Nonsyndromic mitochondrial hearing loss is characterized by audiograms that fall into the moderate-to-profound range and is associated with variants in either the *MT-RNR1* gene encoding the mitochondrial 12S ribosomal RNA or the *MT-TS1* gene encoding the mitochondrial transfer RNA Ser(UCN).[30,31,52] Of particular note, mutations in *MT-RNR1* are associated with predisposition to aminoglycoside ototoxicity.[53] Hearing loss in individuals exposed to aminoglycoside antibiotics who carry susceptibility mutations in *MT-RNR1* is bilateral, severe to profound, and typically develops within a few days to weeks after administration of any amount, including just a single dose, of an aminoglycoside antibiotic.[54] Studies offer conflicting findings with regard to the likelihood of hearing loss in individuals carrying a deafness-causing variant in *MT-RNR1* who are not exposed to aminoglycosides.[53–55]

Age-related hearing loss, or presbycusis, is a common neurosensory deficit. In the United States, presbycusis is present in 40–50% of individuals aged 75 and older. Presbycusis generally affects higher frequencies of sound disproportionately, making it difficult for those with presbycusis to understand speech.[8] Men have presbycusis more frequently than women.[56] Presbycusis is a complex condition influenced by genetic and environmental factors.[13] Much of the literature about age-related hearing loss has focused on environmental factors such as noise exposure.[9,57,58] More recently, however, several susceptibility loci for age-related hearing loss have been identified. Genes implicated in this process using linkage and genome-wide association studies include genes previously implicated in other forms of hearing loss (such as *KCNQ4* and *ACTG1*), and genes involved in oxidative stress (such as *GRM7*, *GRHL2*, mitochondrial oxidative genes, and *N*-acetyltransferase).[9,10,12–14, 20]

Certain environmental (nongenetic) factors play a major etiologic role in hearing loss.[59] In the United States, congenital CMV infection is the most common nongenetic cause of hearing loss among children. Of the 20,000-40,000 infants born with congenital CMV infection each year, 90% have no detectable clinical abnormalities at birth, yet 10–15% of these asymptomatic infants will develop sensorineural hearing loss which can present in early childhood, can be unilateral or bilateral, and is often progressive.[60–62] As a result, congenital CMV infection may go undetected even in children who undergo newborn hearing screening and receive a thorough physical examination in the neonatal period.[16,20,62]

Congenital rubella, which was a common cause of hearing loss in the mid-1960s, occurs less frequently in Western populations today as a result of successful immunization programs.[63,64] According to the World Health Organization, no cases of endemic rubella infection are known to have occurred in the Americas between 2009 and 2012.[65] Similarly, the occurrence of postmeningitic hearing loss in children has been substantially reduced in developed countries as a result of vaccination against *Haemophilus influenzae*.[66] However, other environmental causes for hearing loss—including prematurity and exposure to noise or ototoxic drugs such as aminoglycosides and cyclophosphamides (which may have a genetically determined predisposition in some cases)—persist in the United States today.[20, 67–69]

THE IMPORTANCE OF GENETIC EVALUATION AND GENETIC COUNSELING FOR DEAF AND HARD-OF-HEARING INDIVIDUALS

When a genetic etiology is possible, a clinical genetics evaluation, including genetic counseling, offers a number of potential benefits for children and adults with hearing loss and their families. Benefits can include providing etiologic information, identifying (or allaying concerns about) comorbidities that may need referral for specialty care, planning for future medical and educational needs, facilitating estimations of the likelihood of recurrence, allowing families to better plan for the birth of a deaf or hard-of-hearing child, relieving the guilt that some parents may feel about having a child with hearing loss, enhancing

psychological well-being, dispelling misinformation, and facilitating referral for unrelated hereditary conditions such as familial cancer.[48,70–79] Furthermore, if mitochondrial DNA mutations associated with genetic susceptibility to aminoglycoside ototoxicity are discovered, it may be possible for relatives to avoid precipitating medications.[53–55]

As with any genetics evaluation, clear communication between the genetics professionals and their patients is important for the provision of effective genetics services. Deaf and hard-of-hearing individuals use a variety of communication methods, including spoken and signed language, lip reading, and written notes. Special training may be needed to optimize communication between individuals with hearing loss and genetics professionals. Such training may include (i) training sign language interpreters in medical and genetics terminology and (ii) training genetics professionals to work effectively with sign language interpreters and use a variety of communication aids, including videophones, video relay services, instant messaging, and visual aids.[80]

In addition, deafness is considered by some to be a nonmedical trait. Many deaf individuals consider themselves to be part of a linguistic and cultural minority group, viewing their deafness as a neutral or positive trait.[81,82] By contrast, the medical perspective—which views deafness as a pathology—is pervasive among most hearing individuals and some deaf individuals. This difference in perspective may affect the willingness of some individuals to obtain genetic services and genetic counseling.[83,84] However, when given accurate information about the nature of genetic counseling and how to obtain a referral, Deaf adults are often interested in receiving genetic services in order to learn more about themselves and why they are deaf or hard of hearing. In addition, many Deaf and hard-of-hearing individuals report an enhanced sense of self-understanding and self-identity, as well as an enhanced cultural and group identity, as a result of genetic testing.[72,85] Providing genetic services in a linguistically and culturally sensitive manner has been shown to improve outcomes such as genetics knowledge and understanding.[86,87] Furthermore, using neutral or balanced terminology, such as "chance" instead of "risk," "deaf" or "hearing" instead of "affected" or "unaffected," and exercising caution in the use of terms such as "handicapped," "pathology," and "impairment" can enhance the provision of genetic services to deaf and hard-of-hearing individuals and their families.[86,88,89]

GENETIC TESTING FOR THE ETIOLOGIC DIAGNOSIS OF HEREDITARY HEARING LOSS

Historically, molecular diagnostic tests for hearing loss have used genotyping or DNA sequencing to identify specific hearing loss variants or to screen individual genes, or small collections of genes, for changes associated with hearing loss. This approach has proven to be effective in cases in which there is a single gene, or limited number of genes, responsible for a subtype of hearing loss. Examples include *SLC26A4* gene sequencing in individuals suspected of having Pendred syndrome, *PAX3* gene sequencing in individuals with features of Waardenburg syndrome type I, *MITF* and *SOX10* gene sequencing in individuals with features of Waardenburg syndrome type II, or sequencing of *MYO7A* or *USH2A*, the most common genes involved in Usher syndrome types I and II, respectively.[90,91] Such screening can also be cost effective in individuals with genetically heterogeneous hearing loss phenotypes when a single gene is responsible for a significant percentage of cases. For example, *GJB2* gene sequencing can identify the underlying etiology for many individuals whose clinical presentation is consistent with autosomal recessive nonsyndromic hearing loss.

Today, tests based on next-generation sequencing (NGS) technologies are rapidly replacing many single gene–sequencing tests for hearing loss (**Figure 1**). These tests use disease-targeted exon capture, whole-exome sequencing (WES), or whole-genome sequencing (WGS) strategies. The main advantage of these tests is their ability to address the problem of genetic heterogeneity, wherein many different genes result in phenotypes that cannot be easily distinguished clinically.[92–96] Several NGS tests are now clinically available and can be found by querying the GeneTests and Genetic Testing Registry websites.[97,98]

NGS tests that use disease-targeted exon-capture approaches restrict sequencing to specific genes, such as genes known to be associated with hearing loss. Such tests can provide excellent coverage of the genes selected for study but are limited by our present knowledge of which genes are involved in hearing loss. Furthermore, some tests may sequence only a subset of the genes known to be associated with hearing loss. WES is also based on exon capture but does not rely on a list of genes involved in a particular disease process. Instead, WES seeks to evaluate all exons in the genome for variations. This approach can identify variants in known hearing loss–related genes and genes that have yet to be associated with hearing loss. WGS is not limited to screening exons and therefore has the potential to identify changes outside of exons that may be related to hearing loss.

The ability of WES and WGS approaches to detect a larger subset of all hearing loss–related changes needs to be balanced with the difficulties in interpretation that come from identifying an ever-increasing number of variants, the challenge of causally linking variants in new genes to hearing loss, and the likelihood of identifying genetic susceptibilities unrelated to hearing loss (i.e., incidental findings).[99] In 2013, the ACMG published recommendations for reporting incidental findings from genomic sequencing.[100]

Furthermore, not all regions of the genome are efficiently captured and analyzed by current exon-capture or WGS approaches, and large deletions and duplications, in addition to copy-number and structural variations, may not be efficiently detected.[99] These limitations of NGS technologies may necessitate use of alternative or complementary genetic testing strategies in some cases.

NGS technologies are expected to continue to improve over time, but it will always be important to pay close attention to the performance characteristics of tests, including coverage, analytic sensitivity, the genes that are and are not analyzed, and the types of mutations that are and are not detected. In some cases, it may be helpful to have tests performed in laboratories that

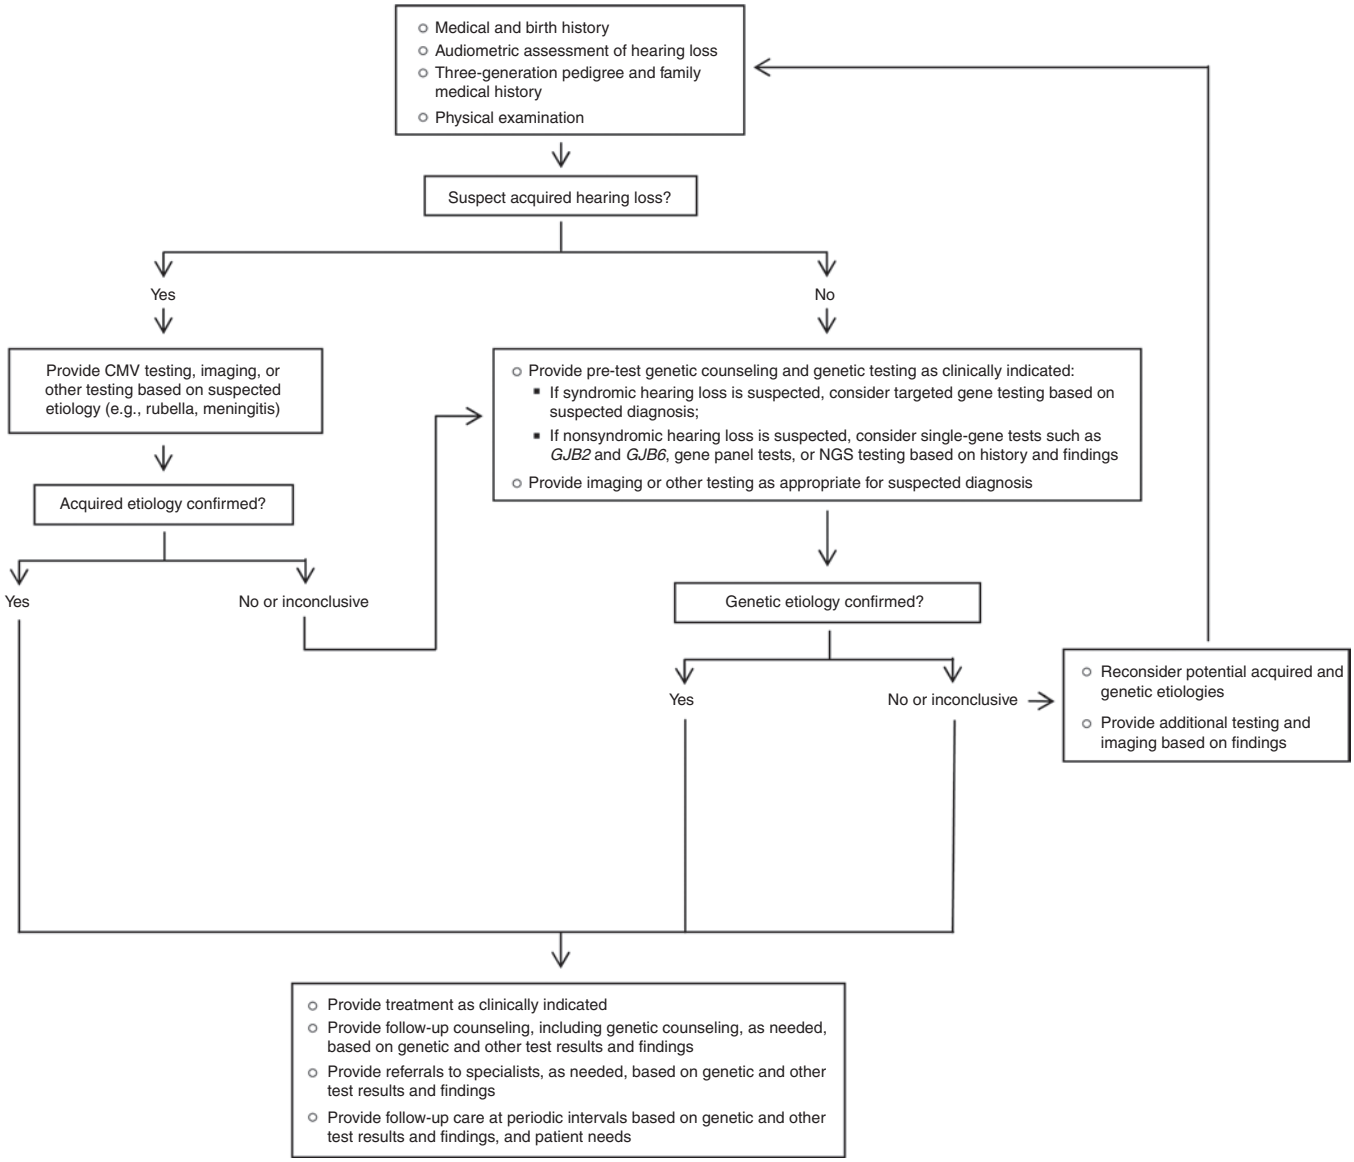

Figure 1 Graphic overview of approaches to the clinical evaluation and etiologic diagnosis of hearing loss. CMV, cytomegalovirus; NGS, next-generation sequencing.

focus on genetic causes of hearing loss because these laboratories may be more likely to report test performance with respect to hearing-related genes and to have developed approaches to specifically analyze relevant regions of the genome that may be refractory to more general NGS approaches.[92–96,99]

OTHER TESTING IMPORTANT TO THE ETIOLOGIC DIAGNOSIS OF HEARING LOSS

Because CMV remains a common cause of pediatric hearing loss, testing for congenital CMV infection by rapid culture or polymerase chain reaction of saliva or urine samples from newborns is recommended as an initial test once a newborn hearing loss is confirmed (**Figure 1**). However, testing for CMV is most diagnostic when done before ~6 weeks of age.[101–105] A negative result most likely excludes CMV as the cause of the hearing loss, but a positive result may not necessarily indicate that the hearing loss is due to CMV infection, especially if obtained in older children who may have been exposed to CMV after birth.

Recent algorithms for the evaluation of hearing loss suggest that other nongenetic tests, such as computed tomography, magnetic resonance imaging, renal ultrasonography, electrocardiography, and ophthalmologic consultation, have an important role because their results can guide genetic testing or interpretation of DNA sequence variants.[106] For example, temporal bone imaging is commonly recommended to look for an enlarged vestibular aqueduct, which would prompt genetic testing for Pendred syndrome.[27,107,108] However, many nongenetic tests have low diagnostic yield in patients with hearing loss.[109] Furthermore, recent advances in genetic testing technologies that permit the analysis of many genes simultaneously at rapidly decreasing cost may soon prompt reassessment of the clinical utility of certain nongenetic tests as part of the initial

workup for the etiologic diagnosis of hearing loss. Such reassessments will need to consider the clinical utility of various nongenetic tests versus the risks associated with those tests, such as the clinical utility of computed tomography and magnetic resonance imaging versus the risks associated with radiation exposure and sedation.[17,109] As evidence for the clinical utility of NGS tests for the etiologic diagnosis of hearing loss is accumulated and evaluated, physicians should continue to rely on their best clinical judgment and consider the use of nongenetic tests for the evaluation of hearing loss on a case-by-case basis. For example, unless cochlear implantation is being considered, auditory neuropathy is detected, progressive hearing loss is identified, or other specific clinical concerns exist, it could be argued that temporal bone imaging might, in some cases, be better used as a complement or follow-up to genetic testing rather than as a part of the initial diagnostic evaluation.[109,110] In addition, in the absence of specific clinical concerns or family history, tests such as electrocardiographic studies, thyroid function testing, urinalysis, and renal ultrasonography might also be postponed until results of genetic testing are obtained, and then ordered as clinically indicated.[109,111,112]

GUIDELINE

1. All newborns and infants with confirmed hearing loss should undergo a comprehensive evaluation in which patient-focused medical and birth histories and a three-generation pedigree and family medical history are obtained, and a physical examination that focuses on dysmorphic physical findings is performed. Evaluation of children and young adults with hearing loss should follow a similar approach. Evaluation of deaf or hard-of-hearing adults should be customized based on the age of onset and other characteristics of the hearing loss (**Figure 1**).
   - The medical and birth histories may be helpful in differentiating between acquired versus inherited causes of hearing loss. Elements of medical and birth histories focused on hearing loss include the following:
     - Prenatal history, including maternal infections (e.g., CMV, rubella) and illnesses (e.g., syphilis), or medication or drug exposures (e.g., thalidomide, retinoic acid)[113,114];
     - Neonatal history, including premature birth, low birth weight, birth hypoxia, hyperbilirubinemia, sepsis, and exposure to ototoxic medications;
     - Postnatal history, including viral illnesses, bacterial meningitis, head trauma, noise exposure, and exposure to ototoxic medications; and
     - Audiometric assessment of the hearing loss, including sensorineural versus conductive or mixed hearing loss; age of onset; progressive, nonprogressive, or fluctuating nature of the hearing loss; laterality, symmetry, severity, and configuration of the hearing loss; and the presence or absence of vestibular dysfunction or auditory neuropathy.
   - The pedigree and family medical history should focus on identifying the following:
     - First- and second-degree relatives with hearing loss or with features commonly associated with hearing loss (such as pigmentary, branchial, or renal anomalies) or sudden cardiac death;
     - A pattern of inheritance;
     - Ethnicity and country of origin;
     - A common origin from ethnically or geographically isolated areas; and
     - Consanguinity.
   - The physical examination should focus on dysmorphic and other physical findings such as the following:
     - Unusual facial appearance, with attention to asymmetry;
     - Pigmentary anomalies;
     - Neck, skin, facial, or ear anomalies;
     - Neurological abnormalities;
     - Balance disturbances;
     - Skeletal abnormalities; and
     - Other unusual physical findings.
2. For individuals with findings that suggest a syndromic genetic etiology for their hearing loss,
   - Pretest genetic counseling should be provided, and, with patient's informed consent, genetic testing, if available, should be ordered to confirm the diagnosis—this testing may include single-gene tests, hearing loss sequencing panels, WES, WGS, chromosome analysis, or microarray-based copy-number analysis, depending on clinical findings;
   - Appropriate studies should be undertaken to determine whether other organs are involved; and
   - Appropriate near-term and long-term screening and management should be arranged, including referrals to specialists, as indicated by the associated manifestations of the particular syndrome.
3. For individuals lacking physical findings suggestive of a known syndrome and having medical and birth histories that do not suggest an environmental cause of hearing loss, a tiered diagnostic approach should be implemented.
   - Pretest genetic counseling should be provided, and, with patient's informed consent, genetic testing should be ordered.
     - Single-gene testing may be warranted in cases in which the medical or family history, or presentation of the hearing loss, suggests a specific etiology. For example, testing for mitochondrial DNA mutations associated with aminoglycoside ototoxicity may be considered for individuals with a history of use of aminoglycoside antibiotics.
     - In the absence of any specific clinical indications and for singleton cases and cases with apparent autosomal recessive inheritance, the next step should be testing for DFNB1-related hearing loss (due to mutations in *GJB2* and adjacent deletions in *GJB6*).

