose medical and/or family history is consistent with any of the following:

1. A relative with a known deleterious STK11 (LKB1) gene mutation; *or*
2. A clinical diagnosis of PJS based on at least 2 of the following features:

    1. At least 2 PJS-type hamartomatous polyps of the small intestine;
    2. Mucocutaneous hyperpigmentation of the mouth, lips, nose, eyes, genitalia, or fingers;
    3. A family history of PJS.

3. Ashkenazi Jewish Testing Panel

Aetna considers medically necessary preconception or prenatal carrier screening for couples of Ashkenazi Jewish ancestry with a panel of genetic tests recommended by the American College of Medical Genetics (ACMG):

1. Tay Sachs disease
2. Canavan disease
3. Cystic fibrosis
4. Familial dysautonomia
5. Bloom syndrome
6. Fanconi anemia
7. Niemann-Pick disease
8. Gaucher disease
9. Mucolipidosis IV

If only one partner is of Ashkenazi Jewish ancestry, then testing of that partner is considered medically necessary. Testing of the other partner is considered medically necessary only if the result of testing of the Ashkenazi Jewish partner is positive.

Aetna considers genetic testing experimental and investigational for any of the following:

1. Age-related macular degeneration
2. Brugada syndrome
3. Choroidal neovascularization (e.g., Retnagene)
4. Congenital stationary night blindness
5. Coronary artery disease
6. Costello syndrome (HRAS gene)
7. Diamond-Blackfan anemia
8. Dilated cardiomyopathy [CMD1A]
9. Epidermolytic hyperkeratosis
10. Familial Alzheimer disease
11. Familial amyotrophic lateral sclerosis (SOD1 mutation)
12. Familial cold urticaria/familial cold autoinflammatory syndrome
13. Familial partial lipodystrophy [FPLD2])
14. Genetic testing panels for nonsyndromic hereditary hearing loss (OtoScope, OtoGenome, OtoSeq)
15. Glioblastoma multiforme
16. Hemiplegic migraine (HM)
17. Hemophilia C (F11 (Factor XI))
18. Heterotaxy
19. Klippel-Feil syndrome
20. Lactose intolerance
21. Legius syndrome (SPRED1 gene)
22. Malignant melanoma
23. May-Hegglin anomaly
24. Mccune-Albright syndrome
25. Mowat-Wilson syndrome (ZEB2 gene)
26. Myoclonus-dystonia (epsilon-sarcoglycan gene (SCGE) deletion analysis)
27. Migrainous vertigo
28. Narcolepsy
29. Oculopharyngeal muscular dystrophy (OPMD) (PABPN1 gene)
30. Parkinson disease
31. Polycystic kidney disease
32. Prostate cancer

33. Seizure disorders (e.g., creatine transporter 1 sequencing for testing parents of individuals with seizures; GABRG2 mutations and SCN1A deletion test for infantile febrile seizures; Generalized epilepsy with febrile seizures plus (GEFS+))
34. Sleep-walking
35. Townes-Brocks syndrome (SALL1 gene)
36. Type 2 diabetes (other than MODY)
37. Very long chain acylCoA dehydrogenase deficiency (VLCADD)
38. von Willebrand factor gene testing.

4. Aetna considers the following tests experimental and investigational:

- EpiSEEK test for epilepsy/seizures
- Exome sequencing
- Home genetic tests
- OncoVue breast cancer risk test
- POLG1 for mitochondrial recessive ataxia syndrome
- SF3B1 and TET2 mutation for myelodysplastic syndrome

Background

According to the American College of Medical Genetics (ACMG), an important issue in genetic testing is defining the scope of informed consent. The obligation to counsel and obtain consent is inherent in the clinician-patient and investigator-subject relationships. In the case of most genetic tests, the patient or subject should be informed that the test might yield information regarding a carrier or disease state that requires difficult choices regarding their current or future health, insurance coverage, career, marriage, or reproductive options. The objective of informed consent is to preserve the individual's right to decide whether to have a genetic test. This right includes the right of refusal should the individual decide the potential harm (stigmatization or undesired choices) outweighs the potential benefits.

DNA-based mutation analysis is not covered for routine carrier testing for the diagnosis of Tay-Sachs and Sandhoff disease. Under accepted guidelines, diagnosis is primarily accomplished through biochemical assessment of serum, leukocyte, or platelet hexosaminidase A and B levels. The literature states that mutation analysis is appropriate for individuals with persistently inconclusive enzyme-based results and to exclude pseudo-deficiency (non-disease related) mutations in carrier couples.

Testing of a member who is at substantial familial risk *for* being a heterozygote (carrier) for a particular detectable mutation that is recognized to be attributable to a specific genetic disorder is only covered for the purpose of prenatal counseling under plans with this benefit (see CPB 0189 - Genetic Counseling).

Confirmation by molecular analysis of inborn errors of metabolism by traditional screening methodologies (e.g., Guthrie microbiologic assays) is covered. Rigorous clinical evaluation should precede diagnostic molecular testing.

In many instances, reliable mutation analysis requires accurate determination of specific allelic variations in a proband (affected individual in a family) before subsequent carrier testing in other at-risk family members can be accurately performed. Coverage of testing for individuals who are not Aetna members is not provided, except under the limited circumstances outlined in the policy section above.

Hereditary non-polyposis colon cancer

Hereditary non-polyposis colon cancer ([HNPCC], Lynch syndrome) is one of the most common cancer predisposition syndromes affecting 1 in 200 individuals and accounting for 13 to 15 % of all colon cancer. HNPCC is defined clinically by early-onset colon carcinoma and by the presence of other cancers such as endometrial, gastric, urinary tract and ovarian found in at least 3 first-degree relatives. Two genes have been identified as being primary responsible for this syndrome: hMLH1 at chromosome band 3p21 accounts for 30 % of HNPCC2,3 and hMLH2 or FCC at chromosome band 2p22 which together with hMLH1 accounts for 90 % of HNPCC.

Unlike other genetic disorders that are easily diagnosed, the diagnosis of HNPCC relies on a very strongly positive family history of colon cancer. Specifically, several organizations have defined criteria that must be met to make the diagnosis of HNPCC.

Although HNPCC lacks strict clinical distinctions that can be used to make the diagnosis, and therefore diagnosis is based on the strong family history, genetic testing is now available to study patient's DNA for mutations to one of the mismatch repair genes. A mutation to one of these genes is a characteristic feature and confirms the diagnosis of HNPCC. Identifying individuals with this disease and performing screening colonoscopies on affected persons may help reduce colon cancer mortality.

Microsatellite instability (MSI) is found in the colorectal cancer DNA (but not in the adjacent normal colorectal mucosa) of most individuals with germline mismatch repair gene mutations. In combination with immunohistochemistry for MSH2 and MLH1,

MSI testing using the Bethesda markers should be performed on the tumor tissue of individuals putatively affected with HNPCC. A result of MSI-high in tumor DNA usually leads to consideration of germline testing for mutations in the MSH2 and MLH1 genes. Individuals with MSI-low or microsatellite stable (MSS) results are unlikely to harbor mismatch repair gene mutations, and further genetic testing is usually not pursued.

HNPCC is caused by germline mutation of the DNA mismatch repair genes. Over 95 % of HNPCC patients have mutations in either MLH1 or MSH2. As a result, sequencing for mismatch repair gene mutations in suspected HNPCC families is usually limited to MLH1 and MSH2 and sometimes MSH6 and PMS2. In general, MSH6 and PMS2 sequence analysis is performed in persons meeting aforementioned criteria for genetic testing for HNPCC, and who do not have mutations in either the MLH1 or MSH2 genes. In addition, single site MSH6 or PMS2 testing may be appropriate for testing family members of persons with HNPCC with an identified MSH6 or PMS2 gene mutation.

HNPCC is a relatively rare disease, which makes screening the entire populace burdensome and ineffective. The incidence of this disease, even among the families of patients with colon cancer, is too small to make screening effective. (See also CPB 0189 - Genetic Counseling and CPB 0227 - BRCA Testing, Prophylactic Mastectomy, and Prophylactic Oophorectomy).

Familial adenomatous polyposis (FAP)

Familial adenomatous polyposis (FAP) is caused by mutation of the adenomatous polyposis coli (APC) gene. According to guidelines from the American Gastroenterological Association (AGA, 2001), adenomatous polyposis coli gene testing is indicated to confirm the diagnosis of familial adenomatous polyposis, provide pre-symptomatic testing for at-risk members (1st degree relatives 10 years or older of an affected patient), confirm the diagnosis of attenuated familial adenomatous polyposis in those with more than 20 adenomas, and test those 10 years or older at risk for attenuated FAP.

The AGA guidelines state that germline testing should first be performed on an affected member of the family to establish a detectable mutation in the pedigree. If a mutation is found in an affected family member, then genetic testing of at-risk members will provide true positive or negative results. The AGA guidelines state that, if a pedigree mutation is not identified, further testing of at-risk relatives should be suspended because the gene test will not be conclusive: a negative result could be a false negative because testing is not capable of detecting a mutation even if present. When an affected family member is not available for evaluation, starting the test process with at-risk family members can provide only positive or inconclusive results. In this circumstance, a true negative test result for an at-risk individual can only be obtained if another at-risk family member tests positive for a mutation.

MYH-associated polyposis

MYH is a DNA repair gene that corrects DNA base pair mismatch errors in the genetic code before replication. Mutation of the MYH gene may result in colon cancer. In this regard, the MYH gene has been found to be significantly involved in colon cancer, both in cases where there is a clear family history of the disease, as well as in cases without any sign of a hereditary cause.

The National Comprehensive Cancer Network (NCCN)'s practice guidelines on colorectal cancer screening (2006) recommended testing for MYH mutations for individuals with personal history of adenomatous polyposis (more than 10 adenomas, or more than 15 cumulative adenomas in 10 years) either consistent with recessive inheritance or with adenomatous polyposis with negative adenomatous polyposis coli (APC) mutation testing. The guideline noted that when polyposis is present in a single person with negative family history, de novo APC mutation should be tested; if negative, testing for MYH should follow. When family history is positive only for a sibling, recessive inheritance should be considered and MYH testing should be done first. In a polyposis family with clear autosomal dominant inheritance, and absence of APC mutation, MYH testing is unlikely to be informative. Members in such family are treated according to the polyposis phenotype, including classical or attenuated FAP.

Factor V Leiden mutation

Factor V Leiden mutation is the most common hereditary blood coagulation disorder in the United States. It is present in 5 % of the Caucasian population and 1.2 % of the African-American population. Factor V Leiden increases the risk of venous thrombosis 3 to 8 fold for heterozygous individuals and 30 to 140 fold for homozygous individuals. Factor V Leiden mutation has been associated with the following complications:

- Cerebrovascular accident and myocardial infarction
- Deep venous thrombosis
- Gallbladder dysfunction
- Preeclampsia and/or eclampsia
- Pulmonary embolism
- Unexplained miscarriage
- Venous thrombosis.

According to the American College of Medical Genetics, Factor V Leiden genetic testing is indicated in the following patients:

- Age less than 50, any venous thrombosis; or
- Myocardial infarction in female smokers under age 50; or
- Recurrent venous thrombosis; or
- Relatives of individuals with venous thrombosis under age 50; or
- Venous thrombosis and a strong family history of thrombotic disease; or
- Venous thrombosis in pregnant women or women taking oral contraceptives; or

- Venous thrombosis in unusual sites (such as hepatic, mesenteric, and cerebral veins).

The ACMG does not recommend random screening of the general population for factor V Leiden. Routine testing is also not recommended for patients with a personal or family history of arterial thrombotic disorders (e.g., acute coronary syndromes or stroke) except for the special situation of myocardial infarction in young female smokers. According to the ACMG, testing may be worthwhile for young patients (less than 50 years of age) who develop acute arterial thrombosis in the absence of other risk factors for atherosclerotic arterial occlusive disease. The ACMG does not recommend prenatal testing or routine newborn screening for factor V Leiden mutation.

The ACMG does not recommend general screening for factor V Leiden mutation before administration of oral contraceptives. The ACMG recommends targeted testing prior to oral contraceptive use in women with a personal or family history of venous thrombosis.

Factor V Leiden screening of asymptomatic individuals with other recognized environmental risk factors, such as surgery, trauma, paralysis, and malignancy is not necessary or recommended by the ACMG, since all such individuals should receive appropriate medical prophylaxis for thrombosis regardless of carrier status. When Factor V Leiden testing is indicated, the ACMG recommends either direct DNA-based genotyping or factor V Leiden-specific functional assay (e.g., activated protein C (APC) resistance). Patients who test positive by a functional assay should then be further studied with the DNA test for confirmation and to distinguish heterozygotes from homozygotes. According to the ACMG, patients testing positive for factor V Leiden or APC resistance should be considered for molecular genetic testing for prothrombin 20210A, the most common thrombophilia with overlapping phenotype for which testing is easily and readily available. The prothrombin 20210A mutation is the second most common inherited clotting abnormality, occurring in 2 % of the general population. It is only a mild risk factor for thrombosis, but may potentiate other risk factors (such as Factor V Leiden, oral contraceptives, surgery, trauma, etc.).

A factor V gene haplotype (HR2) defined by the R2 polymorphism (A4070G) may confer mild APC resistance and interact with the factor V Leiden mutation to produce a more severe APC resistance phenotype (Bernardi et al, 1997; de Visser et al, 2000; Mingozzi et al, 2003). In one study, co-inheritance of the HR2 haplotype increased the risk of venous thromboembolism associated with factor V Leiden by approximately 3-fold (Faioni et al, 1999). However, double heterozygosity for factor V Leiden and the R2 polymorphism was not associated with a significantly higher risk of early or late pregnancy loss than a heterozygous factor V Leiden mutation alone (Zammiti et al, 2006). Whether the HR2 haplotype alone is an independent thrombotic risk factor is still unclear. Several studies have suggested that the HR2 haplotype is associated with a 2-fold increase in risk of venous thromboembolism (Alhenc-Gelas et al, 1999; Jadaon and Dashti, 2005). In contrast, other studies (de Visser 2000; Luddington et al, 2000; Dindagur et al, 2006) found no significant increase in thrombotic risk (GeneTests, University of Washington, Seattle, 2007).

CADASIL

CADASIL (cerebral autosomal dominant arteriopathy with subcortical infarcts and leukoencephalopathy) is a rare, genetically inherited, congenital vascular disease of the brain that causes strokes, subcortical dementia, migraine-like headaches, and psychiatric disturbances. CADASIL is very debilitating and symptoms usually surface around the age of 45. Although CADASIL can be treated with surgery to repair the defective blood vessels, patients often die by the age of 65. The exact incidence of CADASIL in the United States is unknown.

DNA testing for CADASIL is appropriate for symptomatic patients who have a family history consistent with an autosomal dominant pattern of inheritance of this condition. Clinical signs and symptoms of CADASIL include stroke, cognitive defects and/or dementia, migraine, and psychiatric disturbances. DNA testing is also indicated for pre-symptomatic patients where there is a family history consistent with an autosomal dominant pattern of inheritance and there is a known mutation in an affected member of the family. This policy is consistent with guidelines on CADASIL genetic testing from the European Federation of Neurological Societies.

Cystic fibrosis

Cystic fibrosis is the most common potentially fatal autosomal recessive disease in the United States. It is characterized by chronic progressive disease of the respiratory system, malabsorption due to pancreatic insufficiency, increased loss of sodium and chloride in sweat, and male infertility as a consequence of atresia of the vas deferens. Pulmonary disease is the most common cause of mortality and morbidity in individuals with CF. The incidence of this disease ranges from 1:500 in Amish (Ohio) to 1:90,000 in Hawaiian Orientals, and is estimated to be 1:2,500 newborns of European ancestry. It occurs less frequently in people with other ethnic and racial backgrounds. About 1:25 persons of European ancestry is a carrier (or heterozygote), possessing one normal and one abnormal CF gene. Because of recent advances in clinical management of CF, babies born today are expected to live well into middle age.

Currently, the most frequently employed test for CF is the quantitative pilocarpine iontophoresis sweat test. Sweat chloride is more reliable than sweat sodium for diagnostic purposes with a sensitivity of 98 % and a specificity of 83 %. However, this test can not detect CF carriers because the electrolyte content of sweat is normal in heterozygotes (Wallach, 1991). The gene for CF (cystic fibrosis trans-membrane conductance regulator, CFTR) was cloned, and the principal mutant gene in white people (DF508) was characterized in 1989. This mutation is due to a 3-base-pair deletion that results in the loss of a phenylalanine at position 508 from the 1,480-amino acid coding region (Riordan et al, 1989). This mutation is found in approximately 70 % of carriers of European ancestry, but the relative frequency varies from 30 % in Ashkenazi Jews to 88 % in Danes (Cutting et al, 1992). Available evidence indicates that CFTR functions as a chloride channel, although it may also serve other functions. Since then, more than 200 CF mutations have been described. Five of the most common mutations (DF508, G542X, F551D, R553X, N1303K) constitute approximately 85 % of the alleles in the United States (Elias et al, 1991). Thus, screening

procedures that test for these 5 mutations will detect approximately 85 % of CF carriers. The genetic screening test for CF is usually based on mouthwash samples collected by agitating sucrose or saline in the mouth. The DNA of these cells are amplified, digested, and subjected to separation techniques that identify 3 to 5 common mutations.

A National Institutes of Health consensus panel (1997) recommended that genetic testing for CF should be offered to adults with a positive family history of CF, to partners of people with the disease, to couples currently planning a pregnancy, and to couples seeking prenatal testing. However, the panel did not recommend genetic testing of CF to the general public or to newborn infants.

The American College of Obstetricians and Gynecologists (2001) has issued similar recommendations on genetic carrier testing for CF. ACOG recommends that obstetricians should offer CF screening to:

- Couples in whom one or both members are white and who are planning a pregnancy or seeking prenatal care;
- Individuals with a family history of CF; and
- Reproductive partners of people who have CF.

ACOG also recommends that screening should be made available to couples in other racial and ethnic groups. To date, over 900 mutations in the CF gene have been identified. As it is impractical to test for every known mutation, the ACMG Accreditation of Genetic Services Committee has compiled a standard screening panel of 25 CF mutations, which represents the standard panel that ACMG recommends for screening in the U.S. population (Grody et al, 2001). This 25-mutation panel incorporates all CF-causing mutations with an allele frequency of greater than or equal to 0.1 % in the general U.S. population, including mutation subsets shown to be sufficiently predominant in certain ethnic groups, such as Ashkenazi Jews and African Americans. This standard panel of mutations is intended to provide the greatest pan-ethnic detectability that can practically be performed.

The ACOG's update on carrier screening for CF (2011) provided the following recommendations.

- If a patient has been screened previously, CF screening results should be documented but the test should not be repeated.
- Complete analysis of the CFTR gene by DNA sequencing is not appropriate for routine carrier screening.

Fragile X syndrome

Fragile X syndrome is the most common cause of inherited mental retardation, seen in approximately one in 1,200 males and one in 2,500 females. Phenotypic abnormalities associated with Fragile X syndrome include mental retardation, autistic behaviors, characteristic narrow face with large jaw, and speech and language disorders. Fragile X syndrome was originally thought to be transmitted in an X-linked recessive manner; however, the inheritance pattern of fragile X syndrome has been shown to be much more complex.

Standard chromosomal analysis does not consistently demonstrate the cytogenetic abnormality in patients with fragile X syndrome, and molecular diagnostic techniques (DNA testing) have become the diagnostic procedure of choice for fragile X syndrome.

Aetna's policy on coverage of fragile X genetic testing is based on guidelines fromm the ACMG (1994) and the ACOG (1995).

Lactose intolerance

Lactase-phlorizin hydrolase, which hydrolyzes lactose, the major carbohydrate in milk, plays a critical role in the nutrition of the mammalian neonate (Montgomery et al, 1991). Lactose intolerance in adult humans is common, usually due to low levels of small intestinal lactase. Low lactase levels result from either intestinal injury or (in the majority of the world's adult population) alterations in the genetic expression of lactase. Although the mechanism of decreased lactase levels has been the subject of intensive investigation, no consensus has yet emerged.

The LactoTYPE Test (Prometheus Laboratories) is a blood test that is intended to identify patients with genetic-based lactose intolerance. According to the manufacturer, this test provides a more definitive diagnosis and scientific explanation for patients with persistent symptoms.

There is insufficient evidence that the assessment of the genetic etiology of lactose intolerance would affect the management of patients such that clinical outcomes are improved. Current guidelines on the management of lactose intolerance do not indicate that genetic testing is indicated (NHS, 2005; National Public Health Service for Wales, 2005).

Long QT syndrome

Voltage-gated sodium channels are transmembrane proteins that produce the ionic current responsible for the rising phase of the cardiac action potential and play an important role in the initiation, propagation, and maintenance of normal cardiac rhythm. Inherited mutations in the sodium channel alpha-subunit gene (SCN5A), the gene encoding the pore-forming subunit of the cardiac sodium channel, have been associated with distinct cardiac rhythm syndromes such as the congenital long QT3 syndrome (LQT3), Brugada syndrome, isolated conduction disease, sudden unexpected nocturnal death syndrome (SUNDS), and sudden infant death syndrome (SIDS). Electrophysiological characterization of heterologously expressed mutant sodium channels have revealed gating defects that, in many cases, can explain the distinct phenotype associated with the rhythm disorder.

The long QT syndrome (LQTS) is a familial disease characterized by an abnormally prolonged QT interval and, usually, by stress-mediated life-threatening ventricular arrhythmias (Priori et al, 2001). Characteristically, the first clinical manifestations of

LQTS tend to appear during childhood or in teenagers. Two variants of LQTS have been described: a rare recessive form with congenital deafness (Jervell and Lange-Nielsen syndrome, J-LN), and a more frequent autosomal dominant form (Romano-Ward syndrome, RW). Five genes encoding subunits of cardiac ion channels have been associated to LQTS and genotype-phenotype correlation has been identified. Of the 5 genetic variants of LQTS currently identified, LQT1 and LQT2 subtypes involve 2 genes, KCNQ1 and HERG, which encode major potassium currents. LQT3 involves SCN5A, the gene encoding the cardiac sodium current. LQT5 and LQT6 are rare subtypes also involving the major potassium currents.

The principal diagnostic and phenotypic hallmark of LQTS is abnormal prolongation of ventricular repolarization, measured as lengthening of the QT interval on the 12-lead ECG (Maron et al, 1998). This is usually most easily identified in lead II or V1, V3, or V5, but all 12 leads should be examined and the longest QT interval used; care should also be taken to exclude the U wave from the QT measurement.

LQT3 appears to be the most malignant variant and may be the one less effectively managed by beta blockers. LQT1 and LQT2 have a higher frequency of syncopal events but their lethality is lower and the protection afforded by beta-blockers, particularly in LQT1, is much higher. The Jervell and Lange-Nielsen recessive variant is associated with very early clinical manifestations and a poorer prognosis than the Romano-Ward autosomal dominant form. The presence of syndactyly seems to represent a different genetic variant of LQTS also associated with a poor prognosis.

Guidelines on sudden cardiac death from the European College of Cardiology (Priori et al, 2001) state that identification of specific genetic variants of LQTS are useful in risk stratification. The clinical variants presenting association of the cardiac phenotype with syndactyly or with deafness (Jervell and Lange-Nielsen syndrome) have a more severe prognosis. Genetic defects on the cardiac sodium channel gene (SCN5A) are also associated with higher risk of sudden cardiac death. In addition, identification of specific genetic variants may help in suggesting behavioral changes likely to reduce risk. LQT1 patients are at very high risk during exercise, particularly swimming. LQT2 patients are quite sensitive to loud noises, especially when they are asleep or resting.

Genetic testing for LQTS may be indicated in persons with close relatives that have a defined mutation. Genetic testing may also be indicated in individuals with a prolonged QT interval on resting electrocardiogram (a corrected QT interval (QTc) of 470 msec or more in males and 480 msec or more in females) without an identifiable external cause for QTc prolongation. Common external causes of QTc prolongation are listed in the table below.

Table: Common External Causes of Prolongation of QTc Interval
Bradycardia
Heart disease (heart failure, ischemia)
Hypocalcemia
Hypomagnesemia
Hypokalemia
Hypothyroidism
Antiarrhythmic medications (quinidine, procainamide, amiodarone, sotalol, and dofetilide)
Tricyclic and tetracyclic antidepressants (e.g., amitriptyline)
Erythromycin
Cisapride
Pimozide
Thioridazine

Genetic testing for long QT syndrome has not been evaluated in patients who present with a borderline QT interval, suspicious symptoms (e.g., syncope), and no relevant family history (Roden, 2008). In these patients, the incidence of false positive and false negative results and their implications for management remain unknown.

Genetic testing may also be necessary in person with long QT syndrome in sudden death close relatives.

Brugada syndrome

Brugada syndrome is an inherited condition comprising a specific EKG abnormality and an associated risk of ventricular fibrillation and sudden death in the setting of a structurally normal heart. Brugada syndrome is characterized by ST-segment abnormalities on EKG and a high risk of ventricular arrhythmias and sudden death. Brugada syndrome presents primarily during adulthood but age at diagnosis ranges from 2 days to 85 years. Clinical presentations may also include sudden infant death syndrome and sudden unexpected nocturnal death syndrome, a typical presentation in individuals from Southeast Asia.

Brugada et al (2005) reported that Brugada syndrome and LQTS are both due to mutations in genes encoding ion channels and that the genetic abnormalities causing Brugada syndrome have been linked to mutations in the ion channel gene SCN5A. Brugada stated that the syndrome has been identified only recently but an analysis of data from published studies indicates that the disease is responsible for 4 to 12 % of unexpected sudden deaths, and up to 50 % of all sudden death in patients with an apparently normal heart. Brugada explained that Brugada syndrome is a clinical diagnosis based on syncopal or sudden death episodes in patients with a structurally normal heart and a characteristic ECG pattern. The ECG shows ST segment elevation in the primordial leads V1-V3, with a morphology of the QRS complex resembling a right bundle branch block; this pattern may also be caused by J point elevation. When ST elevation is the most prominent feature, the pattern is called "coved-type". When the most prominent feature is J point elevation, without ST elevation the pattern is called "saddle-type". Brugada pointed out that it is important to exclude other causes of ST segment elevation before making the diagnosis of Brugada syndrome. Brugada syndrome is inherited in an autonomic dominant manner with variable penetrance. Most individuals diagnosed with Brugada syndrome have an affected parent. The proportion of cases caused by de novo mutations is estimated at 1 %. Each child of an individual with Brugada syndrome has a 50 % chance of inheriting the mutation. According to Brugada, antiarrhythmic drugs do not prevent sudden death in symptomatic or asymptomatic individuals with Brugada syndrome and that implantation of an automatic cardioverter-defibrillator is the only currently proven effective therapy.

To date the great majority of identified disease-causing mutations have been located in the SCN5A gene encoding the a subunit of the human cardiac voltage-gated sodium channel but such mutations can be identified in, at most, 30 % of affected people. Moreover, a positive genetic test adds little or nothing to the clinical management of such a person (HRUK, 2007). The identification of an SCN5A mutation does, of course, allow screening of family members but the usefulness of genetic screening may be less than for other familial syndromes, however, given that the routine 12-lead EKG (with or without provocative drug testing) appears to be a relatively effective method of screening for the condition.

Hypertrophic cardiomyopathy

Hypertrophic cardiomyopathy (HCM) is a disease of the myocardium in which a portion of the myocardium is hypertrophied without any obvious cause; it is among the most common genetically transmitted cardiovascular diseases.

The genetic abnormalities that cause HCM are heterogeneous. Hypertrophic cardiomyopathy is most commonly due to a mutation in one of 9 genes that results in a mutated protein in the sarcomere. Some of the genes responsible for HCM have not yet been identified, and among those genes that have been identified, the spectrum of possible disease-causing mutations is incomplete. As a result, a thorough evaluation of known genes requires extensive DNA sequencing, which is onerous for routine clinical testing. Less rigorous methods (such as selective sequencing) reduces the likelihood of identifying the responsible mutation.

Population studies have demonstrated that some patients are compound heterozygotes (inheriting 2 different mutations within a single HCM gene), double heterozygotes (inheriting mutations in 2 HCM genes), or homozygotes (inheriting the same mutation from both parents). To be certain of detecting such genotypes, sequencing of candidate genes would need to continue in a given patient even after a single mutation was identified.

In many persons with HCM mutations, the disease can be mild and the symptoms absent or minimal. In addition, phenotypic expression of HCM can be influenced by factors other than the basic genetic defect, and the clinical consequences of the genetic defect can vary. There is sufficient heterogeneity in the clinical manifestations of a given gene mutation that, even when a patient's mutation is known, his or her clinical course can not be predicted with any degree of certainty.

In addition, the prognostic impact of a given mutation may relate to a particular family and not to the population at large. Many families have their own "private" mutations and thus knowledge of the gene abnormalities can not be linked to experience from other families.

Family members with echocardiography evidence of HCM should be managed like other patients with HCM. In general, genetically affected but phenotypically normal family members should not be subjected to the same activity restriction as patients with HCM.

Bos and colleagues (2009) stated that over the past 20 years, the pathogenic basis for HCM, the most common heritable cardiovascular disease, has been studied extensively. Affecting about 1 in 500 persons, HCM is the most common cause of sudden cardiac death (SCD) among young athletes. In recent years, genomic medicine has been moving from the bench to the bedside throughout all medical disciplines including cardiology. Now, genomic medicine has entered clinical practice as it pertains to the evaluation and management of patients with HCM. The continuous research and discoveries of new HCM susceptibility genes, the growing amount of data from genotype-phenotype correlation studies, and the introduction of commercially available genetic tests for HCM make it essential that cardiologists understand the diagnostic, prognostic, and therapeutic implications of HCM genetic testing.

Hudecova et al (2009) noted that the clinical symptoms of HCM are partly dependent on mutations in affected sarcomere genes. Different mutations in the same gene can present as malign with a high-risk of SCD, while other mutations can be benign. The clinical symptomatology can also be influenced by other factors such as the presence of polymorphisms in other genes. Currently, the objective of intensive clinical research is to access the contribution of molecular genetic methods in HCM diagnostics as well as in risk stratification of SCD. It is expected that genetic analyses will have an important consequence in the screening of the relatives of HCM patients and also in the prenatal diagnostics and genetic counseling.

Shephard and Semsarian (2009) stated that genetic heart disorders are an important cause of SCD in the young. While pharmacotherapies have made some impact on the prevention of SCD, the introduction of implantable cardioverter-defibrillator

(ICD) therapy has been the single major advance in the prevention of SCD in the young. In addition, the awareness that most causes of SCD in the young are inherited, means family screening of relatives of young SCD victims allows identification of previously unrecognised at-risk individuals, thereby enabling prevention of SCD in relatives. The role of genetic testing, both in living affected individuals as well as in the setting of a "molecular autopsy", is emerging as a key factor in early diagnosis of an underlying cardiovascular genetic disorder.

The Heart Failure Society of America's practice guideline on "Genetic evaluation of cardiomyopathy" (Hershberger et al, 2009) stated that genetic testing is primarily indicated for risk assessment in at-risk relatives who have little or no clinical evidence of cardiovascular disease. Genetic testing for HCM should be considered for the one most clearly affected person in a family to facilitate family screening and management. Specific genes available for testing for HCM include MYH7, MYBPC3, TNNT2, TNN13, TPM1, ACTC, MYL2, and MYL3. MYH7 and MYBPC each accounts for 30 % to 40 % of mutations; TNNT2 for 10 % to 20 %. Genetic cause can be identified in 35 % to 45 % overall; up to 60 % to 65 % when the family history is positive.

The BlueCross BlueShield Association Technology Evaluation Center (TEC)'s assessement on genetic testing for predisposition to inherited HCM (2010) concluded that the use of genetic testing for inherited HCM meets the TEC criteria for individuals who are at-risk for development of HCM, defined as having a close relative with established HCM, when there is a known pathogenic gene mutation present in an affected relative. In order to inform and direct genetic testing for at-risk individuals, genetic testing should be initially performed in at least 1 close relative with definite HCM (index case) if possible. This testing is intended to document whether a known pathologic mutation is present in the family, and optimize the predictive value of predisposition testing for at-risk relatives. Due to the complexity of genetic testing for HCM and the potential for misinterpretation of results, the decision to test and the interpretation of test results should be performed by, or in consultation with an expert in the area of medical genetics and/or HCM.

The TEC assessment also concluded that genetic testing for inherited HCM does not meet the TEC criteria for predisposition testing in individuals who are at-risk for development of HCM, defined as having a close relative with established HCM, when there is no known pathogenic gene mutation present in an affected relative. This includes:

- Patients with a family history of HCM, with unknown genetic status of affected relatives; and
- Patients with a family history of HCM, when a pathogenic mutation has not been identified in affected relatives.

Arrhythmogenic right ventricular dysplasia/cardiomyopathy (ARVD/C)

Arrhythmogenic right ventricular dysplasia/cardiomyopathy is a condition characterized by progressive fibro-fatty replacement of the myocardium that predisposes individuals to ventricular tachycardia and sudden death. The prevalence of ARVD/C is estimated to be 1 case per 10,000 population. Familial occurrence with an autosomal dominant pattern of inheritance and variable penetrance has been demonstrated. Recessive variants have been reported. It is estimated that half of the individuals have a family history of ARVD/C and the remaining cases are new mutations.

Genetic testing has not been demonstrated to be necessary to establish the diagnosis of ARVD/C or determine its prognosis. Twelve-lead ECG and echocardiography can be used to identify affected relatives.

The genetic abnormalities that cause ARVD/C are heterogeneous. The genes frequently associated with ARVD/C are PKP2 (plakophilin-2), DSG2 (desmoglein-2), and DSP (desmoplakin). A significant proportion of ARVD/C cases have been reported with no linkage to known chromosomal loci; in one report, 50 % of families undergoing clinical and genetic screening did not show linkage with any known genetic loci (Corrado et al, 2000).

Most affected individuals live a normal lifestyle. Management of individuals with ARVD/C is complicated by incomplete information on the natural history of the disease and the variability of disease expression even within families. High-risk individuals with signs and symptoms of ARVD/C are treated with anti-arrhythmic medications and those at highest risk who have been resuscitated or who are unresponsive to or intolerant of anti-arrhythmic therapy may be considered for an ICD.

According to the Heart Failure Society of America's Practice Guideline on the genetic evaluation of cardiomyopathy (2009), the clinical utility for all genetic testing of cardiomyopathies remains to be defined. The guideline stated, "[b]ecause the genetic knowledge base of cardiomyopathy is still emerging, practitioners caring for patients and families with genetic cardiomyopathy are encouraged to consider research participation." The Multidisciplinary Study of Right Ventricular Dysplasia (North American registry) is a 5-year study funded by the National Institutes of Health to determine how the genes responsible for ARVD/C affect the onset, course, and severity of the disease. Enrollment in the study was completed in May 2008 and the study is currently in the follow-up period.

Catecholaminergic polymorphic ventricular tachycardia (CPVT)

Catecholaminergic polymorphic ventricular tachycardia (CPVT) is a highly lethal form of inherited arrhythmogenic disease characterized by adrenergically mediated polymorphic ventricular tachycardia (Liu et al, 2007). Mutations in the cardiac ryanodine receptor (RyR2) gene and the cardiac calsequestrin (CASQ2) gene are responsible for the autosomal dominant and recessive variants of CPVT, respectively. The clinical presentation encompasses exercise- or emotion-induced syncopal events and a distinctive pattern of reproducible, stress-related, bi-directional ventricular tachycardia in the absence of both structural heart disease and a prolonged QT interval.

CPVT typically begins in childhood or adolescence. The mortality rate in untreated individuals is 30 to 50 % by age 40 years. Clinical evaluation by exercise stress testing and Holter monitoring and genetic screening can facilitate early diagnosis. Beta-blockers are the most effective drugs for controlling arrhythmias in CPVT patients, yet about 30 % of patients with CPVT still experience cardiac arrhythmias on beta-blockers and eventually require an implantable cardioverter defibrillator. Liu et al

(2008) stated that molecular genetic screening of the genes encoding the cardiac RyR2 and CASQ2 is critical to confirm uncertain diagnosis of CPVT.

Katz et al (2009) noted that CPVT is a primary electrical myocardial disease characterized by exercise- and stress-related ventricular tachycardia manifested as syncope and sudden death. The disease has a heterogeneous genetic basis, with mutations in the cardiac RyR2 gene accounting for an autosomal-dominant form (CPVT1) in approximately 50 % and mutations in the cardiac CASQ2 gene accounting for an autosomal-recessive form (CPVT2) in up to 2 % of CPVT cases. Both RyR2 and calsequestrin are important participants in the cardiac cellular calcium homeostasis. These researchers reviewed the physiology of the cardiac calcium homeostasis, including the cardiac excitation contraction coupling and myocyte calcium cycling.

Although the clinical presentation of CPVT is similar in many respects to the LQTS, there are important differences that are relevant to genetic testing. CPVT appears to be a more malignant condition, as many people are asymptomatic before the index lethal event and the majority of cardiac events occur before 20 years of age. Affected people are advised to avoid exercise-related triggers and start prophylactic beta-blockers with dose titration guided by treadmill testing.

Genetic testing has been recommended in individuals with clinical features considered typical of CPVT following expert clinical assessment (HRUK, 2008). Clinically the condition is difficult to diagnose in asymptomatic family members as the ECG and echocardiogram are completely normal at rest. Exercise stress testing has been advised in family members in order to identify exercise-induced ventricular arrhythmias, but the sensitivity of this clinical test is unknown. Although the diagnostic yield from genetic testing is less than that for the LQTS (about 50 %) in patients with typical clinical features, a positive genetic test may be of value for the individual patient (given the prognostic implications) and for screening family members (given the difficulties in clinical screening methods) (HRUK, 2008). The RyR2 gene is large and a ''targeted'' approach is usually undertaken, in which only exons that have been previously implicated are examined.

The 2006 guidelines from the American College of Cardiology on management of patients with ventricular arrhythmias and the prevention of sudden cardiac death (Zipes et al, 2006) included the following recommendations for patients with CPVT:

- There is evidence and/or general agreement supporting the use of beta blockers for patients clinically diagnosed on the basis of spontaneous of documented stress-induced ventricular arrhythmias.
- There is evidence and/or general agreement supporting the use of an implantable ICD in combination with beta blockers for survivors of cardiac arrest who have a reasonable expectation of survival with a good functional capacity for more than 1 year.
- The weight of evidence and/or opinion supports the use of beta blockers in patients without clinical manifestations who are diagnosed in childhood based upon genetic analysis.
- The weight of evidence and/or opinion supports the use of an ICD in combination with beta blockers for patients with a history of syncope and/or sustained ventricular tachycardia while receiving beta blockers who have a reasonable expectation of survival with a good functional capacity for more than 1 year.
- The usefulness and/or efficacy of beta blockers is less well established in patients without clinical evidence of arrhythmias who are diagnosed in adulthood based upon genetic analysis.

Hereditary hemochromatosis

Hemochromatosis, a condition involving excess accumulation of iron, can lead to iron overload, which in turn can result in complications such as cirrhosis, diabetes, cardiomyopathy, and arthritis (Burke 1992; Hanson et al, 2001).