  - If initial genetic testing is negative, genetic testing using gene panel tests, NGS technologies such as large sequencing panels targeted toward hearing loss–related genes, WES, or WGS may be considered. Because several tests are clinically available, the clinician must be aware of the genes included in the test (panel) chosen and the performance characteristics of the platform chosen, including coverage, analytic sensitivity, and what types of mutations will be detected. It should be noted that the cost of these new genetic sequencing technologies is decreasing so rapidly that a tiered approach to testing may soon no longer be cost effective. In particular, for large sequencing panels targeted toward hearing loss–related genes, it may, in some cases, already be more cost effective to use NGS technologies as the initial test in the evaluation of hearing loss. However, issues related to genomic testing, such as the likelihood of incidental findings, will have to be addressed.
  - If genetic testing reveals mutation(s) in a hearing loss–related gene, mutation-specific genetic counseling should be provided, followed by appropriate medical evaluations and referrals.
  - If genetic testing fails to identify an etiology for a patient's hearing loss, the possibility of a genetic or acquired etiology remains. This point must be emphasized because it can be misunderstood by clinicians and by patients and their families. For interested patients and families, further genetic testing may be pursued on a research basis.
- Temporal bone imaging by computed tomography or magnetic resonance imaging should be considered as a complement to genetic testing, particularly if the diagnosis remains unclear, if cochlear implantation is being considered, if auditory neuropathy is noted, in cases of progressive hearing loss, or if other clinical concerns exist. The anticipated clinical utility of imaging studies should be balanced against the risks associated with radiation exposure and sedation.
- CMV testing should be done at the same time as genetic testing for infants with congenital hearing loss. For later-onset or progressive hearing loss, CMV testing can be obtained, but the likelihood that a positive test is due to postnatal exposure increases with age.

4. Referral to a multidisciplinary care center, when available, is recommended.
   - A team approach that includes otolaryngologists, clinical geneticists, genetic counselors, audiologists, speech and language specialists, early hearing intervention and family support specialists (which may include other individuals who are deaf or hard of hearing or other parents of deaf or hard-of-hearing children), and other appropriate specialists offers optimal opportunity to provide ongoing management and support of deaf and hard-of-hearing individuals and their families as their needs change over time.
   - For cases in which the genetic evaluation failed to identify an underlying cause, periodic follow-up care every 3 years with a geneticist may be appropriate for several reasons. First, subtle features of syndromic forms of hearing loss may not be apparent at birth or early in childhood but may appear as deaf or hard-of-hearing individuals grow into adulthood. These may prompt additional medical tests or referrals for specialty care. Second, follow-up visits offer the opportunity to inform individuals about new genetic tests that may have become available or changes in the interpretation of previous test results as medical knowledge advances. Finally, follow-up visits may also help identify clinical concerns unrelated to hearing loss, for which referral for specialty care may be appropriate (**Figure 1**).
5. Regardless of whether genetic test results are positive, negative, or inconclusive, results should be communicated through the process of genetic counseling.

DISCLOSURE

C.G.P. has received grant support to develop educational materials on cancer for the Deaf community. H.L.R. is employed by a fee-for-service laboratory that offers diagnostic testing for hearing loss. The other authors declare no conflict of interest.

Neurodevelopmental Manifestations of Mitochondrial Disease

Marni J. Falk, MD

ABSTRACT: Mitochondrial disease is an increasingly recognized but widely heterogeneous group of multisystemic disorders that commonly involve severe neurodevelopmental manifestations in childhood. This review explores the presentation, genetic basis, and diagnostic evaluation of primary mitochondrial disease. Emphasis is placed on neurodevelopmental findings that may be encountered by a Developmental Pediatrician that should provoke consideration of a mitochondrial disorder. The inheritance patterns and mechanisms by which mutations in genes located in either the nuclear or mitochondrial genomes can cause mitochondrial diseases are discussed. A general overview of the current diagnostic evaluation that can be readily initiated by the Developmental Pediatrician is provided, along with a summary of currently available treatment options.

(J Dev Behav Pediatr 31:610–621, 2010) **Index terms:** OXPHOS, mfDNA, nDNA, mitochondrial disease diagnosis.

OVERVIEW OF HUMAN MITOCHONDRIAL DISEASE

A recent development in the world of inherited disease has been the realization that dysfunction of the mitochondrial respiratory chain constitutes a frequent group of disorders that afflict all ages and ethnicities.[1,2] Indeed, mutations in hundreds of discrete genes—originating in either nuclear (nDNA) or mitochondrial (mtDNA) genomes—culminate in energy deficiency and organ failure. The five-complex respiratory chain (RC), also known as the electron transport chain, is the site of oxidative phosphorylation (OXPHOS) within the inner mitochondrial membrane in which the end products of intermediary metabolism are oxidized to generate energy in the form of adenosine triphosphate. *Primary* mitochondrial disease refers to disorders whose underlying genetic cause directly impairs RC composition or function. *Secondary* OXPHOS dysfunction, by contrast, has been described in a host of other genetic or environmental disorders, including other genetic disorders (i.e., Rett syndrome,[3] other metabolic defects,[4–7] chromosomal aneuploidies,[8,9]) or toxicities from drugs (i.e., valproate,[10] statins,[11] pesticides[12,13]). The minimal prevalence of primary mitochondrial disease is one in 5000,[1,2] although pathogenic mutations in mitochondrial DNA (mtDNA) may occur as frequently as one in 200 births.[14]

Primary RC (OXPHOS) dysfunction is commonly characterized by progressive, multisystemic involvement of high-energy demand tissues.[15] Indeed, clinical problems involving three or more systems should invoke consideration of mitochondrial disease into the differential diagnosis. Typical sequelae of RC dysfunction may involve almost any system: neurologic (central, peripheral, or autonomic nervous systems), heart (arrhythmias, cardiomyopathy), skeletal muscle (myopathy), eyes (eye movement abnormalities, vision loss due to retinal or optic nerve disease, ptosis), endocrine organs (diabetes mellitus, hypothyroidism, hypoparathyroidism, growth hormone deficiency, adrenal insufficiency), kidneys (renal tubular acidosis, aminoaciduria, nephropathy), gastrointestinal tract (liver failure, dysmotility), hearing (sensorineural hearing loss, vestibular dysfunction), and/or may cause global metabolic instability with susceptibility to infections and other catabolic stressors.[15] Each gene, and even mutation, implies a different disorder, hence the extensive variability in manifestations, prognosis, and inheritance characteristic of "mitochondrial disease."[16,17]

NEURODEVELOPMENTAL MANIFESTATIONS OF MITOCHONDRIAL DISEASE

Neurologic "Red-Flag" and "Nonspecific" Findings in Mitochondrial Disease

Neurodevelopmental abnormalities are common in primary mitochondrial disease and may present at any age. Table 1 lists both red flag neurologic findings that may present in infants and children with primary mitochondrial disease[15] and a wide range of nonspecific neurologic findings that often occur in combination in mitochondrial disease. By definition, nonspecific presentations also lead to a wide range of other primary diagnoses. Axonal neuropathy and/or autonomic nervous system involvement may occur in mitochondrial disease, although these presentations are more commonly diagnosed in older children and adults. Sensorineural hearing loss is a common finding that occurs in a wide range of

To the Committee Members of the Health Evidence Review Commission:

My name is Devki Saraiya, and I am a licensed, certified genetic counselor at Myriad Genetic Laboratories.

In 2014, the National Comprehensive Cancer Network (NCCN) significantly updated their hereditary cancer guidelines: 1) Created the Genetic/Familial High-Risk Assessment: Colorectal guideline[1] and 2) updated the Genetic/Familial High-Risk Assessment: Breast and Ovarian guideline[2]. Given these updates, I am writing to respectfully comment on the Genetics Advisory Council's review of new genetics CPT codes for 2015.

Comment #1: Update Diagnostic Guideline D1, Non-Prenatal Genetic Testing Guideline Section A)1)a) as follows:

Lynch syndrome (hereditary colorectal and endometrial cancer) services (CPT 81288, 81292-81300, 81317-81319, 81435, 81436) and familial adenomatous polyposis (FAP) services (CPT 81201-81203) should be provided as defined by the NCCN Clinical Practice Guidelines in Oncology. ~~Colorectal Cancer Screening~~ Genetic/Familial High-Risk Assessment: Colorectal. V.2.2104. ***www.nccn.org***

Rationale: The current wording references the NCCN Colorectal Screening guidelines, which as of 5/19/2014 no longer incorporate testing criteria for Lynch syndrome/FAP. The NCCN has created a new guideline "Genetic/Familial High-Risk Assessment: Colorectal V.2.2014" which outlines criteria for Lynch syndrome/FAP services.

Comment #2: Update Diagnostic Guideline D1, Non-Prenatal Genetic Testing Guideline Section A)1)c) as follows:

BRCA1/BRCA2 testing services (CPT 81211-81217) for women with a personal history of breast and/or ovarian cancer and for men with breast cancer should be provided according to the NCCN Clinical Practice Guidelines in Oncology. Genetic/Familial High- Risk Assessment: Breast and Ovarian. ~~V.1.2011 (4/7/11)~~ V.2.2014. ***www.nccn.org***

Rationale: The current wording references the NCCN Genetic/ Familial High-Risk Assessment: Breast and Ovarian guideline from 2011. NCCN has made important updates to BRCA1/2 testing criteria including criteria clarification and incorporation of prostate cancer (Gleason score $\geq$7) in their Genetic/Familial High-Risk Assessment: Breast and Ovarian V.2.2014 guidelines. Given these updates and keeping in line with the GAC's recommendation to update to the NCCN's current hereditary colon guidelines, it is respectfully requested that the GAC utilize the most current version of the breast/ovarian NCCN guidelines.

Comment #3: Update Diagnostic Guideline D1, Non-Prenatal Genetic Testing Guideline Section A)1)b) as follows:

BRCA1/BRCA2 testing services (CPT 81211-81217) for women without a personal history of breast and/or ovarian cancer should be provided to high risk women as defined in Guideline Note 3 or as otherwise defined ~~by the US Preventive Services Task Force~~ by the NCCN Clinical Practice Guidelines in Oncology. Genetic/Familial High-Risk Assessment: Breast and Ovarian. V2.2014.

Rationale: Given proven clinical utility of BRCA1/2 gene testing in both affected and unaffected at-risk individuals, it would be beneficial to provide coverage for members based on current peer-reviewed evidence and expert opinion that is found in the NCCN practice guidelines since there are

significant clinical shortcomings when comparing USPSTF recommendations[3] (currently referenced in the recommendation) to NCCN guidelines:

a) Limiting assessment to first-degree relatives (FDR), as the USPSTF does, will miss a significant number of BRCA mutation carriers inheriting the mutation from their fathers since BRCA1/2 mutations are inherited in an autosomal dominant pattern with sex-limited expression[4]. With USPSTF, close paternal female relatives (paternal aunts, paternal grandmothers, paternal nieces) are not FDRs and their cancer history is not considered, while it is in the NCCN criteria.

b) Requiring ≥2 first-/second-degree relatives affected with ovarian cancer in order to be considered at increased risk, as the USPSTF does, will miss a significant number of BRCA mutations carriers. Numerous studies have been published proving the high prevalence of BRCA1/2 mutations among unselected ovarian cancer patients[5-7]. This issue is addressed in the NCCN guidelines.

c) Failing to include triple negative breast cancer (TNBC) as a risk factor for BRCA mutations, as the USPSTF does, will result in missed BRCA mutation carriers since BRCA1/2 mutation carriers have an increased incidence of TNBC[8-16]. This issue is addressed in the NCCN criteria.

Comment #4: Update Diagnostic Guideline D1, Non-Prenatal Genetic Testing Guideline Section A)2) as follows:

Genetic counseling should precede genetic testing for hereditary cancer. Very rarely, it may be appropriate for a genetic test to be performed prior to genetic counseling for a patient with cancer. If this is done, genetic counseling should be provided as soon as practical. a) Pre and post-test genetic counseling ~~by the following providers~~ should be covered when provided by suitably trained health professional with expertise and experience in cancer genetics.

~~i) Medical Geneticist (M.D.) - Board Certified or Active Candidate Status from the American Board of Medical Genetics~~

~~ii) Clinical Geneticist (Ph.D.) - Board Certified or Active Candidate Status from the American Board of Medical Genetics.~~

~~iii) Genetic Counselor - Board Certified or Active Candidate Status from the American Board of Genetic Counseling, or Board Certified by the American Board of Medical Genetics.~~

~~iv) Advance Practice Nurse in Genetics - Credential from the Genetic Nursing Credentialing Commission.~~

Rationale: The NCCN, multiple published guidelines[1-3, 17-23] and government health plans, including CMS, advocate for a variety of licensed healthcare provider (HCP) types to be able to identify/counsel/test patients at risk of hereditary cancers since several studies have demonstrated that <½ of patients referred for genetic counseling attend a session[24-29]. **The main clinical benefit of testing is the opportunity to prevent/reduce the risk of cancer, a disease with significant financial and economic burden to Oregon Medicaid, families, and society**. While genetics professionals are extremely important, and access to such providers should remain open, limiting access to genetic testing for high risk patients to ONLY those that have met with the above limited provider types will result in fewer mutation carriers identified.

Comment #5: Consider addition of hereditary cancer multi-gene panels to coverage policy

Rationale: The NCCN Genetic/Familial High-Risk Assessment: Breast and Ovarian practice guidelines now provide the option of either a targeted (single syndrome) approach, or a multi-gene (panel) as a first-line test, in evaluation of a high risk patient. According to NCCN, individuals who meet testing criteria for BRCA1/2 may consider either comprehensive BRCA1/2 testing or a multi-gene (panel) test given that multiple genes may contribute to breast/ovarian cancer, and there is

often overlap in the cancers associated with different genes. An advantage of the multi-gene panel test is the ability of a "broad and unbiased" testing approach to detect mutations that might otherwise have gone undetected. This reduction in uninformative negative results increases the number of patients who can be provided with tailored medical management recommendations.

Thank you in advance for your consideration of these comments. Please feel free to contact me if I can provide any additional information or answer any questions.

Warm regards,

Definition of High Risk for Breast Cancer

Question: How should high risk of breast cancer be defined?

Question source: Genetics Advisory Panel

Issue: GN3 defines which patients are at high risk for breast cancer, and therefore eligible for prophylactic procedures such as mastectomy or oophorectomy. The specifications in GN3, and referred to in the non-prenatal genetic testing guideline, are based on USPSTF criteria in place at the time the guideline was created. In 2013, the USPSTF changed their criteria for defining high risk to a recommendation for using one of several screening tools (see below). The NCCN published their own criteria for defining high risk in their 2014 guideline Genetic/Familial High Risk Assessment: Breast and Ovarian. Both the revised USPSTF and NCCN risk groups vary from the current GN3 definition. Additionally, NCCN has published an extensive guideline regarding what procedures should be offered to women based on an algorithm of their risk, which includes genetics as well as multiple other factors.

As staff reviewed this topic, it was identified that the current guideline inappropriately allows prophylactic mastectomy and other treatments based on criteria for further genetic testing, not treatment.

The NCCN 2014 guideline regarding treatment of breast cancer contains this statement:

> Except as outlined in the NCCN Guidelines for Genetic/Familial High-Risk Assessment: Breast and Ovarian and the NCCN Guidelines for Breast Cancer Risk Reduction, prophylactic mastectomy of a breast contralateral to a known unilateral breast cancer is discouraged.

Contralateral mastectomy is still recommended for consideration in cases of invasive lobular carcinoma.

From the USPSTF 2014 recommendations for genetic testing for breast cancer:

> For women who have at least 1 family member with breast, ovarian, or other types of BRCA-related cancer, primary care providers may use 1 of several brief familial risk stratification tools to determine the need for in-depth genetic counseling.
>
> Although several risk tools are available, the tools evaluated by the USPSTF include the Ontario Family History Assessment Tool, Manchester Scoring System, Referral Screening Tool, Pedigree Assessment Tool, and FHS-7. The Referral Screening Tool and FHS-7 are the simplest and quickest to administer. All of these tools seem to be clinically useful predictors of which women should be referred for genetic counseling due to increased risk for potentially harmful BRCA mutations (most sensitivity estimates were >85%), although some models have been evaluated in only 1 study. To determine which patients would benefit from BRCA risk assessment, primary care providers should not use general breast cancer risk assessment models (for example, the National Cancer Institute Breast Cancer

Risk Assessment Tool, which is based on the Gail model) because they are not designed to determine which women should receive genetic counseling or BRCA testing.

In general, these tools elicit information about factors that are associated with increased likelihood of BRCA mutations. Family history factors associated with increased likelihood of potentially harmful BRCA mutations include breast cancer diagnosis before age 50 years, bilateral breast cancer, presence of breast and ovarian cancer, presence of breast cancer in 1 or more male family members, multiple cases of breast cancer in the family, 1 or more family members with 2 primary types of BRCA-related cancer, and Ashkenazi Jewish ethnicity. The USPSTF recognizes that each risk assessment tool has limitations and found insufficient comparative evidence to recommend one tool over another. The USPSTF also found insufficient evidence to support a specific risk threshold for referral for testing.