Hereditary hemochromatosis (HHC) is characterized by inappropriately increased iron absorption from the duodenum and upper intestine, with consequent deposition in various parenchymal organs, notably the liver, pancreas, joints, heart, pituitary gland and skin, with resultant end-organ damage (Limdi and Crampton, 2004). Clinical features may be non-specific and include lethargy and malaise, or reflect target organ damage and present with abnormal liver tests, cirrhosis, diabetes mellitus, arthropathy, cardiomyopathy, skin pigmentation and gonadal failure. Early recognition and treatment (phlebotomy) is essential to prevent irreversible complications such as cirrhosis and hepatocellular carcinoma.

HHC is an autosomal recessive condition associated with mutations of the HFE gene. Two of the 37 allelic variants of the HFE gene, C282Y and H63D, are significantly correlated with HHC. C282Y is the more severe mutation, and homozygosity for the C282Y genotype accounts for the majority of clinically penetrant cases. Hanson et al (2001) reported that homozygosity for the C282Y mutation has been found in 52 to 100 % of previous studies on clinically diagnosed index cases. Five percent of HHC probands were found by Hanson et al to be compound heterozygotes (C282Y/H63D), and 1.5 % were homozygous for the H63D mutation; 3.6 % were C282Y heterozygotes, and 5.2 % were H63D heterozygotes. In 7 % of cases, C282Y and H63D mutations were not present. In the general population, the frequency of the C282Y/C282Y genotype is 0.4 %.

HHC is a very common genetic defect in the Caucasian population. C282Y heterozygosity ranges from 9.2 % in Europeans to nil in Asian, Indian subcontinent, African, Middle Eastern, Australian and Asian populations (Hanson et al, 2001). The H63D carrier frequency is 22 % in European populations.

Accurate data on the penetrance of the different HFE genotypes are not available. But current data suggest that clinical disease does not develop in a substantial proportion of people with this genotype. Available data suggest that up to 38 % to 50 % of C282Y homozygotes may develop iron overload, with up to 10 % to 33 % eventually developing hemochromatosis-associated morbidity (Whitlock et al, 2006). A pooled analysis found that patients with the HFE genotypes C282Y/H63D and H63D/H63D are also at increased risk for iron overload, yet overall, disease is likely to develop in fewer than 1 % of people with these genotypes (Burke, 1992). Thus, DNA-based tests for hemochromatosis identify a genetic risk rather than the disease itself.

Environmental factors such as diet and exposure to alcohol or other hepatotoxins may modify the clinical outcome in patients with hemochromatosis, and variations in other genes affecting iron metabolism may also be a factor. As a result, the clinical condition of iron overload is most reliably diagnosed on the basis of biochemical evidence of excess body iron (Burke, 1992).

Whether it is beneficial to screen asymptomatic people for a genetic risk of iron overload is a matter of debate. To date, population screening for HHC is not recommended because of uncertainties about optimal screening strategies, optimal care for susceptible persons, laboratory standardization, and the potential for stigmatization or discrimination (Hanson et al, 2001; Whitlock et al, 2006). A systematic evidence review prepared for the U.S. Preventive Services Task Force concluded: "Research addressing genetic screening for hereditary hemochromatosis remains insufficient to confidently project the impact of, or estimate the benefit from, widespread or high-risk genetic screening for hereditary hemochromatosis" (Whitlock et al, 2006).

Familial nephrotic syndrome (NPHS1, NPHS2)

Nephrotic syndrome comes in 2 variants: (i) those sensitive to treatment with immunosuppressants (steroid-sensitive), and (ii) those resistant to immunosuppressants (steroid-resistant). Familial forms of nephrotic syndrome are steroid resistant (Niaudet, 2007). Mutations in two genes, NPHS1 and NPHS2, have been associated with a familial nephrotic syndrome. Mutations in the gene for podocin, called NPHS2, also known as familial focal glomerulosclerosis, are observed in patients with both familial and sporadic steroid-resistant nephrotic syndrome (SRNS).

Identifying children with nephrotic syndrome due to NPHS2 mutations can avoid unnecessary exposure to immunosuppressive therapy, because immunosuppressive therapy has not been shown to be effective in treating these children (Niaudet, 2007). Thus, authorities have recommended testing for such mutations in those with a familial history of steroid resistant nephrotic syndrome and children with steroid-resistant disease .

Some have suggested that, to avoid unnecessary exposure to steroid therapy, all children with a first episode of the nephrotic syndrome should be screened for NPHS2 mutations (Niaudet, 2007). However, given that over 85 % of children with idiopathic nephrotic syndrome are steroid-sensitive and only approximately 20 % of steroid-resistant patients have NPHS2 mutations, screening for abnormalities at this genetic locus would identify less than 5 % of all cases. However, screening a child with a first episode of the nephrotic syndrome with a familial history of steroid-resistant nephrotic syndrome has been recommended because they are at increased risk for having a NPHS2 gene mutation.

Mutations in the gene for nephrin, called NPHS1, cause the congenital nephrotic syndrome of Finnish type (CNF) (Niaudet, 2007). CNF is inherited as an autosomal recessive trait, with both sexes being involved equally. There are no manifestations of the disease in heterozygous individuals. Most infants with the CNF are born prematurely (35 to 38 weeks), with a low birth weight for gestational age. Edema is present at birth or appears during the first week of life in 50 % of cases. Severe nephrotic syndrome with marked ascites is always present by 3 months. End-stage renal failure usually occurs between 3 and 8 years of age. Prolonged survival is possible with aggressive supportive treatment, including dialysis and renal transplantation.

The nephrotic syndrome in CNF is always resistant to corticosteroids and immunosuppressive drugs, since this is not an immunologic disease (Niaudet, 2007). Furthermore these drugs may be harmful due to affected individuals' already high susceptibility to infection.

The CNF becomes manifest during early fetal life, beginning at the gestation age of 15 to 16 weeks. The initial symptom is fetal proteinuria, which leads to a more than 10-fold increase in the amniotic fluid alpha-fetoprotein (AFP) concentration (Niaudet, 2007). A parallel, but less important increase in the maternal plasma AFP level is observed. These changes are not specific, but they may permit the antenatal diagnosis of CNF in high risk families in which termination of the pregnancy might be considered. However, false positive results do occur, often leading to abortion of healthy fetuses.

Genetic linkage and haplotype analyses may diminish the risk of false positive results in informative families (Niaudet, 2007). The 4 major haplotypes, which cover 90 % of the CNF alleles in Finland, have been identified, resulting in a test with up to 95 % accuracy.

Authorities do not recommend screening for NPHS1 mutations for all children with the first episode of nephrotic syndrome, for the reasons noted above regarding NPHS2 mutation screening. However, genetic testing may be indicated for infants with congenital nephrotic syndrome (i.e., appearing within the first months of life) who are of Finnish descent and/or who have a family history that suggests a familial cause of congenital nephrotic syndrome. The primary purpose of this testing is for pregnancy planning. Detection of an NPHS1 mutation also has therapeutic implications, as such nephrotic syndrome is steroid resistant.

Primary dystonia (DYT-1)

Dystonia consists of repetitive, patterned, twisting, and sustained movements that may be either slow or rapid. Dystonic states are classified as primary, secondary, or psychogenic depending upon the cause (Jankovic, 2007). By definition, primary dystonia is associated with no other neurologic impairment, such as intellectual, pyramidal, cerebellar, or sensory deficits. Cerebral palsy is the most common cause of secondary dystonia.

Primary dystonia may be sporadic or inherited (Jankovic, 2007). Cases with onset in childhood usually are inherited in an autosomal dominant pattern. Many patients with hereditary dystonia have a mutation in the TOR1A (DYT1) gene that encodes the protein torsinA, an ATP-binding protein in the 9q34 locus. The role of torsinA in the pathogenesis of primary dystonia is unknown. DNA testing for the abnormal TOR1A gene can be performed on individuals with dystonia. The purpose of such testing is to help rule out secondary or psychogenic causes of dystonia, and for family planning purposes.

Malignant melanoma

An estimated 8 to 12 % of persons with melanoma have a family history of the disease, but not all of these individuals have hereditary melanoma (Tsao and Haluska, 2007). In some cases, the apparent familial inheritance pattern may be due to clustering of sporadic cases in families with common heavy sun exposure and susceptible skin type.

A melanoma susceptibility locus has been identified on chromosome 9p21; this has been designated CDKN2A (also known as MTS1 (multiple tumor suppressor 1)) (Tsao and Haluska, 2007). There is a variable rate of CDKN2A mutations in patients with hereditary melanoma. The risk of CDKN2A mutation varies from approximately 10 % for families with at least 2 relatives having melanoma, to more than 40 % for families having multiple affected 1st degree relatives spanning several generations.

Persons at increased risk of melanoma are managed with close clinical surveillance and education in risk-reduction behavior (e.g., sun avoidance, sunscreen use). It is unclear how CDKN2A genetic test information would alter clinical recommendations (Tsao and Haluska, 2007). The negative predictive value of a negative test for a CDKN2A mutation is also not established since many familial cases occur in the absence of CDKN2A mutations. It is estimated that the prevalence of CDKN2A mutation carriers is less than 1 % in high incidence populations. Thus, no mutations will be identifiable in the majority of families presenting to clinical geneticists.

The American Society of Clinical Oncology (ASCO) has issued a consensus report on the utility of genetic testing for cancer susceptibility (ASCO, 1996), and recommendations for the process of genetic testing were updated in 2003 (ASCO, 2003). The report notes that the sensitivity and specificity of the commercially available test for CDKN2A mutations are not fully known. Because of the difficulties with interpretation of the genetic tests, and because test results do not alter patient or family member management, ASCO recommends that CDKN2A testing be performed only in the context of a clinical trial.

The Scottish Intercollegiate Guidelines Network (SIGN, 2003) protocols on management of cutaneous melanoma reached similar conclusions, stating that "[g]enetic testing in familial or sporadic melanoma is not appropriate in a routine clinical setting and should only be undertaken in the context of appropriate research studies."

The Melanoma Genetics Consortium recommends that genetic testing for melanoma susceptibility should not be offered outside of a research setting (Kefford et al, 2002). They state that “[u]ntil further data become available, however, clinical evaluation of risk remains the gold standard for preventing melanoma. First-degree relatives of individuals at high risk should be engaged in the same programmes of melanoma prevention and surveillance irrespective of the results of any genetic testing.”

Charcot-Marie Tooth disease type 1A (PMP-22)

Charcot Marie Tooth disease, also known as peroneal muscular atrophy, progressive neural muscular atrophy, as well as hereditary motor and sensory neuropathy, is 1 of the 3 major types of hereditary neuropathy. With an estimated prevalence of at least 1:2,500 (autosomal dominance), CMT is one of the most common genetic neuromuscular disorders affecting approximately 125,000 persons in the United States. This hereditary peripheral neuropathy is genetically and clinically heterogeneous. It is usually inherited in an autosomal dominant manner, and occasionally in an autosomal recessive manner. Sporadic as well as X-linked cases have also been reported. In the X-linked recessive patterns, only males develop the disease, although females who inherit the defective gene can pass the disease onto their sons. In the X-linked dominant pattern, an affected mother can pass on the disorder to both sons and daughters, while an affected father can only pass it onto his daughters. The clinical manifestations can vary greatly in severity and age of onset. The clinical features may be so mild that they may be undetectable by patients, their families and physicians.

Charcot-Marie-Tooth disease is usually diagnosed by an extensive physical examination, assessing characteristic weakness in the foot, leg, and hand, as well as deformities and impaired function in walking and manual manipulation. The clinical diagnosis is then confirmed by electromyogram and nerve conduction velocity tests, and sometimes by biopsy of muscle and of sural cutaneous nerve. Since CMT is a hereditary disease, family history can also help to confirm the diagnosis. Based on studies of motor nerve conduction velocity, CMT can be further classified into 2 types: (i) CMT Type I -- slow conduction velocity (less than 40 meters/second for the median nerve or less than 15 meters/second for the peroneal nerve) which accounts for 70 % of all CMT cases, and (ii) CMT Type II -- normal or near normal nerve conduction velocity with decreased amplitude which accounts for the remaining 30 % of CMT cases. Charcot Marie Tooth Type I disease is a demyelinating neuropathy with hypertrophic changes in peripheral nerves, and has its onset usually during late childhood. On the other hand, CMT Type II is a non-demyelinating neuronal disorder without hypertrophic changes, and has its onset generally during adolescence.

Both CMT Types I and II are characterized by a slow degeneration of peripheral nerves and roots, resulting in distal muscle atrophy commencing in the lower extremities, and affecting the upper extremities several years later. Symptoms include foot drop or clubfoot, paresthesia in legs, sloping gait, later weakness and atrophy of hands, then arms, absence or reduction of deep tendon reflexes, and occasionally mild sensory loss. Charcot Marie Tooth disease is not a fatal disorder. It does not shorten the normal life expectancy of patients, and it does not affect them mentally. As stated earlier, there is a wide range of variation in the clinical manifestations of CMT -- the degree of severity can vary considerably from patient to patient, even among affected family members within the same generation. The condition can range from having no problems to having major difficulties in ambulation in early adult life, however, the latter is unusual. Most patients are able to ambulate and have gainful employment until old age. Currently, there is no specific treatment for this disease. Management of the majority of patients with CMT disease consists of supportive care with emphasis on proper bracing, foot care, physical therapy and occupational counseling. For example, the legs and shoes can be fitted with light braces and springs, respectively, to overcome foot drop. If foot drop is severe and the disease has become stationary, the ankle can be stabilized by arthrodeses.

The underlying genetic basis for CMT Type I has been characterized. A point mutation in the PMP22 gene which encodes a peripheral myelin protein with an apparent molecular weight of 22,000 or a DNA duplication of a specific region 5 megabases) including the PMP22 gene in the proximal short arm of chromosome 17 (band 17p11.2-p12) has been identified in 70 % of clinically diagnosed patients --- CMT Type IA. Thus, patients with CMT Type IA represent approximately 50 % of all CMT cases. Other CMT Type I patients (CMT Type IB) exhibit an abnormality (Duffy locus) in the proximal long arm of chromosome number 1 (band 1q21-22). Presently, no test is available for the dominant CMTIB gene on chromosome 1. On the other hand, a CMT Type IA DNA test is available commercially. The test is accomplished through a blood sample analysis -- DNAs are extracted from leukocytes of patients and pulsed-field gel electrophoresis is employed to isolate large segments of DNA encompassing CMTIA duplication-specific junction fragments which are then detected by hybridization with aCMTIA duplication-specific probe (CMTIA-REP). This probe identifies the homologous regions that flank the CMTIA duplication monomer unit.

A positive CMTIA DNA test means the presence of a 500 kilobases CMTIA duplication specific junction fragment, and is diagnostic for CMT Type IA. A negative CMT Type IA means the absence of the CMTIA duplication specific junction fragment, and does not rule out a diagnosis of CMT disease. This is because patients with CMT Type IA represent approximately 50 % of all CMT cases. The value of this molecular test in family planning is questionable because of its relatively low detection rate and its inability to predict the severity of the disease. Moreover, it is likely that there are undiscovered CMTI genes since there are dominant CMTI pedigrees who do not have abnormalities at the known chromosome 1 and 17 locations (CMT Type IC). In addition, other investigators have reported X-linked forms of CMTI at the region of Xq13-21, and Xq26.

Since CMT is not life-threatening, rarely severely disabling, and has no specific treatment, it is unclear how the results of this CMT Type I DNA test, which can not predict the severity of the disease, would affect family planning. Moreover, because of its low detection rate, the CMT Type I DNA test appears to be inferior to the conventional means of diagnosis through physical examination, family history, electromyography and nerve conduction velocity studies. Thus, the sole value of genetic testing for CMTIA is to establish the diagnosis and to distinguish this from other causes of neuropathy.

Familial amyotrophic lateral sclerosis (SOD1 Mutation)

Amyotrophic lateral sclerosis (ALS) is a progressive neurodegenerative disease involving both the upper motor neurons (UMN) and lower motor neurons (LMN). UMN signs include hyperreflexia, extensor plantar response, increased muscle tone, and weakness in a topographical representation. LMN signs include weakness, muscle wasting, hyporeflexia, muscle cramps, and fasciculations. In the early stage of the disease, the clinical aspects of ALS can vary. Affected individuals typically present with asymmetric focal weakness of the extremities (stumbling or poor handgrip) or bulbar findings (dysarthria, dysphagia). Other findings include muscle fasciculations, muscle cramps, and lability of affect but not necessarily mood. Regardless of initial symptoms, atrophy and weakness eventually affect other muscles. Approximately 5,000 people in the U.S. are diagnosed with AML each year.

Most people with ALS have a form of the condition that is described as sporadic or non-inherited. The cause of sporadic ALS is largely unknown but probably involves a combination of genetic and environmental factors. About 10 % of people with ALS have a familial form of the condition, which is caused by an inherited genetic mutation, usually as an autosomal dominant trait. The mean age of onset of ALS in individuals with no known family history is 56 years and in familial ALS it is 46 years.

The diagnosis of ALS is based on clinical features, electrodiagnostic testing (EMG), and exclusion of other health conditions with related symptoms. At present, genetic testing in ALS has no value in making the diagnosis. The only genetic test currently available detects the SOD1 mutation. Since only 20 % of familial ALS patients will test positively for an SOD1 mutation, this test has limited value in genetic counseling.

Migrainous vertigo

Migrainous vertigo is a term used to describe episodic vertigo in patients with a history of migraines or with other clinical features of migraine. Approximately 20 to 33 % of migraine patients experience episodic vertigo. The underlying cause of migrainous vertigo is not very well understood. There are no confirmatory diagnostic tests or susceptible genes associated with migrainous vertigo. Other conditions, specifically Meniere's disease and structural and vascular brainstem disease, must be excluded (Black, 2006).

Prostate cancer

At this time, there are no susceptibility genes that have been unequivocally associated with prostate cancer predisposition. Genetic testing for prostate cancer is currently available only within the context of a research study. A special report on prostate cancer genetics by the BlueCross BlueShield Association Technology Evaluation Center (BCBSA, 2008) stated that single-nucleotide polymorphisms (SNPs) do not predict certainty of disease, nor do they clearly predict aggressive versus indolent disease. The report noted that, while the monitoring of high-risk men may improve outcomes, it is also possible that these could be offset by the harms of identifying and treating additional indolent disease.

Type 2 diabetes

Available evidence has shown that screening for a panel of gene variants associated with type 2 diabetes does not substantially improve prediction of risk for the disease than an assessment based on traditional risk factors. Available evidence suggests that both genetic and environmental factors play a role in the development of type 2diabetes. Recent genetic studies have identified 18 gene variants that appear to increase the risk for type 2 diabetes.

A study reported in the New England Journal of Medicine evaluated the potential utility of genetic screening in predicting future risk of type 2 diabetes (Meigs et al, 2008). The investigators analyzed records from the Framingham Offspring Study, which follows a group of adult children of participants of the original Framingham Heart study, to evaluate risk factors for the development of cardiovascular disease, including diabetes. Full genotype results for the 18 gene variants as well as clinical outcomes were available for 2,377 participants, 255 of whom developed type 2 diabetes during 28 years of follow-up. Each participant was assigned a genotype score, based on the number of risk-associated gene copies inherited. The investigators compared the predictive value of the genotype score to that of family history alone or of physiological risk factors. Overall, the genetic score was 17.7 among those who developed diabetes and 17.1 among those who did not. The investigators found that, while the genetic score did help predict who would develop diabetes, once other known risk factors were taken into consideration, it offered little additional predictive power. The investigators concluded that: "[t]he genotype score resulted in the appropriate risk reclassification of, at most, 4 % of the subjects, compared with risk estimates based on age, sex, blood lipids, body mass index, family history, and other standard risk factors." The investigators reported that "[o]ur findings underscore the view that identification of adverse phenotypic characteristics remains the cornerstone of approaches to predicting the risk of type 2 diabetes," the authors said.