Definition of who should be offered genetic testing for breast cancer syndrome rom the 2014 NCCN guideline for genetic testing for breast cancer:

An unaffected individual with a family history of one or more of the following:
-A known mutation in a breast cancer susceptibility gene within the family
-≥2 breast primaries in single individual
-≥2 individuals with breast primaries on the same side of family
-≥1 ovarian cancer primary from the same side of family
-First or second degree relative with breast cancer ≤45 y
-≥1 family member on same side of family with a combination of breast cancer and ≥1 of the following: pancreatic cancer, prostate cancer, sarcoma, adrenocortical carcinoma, brain tumors, endometrial cancer, leukemia/lymphoma; thyroid cancer, dermatologic manifestations and/or macrocephaly, hamartomatous polyps of GI tract; diffuse gastric cancer
-male breast cancer

Current guideline

GUIDELINE NOTE 3, PROPHYLACTIC TREATMENT FOR PREVENTION OF BREAST CANCER IN HIGH RISK WOMEN

Line 195

Bilateral prophylactic breast removal is included on Line 195 for women without a personal history of invasive breast cancer who are at high risk for breast cancer. Prior to surgery, women without a personal history of breast cancer must have a genetics consultation. High risk is defined as:

A) Having a BRCA1/BRCA2 mutation;
B) Having a strong family history of breast cancer, defined as one of the following:
    1) 2 first-degree or second degree relatives diagnosed with breast cancer at younger than an average age of 50 years (at least one must be a first-degree relative);
    2) 3 first-degree or second-degree relatives diagnosed with breast cancer at younger than an average age of 60 years (at least one must be a first-degree relative);

3) 4 relatives diagnosed with breast cancer at any age (at least one must be a first-degree relative);
4) 1 relative with ovarian cancer at any age and, on the same side of the family, either 1 first-degree relative (including the relative with ovarian cancer) or second-degree relative diagnosed with breast cancer at younger than age 50 years, or 2 first-degree or second-degree relatives diagnosed with breast cancer at younger than an average age of 60 years, or another ovarian cancer at any age;
5) 1 first-degree relative with cancer diagnosed in both breasts at younger than an average age of 50 years;
6) 1 first-degree or second-degree relative diagnosed with bilateral breast cancer and one first-degree or second-degree relative diagnosed with breast cancer at younger than an average age of 60 years; or,
7) a male relative with breast cancer at any age and on the same side of the family at least 1 first-degree or second-degree relative diagnosed with breast cancer at younger than age 50 years, or 2 first-degree or second-degree relatives diagnosed with breast cancer at younger than an average age of 60 years.

C) A history of LCIS with a family history of breast cancer; or,
D) A history of treatment with thoracic radiation between ages 10 and 30.

Contralateral prophylactic mastectomy is included on Line 195 for women with a personal history of breast cancer and any of the high risk categories listed above. In addition, contralateral prophylactic mastectomy of the unaffected breast is indicated for women with invasive lobular carcinoma.

Prophylactic oophorectomy is included on Line 195 for women who have the BRCA1/BRCA2 mutation.

Expert input:

Dr. Andy Higgens, breast surgeon, Bend

Growing trend nationwide to have contralateral mastectomy for decreasing patient anxiety and decreasing surveillance, despite lack of evidence of improved survival. Commercial insurers are not regulating contralateral mastectomy. The main benefit is peace of mind and symmetry, not medical survival or disease reduction. OHP will be an outlier if contralateral mastectomy is not covered by patient preference. Using risk groups to determine who should have contralateral mastectomy covered is problematic, as this is a rapidly developing area. Someone without a genetic abnormality or a 20% or greater risk of breast cancer would have contralateral mastectomy denied. This is not logical as this patient has more risk than the woman who has never had cancer but meets the NCCN requirement for bilateral prophylactic mastectomy.

Recommends coverage for contralateral mastectomy unless medically contraindicated. Would remove the second paragraph of the proposed new guideline.

Cost effective to do contralateral mastectomy in younger women given cost savings of avoiding years of mammograms and MRIs.

HERC staff recommendation:

1) Modify GN3 as shown below
   a) Wording in green is proposed for possible deletion/non-inclusion based on expert surgical input

[without track changes]

GUIDELINE NOTE 3, PROPHYLACTIC TREATMENT FOR PREVENTION OF BREAST CANCER IN HIGH RISK WOMEN

Line 195

Bilateral prophylactic breast removal and/or oophorectomy are included on Line 195 for women without a personal history of invasive breast cancer who meet the criteria in the NCCN Clinical Practice Guidelines in Oncology. Breast Cancer Risk Reduction. V.1.2014 (1/20/14). ***www.nccn.org***. Prior to surgery, women without a personal history of breast cancer must have a genetics consultation as defined in section A2 of the DIAGNOSTIC GUIDELINE D1, NON-PRENATAL GENETIC TESTING GUIDELINE.

Contralateral prophylactic mastectomy is included on Line 195 for women with a personal history of breast cancer and 1) a hereditary breast and/or ovarian cancer syndrome or 2) a lifetime risk of breast cancer >20%. In addition, contralateral prophylactic mastectomy of the unaffected breast is indicated for women with invasive lobular carcinoma.

Preface

U.S. Preventive Services Task Force Recommendation Statement

Release Date: December 2013

The U.S. Preventive Services Task Force (USPSTF) makes recommendations about the effectiveness of specific preventive care services for patients without related signs or symptoms.

It bases its recommendations on the evidence of both the benefits and harms of the service and an assessment of the balance. The USPSTF does not consider the costs of providing a service in this assessment.

The USPSTF recognizes that clinical decisions involve more considerations than evidence alone. Clinicians should understand the evidence but individualize decision making to the specific patient or situation. Similarly, the USPSTF notes that policy and coverage decisions involve considerations in addition to the evidence of clinical benefits and harms.

This article was first published in *Annals of Internal Medicine* on 24 December 2013. Select for copyright and source information.

Return to Table of Contents

Rationale

Importance

The cancer types related to potentially harmful mutations of the BRCA genes are predominantly breast, ovarian, and fallopian tube cancer, although other types are also associated[1]. In the general population, 12.3% of women will develop breast cancer during their lifetime and 2.74% will die of the disease, whereas 1.4% of women will develop ovarian cancer and 1.0% will die of the disease[2]. A woman's risk for breast cancer increases to 45% to 65% by age 70 years if there are clinically significant mutations in either BRCA gene[3, 4]. Mutations in the *BRCA1* gene increase ovarian cancer risk to 39% by age 70 years, and *BRCA2* mutations increase ovarian cancer risk to 10% to 17% by age 70 years[3, 4]. In the general population, these mutations occur in an estimated 1 in 300 to 500 women (0.2% to 0.3%)[5-8]. In a meta-analysis conducted for the USPSTF, the combined prevalence of *BRCA1* and *BRCA2* mutations was 2.1% in a general population of Ashkenazi Jewish women[9].

Detection of Potentially Harmful BRCA Mutations

Genetic risk assessment and BRCA mutation testing is generally a multistep process involving identification of individuals who may be at increased risk for potentially harmful mutations, followed by genetic counseling from suitably trained health care providers and genetic testing of selected high-risk individuals when indicated. Several familial risk stratification tools are clinically useful for selecting patients who should be offered genetic counseling to further determine their candidacy for possible BRCA mutation testing.

Benefits of Testing for Potentially Harmful Mutations

For women whose family history is associated with an increased risk for potentially harmful mutations in the *BRCA1* or *BRCA2* genes, adequate evidence suggests that the benefits of testing for potentially harmful BRCA mutations are moderate.

For women whose family history is not associated with an increased risk for potentially harmful mutations in the *BRCA1* or *BRCA2* genes, there is adequate evidence that the benefits of testing for potentially harmful BRCA mutations are few to none.

Harms of Detection of Potentially Harmful BRCA Mutations and Early Intervention and Treatment

Adequate evidence suggests that the overall harms of detection of and early intervention for potentially harmful BRCA mutations are small to moderate.

USPSTF Assessment

For women whose family history is associated with an increased risk for potentially harmful mutations in the *BRCA1* or *BRCA2* genes, there is moderate certainty that the net benefit of testing for potentially harmful BRCA mutations and early intervention is moderate.

For women whose family history is not associated with an increased risk for potentially harmful mutations in the *BRCA1* or *BRCA2* genes, there is moderate certainty that the net benefit of testing for potentially harmful BRCA mutations and early intervention ranges from minimal to potentially harmful.

Return to Table of Contents

Clinical Considerations

Patient Population Under Consideration

This recommendation applies to asymptomatic women who have not been diagnosed with BRCA-related cancer.

Women who have 1 or more family members with a known potentially harmful mutation in the *BRCA1* or *BRCA2* genes should be offered genetic counseling and testing.

The USPSTF recognizes the potential importance of further evaluating women who have a diagnosis of breast or ovarian cancer. Some women receive genetic testing as part of a cancer evaluation at the time of diagnosis of breast cancer. The USPSTF did not review the appropriate use of BRCA testing in the evaluation of women who are newly diagnosed with breast cancer. That assessment is part of disease management and is beyond the scope of this recommendation. Women who have been diagnosed with breast cancer in the past and who did not receive BRCA testing as part of their cancer care but have a family history of breast or ovarian cancer should be encouraged to discuss further evaluation with their clinician.

These recommendations do not apply to men, although male family members may be identified for testing during evaluation.

Family History Screening and Risk Assessment

Mutations in the BRCA genes cluster in families, exhibiting an autosomal dominant pattern of transmission in maternal or paternal lineage. During standard elicitation of family history information from patients, primary care providers should ask about specific types of cancer, primary cancer sites, which family members were affected, relatives with multiple types of primary cancer, and the age at diagnosis and sex of affected family members.

For women who have at least 1 family member with breast, ovarian, or other types of BRCA-related cancer, primary care providers may use 1 of several brief familial risk stratification tools to determine the need for in-depth genetic counseling.

Although several risk tools are available, the tools evaluated by the USPSTF include the Ontario Family History Assessment Tool (Table 1), Manchester Scoring System (Table 2), Referral Screening Tool (Table 3), Pedigree Assessment Tool (Table 4), and FHS-7 (Table 5)[10-19]. The Referral Screening Tool (an updated version, the B-RST, is available at www.breastcancergenescreen.orgThis link goes offsite. Click to read the external link disclaimer and FHS-7 are the simplest and quickest to administer. All of these tools seem to be clinically useful predictors of which women should be referred for genetic counseling due to increased risk for potentially harmful BRCA mutations (most sensitivity estimates were >85%), although some models have been evaluated in only 1 study[9, 20]. To determine which patients would benefit from BRCA risk assessment, primary care providers should not use general breast cancer risk assessment models (for example, the National Cancer Institute Breast Cancer Risk Assessment Tool, which is based on the Gail model) because they are not designed to determine which women should receive genetic counseling or BRCA testing.

In general, these tools elicit information about factors that are associated with increased likelihood of BRCA mutations. Family history factors associated with increased likelihood of potentially harmful BRCA mutations include breast cancer diagnosis before age 50 years, bilateral breast cancer, presence of breast and ovarian cancer, presence of breast cancer in 1 or more male family members, multiple cases of breast cancer in the family, 1 or more family members with 2 primary types of BRCA-related cancer, and Ashkenazi Jewish ethnicity. The USPSTF recognizes that each risk assessment tool has limitations and found insufficient comparative evidence to recommend one tool over another. The USPSTF also found insufficient evidence to support a specific risk threshold for referral for testing.

Genetic Counseling

Genetic counseling about BRCA mutation testing may be done by trained health professionals, including trained primary care providers. Several professional organizations describe the skills and training necessary to provide comprehensive genetic counseling. The process of genetic counseling includes detailed kindred analysis and risk assessment for potentially harmful BRCA mutations; education about the possible results of testing and their implications; identification of affected family members who may be preferred candidates for testing; outlining options for screening, risk-reducing medications, or surgery for eligible patients; and follow-up counseling for interpretation of test results.

BRCA Mutation Testing

Adequate evidence suggests that current genetic sequencing tests can accurately detect BRCA mutations. Testing for BRCA mutations should be done only when an individual has personal or family history that suggests an inherited cancer susceptibility, when an individual has access to a health professional who is trained to provide genetic counseling and interpret test results, and when test results will aid in decision making. Initial testing of a family member who has breast

or ovarian cancer is the preferred strategy in most cases, but it is reasonable to test if no affected relative is available. It is essential that before testing, the individual is fully informed about the implications of testing and has expressed a desire for it.

The type of mutation analysis required depends on family history. Individuals from families with known mutations or from ethnic groups in which certain mutations are more common (for example, Ashkenazi Jewish women) can be tested for these specific mutations.

Individuals without linkages to families or groups with known mutations receive more comprehensive testing. In these cases, when possible, testing should begin with a relative who has breast or ovarian cancer to determine whether affected family members have a clinically significant mutation.

Tests for BRCA mutations are highly sensitive and specific for known mutations, but interpretation of results is complex and generally requires posttest counseling. Test results for genetic mutations are reported as positive (that is, potentially harmful mutation detected), variants of uncertain clinical significance, uninformative-negative, or true-negative. Women who have relatives with known BRCA mutations can be reassured about their inherited risk for a potentially harmful mutation if the results are negative (that is, a true negative). Some studies suggest increased breast cancer risk in some women with true-negative results[21-24]. However, a comprehensive meta-analysis conducted for the USPSTF that included these studies found that breast cancer risk is generally not increased in women with true-negative results[9]. An uninformative-negative result occurs when a woman's test does not detect a potentially harmful mutation but no relatives have been tested or no mutations have been detected in tested relatives. Available tests may not be able to identify mutations in these families. Risk for breast cancer is increased in women with uninformative-negative results[9].

Timing of Screening

Consideration of screening for potentially harmful BRCA mutations should begin once women have reached the age of consent (18 years). Primary care providers should periodically assess all patients for changes in family history (for example, comprehensive review at least every 5 to 10 years[25]).

Interventions for Women Who Are BRCA Mutation Carriers

Interventions that may reduce risk for cancer or cancer-related death in women who are BRCA mutation carriers include earlier, more frequent, or intensive cancer screening; risk-reducing medications (for example, tamoxifen or raloxifene); and risk-reducing surgery (for example, mastectomy or salpingo-oophorectomy). However, the strength of evidence varies across the types of interventions.

Evidence is lacking on the effect of intensive screening for BRCA-related cancer on clinical outcomes in women who are BRCA mutation carriers. Medications, such as tamoxifen and raloxifene, have been shown to reduce the incidence of invasive breast cancer in high-risk

women in the general population, but they have not been studied specifically in women who are BRCA mutation carriers[9, 20, 26].

In high-risk women and those who are BRCA mutation carriers, cohort studies of risk-reducing surgery (mastectomy and salpingo-oophorectomy) showed substantially reduced risk for breast or ovarian cancer. Breast cancer risk was reduced by 85% to 100% with mastectomy[27-29] and by 37% to 100% with oophorectomy, and ovarian cancer risk was reduced by 69% to 100% with oophorectomy or salpingo-oophorectomy[26]. Salpingo-oophorectomy was also associated with a 55% relative reduction in all-cause mortality (as measured during the course of the study) in women with *BRCA1* or *BRCA2* mutations and without a history of breast cancer[27].

Other Approaches to Prevention

The USPSTF recommendations on medications for breast cancer risk reduction are available on the USPSTF Web site (www.uspreventiveservicestaskforce.org).

The USPSTF recommends against screening for ovarian cancer in women. This recommendation does not apply to women with known genetic mutations that increase their risk for ovarian cancer (for example, BRCA mutations).

Useful Resources

The National Cancer Institute Cancer Genetics Services Directory provides a list of professionals who offer services related to cancer genetics, including cancer risk assessment, genetic counseling, and genetic susceptibility testing (available at http://www.cancer.gov/cancertopics/genetics/directoryThis link goes offsite. Click to read the external link disclaimer).

Return to Table of Contents

Other Considerations

Although some studies have reported that women prefer in-person genetic counseling, telephone- or computer-based counseling may be considered for women who would not otherwise have access to these services.

Research Needs and Gaps

Research on risk assessment and testing for BRCA mutations has focused on short-term outcomes for highly selected women in referral centers. Additional studies are needed, including comparative effectiveness trials of approaches to risk screening and strategies to improve access to genetic counseling and BRCA testing for high-risk individuals.

Another unresolved question is what specific training is needed (for persons other than trained genetic counselors) to provide genetic counseling. It would be helpful to understand which

methods of delivery of genetic counseling are most effective, including those that can increase access to genetic counseling in rural or other settings. Trials comparing types of providers and protocols could address these questions.

What happens after patients are identified as high-risk in clinical settings is unknown. The consequences of genetic testing for individuals and their relatives require more study. Well-designed investigations using standardized measures and diverse study populations are needed.

An expanded database or registry of patients receiving genetic counseling for inherited breast and ovarian cancer susceptibility or who are tested for BRCA mutations would provide useful information about predictors of cancer and response to interventions. Additional data are needed from women of varying socioeconomic, racial, and ethnic groups.

For women who are mutation carriers, studies about the effectiveness of intensive cancer screening and risk-reducing medications and the effects of age at intervention on improving long-term outcomes are needed. This research would increase knowledge of the relative benefits and harms of interventions that are provided on the basis of genetic risk information.

Discussion

Burden of Disease

Breast cancer is the second most common cancer in women in the United States and is the second leading cause of cancer death[30, 31]. In 2013, an estimated 232,340 women in the United States will be diagnosed with breast cancer and 39,620 women will die of the disease[32]. According to lifetime risk estimates for the general population, 12.3% of women will develop breast cancer during their lives and 2.74% will die of it[2].

Ovarian cancer is the fifth leading cause of cancer death in women in the United States[31], accounting for an estimated 22,240 new cases and 14,030 deaths in 2013[33]. According to lifetime risk estimates for the general population, 1.4% of women will develop ovarian cancer during their lives and 1.0% will die of it[2].

Estimates of the prevalence of potentially harmful BRCA mutations vary by population. The estimated prevalence is 0.2% to 0.3% in the general population of women[5-8], 6.0% in women with cancer onset before age 40 years[8, 34, 35], and 2.1% in the general population of Ashkenazi Jewish women[36-39]. In a meta-analysis of studies in which recruitment was based on family history of breast or ovarian cancer, *BRCA1* mutation prevalence was 13.6%, *BRCA2* mutation prevalence was 7.9%, and prevalence of either mutation was 19.8%[9].

Scope of Review

This recommendation applies to women who have no signs or symptoms of BRCA-related cancer. For its updated evidence review, the USPSTF considered risk assessment, genetic

counseling, and genetic testing for potentially harmful *BRCA1* or *BRCA2* mutations in asymptomatic women with a family history of breast or ovarian cancer but no personal history of cancer or known potentially harmful BRCA mutations in their family. The USPSTF also reviewed interventions aimed at reducing the risk for BRCA-related cancer in women with potentially harmful BRCA mutations, including intensive cancer screening (for example, earlier and more frequent mammography or magnetic resonance imaging of the breast), medications (for example, tamoxifen or raloxifene), and risk-reducing surgery (for example, mastectomy or oophorectomy). Studies about patients with current or past breast or ovarian cancer were excluded unless they were designed to address screening issues in women without cancer (for example, retrospective or case–control studies).

Accuracy of Familial Risk Assessment

The USPSTF reviewed several tools that could be used in primary care settings to predict individual risk for breast cancer and potentially harmful BRCA mutations.

Tools specifically designed to determine risk for BRCA-related cancer are primarily intended for use by nongeneticist health care providers to guide referral to genetic counselors for more definitive evaluation. Models that have been validated in studies include the Ontario Family History Assessment Tool (Table 1), Manchester Scoring System (Table 2), Referral Screening Tool (Table 3), Pedigree Assessment Tool (Table 4), and FHS-7 (Table 5)[10-19]. In general, these tools elicit information about factors associated with increased likelihood of BRCA mutations. They are clinically useful predictors of which women should be referred for genetic counseling because of increased risk for potentially harmful BRCA mutations (most sensitivity estimates were >85%), although some models have been evaluated in only 1 study[9, 20]. The USPSTF recognizes that each risk assessment tool has limitations and found insufficient evidence to recommend one tool over another.

Accuracy of BRCA Mutation Testing

The type of mutation analysis done depends on family history. Individuals from families with known mutations or from ethnic groups with common mutations (for example, Ashkenazi Jewish women) can be tested specifically for these mutations. The sensitivity and specificity of analysis techniques are measured by individual clinical laboratories and are not publicly available. Individuals without linkages to families or groups with known mutations receive more comprehensive testing. In these cases, guidelines recommend initial testing of a relative with known breast or ovarian cancer, when possible, to check for the presence of clinically significant mutations.

Effectiveness of BRCA Mutation Testing and Early Detection and Treatment

To understand the potential benefits and harms of genetic counseling, the USPSTF reviewed 18 studies[40-57] published since its previous review. Studies generally reported positive (or no negative) psychological effects, increased accuracy of risk perception, or decreased intention to have genetic testing.

Genetic counseling significantly decreased breast cancer worry in 8 studies[44–46, 48, 50, 53–55]. Three studies[41, 44, 49] reported decreased or no changes in general anxiety and depression after genetic counseling, whereas other studies found no significant differences in anxiety scores[48, 50]. However, 1 of these studies noted an increase in state anxiety scores after genetic counseling[44]. Eight studies published since 2004 reported improved accuracy of risk perception after genetic counseling[41, 42, 44-47, 49, 50, 52]. Two studies reported decreased intention to have genetic testing after genetic counseling[45, 46].

Interventions that may reduce risk for cancer in women who are BRCA mutation carriers include: earlier, more frequent, or intensive cancer screening; use of selective estrogen receptor modulators as risk-reducing medications (for example, tamoxifen or raloxifene); and risk-reducing surgery (for example, mastectomy or salpingo-oophorectomy).

Evidence is lacking on the effect of intensive screening for BRCA-related cancer on clinical outcomes in women who are BRCA mutation carriers.

Selective estrogen receptor modulators reduced the incidence of invasive breast cancer in several randomized, controlled trials[58-64], although clinical trials of tamoxifen and raloxifene have not been conducted specifically in women who are BRCA mutation carriers. In a meta-analysis of trials published to date[26, 65], tamoxifen and raloxifene reduced the incidence of estrogen receptor–positive invasive breast cancer, with 7 fewer events per 1000 women for tamoxifen (4 trials) and 9 fewer events per 1000 women for raloxifene (2 trials), assuming 5 years of treatment. Selective estrogen receptor modulators do not reduce risk for estrogen receptor–negative breast cancer, which includes 69% of breast cancer cases associated with *BRCA1* mutations and 16% associated with *BRCA2* mutations[66].

In cohort studies of high-risk women and those who are BRCA mutation carriers, risk-reducing surgery (for example, mastectomy or salpingo-oophorectomy) substantially reduced risk for breast or ovarian cancer. Mastectomy reduced breast cancer risk by 85% to 100%, and oophorectomy or salpingo-oophorectomy reduced ovarian cancer risk by 69% to 100% and breast cancer risk by 37% to 100%[9]. In 1 fair-quality prospective cohort study[27], salpingo-oophorectomy was also associated with a 55% relative reduction in all-cause mortality (as measured during the course of the study) in women with *BRCA1* and *BRCA2* mutations without a history of breast cancer. Breast cancer risk reduction associated with oophorectomy was more pronounced in women who were premenopausal at the time of surgery[27, 67].

Potential Harms of Cancer Screening and Treatment

Intensive screening for breast and ovarian cancer is associated with false-positive results, unnecessary imaging, and unneeded surgery. In 2 studies comparing mammography with magnetic resonance imaging for breast cancer screening in which 18% to 100% of study participants were BRCA mutation carriers, mammography was associated with higher false-positive rates (14% vs. 5.5% in the first round of screening; $P < 0.001$[68]; 15% vs. 11% in another study[69]) and more false-negative results (12 vs. 1 case in the first round of screening; 12 vs. 4 cases in subsequent rounds[68]. In a retrospective analysis of a cohort of women with potentially harmful BRCA mutations or first-degree relatives with BRCA mutations, those who were

screened with mammography were more likely to have unneeded imaging than those who were screened with magnetic resonance imaging; however, rates of unneeded biopsy were similar[69].

Risk-reducing medications (for example, tamoxifen or raloxifene) can increase risk for thromboembolic events (4 to 7 events per 1000 women over 5 years). Tamoxifen increased the risk for endometrial cancer (4 to 5 cases per 1000 women) compared with placebo or raloxifene, and it also increased risk for cataracts (15 per 1000 women) compared with raloxifene[26, 65].

Data on the long-term physical harms of risk-reducing mastectomy are limited. In high-risk women having risk-reducing mastectomy with immediate reconstruction, 21% in 1 series had complications (for example, hematoma, contracture, or implant rupture)[70]. In another series, 64% reported postsurgical symptoms (for example, numbness, pain, tingling, infection, swelling, breast hardness, bleeding, organizing hematoma, failed reconstruction, breathing problems, thrombosis, and pulmonary embolism)[71]. After risk-reducing oophorectomy, 5% of women in 1 study had postsurgical complications (for example, wound infection, bladder or uterine perforation, or small-bowel obstruction)[72].

Seven observational studies provided data on psychological distress due to risk-reducing mastectomy[71, 73-76] or oophorectomy[25, 77]. In 1 study of 90 women who had risk-reducing bilateral mastectomy[73, 74], there were significant reductions in scores for anxiety and sexual pleasure and no significant differences in depression scores, body image concerns, or other measures. In another study[75], there were no significant differences in psychological measures between women who had risk-reducing mastectomy and a reference sample that did not have the procedure. Ten years after risk-reducing mastectomy, most women in another study reported that their family lives were unchanged, but 39% reported negative effects on spousal relationships because of decreased sensation and changed body appearance[76]. After risk-reducing salpingo-oophorectomy, premenopausal women reported significant worsening of vasomotor symptoms and decreased sexual function[77].

Estimate of Magnitude of Net Benefit

For women whose family history is associated with an increased risk for potentially harmful mutations in the *BRCA1* or *BRCA2* genes, the USPSTF found adequate evidence that the benefits of testing, detection, and early intervention are moderate. For women whose family history is not associated with an increased risk for potentially harmful mutations in the *BRCA1* or *BRCA2* genes, the USPSTF found adequate evidence that the benefits of testing, detection, and early intervention are few to none. The USPSTF found adequate evidence that the overall harms of testing, detection, and early intervention are small to moderate.

For women whose family history is associated with an increased risk for potentially harmful mutations in the *BRCA1* or *BRCA2* genes, the USPSTF concludes with moderate certainty that the net benefit of testing, detection, and early intervention is moderate. For women whose family history is not associated with an increased risk for potentially harmful mutations in the *BRCA1* or *BRCA2* genes, the USPSTF concludes with moderate certainty that the net benefit of testing, detection, and early intervention ranges from minimal to potentially harmful.

How Does Evidence Fit With Biological Understanding?

The *BRCA1* and *BRCA2* genes are tumor suppressor genes. Mutations of these genes have been linked to hereditary breast and ovarian cancer. Risks for breast, ovarian, and other types of BRCA-related cancer are greatly increased in patients who have inherited potentially harmful *BRCA1* or *BRCA2* mutations. Genetic testing may identify such mutations. Several options are available to manage cancer risk in patients who are found to be mutation carriers.

Response to Public Comments

A draft version of this recommendation statement was posted for public comment on the USPSTF Web site from 2 April through 29 April 2013. In response to comments, the USPSTF clarified that this recommendation statement applies to women. It also expanded the recommendation to include women who have family members with tubal or peritoneal (in addition to breast or ovarian) cancer. The USPSTF clarified that it recognizes the potential importance of further evaluating women who have a diagnosis of breast or ovarian cancer; however, that assessment is part of disease management and is beyond the scope of this recommendation.

The USPSTF added that it found insufficient evidence to recommend one risk assessment tool over another or to support a specific risk threshold for referral for genetic counseling and BRCA testing. It also added a compilation of risk assessment tools (Tables 1 to 5). Although the preferred BRCA testing strategy is initial testing of a family member with breast or ovarian cancer, the USPSTF clarified that it is reasonable to start testing in an unaffected individual if no affected relative is available. Because of the complexity of BRCA test results, the USPSTF also suggests posttest counseling. It also clarified and updated information on BRCA testing, other resources, and recommendations of other groups.

Return to Table of Contents

Update of Previous USPSTF Recommendation

In 2005, the USPSTF recommended that women whose family history is associated with an increased risk for potentially harmful mutations in the *BRCA1* or *BRCA2* genes be referred for genetic counseling and evaluation for BRCA testing. It also recommended against routine referral for genetic counseling or routine BRCA testing for women whose family history is not associated with an increased risk for potentially harmful mutations in the *BRCA1* or *BRCA2* genes[78].

This recommendation statement reaffirms the USPSTF's previous recommendation. Since 2005, family history risk stratification tools have been developed and validated for use in primary care practice to guide referral for BRCA genetic counseling (Tables 1 to 5). In addition, the potential benefits and harms of medications for breast cancer risk reduction have been studied for longer follow-up periods, and more information is available about the potential psychological effects of genetic counseling and risk-reducing surgery.

Return to Table of Contents

Recommendations of Other Groups

The National Comprehensive Cancer Network provides specific criteria for genetic counseling and testing[1]. The American Congress of Obstetricians and Gynecologists recommends genetic risk assessment for women who have more than a 20% to 25% risk for an inherited predisposition to breast and ovarian cancer and states that it may be helpful for patients with more than a 5% to 10% risk[79]. The American Society of Clinical Oncology recommends genetic testing when there is personal or family history suggestive of genetic cancer susceptibility, the test can be adequately interpreted, and the results will aid in diagnosis or medical management of the patient or family member who has hereditary risk for cancer. It also recommends genetic testing only when pretest and posttest counseling are included[80]. The National Society of Genetic Counselors has issued practice guidelines for risk assessment and genetic counseling for hereditary breast and ovarian cancer. It recommends that genetic testing should be offered to individuals with a personal or family history suggestive of an inherited cancer syndrome, when the test can be adequately interpreted, if testing will influence medical management of the patient or relative, when potential benefits outweigh potential risks, if testing is voluntary, and when the individual seeking testing or a legal proxy can provide informed consent[81]. The European Society for Medical Oncology recommends that all patients who may be referred for BRCA testing should first complete informed consent and genetic counseling and patients who are mutation carriers should be encouraged to advise close family members to obtain genetic counseling[82]. The Society of Gynecologic Oncologists recommends genetic risk assessment for individuals with a personal risk of more than approximately 20% to 25% for an inherited predisposition to cancer and states that it may be helpful for patients with more than approximately 5% to 10% risk. Genetic testing for cancer predisposition requires informed consent that should encompass pretest education and counseling about the risks, benefits, and limitations of testing, including the implications of both positive and negative genetic test results[83].

Structured Abstract

Purpose: To review new evidence on the benefits and harms of risk assessment, genetic counseling, and genetic testing for BRCA-related cancer in women for the U.S. Preventive Services Task Force.

Data Sources: MEDLINE and PsycINFO (January 2002 to December 31, 2012), Cochrane Central Register of Controlled Trials and Cochrane Database of Systematic Reviews (4th Quarter 2012), Scopus, and reference lists were searched for English-language studies of benefits and harms of risk assessment, genetic counseling, genetic testing, and interventions to reduce BRCA-related cancer and mortality.

Data Synthesis: Thirteen general risk models, such as the Gail model, are modest predictors of individual risk for breast cancer (c-statistic, 0.55 to 0.65). Five familial risk models for nongenetics specialists to guide referrals to genetic counseling accurately predict individual risk for BRCA mutations (c-statistic, >0.80). No studies reported harms of risk assessment. Sixteen studies indicated that genetic counseling decreases cancer worry, anxiety, and depression; increases the accuracy of risk perception; and decreases intention for mutation testing.

Thirty-two new studies and 38 earlier studies provided data for meta-analysis estimates of the prevalence and penetrance of BRCA mutations. Prevalence varies by population: 0.2 to 0.3 percent in general populations, 3 percent in women with breast cancer, 6 percent in women with breast cancer onset before age 40 years, 10 percent in women with ovarian cancer, and 20 percent in high-risk families. Among Ashkenazi Jewish women, prevalence is 2 percent in unselected populations and 10 percent in high-risk families. The penetrance of BRCA mutations differs by test result. Breast cancer penetrance to age 70 years if the test is positive is 46 to 71 percent for *BRCA1* or *BRCA2*; ovarian cancer penetrance is 41 to 46 percent for *BRCA1* and 17 to 23 percent for *BRCA2*. No estimates were available for women with variants of uncertain significance. The standardized incidence rate for breast cancer is 3.81 (95% CI, 3.06 to 4.75) for uninformative negative test results and 1.13 (95% CI, 0.81 to 1.58) for true negative results. Estimates for ovarian cancer were highly heterogeneous. Breast cancer worry and anxiety increased after testing in women with positive results and decreased in others, although results differed across studies. Risk perception improved after receiving test results.

No trials of the effectiveness of intensive screening for breast or ovarian cancer in women who are mutation carriers have been published. False-positive rates, unnecessary imaging, and unneeded surgery were higher in women undergoing intensive screening. Most women experienced no anxiety after screening with magnetic resonance imaging, mammography, or clinical breast examination, although women recalled for additional testing had transient anxiety. There are no trials of risk-reducing medications specifically in women who are mutation carriers. Tamoxifen and raloxifene reduced invasive breast cancer by 30 to 68 percent in placebo-controlled trials enrolling women with various levels of risk; tamoxifen had a greater effect than raloxifene in a head-to-head trial. Results suggested that reduction was greater in women with more relatives with breast cancer, but confidence intervals overlapped and results were not specific for women who are mutation carriers. Tamoxifen and raloxifene increased thromboembolic events and tamoxifen increased endometrial cancer and cataracts. In high-risk

women and women who are mutation carriers, risk-reducing mastectomy reduced breast cancer by 85 to 100 percent and breast cancer mortality by 81 to 100 percent; risk-reducing salpingo-oophorectomy reduced breast cancer by 37 to 100 percent, ovarian cancer by 69 to 100 percent, and all-cause mortality by 55 to 100 percent. Some women experienced physical complications of surgery, postsurgical symptoms, or changes in body image; some had improved anxiety.

Limitations: Including only English-language articles and studies applicable to the United States; varying number, quality, and applicability of studies.

Conclusions: Risk assessment using familial risk models to guide referrals is accurate. Genetic counseling reduces distress, improves risk perception, and reduces intention for testing. Genetic testing provides risk estimates for specific populations depending on test results. A true negative test indicates no increased risk for breast cancer. The effectiveness of intensive screening is not known, but it increases false-positive results and procedures. Tamoxifen and raloxifene reduce risk for breast cancer, but have adverse effects. Risk-reducing mastectomy and salpingo-oophorectomy are effective in reducing breast and ovarian cancer. Several evidence gaps remain and additional studies are necessary to better inform practice.

CHAPTER 1. INTRODUCTION

Purpose of Review and Prior USPSTF Recommendation

This systematic review is an update of the evidence for the U.S. Preventive Services Task Force (USPSTF) on the effectiveness and adverse effects of risk assessment, genetic counseling, and genetic testing for breast cancer susceptibility gene (BRCA)–related cancer in women who do not have cancer but are potentially at increased risk. Its purpose is to evaluate and summarize evidence addressing specific key questions important to the USPSTF as it considers new recommendations for primary care practice.

In 2005, based on results of a previous review,[1,2] the USPSTF recommended against routine referral for genetic counseling or routine BRCA testing for women whose family histories are not associated with increased risks for deleterious mutations in breast cancer susceptibility gene 1 (*BRCA1*) or breast cancer susceptibility gene 2 (*BRCA2*) (D recommendation).[3] The USPSTF also recommended that women whose family histories are associated with increased risks for mutations in the *BRCA1* or *BRCA2* genes be referred for genetic counseling and evaluation for BRCA testing (B recommendation).

The USPSTF concluded that the potential harms of routine referral for genetic counseling or BRCA mutation testing in women without family history risk outweigh the benefits, and that the benefits of referring women with family history risk to suitably trained health care providers outweigh the harms. Benefits included improved accuracy of risk assessment and pretest probability for testing and improved patient knowledge, risk perception, and psychological and health outcomes. Potential harms included inaccurate risk assessment; inappropriate testing; misinterpretation of test results; and ethical, legal, and social implications; among others.