A similar study among Swedish and Finnish patients, published in the same issue of the New England Journal of Medicine, also found only a small improvement in risk estimates when genetic factors were added to traditional risk factors (Lyssenko et al, 2008).

The OncoVue breast cancer risk test

The OncoVue breast cancer risk test (Intergenetics, Inc., Oklahoma City, OK) is a genetic-based breast cancer risk test that incorporates both individualized genetic-based single nucleotide polymorphisms (SNPs) and personal history measures to arrive at an estimate of a woman’s breast cancer risk at various stages in her life.

Cells that are collected from the inside of the cheek are analyzed using thousands of proprietary (Intergenetic, Inc.) combinations of multiple genes. The genetic information and the data from the medical history are combined to assign a numeric value that tells a woman's lifetime risk of developing breast cancer. Her OncoVue risk test will tell her if she is standard, moderate or high risk for developing breast cancer during each stage of her life.

OncoVue is based on an un-published case-controlled associative study that examined common genetic polymorphisms and medical history variables. Currently, 117 common polymorphisms (mostly SNPs) located in over 87 genes believed to alter breast cancer risk are examined. Most result in amino acid changes in the proteins encoded by the genes in which they occur. The medical history variables include answers to questions concerning women’s reproductive histories, family histories of cancer and a few other questions related to general health.

There are no published controlled studies on the OncoVue breast cancer risk test in the peer-reviewed medical literature.

Gail (2009) evaluated the value of adding SNP genotypes to a breast cancer risk model. Criteria that are based on 4 clinical or public health applications were used to compare the National Cancer Institute's Breast Cancer Risk Assessment Tool (BCRAT) with BCRATplus7, which includes 7 SNPs previously associated with breast cancer. Criteria included number of expected life-threatening events for the decision to take tamoxifen, expected decision losses (in units of the loss from giving a mammogram to a woman without detectable breast cancer) for the decision to have a mammogram, rates of risk re-classification, and number of lives saved by risk-based allocation of screening mammography. For all calculations, the following assumptions were made: Hardy-Weinberg equilibrium, linkage equilibrium across SNPs, additive effects of alleles at each locus, no interactions on the logistic scale among SNPs or with factors in BCRAT, and independence of SNPs from factors in BCRAT. Improvements in expected numbers of life-threatening events were only 0.07 % and 0.81 % for deciding whether to take tamoxifen to prevent breast cancer for women aged 50 to 59 and 40 to 49 years, respectively. For deciding whether to recommend screening mammograms to women aged 50 to 54 years, the reduction in expected losses was 0.86 % if the ideal breast cancer prevalence threshold for recommending mammography was that of women aged 50 to 54 years. Cross-classification of risks indicated that some women classified by BCRAT would have different classifications with BCRATplus7, which might be useful if BCRATplus7 was well calibrated. Improvements from BCRATplus7 were small for risk-based allocation of mammograms under costs constraints. The author reported that the gains from BCRATplus7 were small in the applications examined and that models with SNPs, such as BCRATplus7, have not been validated for calibration in independent cohort data. The author concluded that additional studies are needed to validate a model with SNPs and justify its use.

There is insufficient evidence on the effectiveness of the OncoVue breast cancer risk test in determining a woman’s breast cancer risk at various stages in her life.

The phosphatase and tensin homolog (PTEN) gene test

Phosphatase and tensin homolog (PTEN) hamartoma tumor syndrome is an autosomal dominant group of disorders with significant clinical overlap, most notably predisposition to hamartomatous polyposis of the gastro-intestinal tract. Laurent-Puig et al (2009) stated that the occurrence of KRAS mutation is predictive of non-response and shorter survival in patients treated by anti-epidermal growth factor receptor (anti-EGFR) antibody for metastatic colorectal cancer (mCRC), leading the European Medicine Agency to limit its use to patients with wild-type KRAS tumors. However, only 50 % of these patients will benefit from treatment, suggesting the need to identify additional biomarkers for cetuximab-based treatment efficacy. These investigators retrospectively collected tumors from 173 patients with mCRC. All but 1 patient received a cetuximab-based regimen as second-line or greater therapy. KRAS and BRAF status were assessed by allelic discrimination. EGFR amplification was assessed by chromogenic in situ hybridization and fluorescent in situ hybridization, and the expression of PTEN was assessed by immunochemistry. In patients with KRAS wild-type tumors (n = 116), BRAF mutations (n = 5) were

weakly associated with lack of response ($p = 0.063$) but were strongly associated with shorter progression-free survival ($p < 0.001$) and shorter overall survival (OS; $p < 0.001$). A high EGFR polysomy or an EGFR amplification was found in 17.7 % of the patients and was associated with response ($p = 0.015$). PTEN null expression was found in 19.9 % of the patients and was associated with shorter OS ($p = 0.013$). In multi-variate analysis, BRAF mutation and PTEN expression status were associated with OS. The authors concluded that BRAF status, EGFR amplification, and cytoplasmic expression of PTEN were associated with outcome measures in KRAS wild-type patients treated with a cetuximab-based regimen. They stated that more studies in clinical trial cohorts are needed to confirm the clinical utility of these markers.

Siena et al (2009) noted that the monoclonal antibodies panitumumab and cetuximab that target the EGFR have expanded the range of treatment options for mCRC. Initial evaluation of these agents as monotherapy in patients with EGFR-expressing chemotherapy-refractory tumors yielded response rates of approximately 10 %. The realization that detection of positive EGFR expression by immunostaining does not reliably predict clinical outcome of EGFR-targeted treatment has led to an intense search for alternative predictive biomarkers. Oncogenic activation of signaling pathways downstream of the EGFR, such as mutation of KRAS, BRAF, or PIK3CA oncogenes, or inactivation of the PTEN tumor suppressor gene is central to the progression of colorectal cancer. Tumor KRAS mutations, which may be present in 35 % to 45 % of patients with colorectal cancer, have emerged as an important predictive marker of resistance to panitumumab or cetuximab treatment. In addition, among colorectal tumors carrying wild-type KRAS, mutation of BRAF or PIK3CA or loss of PTEN expression may be associated with resistance to EGFR-targeted monoclonal antibody treatment, although these additional biomarkers require further validation before incorporation into clinical practice. Additional knowledge of the molecular basis for sensitivity or resistance to EGFR-targeted monoclonal antibodies will allow the development of new treatment algorithms to identify patients who are most likely to respond to treatment and could also provide rationale for combining therapies to overcome primary resistance. The use of KRAS mutations as a selection biomarker for anti-EGFR monoclonal antibody (e.g., panitumumab or cetuximab) treatment is the first major step toward individualized treatment for patients with mCRC.

Epsilon-sarcoglycan gene (SCGE) deletion analysis

Myoclonus-dystonia (M-D), an autosomal dominant inherited movement disorder, has been associated with mutations in the epsilon-sarcoglycan gene (SCGE) on 7q21. Raymond et al (2008) noted that M-D due to SGCE mutations is characterized by early onset myoclonic jerks, often associated with dystonia. Penetrance is influenced by parental sex, but other sex effects have not been established. In 42 affected individuals from 11 families with identified mutations, these researchers found that sex was highly associated with age at onset regardless of mutation type; the median age onset for girls was 5 years versus 8 years for boys ($p < 0.0097$). Moreover, the authors found no association between mutation type and phenotype.

Ritz et al (2009) stated that various mutations within the SGCE gene have been associated with M-D, but mutations are detected in only about 30 % of patients. The lack of stringent clinical inclusion criteria and limitations of mutation screens by direct sequencing might explain this observation. Eighty-six M-D index patients from the Dutch national referral center for M-D underwent neurological examination and were classified according to previously published criteria into definite, probable and possible M-D. Sequence analysis of the SGCE gene and screening for copy number variations were performed. In addition, screening was carried out for the 3 bp deletion in exon 5 of the DYT1 gene. Based on clinical examination, 24 definite, 23 probable and 39 possible M-D patients were detected. Thirteen of the 86 M-D index patients carried a SGCE mutation: 7 nonsense mutations, 2 splice site mutations, 3 missense mutations (2 within 1 patient) and 1 multi-exonic deletion. In the definite M-D group, 50 % carried an SGCE mutation and 1 single patient in the probable group (4 %). One possible M-D patient showed a 4 bp deletion in the DYT1 gene (c.934_937delAGAG). The authors concluded that mutation carriers were mainly identified in the definite M-D group. However, in 50 % of definite M-D cases, no mutation could be identified.

Home genetic tests

Walker (2010) stated that according to an undercover investigation by the Government Accountability Office (GAO), home genetic tests often provide incomplete or misleading information to consumers. For the GAO investigation, investigators purchased 10 tests each from 4 different direct-to-consumer genetic tests companies: 23andMe, deCode Genetics, Navigenics, and Pathway Genomics. Five saliva donors each sent 2 DNA samples to each company. In one sample, the donor used his or her real personal and medical information, and for the second sample, they developed faux identifying and medical information. The results, according to the GAO, were far from precise. For example, a donor was told by a company that he had a "below average" risk of developing hypertension, but a second company rated his risk as "average", while a third company, using DNA from the same donor, said the sample revealed an "above average" risk for hypertension. In some cases, the results conflicted with the donor's real medical condition. None of the genetic tests currently offered to consumers has undergone FDA pre-market review.

Familial Cold Autoinflammatory Syndrome

Familial cold autoinflammatory syndrome (FCAS), also known as familial cold urticaria (FCU), is an autosomal dominant condition characterized by rash, conjunctivitis, fever/chills and arthralgias elicited by exposure to cold -- sometimes temperatures below 22° C (72° F). It is rare and is estimated as having a prevalence of 1 per million people and mainly affects Americans and Europeans. Familial cold autoinflammatory syndrome is one of the cryopyrin-associated periodic syndromes (CAPS) caused by mutations in the CIAS1/NALP3 (also known as NLRP3) gene at location 1q44. Familial cold autoinflammatory syndrome shares symptoms, and should not be confused, with acquired cold urticaria, a more common condition mediated by different mechanisms that usually develop later in life and are rarely inherited. There is insufficient evidence to support the use of genetic testing in the management of patients with FCAS/FCU. UpToDate reviews on "Cold urticaria" (Maurer, 2011) and "Cryopyrin-associated periodic syndromes and related disorders" (Nigrovic, 2011) do not mention the use of genetic testing.

Santome Collazo et al (2010) noted that congenital adrenal hyperplasia (CAH) is not an infrequent genetic disorder for which mutation-based analysis for CYP21A2 gene is a useful tool. An UpToDate review on "Diagnosis of classic congenital adrenal hyperplasia due to 21-hydroxylase deficiency" (Merke, 2011) states that "[g]enetic testing also can be used to evaluate borderline cases. Genetic testing detects approximately 95 percent of mutant alleles". Furthermore, the Endocrine Society's clinical practice guideline on congenital adrenal hyperplasia (Speiser et al, 2010) suggested genotyping only when results of the adrenocortical profile following cosyntropin stimulation test are equivocal or for purposes of genetic counseling. The Task Force recommends that genetic counseling be given to parents at birth of a CAH child, and to adolescents at the transition to adult care.

Malignant Hyperthermia

Wappler (2010) stated that malignant hyperthermia (MH)-susceptible patients have an increased risk during anesthesia. The aim of this review was to present current knowledge about pathophysiology and triggers of MH as well as concepts for safe anesthesiological management of these patients. Trigger substances and mechanisms have been well-defined to date. Anesthesia can be safely performed with i.v. anesthetics, nitrous oxide, non-depolarizing muscle relaxants, local anesthetics as well as xenon. Attention must be directed to the preparation of the anesthetic machine because modern work-stations need longer cleansing times than their predecessors. Alternatively, activated charcoal might be beneficial for elimination of volatile anesthetics. Day case surgery can be performed in MH-susceptible patients, if all safety aspects are regarded. Whether there is an association between MH susceptibility and other disorders is still a matter of debate. The authors concluded that the incidence of MH is low, but the prevalence can be estimated as up to 1: 3,000. Because MH is potentially lethal, it is relevant to establish management concepts for peri-operative care in susceptible patients. This includes pre-operative genetic and in-vitro muscle contracture test (IVCT), preparation of the anesthetic work-station, use of non-triggering anesthetics, adequate monitoring, availability of sufficient quantities of dantrolene and appropriate post-operative care. Taking these items into account, anesthesia can be safely performed in susceptible patients.

Moreover, an UpToDate review on "Susceptibility to malignant hyperthermia" (Litman, 2011) states that "the contracture test is performed at specific centers around the world (four in the United States). Following testing, the referring physician receives a report indicating whether testing was positive, negative, or equivocal. Positive or equivocal results should be followed-up with genetic testing. Referral information can be found on the Malignant Hyperthermia Association of the United States (MHAUS) website". Genetic testing for MH is indicated in the following groups:

- Patients with a positive or equivocal contracture test to determine the presence of a specific mutation.
- Individuals with a positive genetic test for MH in a family member.
- Patients with a clinical history suspicious for MH (acute MH episode, masseter muscle rigidity, post-operative myoglobinuria, heat or exercise induce rhabdomyolysis) who are unable or unwilling to undergo contracture testing.

Sleep-Walking

Licis et al (2011) stated that sleep-walking is a common and highly heritable sleep disorder. However, inheritance patterns of sleep-walking are poorly understood and there have been no prior reports of genes or chromosomal localization of genes responsible for this disorder. These researchers described the inheritance pattern of sleep-walking in a 4-generation family and identified the chromosomal location of a gene responsible for sleep-walking in this family. A total of 9 affected and 13 unaffected family members of a single large family were interviewed and DNA samples collected. Parametric linkage analysis was performed. Sleep-walking was inherited as an autosomal dominant disorder with reduced penetrance in this family. Genome-wide multi-point parametric linkage analysis for sleep-walking revealed a maximum logarithm of the odds score of 3.44 at chromosome 20q12-q13.12 between 55.6 and 61.4 cM. The authors described the first genetic locus for sleep-walking at chromosome 20q12-q13.12; and concluded that sleep-walking may be transmitted as an autosomal dominant trait with reduced penetrance.

In an editorial that accompanied the afore-metnioned study, Dogu and Pressman (2011) noted that "[a]ccording to currently accepted evidence-based theories, the occurrence of sleepwalking requires genetic predisposition, priming factors such as severe sleep deprivation or stress, and, in addition, a proximal trigger factor such as noise or touch. These factors form the background for a “perfect storm,” all of which must occur before a sleepwalking episode will occur. Hereditary factors likely play an important role, with recessive and multifactorial inheritance patterns having been reported. A recent genetic study has shown that the HLADQB1*05 Ser74 variant is a major susceptibility factor for sleepwalking in familial cases, but this finding has yet to be replicated. Another study attempted to find a causal relationship between sleepwalking and sleep-disordered breathing in cosegregated families of both disorders. However, this study was limited by the absence of molecular data .... The current diagnosis of sleepwalking is based almost entirely on clinical history. There are no objective, independent means of confirming the diagnosis. Additionally, treatment of sleepwalking is symptomatic, aimed at suppressing arousal or reducing deep sleep. identification of causative genes may eventually permit development of an independent test and treatments aimed at the underlying causes of this disorder".

Choroidal Neovascularization

RetnaGene AMD (Sequenom Center for Molecular Medicine) is a laboratory developed genetic test to assess the risk of developing choroidal neovascularization (CNV), the wet form of age-related macular degeneration (AMD), a common eye disorder of the elderly that can lead to blindness. The test identifies at-risk Caucasians, age 60 and older. A report of the American Academy of Ophthalmology (Stone, et al., 2012) recommends avoidance of routine genetic testing for genetically complex disorders like age-related macular degeneration and late-onset primary open-angle glaucoma until specific treatment or surveillance strategies have been shown in one or more published clinical trials to be of benefit to individuals with specific disease-associated genotypes. The report recommends that, in the meantime, genotyping of such patients should be confined to

research studies. The report stated that complex disorders (e.g., age-related macular degeneration and glaucoma) tend to be more common in the population than monogenic diseases, and the presence of any one of the disease-associated variants is not highly predictive of the development of disease. The report stated that, in many cases, standard clinical diagnostic methods like biomicroscopy, ophthalmoscopy, tonography, and perimetry will be more accurate for assessing a patient's risk of vision loss from a complex disease than the assessment of a small number of genetic loci. The report said that genetic testing for complex diseases will become relevant to the routine practice of medicine as soon as clinical trials can demonstrate that patients with specific genotypes benefit from specific types of therapy or surveillance. The report concluded that, until such benefit can be demonstrated, the routine genetic testing of patients with complex eye diseases, or unaffected patients with a family history of such diseases, is not warranted.

Malignant Hyperthermia

Central core disease (CCD) also known as central core myopathy and Shy-Magee syndrome, is an inherited neuromuscular disorder characterized by central cores on muscle biopsy and clinical features of a congenital myopathy. Prevalence is unknown but the condition is probably more common than other congenital myopathies. CCD typically presents in infancy with hypotonia and motor developmental delay and is characterized by predominantly proximal weakness pronounced in the hip girdle; orthopedic complications are common and malignant hyperthermia susceptibility (MHS) is a frequent complication.

Malignant hyperthermia (MH) or malignant hyperpyrexia is a rare but severe pharmacogenetic disorder that occurs when patients undergoing anesthesia experience a hyperthermic reaction when exposed to certain anesthetic agents. Anesthetic agents that may trigger MH are desflurane, enflurane, halothane, isoflurane, sevoflurane, and suxamethonium chloride. MH usually occurs in the operating theater, but can occur at anytime during anesthesia and up to an hour after discontinuation.

CCD and MHS are allelic conditions both due to (predominantly dominant) mutations in the skeletal muscle ryanodine receptor (RYR1) gene, encoding the principal skeletal muscle sarcoplasmic reticulum calcium release channel (RyR1). Altered excitability and/or changes in calcium homeostasis within muscle cells due to mutation-induced conformational changes of the RyR protein are considered the main pathogenetic mechanism(s).

The diagnosis of CCD is based on the presence of suggestive clinical features and central cores on muscle biopsy; muscle MRI may show a characteristic pattern of selective muscle involvement and aid the diagnosis in cases with equivocal histopathological findings. Mutational analysis of the RYR1 gene may provide genetic confirmation of the diagnosis. Further evaluation of the underlying molecular mechanisms may provide the basis for future rational pharmacological treatment.

The reference standard test for establishing a clinical diagnosis of MHS is the caffeine halothane contracture test (CHCT) in the United States, and the in vitro contracture test (IVCT) in Europe and Australasia. The CHCT and IVCT are similar and measure the muscle contracture in the presence of the anesthetic halothane and caffeine. Both tests categorize patients as being MHS, MH equivocal (MHE), or MH negative (MHN). These tests are invasive and must be performed using a skeletal muscle biopsy that is < 5 hours old. Sequence variants in the ryanodine receptor 1 (skeletal) (RYR1) gene have been shown to be associated with MH susceptibility (MHS) and are found in up to 80% of patients with confirmed MH, usually with an autosomal dominant pattern of inheritance. Although additional genetic loci have been associated with MH, the contribution of these other loci to MH is low.

Genetic testing for RYR1 sequence variants from commercial providers is performed by polymerase chain reaction (PCR) followed by direct sequencing. Genetic tests for RYR1 sequence variants can be performed to either identify sequence variants in genetic hot spots of the RYR1 gene that cover all exons on which causative MH variants can be found, or for screening of sequence variants across the entire 106 exons of the RYR1 gene.

Examples of commercially available tests are: Malignant Hyperthermia/Central Core Disease (570-572) RYR1 Sequencing (Prevention Genetics); Malignant hyperthermia (RYR1 gene sequenced analysis, partial) (University of Pittsburgh Medical Center, Division of Molecular Diagnostics [UPMC Molecular Diagnostics]).