The 2005 USPSTF recommendation was intended for the primary prevention of cancer and applied to women without previous diagnoses of breast or ovarian cancer, consistent with the USPSTF scope of preventive care for the general population. Recommendations for men and women with cancer were not included. The 2005 USPSTF recommendation is included in the Affordable Care Act for covered preventive services,[4] and provided the basis for a Healthy People 2020 objective to increase the proportion of women with family histories of breast or ovarian cancer who receive genetic counseling.[5]

The previous systematic review[1,2] identified several research limitations and evidence gaps. The review concluded that a primary care approach to genetic risk assessment and BRCA mutation testing had not been evaluated, and evidence was lacking to determine the benefits and harms of this approach for women without cancer. Risk assessment, genetic counseling, and mutation testing did not cause adverse psychological outcomes, and counseling improved distress and risk perception in the highly-selected populations studied. Studies of intensive cancer screening approaches, such as earlier and more frequent mammography, were inconclusive. Trials of risk-reducing medications, such as tamoxifen and raloxifene, reported reduced breast cancer incidence in women with varying baseline levels of risk compared with placebo, but also increased adverse effects. Observational studies of risk-reducing mastectomy and salpingo-

oophorectomy reported reduced breast and ovarian cancer outcomes in women who were mutation carriers.

Limitations identified by the previous review included:

- The quality and generalizability of studies varied.
- Although several risk assessment tools were available, most were designed for use by genetics specialists rather than primary care providers.
- Methods of risk stratification were subject to misclassification, and data to guide clinicians in the best approach were lacking.
- Studies of the effectiveness of genetic counseling on patient decisions and outcomes were lacking.
- Most studies of BRCA mutation testing were conducted in highly-selected samples of women, many with preexisting breast or ovarian cancer or from previously identified kindreds.
- Family history risk was often based on self-reported information; thus, the accuracy of risk stratification was limited by the accuracy of reported family history.
- In some cases, data to determine penetrance came exclusively from one study, and when multiple studies were available, they were heterogeneous and likely unreliable. (Penetrance is the probability of developing breast or ovarian cancer in women who have a known *BRCA1* or *BRCA2* mutation.)
- Most studies used research laboratory techniques to detect clinically significant mutations that differed from the DNA sequencing available clinically.
- The clinical significance of mutations was determined by each study.
- The applicability of studies based on highly-selected women in research settings to the general screening population was questionable.
- Data were not available to determine the optimal age at which to test and how age at testing influenced estimates of benefits and adverse effects.
- The long-term impact of testing was unknown, and most studies followed patients for less than 1 year.
- Studies did not evaluate psychological aspects of medical outcomes.
- Few data were available about the impact of testing on family members.
- Treatment effects were influenced by several variables that were not available and not easily factored into estimates of clinical outcomes.

Evidence gaps identified by the previous review included:

- Impact of screening in the general population.
- Patient-centered issues, such as access to testing; effectiveness of screening approaches, including risk stratification; use of system supports; and patient acceptance and education.
- Studies about who should perform risk assessment and genetic counseling services, and what skills are needed.
- Studies about what happens after patients are identified as high-risk in clinical settings.

- The consequences of genetic testing for individuals and their relatives.
- Well-designed investigations using standardized measures and enrolling subjects who reflect the general population, including minority women.
- Information about predictors of cancer, response to interventions, and other modifying factors from an expanded database or registry of patients who are counseled and tested for BRCA mutations.
- Additional research on interventions, including trials of risk-reducing medications that enroll women who are mutation carriers, evaluations of the effect of age at intervention, measurement of long-term outcomes, and factors related to acceptance of risk-reducing interventions.

Condition Definition

Clinically significant, or deleterious, mutations in the *BRCA1* and *BRCA2* genes are associated with increased risks for breast, ovarian, fallopian tube, and peritoneal cancer in women.[6,7] Often referred to as the Hereditary Breast and Ovarian Cancer syndrome, this condition is described as BRCA-related cancer in this review to explicitly include fallopian tube and peritoneal cancer. Research indicates that BRCA-related fallopian tube cancer has probably been misdiagnosed as ovarian cancer in the past.[8-10] These mutations are also associated with male breast cancer and, to a lesser degree, pancreatic and early-onset prostate cancer; *BRCA2* mutations are associated with melanoma. Although all of these types of cancer are considered during familial risk assessment, studies with these cancer outcomes are outside the scope of this review. BRCA mutations cluster in families exhibiting an autosomal dominant pattern of transmission in either the maternal or paternal lineage.

Recent estimates indicate that clinically significant mutations in either of the BRCA genes increase a woman's risk of breast cancer by age 70 years to 45 to 65 percent.[11,12] *BRCA1* mutations increase ovarian, fallopian tube, or peritoneal cancer risk to 39 percent, and *BRCA2* mutations to 10 to 17 percent.[11,12] These mutations are estimated to occur in 1 in 300 to 500 women in the general population,[13-16] and account for 5 to 10 percent of breast cancer overall.[13,17]

Specific BRCA mutations, known as founder mutations, are clustered among certain ethnic groups, including Ashkenazi Jews,[18-20] blacks,[21] and Hispanics,[22,23] and among families in the Netherlands,[24] Iceland,[25,26] and Sweden.[27] Several additional genes not included in this review are also associated with hereditary susceptibility to breast and ovarian cancer,[7,28,29] but are not commonly tested.

Specific cancer phenotypes are also associated with BRCA mutations even in the absence of family history, including triple-negative breast cancer and high-grade serous ovarian or fallopian tube cancer.[30-35] Pathologic and clinical characteristics of tumors also differ by the type of mutation. In a series of 3,797 cases of breast cancer in women who were *BRCA1* mutation carriers, 78 percent were estrogen receptor (ER)–negative, 79 percent progesterone receptor (PR)–negative, 90 percent human epidermal growth factor receptor 2 (HER2)–negative, and 69 percent triple-negative.[36] The proportion of ER-negative cases decreased with increasing age. In

a series of 2,392 cases of breast cancer in women who were *BRCA2* mutation carriers, 23 percent were ER-negative, 36 percent PR-negative, 87 percent HER2-negative, and 16 percent triple-negative.[36] These characteristics are important in determining cancer treatment and prognosis.

Prevalence and Burden of Disease

Breast cancer is the second most common cancer in women in the United States after nonmelanoma skin cancer, and is the second leading cause of cancer death after lung cancer.[37,38] In 2013, an estimated 232,340 women in the United States will be diagnosed with breast cancer and 39,620 women will die from it.[28] According to lifetime risk estimates for the general population, 12.3 percent (95% confidence interval [CI], 12.2 to 12.4) of women will develop breast cancer sometime during their lives, and 2.8 percent (95% CI, 2.76 to 2.80) will die from it.[39] The 5-year relative survival rate for all stages of breast cancer in the United States is 89 percent, but improves to 99 percent with localized disease. Five-year relative survival rates for women with regional and distant disease are 84 and 23 percent, respectively.[39]

Ovarian cancer is the fifth leading cause of cancer death in women in the United States,[38] accounting for an estimated 22,240 new cases and 14,030 deaths in 2013.[40] According to lifetime risk estimates for the general population, 1.40 percent (95% CI, 1.38 to 1.43) of women will develop ovarian cancer sometime during their lives and 1.02 percent (95% CI, 1.01 to 1.03) will die from it.[39] The 5-year relative survival rate for all stages of ovarian cancer in the United States is 44 percent, but may improve to 92 percent for women whose disease is detected and treated in early stages.[39] However, up to 75 percent of women with ovarian cancer have nonlocalized disease at the time of diagnosis because early stages are often asymptomatic. Five-year relative survival rates for women with regional and distant disease are 72 and 27 percent, respectively.[39]

Rationale for Screening/Screening Strategies

BRCA-related cancers are associated with family histories of these cancer types. Approximately 5 to 10 percent of women with breast cancer have a mother or sister with breast cancer, and up to 20 percent have either a first- or second-degree relative with breast cancer.[41-45] Although most of these women do not have BRCA mutations, some women report family history patterns that suggest their presence. Genetic risk assessment and BRCA mutation testing involve determining individual risk for clinically significant BRCA mutations followed by mutation testing of high-risk individuals. Mutation testing of appropriate candidates could lead to increased awareness of cancer risk and effective use of interventions to reduce BRCA-related cancer incidence and mortality.

Risk Assessment and Genetic Counseling

Several characteristics are associated with an increased likelihood of deleterious BRCA mutations,[46-49] including breast cancer diagnosed at an early age (before age 40 or 50 years), bilateral breast cancer, triple-negative breast cancer diagnosed before age 50 years, history of both breast and ovarian cancer, breast cancer in male relatives, multiple cases of breast cancer in

the family, both breast and ovarian cancer in the family, family members with two primary breast cancers, and Ashkenazi Jewish ancestry. These and other individual and family characteristics can be used to assess personal cancer risk and the need for referral for additional evaluation and testing. Approaches to assessing personal risk for BRCA mutation status range from simple checklists of criteria to comprehensive kindred analysis requiring expertise in cancer genetics. Practice and coverage standards in the United States generally follow the National Comprehensive Cancer Network (NCCN) referral criteria for genetic counseling (described in **Appendix A1**).[50]

Genetic counseling is the process of identifying and counseling individuals who are at risk for familial or inherited cancer and is recommended prior to BRCA mutation testing.[50-52] Services include comprehensive evaluations of familial risk for inherited disorders using kindred analysis and models to estimate risk. These include models based on logistic regression (e.g., Couch[46]), Bayesian analysis (e.g., BRCAPRO,[12,53] BOADICEA[54]), and patient data (Myriad prevalence tables[55]), among others. Some models are more appropriate for specific patients, and model accuracy varies across different populations.[56] In the course of an evaluation for BRCA-related cancer, other cancer syndromes are sometimes identified. Genetic counseling also includes identification of candidates for testing, patient education, discussion of the benefits and harms of genetic testing, interpretation of results after testing, and discussion of management options. Some genetic counseling programs offer their services by telephone.

Providers of genetic counseling may be genetic counselors,[57-59] nurse educators,[60,61] or other health professionals with comparable skills.[62] Accreditation standards from specialty groups specifically outline essential training and skills for genetics professionals.[63]

Mutation Testing

The NCCN provides specific criteria for genetic testing.[50] Guidelines recommend that mutation testing begin with a relative with known BRCA-related cancer, including male relatives, to determine if a clinically significant mutation is segregating in the family before testing individuals without cancer.[50] If an affected family member is not available, then the relative with the highest probability of mutation should be tested. Ideally, results of the initial test will guide testing decisions of other family members. However, the optimal candidate may not be available for testing, limiting the interpretation of results. Individuals without cancer meeting NCCN criteria for testing include those from families with known *BRCA1* or *BRCA2* mutations or from families with extensive cancer history (further described in **Appendix A1**).

The type of mutation analysis required also depends on family history (**Table 1**). A small number of clinically significant *BRCA1* and *BRCA2* mutations have been found repeatedly in different families, including the three founder mutations common in the Ashkenazi Jewish population. However, most identified mutations have been found in only a few families.[64] Individuals from families with known mutations or from ethnic groups with common mutations can be tested specifically for them. Several clinical laboratories in the United States test for specific mutations or sequence specific exons. The sensitivity and specificity of analytic techniques are determined by the laboratories and are not generally available.

Individuals without linkages to known mutations can determine their mutation status by direct DNA sequencing. A commercial laboratory, Myriad Genetic Laboratories, previously held a patent on this procedure and provided most of the testing in the United States. Myriad reports analytic sensitivity and specificity as both greater than 99 percent.[65] Approximately 12 percent of high-risk families without a *BRCA1* or *BRCA2* coding-region mutation may have other clinically significant genomic rearrangements.[65,66] Many of these mutations can be tested using the BRCA Rearrangement Test, now available as a subsequent step in testing.

Tests may indicate positive (i.e., BRCA mutation detected), variant of uncertain clinical significance (i.e., an abnormality of the BRCA gene, but unknown if it is associated with an increased risk for cancer), uninformative negative, or true negative results. A true negative result represents the absence of a mutation in an individual who has relatives with cancer and known BRCA mutations. An uninformative negative also indicates the absence of a mutation in an individual; however, information about her relatives is not definitive because either a mutation was not detected by their tests or they have not been tested.

Interventions

Interventions to reduce risk for cancer in women who are BRCA mutation carriers include earlier, more frequent, or intensive cancer screening; risk-reducing medications; and risk-reducing surgery. Cancer screening recommendations specifically for women who are BRCA mutation carriers are outside the scope of the USPSTF. The NCCN recommends that women who are BRCA mutation carriers conduct monthly breast self-examinations beginning by age 18 years, annual or semiannual clinician breast examinations beginning at age 25 years, and annual mammography and breast magnetic resonance imaging (MRI) beginning at age 25 years or individualized based on the earliest age of onset in the family.[50] The NCCN also recommends that women consider risk-reducing mastectomy and salpingo-oophorectomy, monitoring with transvaginal ultrasound (TVUS) and cancer antigen-125 (CA-125) levels every 6 months for women not undergoing salpingo-oophorectomy, and risk-reducing medications.

Tamoxifen, a selective estrogen receptor modulator (SERM), is considered a candidate for breast cancer risk reduction based on its effectiveness in preventing recurrences in women with breast cancer.[67] Placebo-controlled randomized, controlled trials (RCTs) of tamoxifen indicate reduced primary ER-positive breast cancer in women with family histories of breast cancer.[68-72] Raloxifene, another SERM used primarily for treating osteoporosis, also reduced risk for breast cancer in trials of women with various levels of breast cancer risk.[73,74] SERMs also have important adverse effects, including thromboembolism, endometrial cancer (tamoxifen), and vasomotor and other symptoms.[75,76] Exemestane, an aromatase inhibitor, also reduces risk for primary breast cancer in women with increased risk[77] and is in clinical use, but is not approved by the U.S. Food and Drug Administration for this indication. The USPSTF currently recommends consideration of risk-reducing medications for women who are at increased risk for breast cancer and low risk for complications, and discourages its use in average-risk women.[78]

Risk-reducing mastectomy and salpingo-oophorectomy are also options for women who are BRCA mutation carriers.[79-82] Bilateral total simple mastectomy with or without reconstruction is

currently the most common approach.[83,84] This procedure provides more complete removal of breast tissue than the previously used subcutaneous mastectomy. However, no procedure completely removes all breast tissue[85] and breast cancer can still occur postmastectomy.[86] Surgical reports indicating the potential for cancer occurrence after bilateral oophorectomy have led to more extensive procedures to remove potential tumor sites, such as bilateral salpingo-oophorectomy with or without hysterectomy.[87,88] Despite this approach, the occurrence of peritoneal carcinomatosis remains a possibility.[89-91]

Current Clinical Practice

Guidelines recommend testing for mutations only when an individual has personal or family history of cancer suggestive of inherited cancer susceptibility, the test can be adequately interpreted, and results will aid in management.[51,92]

Actual practices in the United States are unclear. The lack of effectiveness trials, differing interpretations of existing research among specialties, variability of insurance coverage, and direct-to-consumer advertising targeting patients, physicians, and health systems have resulted in highly variable clinical practices. The initial focus of mutation testing has been on patients with cancer. For women without cancer or relatives with known BRCA mutations, an integrated clinical pathway generally involves a series of sequential steps, including: 1) risk stratification and referral for genetic counseling, 2) genetic counseling for women identified with increased risk based on family history information, 3) BRCA mutation testing for women or their relatives with significant familial risk, and 4) interventions to reduce risk based on benefits, harms, and patient preferences.

In practice, these steps may not be sequential or clearly defined. In the United States, genetic testing is marketed directly to consumers, who may bypass preceding steps. In surveys, many clinicians were unfamiliar with genetic tests and criteria for referral or testing.[93,94] Some clinicians provide risk assessment, testing, and risk-reducing surgery without using comprehensive risk assessment methods or involving genetic counselors. Screening MRI is often performed based on risk criteria or other considerations that have not been evaluated for effectiveness, while risk-reducing medications are rarely used.[95]

Relevant data describing current clinical practice was collected through the Michigan Department of Community Health Cancer Genomics Program using statewide telephone surveys and a clinical genetic counseling database. Results indicated that approximately 8 percent of women without breast or ovarian cancer had two or more first- or second-degree relatives with breast or ovarian cancer.[96] Among women without cancer who had family histories indicating that they would probably benefit from genetic counseling, 35.7 percent received genetic counseling and 9.8 percent had genetic testing during 2009. Most referrals of women without cancer were made by obstetricians/gynecologists, primary care physicians, or patients themselves, comprising 44.3 percent of patients counseled. Among women without cancer who saw genetic counselors, 55.2 percent underwent genetic testing. Of these, results indicated 91.6 percent were negative, 3.9 percent were positive, and 4.5 percent were variants of unknown significance. Respondents described their top three reasons for declining testing after receiving

genetic counseling as: 1) not being the best candidate, 2) the test was not clinically indicated, and 3) inadequate insurance coverage.

The uptake of specialized services after genetic testing is generally high among women with positive test results that indicate the presence of clinically significant BRCA mutations.[97,98] In a recent study of women who had genetic testing in a U.S. university-based cancer risk program, women with positive results were significantly more likely to have risk-reducing salpingo-oophorectomy and screening with TVUS and serum CA-125 testing, while those with true negative results were less likely to have these procedures.[99] Among women with variants of uncertain significance and uninformative negative results, 12 percent had risk-reducing salpingo-oophorectomy, 37 percent had TVUS, and 34 percent had serum CA-125 testing.

Recommendations of Other Groups

Current recommendations of other professional groups are described in **Table 2**.

CHAPTER 2. METHODS

Analytic Framework and Key Questions

Based on evidence gaps identified from the previous review,[1,2] the USPSTF and Agency for Healthcare Research and Quality (AHRQ) determined the key questions for this update using the methods of the USPSTF.[100] Investigators created an analytic framework incorporating the key questions and outlining the patient populations, interventions, outcomes, and potential adverse effects (**Figure 1**). Definitions are described in **Appendix A2** and key questions are outlined in **Figure 1**. A draft research plan describing the analytic framework, key questions, scope, and systematic review approach was posted on the USPSTF Web site for public comment for 30 days in March and April 2012. A total of 213 comments from 54 respondents were received and reviewed, and the research plan was modified after discussion with investigators, the AHRQ Medical Officer, and USPSTF members. In addition, the USPSTF requested information about the impact of genetic testing on family members and the effects of direct-to-consumer marketing of BRCA genetic tests. These are described in supplementary sections of the review.

The target population included women without cancer or known deleterious BRCA mutations who are seen in clinical settings applicable to U.S. primary care practice, although the ideal candidate for mutation testing could be a male or female relative with cancer. The conditions of interest were BRCA mutation carrier status and BRCA-related cancer (predominantly breast, ovarian, fallopian tube, and peritoneal).

Search Strategies

In conjunction with a research librarian, investigators used the National Library of Medicine's Medical Subject Headings keyword nomenclature to search the Cochrane Central Register of Controlled Trials and Cochrane Database of Systematic Reviews (2005 through the 4th Quarter 2012), Health Technology Assessment, National Health Sciences Economic Evaluation Database, Database of Abstracts of Reviews of Effects (4th Quarter 2012), and MEDLINE and PsycINFO (2004 to December 31, 2012) for relevant English-language studies, systematic reviews, and meta-analyses. Search strategies are listed in **Appendix B1**. Secondary referencing involved manually reviewing reference lists of papers and reviewing citations of key studies using Scopus.

Study Selection

Investigators developed inclusion and exclusion criteria for abstracts and articles based on the target population, key questions, and outcome measures (**Appendix B2**). New research conducted in the United States or in similar populations that receive services and interventions applicable to U.S. medical practice published in 2003 or later was considered. After an initial review of abstracts, full-text articles were reviewed using additional inclusion criteria. In addition, studies from the previous review that met inclusion criteria for this update were

included in summary tables and meta-analysis in order to build on prior relevant research.

RCTs, systematic reviews, prospective and retrospective cohort studies, case-control studies, and diagnostic accuracy evaluations that addressed key questions 1, 2, and 4 were included. These include studies of the accuracy of risk assessment methods, outcomes of genetic counseling and testing, and effectiveness studies of interventions to reduce risk of BRCA-related cancer in women who are mutation carriers. Risk assessment methods were included only if they were designed for use by nongenetics specialists to guide referrals and were feasible for clinical settings (i.e., brief, nontechnical, did not require special training to administer or interpret). Evaluation of complex models used in genetic counseling was outside the scope of this review. Interventions include intensive screening (e.g., earlier and more frequent mammography, breast MRI), risk-reducing medications (e.g., tamoxifen, raloxifene), and risk-reducing surgery (e.g., mastectomy, salpingo-oophorectomy). For intensive screening interventions, when effectiveness studies were not available, studies that reported test characteristics of screening modalities, such as sensitivity and specificity, were included. Only medications approved by the U.S. Food and Drug Administration for cancer risk reduction were considered, consistent with the scope of the USPSTF.

Studies of any design were included to describe potential adverse effects of risk assessment, genetic counseling, mutation testing, and risk-reducing interventions (key questions 3 and 5). Potential adverse effects include inaccurate risk assessment; inappropriate testing; false-positive and false-negative results; false reassurance; incomplete testing; misinterpretation of the test result; anxiety; cancer worry; immediate and long-term harms associated with breast imaging, risk-reducing medications, and risk-reducing surgery; and ethical, legal, and social implications.

Data Abstraction and Quality Rating

An investigator abstracted data about the study design and setting; participant characteristics; data collection procedures; numbers enrolled and lost to followup; methods of exposure and outcome ascertainment; analytic methods, including adjustment for confounders; and outcomes. A second investigator confirmed the accuracy of key data. By using predefined criteria for RCTs, systematic reviews, cohort, case-control, and diagnostic accuracy studies developed by the USPSTF,[100,101] two investigators rated the quality of studies (good, fair, poor) and resolved discrepancies by consensus (**Appendix B3**).

Quality could not be assessed for many studies with designs that did not have predefined quality criteria, such as descriptive, cross-sectional, before-after, and case-series. For studies of penetrance (i.e., the probability of developing breast or ovarian cancer in women who have known *BRCA1* or *BRCA2* mutations) that computed a standardized incidence ratio (SIR) as the summary measure, we considered several factors to determine study quality in the absence of predefined criteria. Studies were considered high-quality if: 1) genotypes were known by direct measurement or inference from genotypes of relatives rather than probabilistically assigned; 2) breast and ovarian cancer outcomes were determined prospectively after ascertainment of the family genetic profile; 3) important covariates were measured for all individuals and accounted for in the analysis, including use of risk-reducing surgery and medications, age, Ashkenazi

Jewish ancestry, race or ethnicity, and vital status; and 4) reported family history was validated by review of medical records of family members.

The applicability of studies was determined using the population, intervention, comparator, outcomes, timing of outcomes measurement, and setting format adapted to this topic.[102]

Data Synthesis

We assessed the aggregate quality of the body of evidence for each key question (good, fair, poor) by using methods developed by the USPSTF based on the number, quality, and size of studies and consistency of results between studies.[100] Studies were considered consistent if outcomes were generally in the same direction of effect and ranges of effect sizes were narrow.

Statistical Meta-Analysis

To determine clinical outcomes related to various mutation testing results, we combined data in several meta-analyses to obtain estimates of mutation prevalence, penetrance, and relative risk for developing breast or ovarian cancer. These include estimates for women from unselected populations, high-risk cohorts, and Ashkenazi Jewish populations with tests indicating BRCA-positive (i.e., detected *BRCA1* or *BRCA2* mutations), variant of uncertain significance, uninformative negative, and true negative results using data from studies meeting inclusion criteria. Relevant studies from the previous review as well as those identified for this update were included in the meta-analyses.

To determine the appropriateness of meta-analysis, we considered clinical and methodological diversity and assessed statistical heterogeneity. We abstracted or calculated estimates of prevalence, penetrance, and relative risk (risk ratio [RR] or SIR) and their standard errors (SEs) from each study and used them in the meta-analysis. When the SIR was not reported, but the studies reported data for observed and expected numbers of cancer cases, or the study only reported the observed number of cancer cases and we could calculate the expected number of cancer cases from Surveillance Epidemiology and End Results data,[39] we calculated the SIR and its CI based on observed and expected numbers of cancer cases using the relationship between the Poisson distribution and the chi-square distribution.[103]

We assessed the presence of statistical heterogeneity among the studies by using standard chi-square tests, and the magnitude of heterogeneity by using the I^2 statistic.[104] We used a random-effects model to combine data for prevalence, penetrance, and relative risk while accounting for variation among studies. In general, when there is no variation among studies, the random-effects model yields the same results as a fixed-effects model without a study effect.[105] To account for clinical heterogeneity, we stratified analyses by clinical characteristics (e.g., breast vs. ovarian cancer, levels of risk, or methods used to select probands for BRCA-positive women) when necessary. We conducted sensitivity analyses to assess the robustness of results that considered variation from outlying studies. The results of the sensitivity analyses indicated no major differences from the main analysis. All analyses were performed using Stata/IC 12.1 (StataCorp, College Station, TX) and SAS 9.3 (SAS Institute, Cary, NC).

External Review

The draft report was reviewed by content experts, USPSTF members, AHRQ Project Officers, and collaborative partners and revised prior to finalization (**Appendix B4**).

Response to Comments Received During the Public Comment Period

A draft version of this evidence report was posted for public comment on the USPSTF Web site from April 2 to April 29, 2013. Comments were contributed by seven individuals and primarily concerned the scope of the review (i.e., include women with existing cancer, men, other types of mutations); issues that were already addressed by the systematic review, but were missed by the respondent (e.g., effect of risk-reducing salpingo-oophorectomy before and after menopause); studies or topics of interest that had no publications meeting inclusion criteria (e.g., testosterone supplements to reduce breast cancer risk); and comments about the recommendation statement. These comments did not lead to important changes in the systematic review.

CHAPTER 3. RESULTS

We reviewed 5,268 references from electronic searches, reference lists, and manual searches of recently published studies. After applying inclusion and exclusion criteria, we reviewed 1,600 full-text papers. Of these, 140 provided data addressing one or more of the key questions and were included in the systematic review. **Appendix B5** shows the results of our literature search and selection process and **Appendix B6** lists the excluded full-text papers. Included studies and quality ratings are in **Appendixes C1 to C4**.

Key Question 1. Does Risk Assessment, Genetic Counseling, and Genetic Testing Lead to Reduced Incidence of BRCA-Related Cancer and Reduced Cause-Specific and All-Cause Mortality?

No studies addressed the overarching issues of key question 1.

Key Question 2a. What Is the Accuracy of Methods to Assess Familial Cancer Risk for BRCA-Related Cancer When Performed by a Nongenetics Specialist in a Clinical Setting?

Key Question 3a. What Are the Potential Adverse Effects of Risk Assessment?

Summary

Several studies of risk stratification methods for nongenetics specialists met inclusion criteria for key question 2a, but no studies met criteria for key question 3a regarding potential adverse effects. The sensitivity of self-reported family cancer history in first-degree relatives varied between 65 and 82 percent for breast cancer and was 50 percent for ovarian cancer in validation studies, although specificity was greater than 90 percent. Referral criteria have been developed by several groups, but their accuracy has not been evaluated. A published systematic review of studies of 13 general breast cancer risk models and 11 studies of five familial risk models provided accuracy measures. Reference standards varied across studies, limiting comparisons between methods. General breast cancer risk models, such as the Gail model, are modest predictors for individuals (c-statistic, 0.55 to 0.65). Familial risk models, including the Ontario Family History Assessment Tool (FHAT), Manchester Scoring System, Referral Screening Tool (RST), Pedigree Assessment Tool (PAT), and FHS-7, predict risk specifically for BRCA mutations and are intended to guide referrals to genetic counseling. Studies indicated high accuracy for these models (c-statistic, >0.80), although some models have only been evaluated in single studies.

Evidence

This key question focuses on the evaluation of a patient's individual familial risk for BRCA-related cancer in a clinical setting by a nongenetics specialist for the purpose of initiating appropriate referrals for more comprehensive evaluations by genetic counselors and other specialists. These methods of risk stratification and referral differ from those intended for comprehensive evaluations. Risk models have been developed that predict the probability of developing breast cancer or the likelihood of having a mutation. Although the mutation probability is linked to family history, BRCA mutations explain only a small proportion of the familial aggregation of breast cancer, and even less of the hereditable variance in risk in a population.

Determination of Family History

Family history of BRCA-related cancer is important in estimating individual risk for a *BRCA1* or *BRCA2* mutation in women without cancer or known family mutations. Among women with first-degree relatives with cancer, the relative risk for cancer has been estimated in meta-analyses as 2.1 (95% CI, 2.0 to 2.2) for breast cancer[43] and 3.1 (95% CI, 2.6 to 3.7) for ovarian cancer.[106] Decisions about referral, testing, and risk-reducing interventions are often based on self-reports of family histories that include type of cancer, relationship within the family, and age of onset. Appropriate decisions rely on family histories that are accurately reported by women and correctly obtained by clinicians.

The accuracy of family cancer history information was determined in studies that validated self-reported family histories with medical records. In one study, a report of breast cancer in a first-degree relative of a healthy individual had a sensitivity of 82 percent, specificity of 91 percent, positive likelihood ratio of 8.9 (95% CI, 5.4 to 15.0), and negative likelihood ratio of 0.20 (95% CI, 0.08 to 0.49).[107] A more recent population-based study in the United States indicated the accuracy of self-reported breast cancer history in a first-degree relative as 64.9 percent sensitivity and 99.0 percent specificity.[108] In this study, the accuracy for first-degree relatives was higher than for second-degree relatives. For ovarian cancer, a report of ovarian cancer in a first-degree relative was less reliable than for breast cancer, and had a sensitivity of 50 percent, specificity of 99 percent, positive likelihood ratio of 34.0 (95% CI, 5.7 to 202.0), and negative likelihood ratio of 0.51 (95% CI, 0.13 to 2.10).[107]

Referral Guidelines

Referral guidelines have been developed by health maintenance organizations,[109] professional organizations,[51,92] cancer programs,[50,110] State and national health programs,[111-113] and investigators[114] to assist nongenetics specialists in identifying women who are at potentially increased risk for BRCA mutations. Although specific items vary among the guidelines, most include questions about personal and family history of BRCA mutations, breast and ovarian cancer, age at diagnosis, bilateral breast cancer, and Ashkenazi Jewish ancestry. Most guidelines are intended to lead to a referral for more extensive genetic evaluations and counseling, not directly to testing. Although guidelines vary, practice and coverage standards in the United States generally follow the NCCN referral criteria for genetic counseling (described in **Appendix**

A1).[50] The effectiveness of this approach in improving breast cancer outcomes has not been evaluated.

General Risk Stratification Models to Predict Individual Risk for Breast Cancer in Primary Care Settings

Although used in clinical settings, general risk stratification models predicting individual risk for breast cancer were not developed to identify women with increased probabilities of BRCA mutations.

A recent systematic review[115,116] included 19 studies[117-137] evaluating 13 risk stratification models to identify women with increased risk for breast cancer (**Table 3**). Models specifically evaluating risk for *BRCA1* and *BRCA2* mutations were outside the scope of this review and were not included.

Most general risk models are based on the Breast Cancer Risk Assessment Tool, also referred to as the Gail model. This model was derived from multivariate logistic regression analysis of identified risk factors for breast cancer,[128] and subsequently modified with Surveillance Epidemiology and End Results data.[126] Subsequent models use a similar approach, but vary in their use of reference standards and included variables. The original Gail model included age, age at menarche, age at first birth, family history of breast cancer in first-degree relatives, number of prior breast biopsies, and history of atypical hyperplasia.[128] Subsequent models include one or more of these variables in addition to other factors (**Table 3**).

Most models accurately predict breast cancer incidence in populations of women. For most models in the studies, the expected numbers of cases of breast cancer closely matched the observed numbers (calibration: estimated/observed [E/O], 0.90 to 1.10).[119,121-124,126,127,129,135,136] However, they are only modestly accurate in predicting breast cancer risk for individuals. In studies, discriminatory accuracy was expressed as concordance statistics, determined by the area under the receiver-operating characteristic curve (c-statistic). Values ranged from 0.55 to 0.65 across the studies,[117-124,126,127,129,131-135] which is comparable to age alone as a predictor.

Familial Risk Stratification Models to Predict Individual Risk for BRCA Mutations in Primary Care Settings

Familial risk stratification models for BRCA-related cancer are primarily intended for use by nongenetics specialists to guide patient referrals to genetic counselors for more definitive evaluations. Several models have been developed and evaluated, including the FHAT, Manchester Scoring System, RST, PAT, and FHS-7. Ten studies describing performance characteristics of these models met inclusion criteria for this review (**Table 4**, **Appendix C5**).[56,138-146] Included studies met criteria for fair or good quality and compared the referral models to validated risk assessment models, including BRCAPRO, Claus, Myriad, BOADICEA, Tyrer-Cuzick, and Penn II. Studies of the RST, PAT, and FHS-7 were published after the previous USPSTF systematic review.

FHAT. The FHAT is a 17-question instrument developed to assist Canadian clinicians in

selecting patients for referral to genetic counseling.[142] The referral threshold is equivalent to doubling the general population lifetime risk for breast or ovarian cancer (22%). In the FHAT, points are assigned according to the number of relatives, third-degree or closer, who are diagnosed with breast, ovarian, colon, or prostate cancer; age at diagnosis; and type of primary cancer and number of primary cancer cases. Patients with scores of 10 or more points warrant referral. FHAT results were compared with Claus and BRCAPRO estimates for 184 women with incident familial and nonfamilial breast cancer.[142] The sensitivity and specificity of the FHAT for a clinically significant *BRCA1* or *BRCA2* mutation were 94 and 51 percent, respectively. This compares with sensitivity and specificity of 74 and 79 percent for a 20 percent threshold for having a clinically significant *BRCA1* or *BRCA2* mutation using BRCAPRO, and 74 and 54 percent using Claus methods. Additional validation studies of the FHAT have replicated its accuracy,[145] and its concordance statistics range from 0.68 to 0.83 across a wide variety of conditions.[144,146]

Manchester Scoring System. The Manchester Scoring System was developed in the United Kingdom to predict *BRCA1* or *BRCA2* mutations at the 10 percent likelihood level.[141] Points are assigned depending on type of cancer (breast, ovarian, pancreatic, or prostate), affected family members, and age at diagnosis. The model provides scores for *BRCA1* and *BRCA2* mutations separately. The scoring system was validated in three sample sets in other regions of the United Kingdom and compared with other existing models. In validation studies, the Manchester model (combined *BRCA1* and *BRCA2*) had 58 to 93 percent sensitivity, 33 to 71 percent specificity, and concordance statistics of 0.75 to 0.80, comparing well with the other models tested.[56,139,141,144,145]

RST. The RST was developed to help primary care clinicians make appropriate referrals for genetic counseling in response to the USPSTF 2005 recommendation.[140] The RST is a clinical scoring tool that uses a checklist of risk information, including breast cancer at age 50 years or younger in self or relatives, ovarian cancer at any age in self or relatives, two or more breast cancer cases after age 50 years on the same side of the family, male breast cancer, and Jewish ancestry. The referral threshold is reached with two or more positive responses. It was designed for simplicity, and is the least complicated model to administer for screening purposes. In an evaluation study, the RST was administered to 2,464 unselected women undergoing screening mammography in a U.S. health care system.[140] Results were compared against validated risk assessment models, including BRCAPRO, Myriad II, BOADICEA, and FHAT. The RST demonstrated a sensitivity of 81 percent, specificity of 92 percent, and concordance statistic of 0.87. A revised model is also available online.[147]

PAT. The PAT was also designed to identify women at increased risk for BRCA-related cancer in U.S. primary care settings.[143] The PAT uses a point scoring system based on information from first-, second-, and third-degree relatives regarding breast cancer onset at ages younger or older than 50 years; ovarian cancer at any age; male breast cancer; and Ashkenazi Jewish ancestry. Performance characteristics were determined in a study of 3,906 women without cancer undergoing screening mammography at a U.S. community hospital.[143] Results were compared against the Myriad II and Gail models. The PAT had optimal sensitivity of 100 percent and specificity of 93 percent at scores of 8 or more. The PAT had a concordance statistic of 0.96, which was much higher than results using the Gail 5-year (0.39) or lifetime estimate (0.59).