Hereditary Hemorrhagic Telangiectasia

Hereditary hemorrhagic telangiectasia (HHT), also called Osler-Weber-Rendu syndrome, is an autosomal dominant trait disorder that results in the development of multiple abnormalities in the blood vessels. Some arterial vessels flow directly into veins rather than into the capillaries resulting in arteriovenous malformations. When they occur in vessels near the surface of the skin, where they are visible as red markings, they are known as telangiectases (the singular is telangiectasia). Nosebleeds are very common in people with HHT, and more serious problems may arise from hemorrhages in the brain, liver, lungs, or other organs. Forms of HHT include type 1, type 2, type 3, and juvenile polyposis/hereditary hemorrhagic telangiectasia syndrome. People with type 1 tend to develop symptoms earlier than those with type 2, and are more likely to have blood vessel malformations in the lungs and brain. Type 2 and type 3 may be associated with a higher risk of liver involvement. Women are more likely than men to develop blood vessel malformations in the lungs with type 1, and are also at higher risk of liver involvement with both type 1 and type 2. Individuals with any form of hereditary hemorrhagic telangiectasia, however, can have any of these problems.

Genetic testing utilizes a blood test to determine whether or not an at risk individual carries the genes responsible for the development of disease. Mutations in two genes, endoglin and ALK-1, have been shown to be responsible for pure HHT, with the disease subtypes designated HHT1 and HHT2. Mutations in Smad4 result in a juvenile polyposis-HHT overlap syndrome.

In 2010, Shah and group wrote that hereditary hemorrhagic telangiectasia (HHT) is an autosomal dominant disorder with age-dependent penetrance characterized by recurrent epistaxis, mucocutaneous telangiectasias, and visceral arteriovenous malformations (AVMs). AVMs can occur in multiple organs, including brain, liver, and lungs, and are associated with a large

portion of disease morbidity. Pulmonary AVMs (PAVMs) can be asymptomatic or manifest as dyspnea and hypoxemia secondary to shunting. The presence of untreated PAVMs can also lead to transient ischemic attacks, stroke, hemothorax, and systemic infection, including cerebral abscesses. Definitive diagnosis is made when three or more clinical findings are present, which include the features mentioned above and a first-degree relative diagnosed with HHT. Diagnosis is suspected when two findings are present. Genetic testing can help confirm diagnosis. Mutations in three genes are known to cause disease: ENG, ACVRL1, and SMAD4. Genetic testing involves sequence and duplication/deletion analysis and identifies a mutation in roughly 80% of patients with clinical disease.

The textbook *Flint: Cummings Otolaryngology: Head & Neck Surgery* (2010) states that genetic testing is available for prenatal diagnosis of hereditary hemorrhagic telangiectasia. This is important, because catastrophic hemorrhage can occur in children with clinically silent disease, thus screening imaging for cerebral and pulmonary arteriomalformations is indicated in children who have a family history.

According to the textbook of *Feldman: Sleisenger and Fordtran's Gastrointestinal and Liver Disease* (2010), genetic testing to detect mutations in the ENG, ALK-1, or MAHD4 genes may be helpful in selected cases. Patients suspected of having HHT should be screened for cerebral and pulmonary arteriovenous malformations (AVMs), and family members of the patient should consider genetic testing.

The textbook *Cassidy: Management of Genetic Syndromes* (2005), reports that, to date, mutation testing has not been widely used in the diagnosis of HHT. However, mutations in either ALK1 or endoglin have been demonstrated in over 70% of unrelated, affected individuals tested using direct gene sequencing of genomic DNA. Genetic testing for HHT will have an important role in both the testing of individuals for whom the diagnosis is uncertain and in presymptomatic testing of young adults at risk of HHT.

In 2006, Bossler and group describe the results of mutation analysis on a consecutive series of 200 individuals undergoing clinical genetic testing for HHT. The observed sensitivity of mutation detection was similar to that in other series with strict ascertainment criteria. A total of 127 probands were found, with sequence changes consisting of 103 unique alterations, 68 of which were novel. In addition, eight intragenic rearrangements in the ENG gene and two in the ACVRL1 gene were identified in a subset of coding sequence mutation-negative individuals. Most individuals tested could be categorized by the number of HHT diagnostic criteria present. Surprisingly, almost 50% of the cases with a single symptom were found to have a significant sequence alteration; three of these reported only nosebleeds. The authors concluded, "genetic testing can confirm the clinical diagnosis in individuals and identify presymptomatic mutation carriers. As many of the complications of HHT disease can be prevented, a confirmed molecular diagnosis provides an opportunity for early detection of AVMs and management of the disease."

Spinal Muscular Atrophy

Spinal muscular atrophy (SMA), which has an estimated prevalence of 1 in 10,000, is characterized by proximal muscle weakness resulting from the degeneration of anterior horn cells in the spinal cord. SMA type I is typically diagnosed at birth or within the first 3 to 6 months of life; affected children are unable to sit unassisted and usually die from respiratory failure within 2 years. Those with SMA type II, which is diagnosed before 18 months of age, are unable to stand or walk unaided, although they may be able to sit and may survive beyond age 4. The clinical features of SMA types III and IV are milder and manifest after 18 months of age or in adulthood, respectively. SMA is inherited in an autosomal recessive manner and is caused by alterations in the survival motor neuron 1 (SMN1) gene located on chromosome 5 at band q12.2 to q13.3. Approximately 95% of SMA patients have the condition as a result of a homozygous deletion involving at least exon 7 of SMN1. Approximately 5% are compound heterozygotes, with a deletion in 1 allele of SMN1 and a subtle intragenic variation in the other. SMN2, a gene nearly identical in sequence to SMN1, is located in the same highly repetitive region on chromosome 5. Although it does not cause SMA, it has been shown to modify the phenotype of the condition; those with the milder SMA types II or III tend to have more copies of SMN2 than those with the severe type I.

SMN1 deletions are detected by polymerase chain reaction (PCR) amplification of exon 7 of the SMN genes, followed by restriction fragment length polymorphism (RFLP) analysis. Following amplification, exon 7 of SMN2 will be cut with the restriction enzyme DraI, while exon 7 of SMN1 will remain intact. SMA patients with homozygous SMN1 deletions will show an absence of the uncut SMN1 exon 7 PCR products. To detect heterozygous SMN1 deletions in SMA carriers or compound heterozygotes, quantitative PCR (qPCR) is performed. To identify subtle intragenic variations in SMA patients found to have only 1 copy of the deletion, the SMN1 gene is typically sequenced. Candidates for diagnostic testing include infants, children, and adults with generalized hypotonia and proximal muscle weakness of unknown etiology. Carrier testing may be offered to couples considering pregnancy, including those with a family history of SMA, and prenatal diagnosis should be made available to all identified carriers.

Genetic Test Panels for Nonsyndromic Hearing Loss

There is limited published evidence for the clinical validity and clinical utility of specific genetic test panels for nonsyndromic hearing loss. A number of test panels are currently available commercially (e.g., OtoScope, OtoGenome, OtoSeq. The genes included in these test panels differ siginficantly, and there is limited published information on their clinical utlity and clinical validity.

Hearing loss may be classified as either syndromic or nonsyndromic. Nonsyndromic hearing loss is defined by the absence of malformations of the external ear or other medical problems in the affected individual. With the syndromic hearing loss, malformations of the external ear and/or other medical problems are present. Approximately 50% of nonsyndromic hearing loss can be attributed to a genetic cause, and may be inherited in an autosomal recessive (70% of patients), autosomal dominant (20%

of patients), with mitochondrial, X-linked and other genetic causes making up the remainder of patients.

Sequence variants in approximately 60 genes and some micro-RNAs have been associated with causing nonsyndromic hearing loss. Micro-RNAs are post-transcriptional regulators that consist of 20-25 nucleotides. Usher and Pendred syndromes are the most common forms of the approximately 400 forms of syndromic hearing loss. Both have autosomal recessive inheritance. Usher syndrome is characterized by sensorineural hearing loss and later development of retinitis pigmentosa. Usher syndrome has three forms that vary by the profundity of hearing loss and whether vestibular dysfunction is present. The three types of Usher syndrome have been associated with sequence variants in 9 different genes. Pendred syndrome is characterized by congenital hearing loss and euthyroid goiter that develops in the second or third decade of life. Pendred syndrome is associated with sequence variants in the SLC26A4 gene. Some of the genes associated with Usher and Pendred syndromes may also be associated with nonsyndromic hearing loss.

The OtoSCOPE test has been developed to make use of next generation sequencing capabilities, to simultaneously test for sequence variants in 66 genes associated with nonsyndromic hearing loss as well as both Usher and Pendred syndromes. The claimed advantage of the OtoScope test is that simultaneous analysis of the 66 genes included in the test may reduce the time and cost compared with genetic testing of individual genes.

the OtoSCOPE genetic testing for hereditary hearing loss is considered investigational/experimental because there is inadequate evidence in the peer-reviewed published clinical literature regarding its effectiveness.

Published evidence for the OtoSeq test panel includes an epidemiological study of the use of a component of the OtoSeq panel in identifying certain hearing loss genes in 34 Pakistani families (Shahzad, et al., 2013). In addition, there is a prelimary study of the performance of the OtoSeq in 8 individuals with hearing loss, comparing the results of Next Generation Sequencing with Sanger Sequencing (Sivakumaran, et al., 2013). There is insufficient published information about the performance and clinical utility of this test.

Heterotaxy

Bedard et al (2011) noted that patients with heterotaxy have characteristic cardiovascular malformations, abnormal arrangement of their visceral organs, and midline patterning defects that result from abnormal left-right patterning during embryogenesis. Loss of function of the transcription factor ZIC3 causes X-linked heterotaxy and isolated congenital heart malformations and represents one of the few known monogenic causes of congenital heart disease. The birth incidence of heterotaxy-spectrum malformations is significantly higher in males, but the authors' previous work indicated that mutations within ZIC3 did not account for the male over-representation. Therefore, cross species comparative sequence alignment was used to identify a putative novel fourth exon, and the existence of a novel alternatively spliced transcript was confirmed by amplification from murine embryonic RNA and subsequent sequencing. This transcript, termed Zic3-B, encompasses exons 1, 2, and 4 whereas Zic3-A encompasses exons 1, 2, and 3. The resulting protein isoforms are 466 and 456 amino acid residues respectively, sharing the first 407 residues. Importantly, the last 2 amino acids in the 5th zinc finger DNA binding domain are altered in the Zic3-B isoform, indicating a potential functional difference that was further evaluated by expression, subcellular localization, and transactivation analyses. The temporo-spatial expression pattern of Zic3-B overlaps with Zic3-A in-vivo, and both isoforms are localized to the nucleus in-vitro. Both isoforms can transcriptionally activate a Gli binding site reporter, but only ZIC3-A synergistically activates upon co-transfection with Gli3, suggesting that the isoforms are functionally distinct. The authors concluded that screening 109 familial and sporadic male heterotaxy cases did not identify pathogenic mutations in the newly identified fourth exon and larger studies are necessary to establish the importance of the novel isoform in human disease.

Tariq et al (2011) heterotaxy-spectrum cardiovascular disorders are challenging for traditional genetic analyses because of clinical and genetic heterogeneity, variable expressivity, and non-penetrance. In this study, high-resolution single nucleotide polymorphisms (SNPs) genotyping and exon-targeted array comparative genomic hybridization (CGH) platforms were coupled to whole-exome sequencing to identify a novel disease candidate gene. SNP genotyping identified absence-of-heterozygosity regions in the heterotaxy proband on chromosomes 1, 4, 7, 13, 15, 18, consistent with parental consanguinity. Subsequently, whole-exome sequencing of the proband identified 26,065 coding variants, including 18 non-synonymous homozygous changes not present in dbSNP132 or 1000 Genomes. Of these 18, only 4 -- 1 each in CXCL2, SHROOM3, CTSO, RXFP1 -- were mapped to the absence-of-heterozygosity regions, each of which was flanked by more than 50 homozygous SNPs, confirming recessive segregation of mutant alleles. Sanger sequencing confirmed the SHROOM3 homozygous missense mutation and it was predicted as pathogenic by 4 bio-informatic tools. SHROOM3 has been identified as a central regulator of morphogenetic cell shape changes necessary for organogenesis and can physically bind ROCK2, a rho kinase protein required for left-right patterning. Screening 96 sporadic heterotaxy patients identified 4 additional patients with rare variants in SHROOM3. The authors concluded that using whole exome sequencing, the authors identify a recessive missense mutation in SHROOM3 associated with heterotaxy syndrome and identify rare variants in subsequent screening of a heterotaxy cohort, suggesting SHROOM3 as a novel target for the control of left-right patterning. This study revealed the value of SNP genotyping coupled with high-throughput sequencing for identification of high yield candidates for rare disorders with genetic and phenotypic heterogeneity.

Also, UpToDate reviews on "Clinical manifestations, pathophysiology, and diagnosis of atrioventricular (AV) canal defects" (Fleishman and Tugertimur, 2013) and "Congenital heart disease (CHD) in the newborn: Presentation and screening for critical CHD" (Altman, 2013) do not mention the use of genetic testing as a management tool.

Mitochondrial Recessive Ataxia Syndrome

Lee et al (2007) stated that spino-cerebellar ataxia (SCA) is a heterogeneous group of neurodegenerative disorders with common features of adult-onset cerebellar ataxia. Many patients with clinically suspected SCA are subsequently diagnosed with common

SCA gene mutations. Previous reports suggested some common mitochondrial DNA (mtDNA) point mutations and mitochondrial DNA polymerase gene (POLG1) mutations might be additional underlying genetic causes of cerebellar ataxia. These researchers tested whether mtDNA point mutations A3243G, A8344G, T8993G, and T8993C, or POLG1 mutations W748S and A467T are found in patients with adult-onset ataxia who did not have common SCA mutations. A total of 476 unrelated patients with suspected SCA underwent genetic testing for SCA 1, 2, 3, 6, 7, 8, 10, 12, 17, and DRPLA gene mutations. After excluding these SCA mutations and patients with paternal transmission history, 265 patients were tested for mtDNA mutations A3243G, A8344G, T8993G, T8993C, and POLG1 W748S and A467T mutations. No mtDNA A3243G, A8344G, T8993G, T8993C, or POLG1 W748S and A467T mutation was detected in any of the 265 ataxia patients, suggesting that the upper limit of the 95 % confidence interval (CI) for the prevalence of these mitochondrial mutations in Chinese patients with adult-onset non-SCA ataxia is no higher than 1.1 %. The authors concluded that the mtDNA mutations A3243G, A8344G, T8993G, T8993C, or POLG1 W748S and A467T are very rare causes of adult-onset ataxia in Taiwan. Routine screening for these mutations in ataxia patients with Chinese origin is of limited clinical value.

Gramstad et al (2009) noted that mutations in the catalytic subunit of polymerase gamma (POLG1) produce a wide variety of neurological disorders including a progressive ataxic syndrome with epilepsy: mitochondrial SCA and epilepsy (MSCAE). The authors' earlier studies of patients with this syndrome raised the possibility of more prominent right than left hemisphere dysfunction. To investigate this in more detail, 8 patients (6 women, 2 men; mean age of 22.3 years) were studied. All completed an intelligence test (Wechsler Adult Intelligence Scale; WAIS), and 4 were also given memory tests and a comprehensive neuropsychological test battery. Patients with MSCAE showed significant cognitive dysfunction. Mean Verbal IQ (84.3) was significantly better than Performance IQ (71.8) ($t = 5.23$, $p = 0.001$), but memory testing and neuropsychological testing failed to detect a consistent unilateral dysfunction. The authors concluded that further studies are needed to define the profile and development of cognitive symptoms in this disorder.

Isohanni et al (2011) stated that mitochondrial DNA polymerase γ (POLG1) mutations in children often manifest as Alpers syndrome, whereas in adults, a common manifestation is mitochondrial recessive ataxia syndrome (MIRAS) with severe epilepsy. Because some patients with MIRAS have presented with ataxia or epilepsy already in childhood, these investigators searched for POLG1 mutations in neurologic manifestations in childhood. They investigated POLG1 in 136 children, all clinically suspected to have mitochondrial disease, with one or more of the following: ataxia, axonal neuropathy, severe epilepsy without known epilepsy syndrome, epileptic encephalopathy, encephalohepatopathy, or neuropathologically verified Alpers syndrome. A total of 7 patients had POLG1 mutations, and all of them had severe encephalopathy with intractable epilepsy. Four patients had died after exposure to sodium valproate. Brain MRI showed parieto-occipital or thalamic hyper-intense lesions, white matter abnormality, and atrophy. Muscle histology and mitochondrial biochemistry results were normal in all. The authors concluded that POLG1 analysis should belong to the first-line DNA diagnostic tests for children with an encephalitis-like presentation evolving into epileptic encephalopathy with liver involvement (Alpers syndrome), even if brain MRI and morphology, respiratory chain activities, and the amount of mitochondrial DNA in the skeletal muscle are normal. POLG1 analysis should precede valproate therapy in pediatric patients with a typical phenotype. However, POLG1 is not a common cause of isolated epilepsy or ataxia in childhood.

Tang et al (2012) determined the prevalence of MNGIE-like phenotype in patients with recessive POLG1 mutations. Mutations in the POLG1 gene, which encodes for the catalytic subunit of the mitochondrial DNA polymerase gamma essential for mitochondrial DNA replication, cause a wide spectrum of mitochondrial disorders. Common phenotypes associated with POLG1 mutations include Alpers syndrome, ataxia-neuropathy syndrome, and progressive external ophthalmoplegia (PEO). Mitochondrial neuro-gastro-intestinal encephalomyopathy (MNGIE) is an autosomal recessive disorder characterized by severe gastrointestinal dysmotility, cachexia, PEO and/or ptosis, peripheral neuropathy, and leukoencephalopathy. MNGIE is caused by TYMP mutations. Rare cases of MNGIE-like phenotype have been linked to RRM2B mutations. Recently, POLG1 mutations were identified in a family with clinical features of MNGIE but no leukoencephalopathy. The coding regions and exon-intron boundaries of POLG1 were sequence analyzed in patients suspected of POLG1-related disorders. Clinical features of 92 unrelated patients with 2 pathogenic POLG1 alleles were carefully reviewed. Three patients, accounting for 3.3 % of all patients with 2 pathogenic POLG1 mutations, were found to have clinical features consistent with MNGIE but no leukoencephalopathy. Patient 1 carries p.W748S and p.R953C; patient 2 is homozygous for p.W748S, and patient 3 is homozygous for p.A467T. In addition, patient 2 has a similarly affected sibling with the same POLG1 genotype. POLG1 mutations may cause MNGIE-like syndrome, but the lack of leukoencephalopathy and the normal plasma thymidine favor POLG1 mutations as responsible molecular defect.

Furthermore, UpToDate reviews on "Overview of the hereditary ataxias" (Opal and Zoghbi, 2013a) and "The spinocerebellar ataxias" (Opal and Zoghbi, 2013b) do not mention the use of POLG1 genetic testing.

Myelodysplastic Syndromes

National Comprehensive Cancer Network's clinical practice guideline on "Myelodysplastic syndromes" (2014) stated that further evaluations are necessary to establish the role of these genetic lesions on risk stratification systems in myelodysplastic syndrome. The guidelines stated that mutations in TET2 are among the most common mutations reported in patients with myelodysplastic syndromes (about 20 % of cases). Mutations in SF3B1 are one of several common molecular abnormalities involving the RNA splicing machinery, occurring in 14.5 to 16.0 % of MDS cases.