FHS-7. The FHS-7 is a seven-question instrument about family history of breast, ovarian, and colorectal cancer.[138] It was developed as a simple instrument for primary care settings for screening and referral purposes. The questions include first-degree relatives with breast or ovarian cancer, any relatives age 50 years and younger with breast cancer, bilateral breast cancer, breast and ovarian cancer in the same person, male breast cancer, two or more relatives with breast and/or ovarian cancer, and two or more relatives with breast and/or colon cancer. A single positive response is the threshold for referral. In an evaluation study in Brazil, the FHS-7 was administered to 9,218 women during routine visits to primary care clinics. Results were compared with Claus, Gail, Tyrer-Cuzick, and Penn II models. The FHS-7 had a sensitivity of 88 percent, specificity of 56 percent, and concordance statistic of 0.96.[138]

Key Questions 2b, 3b. What Are the Benefits and Potential Adverse Effects of Genetic Counseling in Determining Eligibility for Genetic Testing for BRCA-Related Cancer?

Summary

Sixteen new studies evaluated the benefits and harms of genetic counseling, including a systematic review; RCTs; and cohort, case-control, and before-after studies of distress, accuracy of risk perception, and intention for testing. Results indicated that counseling decreases cancer worry, anxiety, and depression; increases the accuracy of risk perception; and decreases intention for mutation testing. Face-to-face counseling was preferred in some studies. Limitations of studies included dissimilar comparison groups and small sizes.

Evidence

Twenty-seven studies met inclusion criteria, including 16 published since the prior review[148-165] and 11 included previously[57-60,62,166-171] (**Table 5**, **Appendix C6**). Studies provided data about distress due to genetic counseling for BRCA-related cancer measured as worry, anxiety, or depression. Additional outcomes included intention for genetic testing and accuracy of risk perception. Results for key questions 2b and 3b are both presented in this section of the review because studies generally provided measures for both benefits and harms.

Eleven studies included in the previous review indicated that breast cancer worry usually decreased after genetic counseling, and women preferred personal contact over computer software or telephone counseling.[57-60,62,166-171] Also, studies showed that measures of anxiety and depression generally decreased or did not differ with counseling.[59,62,166,167,169-171] Risk perception was not well reported in previous studies and results were inconclusive.[57-59,166-171] Studies also showed that women's intention to pursue genetic testing decreased after counseling.[57,58,60]

The new studies include one fair-quality systematic review,[165] seven RCTs (six fair-quality[152,154,155,157,160,164] and one poor-quality[151]), one fair-quality prospective cohort study,[161,162] one good-quality case-control study,[148] and six studies with before-after designs for which quality rating criteria were not available.[149,150,153,156,158,159,163] Limitations of studies included inadequate

reporting of randomization technique,[151,152,154,157,160,164] noncomparable groups at baseline,[151,161,162] and no specified eligibility criteria.[151]

Studies enrolled from 64 to 1,971 women with family histories of breast and ovarian cancer who were seeking genetic counseling and were potentially interested in receiving genetic testing for BRCA mutations. Several studies compared different types of genetic counseling[152,154,155,157,164] and genetic counseling versus no counseling,[148,151,160-162] while others compared outcomes before and after genetic counseling.[149,150,153,156,158,159,163] The types of genetic counseling services provided are summarized in **Table 6**.

Studies used the Cancer Worry Scale (CWS) and the State-Trait Anxiety Inventory (STAI) to measure breast cancer worry; the Hospital Anxiety and Depression Scale (HADS), Impact of Events Scale (IES), General Health Questionnaire (GHQ), and Visual Analogue Scale to measure anxiety and depression; and general Likert scales to measure intention to undergo genetic testing and risk perception. These are described in **Table 7**.

Breast Cancer Worry

No studies reported increases in measures of breast cancer worry after women received genetic counseling; eight studies reported decreases,[150,152-155,157,158,162] while one study reported no changes.[151]

A fair-quality RCT measuring worry with the CWS reported that women who received either in-person or telephone counseling had significant decreases in worry after counseling compared with the control group who did not receive counseling (mean decrease from baseline, 0.90 in-person vs. 0.82 telephone vs. 0.38 none; $p=0.002$).[157] More women in the in-person counseling group felt they could discuss their concerns during counseling sessions compared with women who received telephone counseling (77.4% vs. 67.3%, respectively; $p<0.05$). Fewer women in the in-person counseling group said they would have preferred another type of counseling (14.9% vs. 37.0%, respectively; $p<0.001$).

A fair-quality RCT reported decreases in worry after both group and individual genetic counseling compared with a noncounseling control group (mean change from baseline, -0.7 group vs. -0.9 individual vs. +0.1 none; $p<0.001$).[152] Another study comparing a computer intervention with an in-person counseling session reported significant decreases in both groups after counseling, with no differences between groups.[154] Only one poor-quality RCT reported no significant difference in cancer worry after telephone counseling compared with a control group not receiving counseling, as measured on a three-item, 4-point Likert scale.[151]

A fair-quality prospective cohort study reported that more women receiving counseling experienced decreases in cancer-specific distress, as measured by the IES.[162] The cancer-specific distress of women with counseling decreased more from baseline to 1 year postcounseling (from 52% to 41%) compared with high-risk women referred for mammography with no genetic counseling (from 41% to 35%), or with a random sample from the general population (from 32% to 30%) with no counseling.[162] Although more women who had genetic counseling experienced a decrease in cancer-specific distress, this difference was only statistically significant when

compared with women in the general population (p=0.006).

Similarly, two before-after studies, using a modified CWS, reported reductions in cancer worry after genetic counseling compared with baseline.[153,158] One reported a reduction after 1 month, which became statistically significant after 1 year of followup (mean, 11.6 at baseline vs. 10.9 at 1 month vs. 10.8 at 1 year; p<0.001 for change from baseline to 1 year).[158] While the other reported reductions after 9 months that remained after 6 years, they were not statistically significant (mean, 11.54 at baseline vs. 10.37 at 9 months vs. 10.35 at 6 years; p=0.29), and no statistically significant difference was observed in those who did not receive counseling (mean, 11.29 at baseline vs. 10.39 at 9 months vs. 10.65 at 6 years; p=0.44).[153]

One before-after study (in two publications) using the IES reported that women's levels of worry decreased over time from initial levels, particularly after they were informed of their risks.[149,150] One fair-quality RCT reported significant reductions in cancer worry in women who were at moderate or high risk 6 months after genetic counseling compared with baseline, based on CWS scores.[155] Reductions were also significant when compared with women who only attended initial in-person precounseling sessions.

Anxiety and Depression

No studies reported significant increases in anxiety and depression after receiving genetic counseling; three studies reported significant decreases in anxiety and depression,[154,163,164] while three studies reported no changes.[150,158,162]

A good-quality RCT compared women receiving genetic counseling from a nurse specialist in addition to resources about informing at-risk relatives, a pamphlet, and a videotape versus women receiving the standard care given at the clinic, which was genetic counseling from a specialist nurse with no additional resources.[164] Both groups reported significant decreases in mean anxiety and depression scores, as measured by the HADS, at 2 weeks and 8 months after counseling (p<0.01 over time). However, there were no significant differences between groups at any time point and none of the mean scores reached the clinical threshold (score of ≥8).

Another study reported significant decreases in mean anxiety scores, as measured by the STAI, from before genetic counseling, when scores indicated high anxiety (score >22), to immediately and 6 months after genetic counseling, when scores fell below the threshold for high anxiety (22.22 vs. 18.77 vs. 16.98, respectively; p<0.001).[163] However, in a fair-quality RCT, anxiety scores at baseline indicated high anxiety and significantly increased from baseline to 3 months following counseling (Genetic Risk Assessment in the Clinical Environment [GRACE], 40.00 to 56.28 to 52.15 vs. counseling, 35.73 to 47.78 to 51.19; p<0.01 over time), as measured by the STAI.[154] While participants' scores in the GRACE group improved slightly at followup, they never returned to their baseline levels.

No significant differences in anxiety or depression scores were found in a fair-quality cohort study comparing women receiving genetic counseling with a high-risk reference sample and a random sample from the general population.[162] The number of women meeting clinical thresholds for anxiety and depression, as measured by the HADS, was low (<12% anxiety and

<2% depression). However, slightly more women in the counseling group had moderate levels of distress, as measured by the IES (12% vs. 8%). A before-after study reporting anxiety outcomes from baseline to 1 year after genetic counseling also reported no significant differences, though all mean scores were above the clinical threshold for psychiatric disorders.[158] In another before-after study, no significant changes in women's anxiety or depression scores were detected over time, regardless of their levels of risk.[150] In this study, only baseline scores indicated mild anxiety, and followup scores were below the clinical threshold for anxiety, as measured by the HADS.[150]

Risk Perception

A fair-quality systematic review of 19 studies published before February 2007 reported results of studies of risk perception after genetic counseling.[165] In these studies, risk perception was measured by changes in the proportion of women who accurately perceived their own risk, and by the degree of overestimation or underestimation of risk. Overall, the accuracy of risk perception increased from an average of 42 percent accuracy before counseling to 58 percent after counseling. Women who continued to overestimate their risks did so by approximately 18 percent (range, 6% to 40%), which was an improvement of approximately 8 percent after counseling. Seven studies indicated that counseling that delivered information about family history, heredity, and personal risk estimates positively influenced risk perception accuracy. Three of five studies showed significant improvement in risk accuracy when education about heredity was included, and three of six studies showed an improvement in risk accuracy when facilitating informed decisionmaking and adaptation to personal risk was part of counseling.

Eight studies published since 2004,[152,156-158,160,161,163,169] including four cited in the 2007 published systematic review,[152,156,158,169] were consistent in reporting improved accuracy of breast cancer risk perception after genetic counseling. One study reported less accuracy.[153] These findings differ from the prior USPSTF review, in which results were inconclusive.[57-59,166-171] The recent studies measured risk perception using subjects' self-rated lifetime risk of breast cancer compared with the general population (0- to 100-point scale), lifetime likeliness of developing breast cancer on a 5-point Likert scale, and comparisons between risk estimates of subjects and counselors.

A fair-quality RCT measuring perceived breast cancer risk on a 5-point scale and rating chances of diagnosis from 0 to 100 percent reported that women overestimated their risks of breast cancer by an average of 25 percentage points.[151] The proportion of women underestimating their risks was larger among women with perceived lower risks (40%) than in those who perceived it as the same (16%), higher (10%), or much higher (5%) than the risks of other women ($p=0.009$). Women with the highest overestimations were more likely to improve their accuracy with counseling ($p<0.0001$), although counseling was effective in improving accuracy only in women age 50 years or younger ($p=0.0040$).

A fair-quality RCT reported no differences in risk accuracy between telephone and in-person counseling.[157] Accuracy significantly improved over time for both groups ($p<0.001$), and was better than in a control group that did not receive genetic counseling ($p<0.001$).

A before-after study measured risk perception using a 5-point scale ranging from 1 (chances of breast cancer much lower than the average woman) to 5 (chances much higher than the average woman). There was a significant decrease from baseline to 1 week (mean, 4.29 vs. 3.83; p=0.00) and at 1 week compared with a control group (mean, 3.83 vs. 3.97; p=0.01). However, perception of risk increased at 9 months (mean, 3.99) and after 6 years (mean, 4.08), without returning to baseline levels.[153]

Only one before-after study assessed the accuracy of risk perception for developing ovarian cancer.[159] In this study, all women underestimated their risks of developing ovarian cancer by 5 percent 6 months after counseling.

Intent to Participate in Genetic Testing

Two studies reported decreased intention to undergo genetic testing after genetic counseling.[152, 157] A study comparing telephone counseling versus in-person counseling versus no counseling used a four-question measure to determine women's intentions to pursue genetic testing.[157] Participants' combined baseline scores for their intention to pursue genetic testing was 2.22 and there were no significant differences between groups at baseline. After counseling, the control group had increased intention scores, while the two counseling groups had decreased scores (mean change from baseline, +0.51 control vs. -0.61 in-person vs. -0.52 telephone; p<0.001).

A fair-quality RCT reported decreased interests in genetic testing 6 months after group and individual counseling.[152] Interests in testing for both counseling groups decreased significantly more than in the control group (mean decrease from baseline, 0.7 group vs. 0.6 individual vs. 0.2 control; p<0.01).

Key Question 2c. What Is the Clinical Validity of Genetic Testing for Deleterious Mutations in Women With Increased Risk for BRCA-Related Cancer?

Summary

In the context of this key question, clinical validity is how consistently and accurately BRCA mutation status predicts risk for BRCA-related cancer. This review describes clinical validity using the measures of prevalence and penetrance of BRCA mutations. Thirty-two new cohort, cross-sectional, and descriptive studies were combined with 38 earlier studies for meta-analysis estimates of the prevalence and penetrance of BRCA mutations in various groups of women. Limitations include heterogeneity of studies, differences between laboratory techniques for research and clinical care, lack of studies outside of high-risk populations, bias in estimates from women or families with cancer, and no studies of penetrance in women with test results indicating variants of uncertain significance.

Prevalence is the frequency of BRCA mutations in the population. Estimates of prevalence in high-risk populations overestimate assumptions of prevalence in unselected populations, but

inform an individual's likelihood of carrying a BRCA mutation and candidacy for testing. Estimates of the prevalence of BRCA mutations vary by population: 0.2 to 0.3 percent in unselected women; 1.8 percent for *BRCA1* and 1.3 percent for *BRCA2* in women with breast cancer; 6 percent in women with breast cancer onset at age 40 years or younger; 4.4 percent for *BRCA1* and 5.6 percent for *BRCA2* in women with ovarian cancer; and 13.6 percent for *BRCA1*, 7.9 percent for *BRCA2*, and 19.8 percent for both combined in women with high-risk families. For Ashkenazi Jewish women, prevalence is 2.1 percent in unselected populations and 10.2 percent in those with high-risk families.

Penetrance is the likelihood of developing breast or ovarian cancer for a given BRCA genotype, and is age dependent. Estimates of the penetrance of BRCA mutations differ by test result. In high-risk women with positive test results, risks for breast cancer to age 70 years include 46 percent for *BRCA1* and 50 percent for *BRCA2* when a single family member is tested, and 70 percent for *BRCA1* and 71 percent for *BRCA2* when multiple family members are tested. Risks for ovarian cancer to age 70 years in high-risk women with positive test results are 41 percent for *BRCA1* and 17 percent for *BRCA2* when a single family member is tested, and 46 percent for *BRCA1* and 23 percent for *BRCA2* when multiple family members are tested. Risks for Ashkenazi Jewish women to age 75 years is 34 percent for breast cancer and 21 percent for ovarian cancer.

In women with uninformative negative test results, the SIR for breast cancer is 3.81 (95% CI, 3.06 to 4.75). In women with true negative test results, the SIR for breast cancer is 1.13 (95% CI, 0.81 to 1.58). Estimates for ovarian cancer are highly heterogeneous and cannot be combined in meta-analysis.

Evidence

A total of 32 studies of prevalence and penetrance not included in the prior review met inclusion criteria,[21,172-202] in addition to 38 studies included in the prior review[13,15,16,19,20,46,47,122,188,203-231] (**Appendixes C7** and **C8**). Studies estimated prevalence for high-risk and Ashkenazi Jewish populations and penetrance for BRCA-positive, uninformative negative, and true negative results (**Figure 2**). No studies provided risk estimates for women with variants of uncertain significance. Most studies used a variety of research laboratory techniques to detect clinically significant mutations that differ from the DNA sequencing that is clinically available.

Prevalence

Unselected Populations. No direct measures of the prevalence of clinically significant *BRCA1* or *BRCA2* mutations in the general, nonJewish U.S. population have been published. Models estimate it to be about 0.2 to 0.3 percent.[13-16]

High-Risk Populations. Studies provide prevalence estimates for three different types of high-risk groups: 1) women with early-onset breast or ovarian cancer (e.g., before age 45 years), 2) women with breast or ovarian cancer from selected high-risk cohorts (e.g., consecutive cases from cancer registries or surgical units), and 3) women from high-risk families based on family history of breast and/or ovarian cancer (**Table 8**). Prevalence estimates based on high-risk groups

overestimate prevalence in unselected or general populations.[15] However, women from high-risk groups are the most likely candidates for BRCA testing and identifying them can guide testing decisions within a family.

Early-Onset Breast or Ovarian Cancer. Eleven studies reported prevalence estimates for women with early-onset breast or ovarian cancer.[13,16,174,195,199,204,207,208,218,220,223]

For *BRCA1*, the meta-analysis indicated a prevalence of 4.26 percent (95% CI, 2.61 to 6.87; 10 studies)[13,16,174,195,204,207,208,218,220,223] in women diagnosed with breast cancer at age 40 years or younger, and 5.17 percent (95% CI, 2.39 to 9.59; 2 studies)[13,195] in those diagnosed with ovarian cancer at age 40 years or younger (**Table 1**). For *BRCA2*, prevalence was 2.90 percent (95% CI, 1.35 to 6.14; 5 studies)[13,16,174,195,220] in women diagnosed with breast cancer at age 40 years or younger, and 0.64 percent (95% CI, 0.02 to 3.50) in those diagnosed with ovarian cancer at age 40 years or younger, based on only one study.[195] For *BRCA1* or *BRCA2*, the combined prevalence estimate was 5.98 percent (95% CI, 1.87 to 17.47)[16,208,220] in women diagnosed with breast cancer at age 40 years or younger. Additional estimates are described in **Table 9** and suggest higher prevalence rates in women with younger ages of cancer onset. While subject selection for the youngest age group (≤35 years) in these studies was based primarily on age at diagnosis of breast or ovarian cancer, some studies used family history information to select subjects for the older age group (≤45 years).

High-Risk Cohorts. Results of a meta-analysis of four studies based on data from breast cancer case series indicated a combined prevalence estimate for *BRCA1* of 1.84 percent (95% CI, 0.72 to 4.63).[13,194,204,223] The prevalence of *BRCA2* was 1.31 percent (95% CI, 0.67 to 1.95), based on one study.[13]

Results of a meta-analysis of four studies based on data from ovarian cancer case series indicated a combined prevalence estimate for *BRCA1* of 4.41 percent (95% CI, 2.47 to 7.74),[195,204,216, 228] with substantial heterogeneity among studies (I^2=70%; p=0.006). The prevalence of *BRCA2* was 5.61 percent (95% CI, 4.13 to 7.09), based on one study.[195]

Prevalence was also reported for racial and ethnic minorities in three studies;[195,204,223] however, the studies were small, few mutations were detected, and results were not conclusive.