Exome Sequencing

A special report on "Exome sequencing for clinical diagnosis of patients with suspected genetic disorders" by the BCBSA's Technology Evaluation Center (2013) stated that "Exome sequencing has the capacity to determine in a single assay an individual's exomic variation profile, limited to most of the protein coding sequence of an individual (approximately 85 %), composed of about 20,000 genes, 180,000 exons (protein-coding segments of a gene), and constituting approximately 1 % of the

whole genome. It is believed that the exome contains about 85 % of heritable disease-causing mutations …. Exome sequencing, relying on next-generation sequencing technologies, is not without challenges and limitations …. Detailed guidance from regulatory or professional organizations is under development, and the variability contributed by the different platforms and procedures used by clinical laboratories offering exome sequencing as a clinical service is unknown …. Currently, the diagnostic yield for single-gene disorders appears to be no greater than 50 % and possibly less, depending on the patient population and provider expertise. Medical management options may be available for only a subset of those diagnosed".

May-Hegglin Anomaly

Strasser et al (2012) stated that Alport syndrome (ATS) is a type-IV collagen inherited disorder, caused by mutations in COL4A3 and COL4A4 (autosomal recessive) or COL4A5 (X-linked). Clinical symptoms include progressive renal disease, eye abnormalities and high-tone sensori-neural deafness. A renal histology very similar to ATS is observed in a subset of patients affected by mutations in MYH9, encoding non-muscle-myosin Type IIa -- a cytoskeletal contractile protein. MYH9-associated disorders (May-Hegglin anomaly, Epstein and Fechtner syndrome, and others) are inherited in an autosomal dominant manner and characterized by defects in different organs (including eyes, ears, kidneys and thrombocytes). These researchers described here a 6-year old girl with hematuria, proteinuria, and early sensori-neural hearing loss. The father of the patient is affected by ATS, the mother by isolated inner ear deafness. Genetic testing revealed a pathogenic mutation in COL4A5 (c.2605G>A) in the girl and her father and a heterozygous mutation in MYH9 (c.4952T>G) in the girl and her mother. The paternal COL4A5 mutation seems to account for the complete phenotype of ATS in the father and the maternal mutation in MYH9 for the inner ear deafness in the mother. It has been discussed that the interaction of both mutations could be responsible for both the unexpected severity of ATS symptoms and the very early onset of inner ear deafness in the girl.

An UpToDate review on "Congenital and acquired disorders of platelet function" (Coutre, 2013) states that "Giant platelet disorders -- Inherited platelet disorders with giant platelets are quite rare (picture 2 and algorithm 1 and table 4). These include platelet glycoprotein abnormalities (e.g., Bernard-Soulier syndrome), deficiency of platelet alpha granules (e.g., gray platelet syndrome), the May-Hegglin anomaly, which also involves the presence of abnormal neutrophil inclusions (i.e., Dohle-like bodies), and some kindreds with type 2B von Willebrand disease (the Montreal platelet syndrome)". This review does not mention the use of genetic testing as a management tool for giant platelet disorders.

UpToDate reviews on "Inborn errors of metabolism: Epidemiology, pathogenesis, and clinical features" (Sutton, 2013a) and "Inborn errors of metabolism: Classification" (Sutton, 2013b) do not mention the use of genetic testing as a management tool.

Very Long Chain AcylCoA Dehydrogenase Deficiency (VLCADD)

An UpToDate review on "Newborn screening" (Sielski, 2013) states that "MS-MS [tandem mass spectrometry] detects more cases of inborn errors of metabolism than clinical diagnosis. In a study from New South Wales and the Australian Capital Territory, Australia, the prevalence of 31 inborn errors of metabolism affecting the urea cycle, amino acids (excluding PKU), organic acids, and fatty acid oxidation detected by MS-MS in 1998 to 2002 was 15.7 per 100,000 births, compared to 8.6 to 9.5 per 100,000 births in the four four-year cohorts preceding expanded screening. The increased rate of diagnosis was most apparent for the medium-chain and short-chain acyl-Co-A dehydrogenase deficiencies. Whether all children with disorders detected by MS-MS would have become symptomatic is uncertain …. The American Academy of Pediatrics has developed newborn screening fact sheets for 12 disorders, biotinidase deficiency, congenital adrenal hyperplasia, congenital hearing loss, congenital hypothyroidism, cystic fibrosis, galactosemia, homocystinuria, maple syrup urine disease, medium-chain acyl-coenzyme A dehydrogenase deficiency, PKU, sickle cell disease and other hemoglobinopathies, and tyrosinemia …. With the use of tandem mass spectrometry (MS-MS), the prevalence of a confirmed metabolic disorder detected by newborn screening is 1:4000 live births (about 12,500 diagnoses each year) in the United States. The most commonly diagnosed conditions are hearing loss, primary congenital hypothyroidism, cystic fibrosis, sickle cell disease, and medium-chain acyl-CoA dehydrogenase deficiency". This review does not mention very long chain acylCoA dehydrogenase deficiency.

Congenital Stationary Night Blindness

According to Orphanet (a portal for rare diseases and orphan drugs), congenital stationary night blindness (CSNB) is an inherited retinal disorder that predominates on rods. It is a rare disease; and 3 types of transmission can be found: (i) autosomal dominant, (ii) recessive, and (iii) X-linked recessive. The affection is heterogeneous. The only symptom is hemeralopia with a moderate loss of visual acuity. Both the funduscopy and visual field are normal. In recessive forms, the "b" wave on the electroretinogram/electroretinography (ERG) is not found in the scotoscopic study, while the "a" wave is normal and increases with light intensity. In dominant forms, the "b" wave is seen. Levels of rhodopsine are normal and regenerate normally. Signal transmission may be the affected function. There is no specific treatment for CSNB. http://www.orpha.net/consor/cgi-bin/OC_Exp.php?lng=EN&Expert=215.

According to Genetic Home Reference, X-linked CSNB is a disorder of the retina. People with this condition typically have difficulty seeing in low light (night blindness). They also have other vision problems, including reduced acuity, high myopia, nystagmus, and strabismus. Color vision is typically not affected by this disorder. The visual problems associated with this condition are congenital. They tend to remain stable (stationary) over time. Researchers have identified 2 major types of X-linked CSNB: (i) the complete form, and (ii) the incomplete form. The types have very similar signs and symptoms. However, everyone with the complete form has night blindness, while not all people with the incomplete form have night blindness. The types are distinguished by their genetic cause and by the results of ERG. http://ghr.nlm.nih.gov/condition/x-linked-congenital-stationary-night-blindness.

In general, the diagnosis of X-linked CSNB can be made by ophthalmologic examination (including ERG) and family history consistent with X-linked inheritance (Boycott et al, 2012) http://www.ncbi.nlm.nih.gov/books/NBK1245/.

According to a Medscape review on "The Genetics of Hereditary Retinopathies and Optic Neuropathies" (Iannaccone, 2005), CSNB can be inherited according to all Mendelian inheritance patterns; 2 X-linked and 2 autosomal dominant genes have been cloned. In all types of CSNB, night vision is congenitally but non-progressively impaired and the retinal examination is normal. Most CSNB patients also have congenital nystagmus as the presenting sign, which can create a differential diagnostic challenge with Leber congenital amaurosis. Typically, patients with complete X-linked CSNB are also moderate-to-high myopes. The X-linked CSNB forms, which are the most common ones, all share an electronegative electroretinogram response similar to that seen in X-linked retinoschisis, and are distinguished in CSNB type 1 (also known as complete CSNB) and CSNB type 2 (incomplete CSNB) based on additional electroretinogram features, a distinction that has been confirmed at the genetic level". http://www.medscape.com/viewarticle/501761_6.

Price et al (1988) reported that 7 of 8 patients presented initially or were followed for decreased acuity and nystagmus without complaints of night blindness. The diagnosis of CSNB was established with ERG and dark adaptation testing. They stated that careful electrodiagnostic testing is needed to provide accurate genetic counseling. Two patients showed pupillary constriction to darkness, which is a sign of retinal disease in young patients.

Lorenz et al (1996) presented the clinical data of 2 families with X-linked incomplete CSNB previously undiagnosed; ERG recordings in both families were suggestive of CSNB. The ERG of the obligate carrier was normal. In an attempt to distinguish between the complete and the incomplete type, and to identify further carrier signs, scotopic perimetry and dark adaptation were performed in both affected males and carriers. Scotopic perimetry tested the rod-mediated visual pathway in its spatial distribution. In affected males with non-recordable ERGs, scotopic perimetry and dark adaptation disclosed residual rod function indicating an incomplete type. In carriers, there was a sensitivity loss at 600 nm, which may be a new carrier sign. The authors concluded that correct diagnosis of the different forms of CSNB together with the identification of carriers is important for (i) genetic counseling, and (ii) linkage studies to identify the gene(s) for CSNB.

Kim et al (2012) evaluated the frequency of negative waveform ERGs in a tertiary referral center. All patients who had an ERG performed at the electrophysiology clinic at Emory University from January 1999 through March 2008 were included in the study. Patients with b-wave amplitude less than or equal to a-wave amplitude during the dark-adapted bright flash recording, in at least 1 eye, were identified as having a "negative ERG". Clinical information, such as age, gender, symptoms, best corrected visual acuity, and diagnoses were recorded for these patients when available. A total of 1,837 patients underwent ERG testing during the study period. Of those, 73 patients had a negative ERG, for a frequency of 4.0 %. Within the adult (greater than or equal to 18 years of age) and pediatric populations, the frequencies of a negative ERG were 2.5 and 7.2 %, respectively. Among the 73 cases, negative ERGs were more common among male than female patients, 6.7 % versus 1.8 % ($p < 0.0001$). Negative ERGs were most common among male children and least common among female adults, 9.6 % versus 1.1 %, respectively, ($p < 0.0001$). Overall in this group of patients, the most common diagnoses associated with a negative ERG were CSNB (n = 29) and X-linked retinoschisis (XLRS, n = 7). The authors concluded that the overall frequency of negative ERGs in this large retrospective review was 4.0 %. Negative ERGs were most common among male children and least common among female adults. Despite the growing number of new diagnoses associated with negative ERGs, CSNB, and XLRS appear to be the most likely diagnoses for a pediatric patient who presents with a negative ERG.

It is also interesting to note that in a recently completed clinical trial (last verified June 2012) of "Treatment of Congenital Stationary Night Blindness with an Alga Containing High Dose of Beta Carotene", the selection criteria for participants of this trial do not include genetic testing. They included the following: http://www.clinicaltrials.gov/ct2/show/NCT00569023.

- Isolated rod response markedly reduced (less than 20 % of normal) after 20 mins dark adaptation and improved by 50 % after 2 hrs
- Negative maximal response ("a" wave to "b" wave ratio less than 2)
- Retinal mid-peripheral white dots (more than 3,000 dots).

Appendix

Amsterdam II criteria:

At least 3 relatives must have an HNPCC-related cancer*, and all of the following criteria must be present:

- At least 1 of the relatives with cancer associated with HNPC should be diagnosed before age 50 years; and
- At least 2 successive generations must be affected; and
- FAP should be excluded in the colorectal cancer cases (if any); and
- One must be a 1st-degree relative of the other two; and
- Tumors should be verified whenerver possible.

Revised Bethesda criteria:

Member must meet 1 or more of the following criteria:

- Colorectal cancer is diagnosed in a member with 1 or more 1st-degree relatives with an HNPCC-related cancer*, with one of the cancers diagnosed under age 50 years; or
- Colorectal cancer is diagnosed in a member with 2 or more 1st- or 2nd-degree relatives with an HNPCC-related cancer*, regardless of age; or
- Member has colorectal cancer diagnosed before age 50 years; or
- Member has colorectal cancer with microsatellite instability-high (MSI-H) histology, where cancer is diagnosed before age 60 years; or

- Member has synchronous or metachronous HNPCC-related cancers*, regardless of age.

* Hereditary nonpolyposis colorectal cancer (HNPCC)-related cancers include colorectal, endometrial, gastric, ovarian, pancreas, ureter and renal pelvis, brain (usually glioblastoma as seen in Turcot syndrome), and small intestinal cancers, as well as sebaceous gland adenomas and keratoacanthomas in Muir-Torre syndrome.

HCPCS codes covered if selection criteria are met:

S3840	DNA analysis for germline mutations of the RET proto-oncogene for susceptibility to multiple endocrine neoplasia type 2
S3841	Genetic testing for retinoblastoma
S3842	Genetic testing for von Hippel-Lindau disease
S3844	DNA analysis of the connexin 26 gene (GJB2) for susceptibility to congenital, profound deafness
S3845	Genetic testing for alpha-thalassemia
S3846	Genetic testing for hemoglobin E beta-thalassemia
S3850	Genetic testing for sickle cell anemia
S3852	DNA analysis for APOE epsilon 4 allele for susceptibility to Alzheimer's disease
S3853	Genetic testing for myotonic muscular dystrophy
S3855	Genetic testing for detection of mutations in the presenilin, 1 gene
S3866	Genetic analysis for a specific gene mutation for hypertrophic cardiomyopathy (HCM) in an individual with a known HCM mutation in the family

HCPCS codes not covered for indications listed in the CPB:

S3861	Genetic testing, sodium channel, voltage-gated, type V, alpha subunit (SCN5A) and variants for suspected Brugada syndrome
S3865	Comprehensive gene sequence analysis for hypertrophic cardiomyopathy

Other HCPCS codes related to the CPB:

G0461	Immunohistochemistry or immunocytochemistry, per specimen; first single or multiplex antibody stain
G0462	each additional single or multiplex antibody stain (list separately in addition to code for primary procedure)
S0265	Genetic counseling, under physician supervision, each 15 minutes

ICD-9 codes covered if selection criteria are met:

151.0 - 151.9	Malignant neoplasm of stomach [with 2 HNPCC-related cancers]
152.0 - 152.9	Malignant neoplasm of small intestine, including duodenum [with 2 HNPCC-related cancers]
153.0 - 154.9	Malignant neoplasm of colon [hereditary non-polyposis colorectal cancer (HNPCC) (MLH1, MSH2)
155.0 - 155.2	Malignant neoplasm of liver and intrahepatic bile ducts [with 2 HNPCC cancers]
162.2 - 162.9	Malignant neoplasm of bronchus or lung
170.0 - 170.9	Malignant neoplasm of bone and articular cartilage [osteosarcoma]
171.0 - 171.9	Malignant neoplasm of connective and other soft tissue [soft tissue sarcoma]
174.0 - 175.9	Malignant neoplasm of breast

182.0	Malignant neoplasm of body of uterus
183.0	Malignant neoplasm of ovary and other uterine adnexa [with 2 HNPCC cancers]
188.0 - 188.9	Malignant neoplasm of bladder [transitional cell for microsatellite instability (MSI) testing and MLH1 and MLH2 sequence analysis for HNPCC]
189.0	Malignant neoplasm of kidney, except pelvis [renal cell cancer syndrome]
189.1	Malignant neoplasm of renal pelvis [transitional cell for microsatellite instability (MSI) testing and MLH1 and MLH2 sequence analysis for HNPCC]
189.2	Malignant neoplasm of ureter [transitional cell for microsatellite instability (MSI) testing and MLH1 and MLH2 sequence analysis for HNPCC]
190.5	Malignant neoplasm of retina [retinoblastoma]
191.0 - 191.9	Malignant neoplasm of brain [except glioblastoma multiforme]
193	Malignant neoplasm of thyroid gland [medullary thyroid carcinoma]
194.0	Malignant neoplasm of adrenal gland [adrenocortical carcinoma]
204.00 - 208.92	Leukemias
211.3	Benign neoplasm of colon [hereditary polyposis coli (APC)]
227.0	Benign neoplasm of adrenal gland [hereditary paraganglioma (SDHS, SDHB)]
237.71	Neurofibromatosis, type 1 [von Recklinghausen's disease] [neurofibromin] [not covered for Legius syndrome]
237.72	Neurofibromatosis, type 2 [acoustic neurofibromatosis] [Merlin]
238.1	Neoplasm of uncertain behavior of connective and other soft tissue [hereditary leiomyomatosis]
250.0x - 250.9x w/5th digit of 0 or 2	Type 2 Diabetes mellitus [covered for maturity-onset diabetes of the young (MODY]
253.4	Other anterior pituitary disorders [Kallmann syndrome (FGFR1)]
255.2	Adrenogenital disorders [congenital adrenal hyperplasia]
258.01	Multiple endocrine neoplasia [MEN] type I
259.4	Dwarfism, not elsewhere classified [hypochondroplasia (FGFR 3), thanatophoric dysplasia (FGFR3)]
270.1	Phenylketonuria
270.2	Other disturbances of aromatic amino-acid metabolism [albinism]
270.3	Disturbances of branched-chain amino-acid metabolism
271.0	Glycogenosis [McArdle's disease]
271.1	Galactosemia
272.7	Lipidoses [Fabry/Gaucher (acid beta glucosidase)/Niemann-Pick (sphingomyelin phosphodiesterase)]
273.4	Alpha-1-antitrypsin deficiency
275.01	Hereditary hemochromatosis
275.2	Disorders of magnesium metabolism [Gitelman's syndrome]
275.42	Hypercalcemia (familial hypocalciuric)
277.00 - 277.09	Cystic fibrosis [CTFR]
277.39	Other amyloidosis [hereditary amyloidosis (TTR variants)]
277.5	Mucopolysaccharidosis [type 1 (MPS-1)]
277.85	Disorders of fatty acid oxidation [medium chain acyl coA dehydrogenase deficiency ACADM)]
277.87	Disorders of mitochondrial metabolism [MELAS (mitochondrial encephalopathy) (MTTL1, tRNAleu)]
282.3	Other hemolytic anemias due to enzyme deficiency [pyruvate kinase deficiency (PKD)]
282.40 - 282.49	Thalassemias [alpha globin/beta globin/hemoglobin E]
282.5	Sickle-cell trait [hemoglobin S]
282.7	Other hemoglobinopathies [hemoglobin C]
286.0	Congenital factor VIII disorder [hemophilia A/VWF]
286.1	Congenital factor IX disorder [hemophilia B]

286.3	Congenital deficiency of other clotting factors [prothrombin factor II, 20210A mutation]
287.33	Congenital and hereditary thrombocytopenia [amegakaryocytic]
288.01	Congenital neutropenia [cyclic]
288.02	Cyclic neutropenia [congenital]
299.00 - 299.01	Autistic disorder, current or active state or residual state
317 - 319	Mental retardation
327.25	Congenital central alveolar hypoventilation syndrome
330.0	Leukodystrophy [Canavan disease (aspartoacylase A)]
330.1	Cerebral lipidoses [Tay-Sachs disease]
330.8	Other specified cerebral degenerations in childhood [Rett syndrome (MECP2)] [Leigh syndrome]
333.4	Huntington's chorea [Huntington's disease]
333.6	Genetic torsion dystonia [primary TOR1A (DYT1)]
334.0	Friedreich's ataxia [frataxin]
334.1	Hereditary spastic paraplegia [hereditary spastic paraplegia 3 (SPG3A) and 4 (SPG4, SPAST)]
334.3	Other cerebellar ataxia [spinocerebellar ataxia (ataxin, CACNA1A)] [SCA types 8, 10, 17 and DRPLA)]
334.8	Other spinocerebellar diseases [spinocerebellar ataxia (ataxin, CACNA1A)]
335.10 - 335.19	Spinal muscular atrophy [Kennedy disease (SBMA) (SMN)]
345.10 - 345.11	Generalized convulsive epilepsy [myoclonic epilepsy (MERRF) (MTTK) (tRNAlys)]
356.1	Peroneal muscular atrophy [Charcot-Marie-Tooth disease]
356.2	Hereditary sensory neuropathy [with liability to pressure palsies (HNPP)]
359.0 - 359.1	Congenital hereditary or hereditary progressive muscular dystrophy [Duchene (dystrophin)] [Becker's type] [limb girdle muscular dystrophy (LGMD1, LGMD2)] [not covered for oculopharyngeal muscular dystrophy (OPMD)] [dystrophy [type 1C] [Emery-Dreifuss muscular dystrophy] [fascioscapulohumeral muscular dystrophy]
359.21 - 359.29	Myotonic disorders [myotonic dystrophy (CMPK, ZNF-9)]
359.89	Other myopathies [dysferlin]
362.74	Pigmentary retinal dystrophy [retinitis pigmentosa]
377.39	Other optic neuritis [Leber hereditary optic neuropathy (LHON)]
389.00 - 389.9	Hearing loss [hereditary (Connexin-26, GJB2)]
425.11 - 425.18	Hypertrophic cardiomyopathy
425.4	Other primary cardiomyopathies [arrhythmogenic right ventricular dysplasia/cardiomyopathy (ARVD/C)]
426.82	Long QT syndrome
427.1	Paroxysmal ventricular tachycardia [persons that display exercise- or emotion-induced polymorphic ventricular tachycardia or ventricular fibrillation, occurring in a structurally normal heart]
427.41	Ventricular fibrillation
441.01	Thoracic aneurysm and dissection
448.0	Hereditary hemorrhagic telangiectasia
577.0	Acute pancreatitis [unexplained episode in a child requiring hospitalization with significant concern that hereditary pancreatitis (PRSS1) should be excluded]
577.1	Chronic pancreatitis [unexplained (idiopathic) for hereditary pancreatitis (PRSS1)]
581.0 - 581.9	Nephrotic syndrome [congenital (NPHS1, NPHS2)]
742.2	Reduction deformities of brain [classical lissencephaly]
742.8	Other specified congenital anomalies of nervous system [familial dysautonomia]
755.55	Acrocephalosyndactyly [Pfeiffer syndrome (FGFR1)]
756.0	Anomalies of skull and face bones [Crouzon syndrome (CTFR), Saethre-Chotzen syndrome (TWIST, FGFR2)]
756.4	Chondrodystrophy [achondroplasia]

756.51	Osteogenesis imperfecta
756.83	Ehlers-Danlos syndrome
756.89	Other specified anomalies of muscle, tendon, fascia, and connective tissue [Jackson-Weiss syndrome] [Muencke syndrome (FGFR2)]
757.39	Other specified congenital anomalies of skin [Bloom syndrome]
758.32	Velo-cardio-facial syndrome [22q11 deletion syndrome (CATCH-22)]
759.6	Other hamartoses, not elsewhere classified [Von Hippel Lindau syndrome (VHL)]
759.81	Prader-Willi syndrome [GABRA, SNRPN]
759.82	Marfan syndrome
759.83	Fragile X syndrome
759.89	Other specified anomalies [Angelman syndrome (GABRA, SNRPN) Smith-Lemli-Opitz syndrome]
783.43	Short stature [SHOX-related]
790.5	Other nonspecific abnormal serum enzyme levels [hyper-amylasemia]
995.86	Malignant hyperthermia
V10.05	Personal history of malignant neoplasm of large intestine [with HNPCC related cancers]
V10.06	Personal history of malignant neoplasm of rectum, rectosigmoid junction, and anus
V16.0	Family history of malignant neoplasm of gastrointestinal tract
V17.2	Family history of other neurological diseases
V17.41	Family history of sudden cardiac death (SCD)
V17.49	Family history of other cardiovascular diseases [children or young adults (less than 40 years of age) with a first degree relative with a clinical diagnosis of CPVT, or a first or second degree relative with a defined CPVT mutation]
V18.4	Family history of mental retardation
V18.51	Family history, colonic polyps [members with first-degree relatives (i.e., siblings, parents, and offspring) diagnosed with familial adenomatous polyposis (FAP) or with a documented APC mutation]
V18.59	Family history of other digestive disorders [pancreatitis]
V18.9	Family history of genetic disease carrier
V19.5	Family history of congenital anomalies
V26.31	Testing of female for genetic disease carrier status
V26.34	Testing of male for genetic disease carrier status
V77.0	Special screening for thyroid disorders
V77.3	Special screening for phenylketonuria
V77.4	Special screening for galactosemia
V77.6	Special screening for cystic fibrosis
V77.7	Special screening for other inborn errors of metabolism
V80.3	Special screening for ear diseases
V83.01	Asymptomatic hemophilia A carrier
V83.02	Symptomatic hemophilia A carrier
V83.81	Cystic fibrosis gene carrier
V83.89	Other genetic carrier status
V84.01	Genetic susceptibility to malignant neoplasm of breast [covered for Li-Fraumeni syndrome testing other than OncoVue]

ICD-9 codes not covered for indications listed in the CPB:

172.0 - 172.9	Malignant melanoma of skin
185	Malignant neoplasm of prostate
271.3	Intestinal disaccharidase deficiencies and disaccharide malabsorption [lactose intolerance]
272.6	Lipodystrophy [familial partial lipodystrophy]
277.85	Disorders of fatty acid oxidation [very long chain acylCoA dehydrogenase deficiency (VLCADD)]

284.01	Constitutional red blood cell aplasia [Diamond-Blackfan anemia]
286.2	Congenital factor XI deficiency [hemophilia C]
286.4	von Willebrand's disease
288.2	Genetic anomalies of leukocytes [May-Hegglin anomaly]
307.46	Sleep arousal disorder [somnambulation]
331.0	Alzheimer's disease
332.0 - 332.1	Parkinson's disease
333.2	Myoclonus [-dystonia]
335.20	Amyotrophic lateral sclerosis [familial (SOD1 mutation)]
346.30 - 346.33	Hemiplegic migraine
347.00 - 347.11	Cataplexy and narcolepsy
362.16	Retinal neovascularization NOS
362.50	Macular degeneration (senile), unspecified
362.51	Nonexudative senile macular degeneration
362.52	Exudative senile macular degeneration
368.61	Congenital night blindness
389.00 - 389.9	Hearing loss
410.00 - 410.92	Acute myocardial infarction
411.0 - 411.89	Other acute and subacute forms of ischemic heart disease
412	Other acute and subacute forms of ischemic heart disease
413.0 - 413.9	Angina pectoris
414.00 - 414.9	Other forms of chronic ischemic heart disease
746.89	Other congenital anomalies of heart [Brugada syndrome]
753.12 - 753.14	Polycystic kidney
756.16	Klippel-Feil syndrome
756.59	Other congenital osteodystrophies with bracketed info [Mccune-Albright syndrome]
757.1	Ichthyosis congenita [epidemolytic hyperkatosis]
759.9	Congenital anomaly, unspecified [heterotaxy]
780.31 - 780.32	Febrile convulsions
780.4	Dizziness and giddiness [migrainous vertigo]
V16.3	Family history of malignant neoplasm, breast
V81.0	Special screening for ischemic heart disease
V81.2	Special screening for other and unspecified cardiovascular conditions

Other ICD-9 codes related to the CPB:

V13.69	Personal history of other congenital malformations
V26.32	Other genetic testing of female
V26.33	Genetic counseling
V26.39	Other genetic testing of male
V28.0	Screening for chromosomal anomalies by amniocentesis
V29.3	Observation for suspected genetic or metabolic condition
V77.91	Screening for lipoid disorders
V77.99	Special screening for other and unspecified endocrine, nutritional, metabolic, and immunity disorders
V78.1	Special screening for other and unspecified deficiency anemia
V78.2	Special screening for sickle-cell disease or trait
V78.3	Special screening for other hemoglobinopathies
V78.8	Special screening for other disorders of blood and blood-forming organs

V80.09	Special screening for other neurological conditions
V82.4	Maternal postnatal screening for chromosomal anomalies
V82.71 - V82.79	Genetic screening
V84.09	Genetic susceptibility to other malignant neoplasm
V84.81 - V84.89	Genetic susceptibility to other disease

Factor V Leiden:

CPT codes covered if selection criteria are met:

81241	F5 (coagulation Factor V) (eg, hereditary hypercoagulability) gene analysis, 20210G>A variant

ICD-9 codes covered if selection criteria are met:

410.00 - 412	Myocardial infarction
415.11 - 415.19	Pulmonary embolism and infarction
671.20 - 671.33	Pregnancy complicated by thrombosis
V12.51 - V12.52, V12.55	Personal history of thrombosis
V17.41 - V17.49	Family history of thrombosis

EpiSEEK:

No specific code

ICD-9 codes not covered for indications listed in the CPB:

345.00 - 345.91	Epilepsy and recurrent seizures

POLG1:

No specific code

ICD-9 codes not covered for indications listed in the CPB:

334.3	Other cerebellar ataxia

SF3B1 and TET2:

No specific code

ICD-9 codes not covered for indications listed in the CPB:

238.72 -238.75	Myelodysplastic syndrome

There are no specific codes for the genetic testing listed:

Exome Sequencing

Medical Policy

Subject:	Diagnostic Genetic Testing of a Potentially Affected Individual (Adult or Child)		
Policy #:	GENE.00013	**Current Effective Date:**	04/15/2014
Status:	Revised	**Last Review Date:**	02/13/2014

Description/Scope

This document addresses diagnostic genetic testing of a potentially affected individual (adult or child).

Note(s):

- This document is limited to the use molecular genetic testing and does not provide criteria for karyotype analysis or biochemical testing.
- Please refer to the following documents for additional information on genetic testing:

  GENE.00001 - Genetic Testing for Cancer Susceptibility;
  GENE.00003 - Genetic Testing and Biochemical Markers for the Diagnosis of Alzheimer's Disease;
  GENE.00007 - Cardiac Ion Channel Genetic Testing;
  GENE.00012 - Preconceptional or Prenatal Genetic Testing of a Parent or Prospective Parent;
  GENE.00015 - Predictive Genetic Testing for Non-Malignant Diseases;
  GENE.000021 - Comparative Genomic Hybridization (CGH) Microarray Testing for Developmental Delay, Autism Spectrum Disorder and Mental Retardation

Position Statement

Medically Necessary:

Genetic testing is considered **medically necessary** for diagnostic purposes in individuals with symptoms of a genetic disorder or individuals who are at risk for a late onset genetic disorder or slowly evolving genetic disorder who meet ALL of the following criteria:

- A specific mutation, set of mutations or gene expression profile has been established in the scientific literature to be reliably associated with the disease; **and**
- A biochemical or other test is identified but the results are indeterminate, or the genetic disorder cannot be identified through biochemical or other testing; **and**
- The results of the genetic test could impact the medical management of the individual with a resulting improvement in health outcomes; **and**
- Testing is accompanied by genetic counseling.

Investigational and Not Medically Necessary:

Genetic testing for diagnostic purposes in individuals not meeting the above criteria is considered **investigational and not medically necessary,** including, but not limited to, melanoma (hereditary), amyotrophic lateral sclerosis (ALS, also known as Lou Gehrig's disease) or ataxia telangiectasia.

Diagnostic genetic testing using panels of genes (with or without next generation sequencing), including but not limited to whole genome and whole exome sequencing, is considered **investigational and not medically necessary** unless all components of the panel have been determined to be medically necessary based on the criteria above. However, individual components of a panel may be considered medically necessary when criteria above are met.

Rationale

Diagnosis of a genetic disorder in individuals with suggestive symptoms can typically be made using biochemical testing. However, in limited situations, genetic testing may be used to provide a definitive diagnosis in conjunction with clinical signs and symptoms. Because of the rapidly evolving field of genetic testing, each genetic test must be carefully evaluated to determine whether or not the identified genetic mutations reliably identify a genetic disorder, resulting in the initiation of effective therapy.

There has been a surge of interest in the genetic mutation responsible for ALS. ALS is a progressive neurodegenerative disease which involves both upper and lower motor neurons. The mean age of onset is 56 years in individuals with no known family history of the disease and 46 years in individuals with more than one affected family member (familial ALS or FALS). The average duration of the disease is about three years, but it can vary significantly. Death usually occurs as the result of respiratory failure.

ALS can be inherited in an autosomal recessive, autosomal dominant or X-linked manner. The diagnosis of ALS is typically based on clinical features, electrodiagnostic testing, and exclusion of other health conditions with related symptoms. Researchers have identified several possible causes of ALS including, but not limited to mutations in the gene that produces the superoxide dismutase (SOD1) enzyme. While genetic tests are available to identify mutations in the SOD1 gene, it is not clear how the results of diagnostic genetic testing would improve the care or outcome of the affected individual.

Gene Expression Profiling

Researchers continue to explore the role of genetic function in the development diseases. Gene expression profile (gene expression signature, gene expression pattern [GEP] or RNA expression profiling) assays are being investigated as a tool to assist in the risk stratification and clinical management of individuals with various diseases. GEP assays measure the activity (expression) of RNA in a given tissue or bodily fluid at a given point in time. By measuring the levels of RNA of thousands of genes simultaneously, RNA expression profiling captures the rate at which those genes are expressed in a tissue at a particular moment in time. Because the rate of gene expression changes under pathological conditions, RNA expression profiling can identify genes that may be involved in disease pathogenesis resulting from both environmental and genetic factors, as well as any associated interactions. Dynamic changes in these processes can be studied over time. GEP is being investigated as a means to identify panels of genes for disease risk prediction, to diagnose a disease or condition or for clinical management (Arnett, 2007).

Techniques to identify the GEP of a particular tissue or cell type include, but are not necessarily limited to, northern blotting, cDNA/oligonucleotide microarrays, real-time quantitative polymerase chain reaction (RT-qPCR) and serial analysis of gene expression (SAGE, SuperSAGE). Each of these techniques has intrinsic advantages and limitations (Arcellana-Panlilio, 2002; Arnett, 2007; Kawasaki, 2006).

Whole Genome Sequencing

Whole genome sequencing (WGS), also known as full genome sequencing (FGS), complete genome sequencing, or entire genome sequencing, is a laboratory procedure which seeks to determine an individual's entire DNA sequence, specifying the order of every base pair within the

genome at a single time. WGS allows researchers to study not just the 98 percent of the human genome made up of genes that are in the non-coding and structural regions, but to examine 100 percent of the genome. In humans, this process involves obtaining a DNA sample from the individual (typically from saliva, bone marrow, epithelial cells, or hair) and sequencing an individual's entire chromosomal and mitochondrial DNA. Because of the large volume of genomic data involved in this process, the genomic information is processed by and stored on microprocessors and computers.

Researchers continue to explore the relationship between mutations in the genomic material and the development or presence of disease. The role of WGS in the clinical setting has yet to be established. Research is still being done to determine if WGS can be used to accurately identify the presence of a disease, predict the development of a particular disease in asymptomatic individuals as well as how an individual might respond to pharmacological therapy. It has been theorized that WGS might eventually improve clinical outcomes by preventing the development of disease.

Whole Exome Sequencing

It is estimated that most disease-causing mutations (around 85 percent) of clinically important sequence variants occur within the regions of the genome that encode proteins. While similar to WGS, whole-exome sequencing (WES) reads only the parts of the human genome that encode proteins, leaving the other regions of the genome unread (Choi, 2009). Since most of the errors that occur in DNA sequences that then lead to genetic disorders are located in the exons, sequencing of the exome is being explored as a more efficient method of analyzing an individual's DNA to discover the genetic cause of diseases or disabilities. It has been theorized that sequencing of the human exome can be used to identify genetic variants in individuals to diagnose diseases and to predict the development of a particular disease in asymptomatic individuals without the high cost associated with WGS.

The American College of Medical Genetics and Genomics (ACMG, 2012) published a position statement addressing points to consider in the clinical application of genomic sequencing. The policy statement:

> Was developed primarily as an educational resource for clinical and laboratory geneticists to help them provide quality clinical and laboratory genetic services. Adherence to these Points to Consider is voluntary and, in determining the relevance of and weight to be given to any specific point, the clinical and laboratory geneticist should apply his or her own professional judgment to the specific circumstances presented by the individual patient or specimen.

The document contains indications for whole genome and WES as both screening and diagnostic tools. The ACMG states that clinical diagnostic testing using whole genome or WES is indicated for the following phenotypically affected individuals:

a. The phenotype or family history data strongly implicate a genetic etiology, but the phenotype does not correspond with a specific disorder for which a genetic test targeting a specific gene is available on a clinical basis.
b. A patient presents with a defined genetic disorder that demonstrates a high degree of genetic heterogeneity, making WES or WGS analysis of multiple genes simultaneously a more practical approach.
c. A patient presents with a likely genetic disorder but specific genetic tests available for that phenotype have failed to arrive at a diagnosis.
d. A fetus with a likely genetic disorder in which specific genetic tests , including targeted sequencing tests, available for that phenotype have failed to arrive at a diagnosis.
    i. Prenatal diagnosis by genomic (i.e., next-generation whole exome- or whole genome-) sequencing has significant limitations. The current technology does not support short

turn-around times which are often expected in the prenatal setting. There are high false positive, false negative, and variants of unknown clinical significance rates. These can be expected to be significantly higher than seen when array CGH is used in prenatal diagnosis (2012).

The ACMG document does not include references to peer reviewed literature in support of the recommendations made, or describe the process by which the recommendations were developed.

WES and WGS present ethical questions about informing individuals about incidental findings that have clinical significance. Ongoing discussions continue to explore whether or not, and how to inform individuals about medically relevant mutations in genes unrelated to the diagnostic question (i.e., mutations of unknown significance, non-paternity and sex chromosome abnormalities). This type of information may not only affect the individual being tested, but may also implicate family members. Also, in light of the small sample sizes and the limited number of studies exploring treatment outcomes, there may be safety considerations if a treatment decision is based on WES or WGS findings.

In 2013, the ACMG charged a Working Group with evaluating the need for and principles that would govern recommendations for analyzing and reporting incidental findings from genome and exome sequencing in the clinical context. The Working Group acknowledged that there was insufficient evidence about benefits, risks, and costs of reporting incidental findings to make evidence-based recommendations. However, based on available evidence and clinical consensus among its members, the Working Group determined that reporting some incidental findings might provide medical benefit for the individuals and families of individuals undergoing clinical sequencing. The Working Group recommended that when a report is issued for clinically indicated exome and genome sequencing, a minimum list of conditions, genes and variants should be routinely evaluated and reported to the ordering clinician. The conditions included for reporting were those that the Working Group and external reviewers considered most likely to be verifiable by other diagnostic methods and amenable to medical intervention. A complete list of these specified conditions can be found in the ACMG document. It should be noted that these recommendations address incidental findings sought and reported during clinical sequencing for a specific clinical indication. Conditions that were part of routine newborn screening were not addressed because they have their own assessment criteria and are applied in a specific public health framework. The Working Group recommendations also do not address preconception sequencing, prenatal sequencing, newborn sequencing, or sequencing of healthy children and adults (Green, 2013).

A potential major indication for use is molecular diagnosis of individuals with a phenotype that is suspicious for a genetic disorder or for individuals with known genetic disorders that have a large degree of genetic heterogeneity involving substantial gene complexity. Such individuals may be left without a clinical diagnosis of their disorder, despite a lengthy diagnostic work-up involving a variety of traditional molecular and other types of conventional diagnostic tests. For some of these individuals, WES, after initial conventional testing has failed to make the diagnosis, may return a likely pathogenic variant.

While some of the potential advantages of WES include the fact that it can be carried out more quickly than traditional genetic testing and it may be less expensive than some other tests (for example, WGS), it is not without limitations. WES typically covers only 85–90% of the exome and has no, or limited coverage of other areas of the genome. Areas of concern with this technology include: (1) gaps in the identification of exons prior to sequencing; (2) the need to narrow the large initial number of variants to manageable numbers without losing the likely candidate mutation; (3) difficulty identifying the potential causative variant when large numbers of variants of unknown significance are generated for each individual; (4) whole exome sequencing will not identify chromosomal changes, duplications, large deletions, rearrangements within genes,

epigenetic changes or nucleotide repeats (ACMG, 2012; National Cancer Institute, 2012; Teer, 2010[a]; Teer, 2010[b]).

At this time, there are limitations to WES that prohibit its use in routine clinical care. The limited experience with WES on a population level leads to gaps in understanding and interpreting ancillary information and variants of uncertain significance. As a result, the risk/benefit ratio of WES testing is poorly defined. Because the peer-reviewed literature on WES for clinical purposes consists primarily of case reports and small case series, the clinical applications of WES has yet to be established (Bilgüvar, 2010; Choi, 2009; Clayton-Smith, 2011, Saitsu, 2011; Vissers, 2011).

Background/Overview

Biochemical tests or other common laboratory tests or imaging procedures are typically adequate to diagnose a genetic disorder in symptomatic individuals; therefore, genetic testing plays only a small role in this setting. Additionally, there may be doubt in many cases that identification of genetic mutations identified with a specific disease will result in improved care. While a wide array of genetic medical conditions may be effectively treated or managed, many conditions have no known effective medical recourse. In these instances, there is very little evidence to demonstrate that the added information provided by genetic testing has any significant impact on individual care or outcomes. Conditions that fit into this category include ataxia telangiectasia, ALS, and Alzheimer's disease, among others. In the case of Alzheimer's disease specifically, several genetic alleles have been identified and have commercially available tests to identify them. Unfortunately, identification of these genes in a person's body does not allow improved prevention, care or management of their condition.

GEPs measure the degree of "expression" of multiple genes using a single sample. GEPs provide information about a cell's type, its current activity status and its local environment. GEPs are being investigated as a means to identify panels of genes for disease risk prediction, to diagnose a disease or condition or for clinical management.

Definitions

Amyotrophic lateral sclerosis (ALS,also known asLou Gehrig's disease):A progressive neurodegenerative disorder that affects nerve cells in the spinal cord and brain which eventually results in paralysis and death.

Ataxia telangiectasia: A rare, progressive, neurodegenerative childhood disease that affects the brain and other body systems.

DNA (deoxyribonucleic acid): A type of molecule that contains the code for genetic information.

Exome: All the exons in a genome.

Exon: The portion of the genome that predominantly encodes protein.

First-degree relative: Any relative who is a parent, sibling, or offspring to another.

Gene expression: The process by which a gene is turned on in a cell to make RNA and proteins. Gene expression may be measured by identifying the RNA, or the protein made from the RNA, or what the protein does in a cell.

Gene expression profiling: Any genomic technique that measures the degree of expression of multiple genes from an individual's tissue or cell sample.

Genetic counseling: A process involving the guidance of a specially trained professional in the

evaluation of family history, medical records, and genetic test results, in assessing the risk of genetic diseases, understanding the ramifications of diagnosis, and explanation of available treatment options available.

Genetic molecular testing: A type of test that is used to determine the presence or absence of a specific gene or set of genes to help diagnose a disease, screen for specific health conditions, and for other purposes.

Genome: An organism's entire set of DNA.

Mutation: A change in DNA sequence.

Phenotype: The observable physical or biochemical characteristics of an organism, as determined by both genetic makeup and environmental influences.

Second-degree relative: Any relative who is a grandparent, grandchild, uncle, aunt, niece, nephew, or half-sibling to another.

Whole exome sequencing: A testing method which analyzes the exons (coding regions) of thousands of genes simultaneously using next-generation sequencing techniques.

Whole genome sequencing: A testing method which seeks to determine an individual's entire DNA sequence, specifying the order of every base pair within the genome.

Coding

The following codes for treatments and procedures applicable to this document are included below for informational purposes. Inclusion or exclusion of a procedure, diagnosis or device code(s) does not constitute or imply member coverage or provider reimbursement policy. Please refer to the member's contract benefits in effect at the time of service to determine coverage or non-coverage of these services as it applies to an individual member.

When services are Medically Necessary:

CPT

81228	Cytogenomic constitutional (genome-wide) microarray analysis; interrogation of genomic regions for copy number variants (eg, Bacterial Artificial Chromosome [BAC] or oligo-based comparative genomic hybridization [CGH] microarray analysis)
81229	Cytogenomic constitutional (genome-wide) microarray analysis; interrogation of genomic regions for copy number and single nucleotide polymorphism (SNP) variants for chromosomal abnormalities
81599	Unlisted multianalyte assay with algorithmic analysis [when specified as gene expression profiling reliably associated with a specific disease]

ICD-9 Diagnosis ***[For dates of service prior to 10/01/2014]***
All other diagnoses not listed below as investigational and not medically necessary

ICD-10 Diagnosis ***[For dates of service on or after 10/01/2014]***
All other diagnoses not listed below as investigational and not medically necessary

When services may be Medically Necessary when criteria are met:

CPT

81479	Unlisted molecular pathology procedure [for specific gene testing]

81599 Unlisted multianalyte assay with algorithmic analysis [when specified as gene expression profiling]

ICD-9 Diagnosis ***[For dates of service prior to 10/01/2014]***
All other diagnoses not listed as investigational and not medically necessary

ICD-10 Diagnosis ***[For dates of service on or after 10/01/2014]***
All other diagnoses not listed as investigational and not medically necessary

When services are Investigational and Not Medically Necessary:

CPT

81403

Molecular pathology procedure, Level 4 (eg, analysis of single exon by DNA sequence analysis, analysis of >10 amplicons using multiplex PCR in 2 or more independent reactions, mutation scanning or duplication/deletion variants of 2-5 exons) [when specified as the following]:

- *ANG (angiogenin, ribonuclease, RNase A family, 5)* (eg, amyotrophic lateral sclerosis), full gene sequence

81404

Molecular pathology procedure, Level 5 (eg, analysis of 2-5 exons by DNA sequence analysis, mutation scanning or duplication/deletion variants of 6-10 exons, or characterization of a dynamic mutation disorder/triplet repeat by Southern blot analysis) [when specified as the following]:

- *CDKN2A (cyclin-dependent kinase inhibitor 2A)* (eg, CDKN2A-related cutaneous malignant melanoma, familial atypical mole-malignant melanoma syndrome), full gene sequence
- *SOD1 (superoxide dismutase 1, soluble) (eg, amyotrophic lateral sclerosis), full gene sequence*

81405

Molecular pathology procedure, Level 6 (eg, analysis of 6-10 exons by DNA sequence analysis, mutation scanning or duplication/deletion variants of 11-25 exons, regionally targeted cytogenomic array analysis) [when specified as the following]:

- *TARDBP (TAR DNA binding protein) (eg, amyotrophic lateral sclerosis), full gene sequence*

81406

Molecular pathology procedure, Level 7 (eg, analysis of 11-25 exons by DNA sequence analysis, mutation scanning or duplication/deletion variants of 26-50 exons, cytogenomic array analysis for neoplasia) [when specified as the following]:

- *FUS (fused in sarcoma)* (eg, amyotrophic lateral sclerosis), full gene sequence;
- *OPTN (optineurin)* (eg, amyotrophic lateral sclerosis), full gene sequence

81408

Molecular pathology procedure, Level 9 (eg, analysis of >50 exons in a single gene by DNA sequence analysis) [when specified as the following]:

- *ATM (ataxia telangiectasia mutated)* (eg, ataxia telangiectasia), full gene sequence

ICD-9 Diagnosis ***[For dates of service prior to 10/01/2014]***

172.0-172.9 Malignant melanoma of skin [when test is specified for hereditary melanoma]

Note: BRAF molecular diagnostic testing for melanoma is addressed in a separate document.

334.8 Other spinocerebellar diseases (ataxia telangiectasia)
335.20 Amyotrophic lateral sclerosis

ICD-10 Diagnosis ***[For dates of service on or after 10/01/2014]***

C43.0-C43.9 Malignant melanoma of skin [when test is specified for hereditary melanoma]

Document History

Status	Date	Action
Revised	02/13/2014	Medical Policy & Technology Assessment Committee (MPTAC) review. Medically necessary position statement expanded to address gene expression profiling. Additional investigational and not medically necessary position statement added to address diagnostic genetic testing using panels of genes (with or without next generation sequencing), including but not limited to whole genome and whole exome sequencing. Updated Rationale, Background/Overview, Coding, References and History sections.
	01/01/2014	Updated Coding section with 01/01/2014 CPT descriptor changes.
	07/01/2013	Updated Coding section with 07/01/2013 CPT changes.
Reviewed	02/14/2013	MPTAC review. Updated review date, References and History sections.
	01/01/2013	Updated Coding section to include 01/01/2013 CPT changes; removed 83890-83914, 88384-88386 deleted 12/31/2012.
Reviewed	02/16/2012	MPTAC review. Updated review date, Reference and History sections.
	01/01/2012	Updated Coding section to include 01/01/2012 CPT changes.
	07/13/2011	Updated Coding section; removed S3870 which is now addressed in GENE.00021.
Reviewed	02/17/2011	MPTAC review. Updated review date, Description/Scope, Rationale, Background/Overview, Reference and History sections.
	01/12/2011	Updated Coding section; removed S3865, S3866 which are now addressed in GENE.00017.
Reviewed	02/25/2010	MPTAC review. Updated review date, Reference and History sections. Removed the word "patient" from the title and description and replaced it with the word "individual."
Review	02/26/2009	MPTAC review. Updated review date, Reference, Coding and History sections.
New	02/21/2008	MPTAC initial document development. Document created to addresses diagnostic genetic testing, which was formerly addressed in GENE.00001.

American College of Medical Genetics and Genomics guideline for the clinical evaluation and etiologic diagnosis of hearing loss

Raye L. Alford, PhD, FACMG[1], Kathleen S. Arnos, PhD, FACMG[2], Michelle Fox, MS, CGC[3,4], Jerry W. Lin, MD, PhD[1], Christina G. Palmer, PhD, FACMG[5,6], Arti Pandya, MD, FACMG[7], Heidi L. Rehm, PhD, FACMG[8], Nathaniel H. Robin, MD, FACMG[9], Daryl A. Scott, MD, PhD[10,11] and Christine Yoshinaga-Itano, PhD[12]; ACMG Working Group on Update of Genetics Evaluation Guidelines for the Etiologic Diagnosis of Congenital Hearing Loss; for the Professional Practice and Guidelines Committee

Disclaimer: This guideline is designed primarily as an educational resource for clinicians to help them provide quality medical services. Adherence to this guideline is completely voluntary and does not necessarily assure a successful medical outcome. This guideline should not be considered inclusive of all proper procedures and tests or exclusive of other procedures and tests that are reasonably directed to obtaining the same results. In determining the propriety of any specific procedure or test, the clinician should apply his or her own professional judgment to the specific clinical circumstances presented by the individual patient or specimen. Clinicians are encouraged to document the reasons for the use of a particular procedure or test, whether or not it is in conformance with this guideline. Clinicians also are advised to take notice of the date this guideline was adopted, and to consider other medical and scientific information that becomes available after that date. It also would be prudent to consider whether intellectual property interests may restrict the performance of certain tests and other procedures.

Hearing loss is a common and complex condition that can occur at any age, can be inherited or acquired, and is associated with a remarkably wide array of etiologies. The diverse causes of hearing loss, combined with the highly variable and often overlapping presentations of different forms of hearing loss, challenge the ability of traditional clinical evaluations to arrive at an etiologic diagnosis for many deaf and hard-of-hearing individuals. However, identifying the etiology of a hearing loss may affect clinical management, improve prognostic accuracy, and refine genetic counseling and assessment of the likelihood of recurrence for relatives of deaf and hard-of-hearing individuals. Linguistic and cultural identities associated with being deaf or hard of hearing can complicate access to and the effectiveness of clinical care. These concerns can be minimized when genetic and other health-care services are provided in a linguistically and culturally sensitive manner. This guideline offers information about the frequency, causes, and presentations of hearing loss and suggests approaches to the clinical evaluation of deaf and hard-of-hearing individuals aimed at identifying an etiologic diagnosis and providing informative and effective patient education and genetic counseling.

Genet Med advance online publication 20 March 2014

Key Words: genetics evaluation; deaf; Deaf; genetic counseling; genetic testing; guideline; hard of hearing; hearing loss

DEFINITIONS

Deaf: a community with a distinct culture and language shaped by the experience of being deaf or hard of hearing, which may include deaf, hard-of-hearing, and hearing individuals

deaf: an auditory phenotype characterized by a total or near-total loss of the ability to hear

hard of hearing: an auditory phenotype characterized by a partial loss of the ability to hear

hearing loss: an auditory phenotype characterized by any degree of loss of the ability to hear; depending on cause, hearing loss can be temporary or permanent—this guideline focuses on permanent hearing loss

INTRODUCTION

Two to three of every 1,000 children born in the United States are deaf or have a hearing loss significant enough to affect speech and language development.[1] Early intervention has been shown to be effective in facilitating speech and language development in deaf and hard-of-hearing children.[2] As a result, newborn hearing screening, which began in 2001, is now mandated throughout the United States. Not all childhood hearing loss is present at birth, however, and hearing screening is recommended throughout childhood and adolescence to identify children with later-onset hearing loss and to permit early intervention.[3,4]

Ninety-five percent of newborns with hearing loss identified by newborn hearing screening programs are born to hearing parents, obscuring the fact that the majority of newborns have a hereditary cause for their hearing loss.[5,6] Analysis of family history data from school-aged children in the United States estimated that up to 60% of educationally significant congenital and early-onset hearing loss is caused by genetic factors.[5,6] The majority of genetic hearing loss is inherited in an autosomal recessive pattern and often presents in the absence of a positive family history for hearing loss. One gene, *GJB2*, which encodes the gap junction protein connexin 26, accounts for the largest proportion of autosomal recessive early childhood hearing loss in many populations.[7]

The prevalence of hearing loss increases with age, with 40–50% of the population experiencing hearing loss by age 75.[8] The contribution of genetic causes to cases of adult-onset hearing loss is less clear. However, it is evident that a significant proportion of adult-onset hearing loss is likely to be caused, or strongly influenced, by genetic factors.[9–14]

The goal of a genetics evaluation for deaf and hard-of-hearing individuals of any age is to identify an etiologic diagnosis and, in doing so, enable implementation of an individualized health-maintenance strategy.[15–17] Identification of a previously unrecognized syndromic form of hearing loss can be particularly important because it may allow early management of associated medical concerns. Obtaining an etiologic diagnosis also provides the basis for precise genetic counseling that includes an accurate estimation of the chances for recurrence of hearing loss within families.

AUDIOMETRIC AND CLINICAL ASPECTS OF HEARING LOSS

Hearing loss is typically described in terms related to its clinical presentation. In general, hearing loss is categorized as either syndromic or nonsyndromic, depending on the presence or absence of associated defects in other organ systems. Hearing loss is also typically described by the following:

- The age of onset—congenital, prelingual (before the acquisition of speech), postlingual (after the acquisition of speech), adult-onset, or presbycusis (age-related late-onset hearing loss);
- The type of hearing loss—sensorineural, conductive, mixed, or auditory neuropathy;
- The laterality and symmetry of the hearing loss—unilateral or bilateral, symmetric or asymmetric;
- The stability of the hearing loss—progressive, nonprogressive, or fluctuating;
- The degree of hearing loss—slight (16–25 decibels (dB)), mild (26–40 dB), moderate (41–55 dB), moderately severe (56–70 dB), severe (71–90 dB), or profound (91 dB or greater)[18]; and
- The configuration of the hearing loss as seen on audiometric analysis—sloping, flat, rising, or midfrequency (cookie-bite) loss.

Hearing loss may also be described according to an apparent pattern of inheritance—autosomal recessive, autosomal dominant, X-linked, or matrilineal (mitochondrial). If a specific etiology is known, descriptions of hearing loss may also include the etiologic diagnosis, such as Usher syndrome type 1–related hearing loss or *GJB2*-related hearing loss.[15,16,19,20]

GENETIC AND NONGENETIC ETIOLOGIES OF HEARING LOSS

Hearing loss is among the most etiologically heterogeneous disorders, with more than 400 genetic syndromes that include hearing loss as a feature, more than 100 genes associated with nonsyndromic genetic hearing loss, and a number of nongenetic causes.[20,21] Genes associated with syndromic and nonsyndromic genetic hearing loss encode a variety of proteins involved in the development and function of the auditory system, including transcription factors, structural proteins, gap junction proteins, and ion channels, to name just a few.

An estimated 30% of genetic hearing loss is syndromic. A few syndromes, such as Pendred (enlarged vestibular aqueduct, thyroid problems), Usher (retinitis pigmentosa), Waardenburg (pigmentary anomalies), and branchio-oto-renal (branchial arch and renal anomalies) syndromes, account for substantial percentages of hearing loss in some populations.[20,22–25] Syndromic hearing loss may be transmitted as an autosomal recessive, autosomal dominant, X-linked, or matrilineal trait. A review of individual conditions can be found in *Hereditary Hearing Loss and Its Syndromes* by Toriello and Smith[20] and the online database GeneReviews.[19]

For some syndromic forms of hearing loss, such as Usher syndrome or Pendred syndrome, the nonauditory features can be subtle, especially in early childhood. For others, hearing loss is not the presenting finding or the most pressing concern. For many syndromic forms of hearing loss, there is marked variability in the phenotypic presentation and in the age of onset of syndromic features. This variability can exist both between and within families. For example, hearing loss is observed in only 20–50% of individuals with Waardenburg syndrome. As a result, this diagnosis can be easily missed if specific information about pigmentary changes or gastrointestinal disturbances is not elicited.[26] Furthermore, some hereditary forms of hearing loss, such as neurofibromatosis type 2, enlarged vestibular aqueduct syndrome, and Pendred syndrome, may present

initially as unilateral hearing loss.[19,20,27–29] Given the challenges that can exist in distinguishing between syndromic and nonsyndromic forms of hearing loss, all children and adolescents showing hearing loss without a known etiology, e.g., confirmed *GJB2* mutations or documented congenital cytomegalovirus (CMV) infection, should be evaluated for syndromic conditions by a clinical geneticist.[15,16]

An estimated 70% of genetic hearing loss is nonsyndromic. Nonsyndromic hearing loss may be transmitted as an autosomal recessive (~80%), autosomal dominant (~15%), or X-linked trait (~1%).[20] In addition, matrilineal (mitochondrial) transmission of nonsyndromic hearing loss occurs with a frequency of ~1% in Western nations but has a slightly higher incidence in Spain and East Asian countries including China, Mongolia, Korea, and Japan.[30,31]

Of particular note, the DFNB1 locus, which includes the *GJB2* gene encoding the gap junction protein connexin 26 and the *GJB6* gene encoding the gap junction protein connexin 30, accounts for an estimated 50% of all autosomal recessive nonsyndromic hearing loss and 15–40% of all deaf individuals in a variety of populations.[7,32–38] More than 150 deafness-causing variants have been identified in *GJB2,* but a few common mutations account for a large percentage of alleles in several populations.[7,34–36] *GJB2*-related hearing loss is sensorineural, usually present at birth, typically bilateral and nonprogressive, and can range from mild to profound in severity. However, progressive or later-onset hearing loss—with infants passing their newborn hearing screen—have also been described, particularly in association with nontruncating mutations.[39–42] Nonsyndromic hearing loss due to mutations at the DFNB1 locus may also be caused by (i) interaction of a *GJB2* mutation on one allele and a deletion involving *GJB6* on the other allele or (ii) biallelic deletions involving *GJB6*.[43–45] *GJB6* deletions have been observed in multiple populations, although they appear to be a relatively uncommon explanation for hearing loss in the United States.[46–48] Notably, hearing loss caused by certain dominant mutations in *GJB2*, although uncommon, may present as a syndromic hearing loss, with associated skin findings.[49–51]