High-Risk Families. Additional prevalence estimates for women from referral populations with various levels of family history range from 3.66 percent[174] to 30.8 percent[193] for *BRCA1* and from 6.1 percent[174] to 15.4 percent[193] for *BRCA2* in white, nonHispanic, nonAshkenazi Jewish women.

In 11 studies in which recruitment was based on family history of breast and/or ovarian cancer, results of the meta-analysis indicated *BRCA1* prevalence of 13.58 percent (95% CI, 10.09 to 17.07),[174,183,188,193,194,199,200,202,207,211,232] with significant heterogeneity among studies (I^2=86%; p<0.001). Heterogeneity remained high in a sensitivity analysis that excluded an outlier[193] (I^2=89%; p<0.001). Estimates were similar in sensitivity analyses that excluded two studies with mixed populations of race/ethnicity.[46,194] One study reported a *BRCA1* prevalence of 35.71 percent (95% CI, 26.92 to 44.51) in families with two or more cases of ovarian cancer.[212]

For *BRCA2*, meta-analysis results of eight studies in which recruitment was based on family history of breast and/or ovarian cancer indicated a prevalence of 7.90 percent (95% CI, 5.30 to 10.50).[174,183,188,193,194,199,202,211] One study reported a prevalence estimate of 7.14 percent (95% CI, 2.13 to 12.15) in families with histories of two or more cases of ovarian cancer.[212]

For *BRCA1* and *BRCA2* combined, the prevalence was 19.78 percent (95% CI, 12.98 to 26.57).[46, 174,183,188,193,199,200,207,211] In a study in which subjects were ascertained based on family histories of two or more cases of ovarian cancer, the estimate was 42.86 percent (95% CI, 33.79 to 51.92).[212] In a sensitivity analysis excluding an outlier,[193] prevalence decreased to 15.93 percent (95% CI, 9.21 to 22.66), although there was significant heterogeneity (I^2=94%; p<0.001). Estimates were similar in sensitivity analyses that excluded one study with mixed populations of race/ethnicity.[47]

Prevalence was also reported for racial and ethnic groups from referral populations with various levels of family history risk. One study reported a prevalence of 22.7 percent for *BRCA1* and 8.1 percent for *BRCA2* in 110 Hispanic individuals in a hereditary cancer registry.[21] No *BRCA1* or *BRCA2* mutations were detected in three Hispanic individuals tested in another study.[193] Black individuals presenting for BRCA testing in high-risk clinics had a prevalence of 16.3 percent for *BRCA1* and 11.6 percent for *BRCA2*.[193]

Ashkenazi Jewish. Five studies provided estimates of *BRCA1* prevalence in Ashkenazi Jewish populations unselected by personal or family history of breast cancer,[19,20,191,209,214] and six studies provided estimates for *BRCA2* prevalence[19,20,191,209,214,224] (**Table 10**). These studies reported the prevalence of the three founder mutations, including mutations 5382insC and 185delAG in *BRCA1* and 6174delT in *BRCA2*.

Based on the meta-analysis, prevalence for *BRCA1* was 1.2 percent (95% CI, 0.98 to 1.42)[20,209, 214] and for *BRCA2* was 1.17 percent (95% CI, 0.95 to 1.38)[20,209,214,224] (**Table 11**). For *BRCA1* and *BRCA2* combined, prevalence was 2.08 percent (95% CI, 1.28 to 2.88).[20,191,209, 214] There was significant heterogeneity among studies (I^2=89%; p<0.001), with the most recent publication[191] estimating prevalence at about half the rates of previous studies for both *BRCA1* and *BRCA2*. The new study included fewer women with family or personal histories of breast or ovarian cancer compared with other studies (e.g., personal history, 0.8% vs. 8%).[214] Also, secular trends may have influenced prevalence estimates over time. For example, high-risk families who have already been tested may not have responded to advertisements recruiting participants to more recent studies. In a sensitivity analysis that excluded results from the most recent study, prevalence for the founder mutations was 2.46 percent (95% CI, 2.13 to 2.78),[20,209,214] without significant heterogeneity among studies (I^2=0%; p=0.496).

No new studies provided prevalence estimates for Ashkenazi Jews selected for personal or family histories of breast cancer. From the previous review,[1,2] results of the meta-analysis indicated an estimated prevalence of founder mutations of 10.2 percent (95% CI, 4.2 to 22.9), including 6.4 percent (95% CI, 1.1 to 29) for *BRCA1* and 1.1 percent (95% CI, 0.6 to 2.0) for *BRCA2* in women with family histories of breast or ovarian cancer.[19,47,219]

Penetrance

Penetrance is the probability of developing BRCA-related cancer in women who have a given *BRCA1* or *BRCA2* genotype, and is reported as the cumulative risk to a specified age. The meta-analysis results reflect the age parameters and cancer outcomes provided by the studies for positive, true negative, and uninformative negative test results. There were no studies of penetrance in women with variants of uncertain significance.

BRCA-Positive Results in High-Risk Populations. There were significant methodological differences across studies that reported penetrance in women who were *BRCA1*or *BRCA2* mutation carriers. Results are reported separately depending on whether a single person (**Table 11**) or multiple individuals (**Table 12**) in a family were tested.

Eight studies reported breast cancer penetrance based on testing a single individual per family.[13,15,176,187,188,190,195,225] For *BRCA1* mutations, breast cancer penetrance was 46 percent (95% CI, 40 to 51) to age 70 years[13,15,176,188,190] (**Table 13**); for *BRCA2*, penetrance was 50 percent (95% CI, 40 to 60) to age 70 years.[13,15,176,188,190]

Eight studies reported estimates based on testing multiple individuals per family.[172,173,178,185,192,201,206,210] For *BRCA1* mutations, breast cancer penetrance was 70 percent (95% CI, 61 to 79) to age 70 years;[173,178,185,192,201,206] for *BRCA2*, penetrance was 71 percent (95% CI, 59 to 83) to age 70 years.[173,178,192,201,210] Between-study heterogeneity was significant.

Estimates were not combined across the two types of studies because of significant heterogeneity and large differences between estimates with nonoverlapping CIs. A published meta-analysis that combined all types of studies reported breast cancer penetrance in BRCA-positive women to age 70 years as 57 percent (95% CI, 47 to 66) for *BRCA1* and 49 percent (95% CI, 40 to 57) for *BRCA2*.[12] A second meta-analysis that included 22 studies based on case-series unselected for family history reported estimates of 65 percent (95% CI, 44 to 78) for *BRCA1* and 45 percent (95% CI, 31 to 56) for *BRCA2*.[11] This meta-analysis also reported significant between-study heterogeneity. The results of published meta-analyses differ from the results of this review because they included studies of women with Ashkenazi Jewish ancestry or studies in which only Ashkenazi Jewish founder mutations were tested. These populations were excluded from the meta-analysis reported in this review.

Seven studies reported ovarian cancer penetrance based on testing a single individual per family.[13,15,176,188,190,195,225] For *BRCA1* mutations, ovarian cancer penetrance was 41 percent (95% CI, 32 to 49) to age 70 years;[13,15,176,188,190] for *BRCA2*, penetrance was 17 percent (95% CI, 11 to 24) to age 70 years.[13,15,176,188] There was no significant heterogeneity between studies.

Six studies reported estimates based on testing multiple individuals per family.[173,178,192,201,206,210] For *BRCA1* mutations, ovarian cancer penetrance was 46 percent (95% CI, 35 to 57) to age 70 years;[173,178,192,201,206] for *BRCA2*, penetrance was 23 percent (95% CI, 12 to 34) to age 70 years.[173,178,192,201,210] There was significant heterogeneity between studies.

Estimates for ovarian cancer from studies of testing a single person or multiple individuals per

family were very similar and all studies were combined in additional meta-analyses. Combined measures for *BRCA1* mutations include penetrance of 45 percent (95% CI, 37 to 52) to age 70 years and for *BRCA2*, 19 percent (95% CI, 13 to 25) to age 70 years. These estimates are similar to a published meta-analysis that reported penetrance in BRCA-positive women to age 70 years as 49 percent (95% CI, 40 to 57) for *BRCA1* and 18 percent (95% CI, 13 to 23) for *BRCA2*.[12] A second meta-analysis that included 22 studies based on case-series unselected for family history reported estimates of 39 percent (95% CI, 18 to 54) for *BRCA1* and 11 percent (95% CI, 2.4 to 19) for *BRCA2*.[11]

Studies had several limitations and biases. Many studies selected families for analysis based on personal histories of breast or ovarian cancer (probands). Probands and their family members are more likely to have other risk factors for breast or ovarian cancer that may affect penetrance,[233] and breast or ovarian cancer survivors may have a different spectrum of mutations compared with women with newly diagnosed cancer. Penetrance may also depend on the specific mutation within the gene, and only one study reported penetrance estimates stratified by exons.[172]

BRCA-Positive Results in Ashkenazi Jewish Populations. Several studies described in previous sections of this review provided estimates that included Ashkenazi Jewish along with nonAshkenazi Jewish families. Only one new study reported penetrance in Ashkenazi Jewish families specifically, and these estimates combined women who were *BRCA1* and *BRCA2* mutation carriers.[187] Estimates specifically for *BRCA1* and *BRCA2* were provided in the prior review[1,2] and are similar to a published meta-analysis.[234]

In the previous meta-analysis of 10 studies,[203,204,208,209,213,214,217,226,227,231] breast cancer penetrance was 33.7 percent (95% CI, 24.1 to 44.9) to age 75 years in Ashkenazi Jewish women without family histories of breast or ovarian cancer. In those with family histories, penetrance was 34.7 percent (95% CI, 17.6 to 57.0) to age 75 years, based on nine studies.[47,203,208,209,213,214,217,224,226]

From the previous meta-analysis of five studies,[203,205,221,222,225] ovarian cancer penetrance was 21.4 percent (95% CI, 14.9 to 29.7) to age 75 years in Ashkenazi Jewish women without family histories of breast or ovarian cancer. In those with family histories, penetrance was 18.1 percent (95% CI, 7.6 to 37.3) to age 75 years, based on two studies.[47,222]

Uninformative Negative Results

An uninformative negative result can occur for several reasons, including other family members have not been tested; the family carries a BRCA mutation, but it was not detected because of limitations of the test; the family carries a high-risk mutation in another gene; or no high-risk mutation is segregating in the family.

Three studies provided data to estimate the SIR for the development of breast cancer in women with uninformative negative results compared with estimates for the general population (**Table 15**).[182,189,230] Estimates across studies were very similar, ranging from 3.25 to 3.32. The overall estimate for the SIR for breast cancer was 3.81 (95% CI, 3.06 to 4.75) (**Figure 3**).

The same three studies provided data for SIRs for the development of ovarian cancer in women

with uninformative negative results compared with estimates for the general population (**Figure 3**, **Table 14**).[182,189,230] However, these estimates varied widely across studies (0.85 to 11.6), and could not be combined because of significant heterogeneity (I^2=77.4%; p=0.012). This heterogeneity likely reflects the differing ascertainment criteria for study recruitment. The study with the lowest SIR (0.85 [95% CI, 0.23 to 3.12]) included only first-degree relatives of breast cancer cases.[189] The other studies included families with breast cancer (SIR, 3.88 [95% CI, 0.05 to 21.6])[182] and families with at least two first-degree relatives with ovarian cancer (SIR, 11.6 [95% CI, 3.12 to 29.7]).[230]

True Negative Results

A true negative result is possible for individuals who have relatives with cancer and a known BRCA mutation segregating in the family, but their own results are negative.

Ten studies provided data for the meta-analysis of SIRs for the development of breast cancer in women with true negative results compared with estimates for the general population (**Table 15**).[175,177,180,181,184-186,196,198,201] Although SIR estimates ranged from 0.39 to 2.9 across studies, the CI for all studies included the value 1.0, indicating that the estimated risk was not statistically significantly different from that in the general population. The overall combined SIR estimate for breast cancer is 1.13 (95% CI, 0.81 to 1.58) (**Figure 4**).

Most studies included women as true negatives only if their genotype was known by direct testing or could be inferred from the known genotypes of their relatives (e.g., descendants of an individual who tested negative were inferred to also be mutation negative). However, two studies probabilistically assigned genotypes for a portion of women who were untested and whose genotypes were unknown.[180,186] This approach would bias the results toward the null hypothesis of no difference between groups because of misassignment of genotypes. Also, all studies except one[180] used a prospective design that included only newly diagnosed cancer cases after the identification of the family. A study design that includes cancer diagnoses known prior to the identification of the family could falsely increase the risk estimate in relatives because the family may be more likely to seek testing. Bias could also be introduced in studies that did not control for risk-reducing salpingo-oophorectomy in the analysis.[175,177,180,198]

Two studies provided data for the SIR for the development of ovarian cancer in women with true negative results compared with estimates for the general population, although results differed (**Figure 4**, **Table 15**).[198,201] One study reported an SIR of 0 (95% CI, 0 to 12) for *BRCA1* and 0 (95% CI, 0 to 24) for *BRCA2*.[201] A second study reported an increased risk of ovarian cancer with a SIR of 4.6 (95% CI, 1.2 to 11.7).[198] However, this analysis was not conducted prospectively, and its ascertainment of families with strong family histories of breast and ovarian cancer could bias results. For this same study, the SIR estimate for breast cancer decreased from 5.3 (95% CI, 3.5 to 7.7) to 2.1 (95% CI, 0.4 to 6.2) after accounting for prospectively identified breast cancer cases only.

Key Question 3c. What Are the Potential Adverse Effects of Genetic Testing?

Summary

Thirteen cohort, case-control, and before-after studies reported distress measures and risk perception related to BRCA testing. Limitations of studies included high loss to followup and differences between comparison groups. In these studies, breast cancer worry and anxiety increased for women with positive results and decreased for others, although results differed across studies. Risk perception improved after receiving test results.

Evidence

Thirteen new observational studies met inclusion criteria,[235-249] as well as one included previously.[250] Studies provided data about distress due to BRCA testing measured as worry, anxiety, depression, or other psychosocial outcomes (**Table 16**, **Appendix C9**). No studies described other adverse effects of testing, such as false-positive or false-negative results or unnecessary risk-reducing interventions.

Of eight included cohort studies, five met criteria for good-quality,[239,240,242,245,248,250] two for fair-quality,[238,244] and one for poor-quality.[243] The remaining studies included a fair-quality case-control study[236,247] and five studies with before-after designs for which quality rating criteria were not available.[235,237,241,246,249] Limitations of studies included unclear enrollment of the cohort,[238,243,244] high loss to followup,[244] and significant differences between groups at baseline or lack of reporting of baseline participant characteristics.[238,243,244]

The studies varied in size from 17 to 10,244 women; however, the largest study was dominated by the control group (n=10,000).[240] Studies enrolled women with family histories of breast and ovarian cancer seeking genetic testing for *BRCA1* or *BRCA2* mutations. Several studies reported outcomes by mutation status,[236,238-240,242-245,247,248,250] while others compared outcomes before and after genetic testing.[235,237,241,246,249]

Descriptions of the outcome measures are provided in **Table 7**. The studies used the IES, Cancer-Related Worry scale, and CWS-R to measure breast cancer worry; the STAI, IES, Post-Traumatic Growth Inventory, HADS, GHQ, Swedish Short-Form 36-Item Health Survey, Emotional Approach Coping Scale, Multidimensional Fatigue Symptom Inventory-Short Form, Beck Hopelessness Scale, Brief Symptom Inventory, Beck Depression Inventory, and Center for Epidemiologic Studies-Depression Scale to measure anxiety and depression; and the Pittsburgh Sleep Quality Index to measure sleep disturbances.

Breast Cancer Worry

Five studies reported significant increases in breast cancer worry after receiving BRCA test results.[236,241,248-250] A good-quality prospective cohort study used a single question to measure worry on a four-item Likert scale: "During the last 2 weeks, how often did you worry about

developing breast cancer?"[248] Women who were mutation carriers had a significant increase in worry compared with women with true negative or uninformative results 1 and 7 months after disclosure of genetic testing results ($p<0.05$). A fair-quality case-control study found no differences in worry between women who were carriers and women who were noncarriers with high-risk family history, as reported by the Cancer-Related Worry scale.[236] However, when results were combined for both groups, their levels of worry were significantly higher than that of low-risk women who were not tested ($p=0.022$).

A decrease in breast cancer worry for both women who were carriers and women who were noncarriers from baseline to 3 years after disclosure of genetic test results was reported in one study (mean decrease of 1.3 and 2.2, respectively), as measured by the CWS-R.[238] This decrease was significant for women who were mutation carriers ($p=0.03$) and did not differ between groups. A study of 17 women who were mutation carriers reported an increase in breast cancer worry from baseline to 1 year after disclosure of genetic test results and a decrease at 2 years, though scores remained in the mild distress range, as measured by the IES (5.2 vs. 23.8 vs. 17.2; $p=0.05$).[249] In a good-quality cohort study, women who were carriers had higher breast cancer worry, as measured by the IES, compared with women who did not get tested (mean, 16.1 vs. 12.3, respectively; $p=0.045$).[250] One cohort study included a logistic regression bivariate analysis of responses of women undergoing genetic testing. In women without cancer, a positive genetic test result was associated with distress ($p=0.03$), while a negative result was associated with pleasant experiences with the testing process ($p=0.008$).[241]

Anxiety

Two studies reported significant decreases in anxiety scores after women received genetic test results compared with pretest evaluations, based on HADS and IES scores.[235,243] One study reported a significant decrease regardless of mutation status (mean, 5.6 pretest vs. 4.2 at 1 year posttest; $p<0.001$),[235] while the other reported a significant decrease only in women who were noncarriers ($p=0.001$).[243] A fair-quality prospective cohort study reported an increase in anxiety scores over time on the GHQ.[238] In this study, 18 percent of women who were carriers and 17 percent of women who were noncarriers were identified as having anxiety, based on the GHQ 3 years after receiving genetic test results.

Two prospective cohort studies, one good-quality[248] and one fair-quality,[244] reported significantly higher anxiety scores ($p<0.05$ in both studies), as measured by the IES or IES-R, in women receiving a positive genetic test result compared with women receiving a true negative or uninformative test result. Only one of these studies reported results in the moderate distress range on the IES at baseline for all groups; women with a true negative or uninformative test result had scores decreasing to below case threshold by 7 months.[248] One good-quality prospective cohort study reported higher anxiety scores, as measured by the HADS, in women who did not get genetic testing, but had a family history of breast cancer, compared with women who received a positive genetic test result (mean, 5.3 vs. 4.2, respectively; $p<0.05$).[239,240] However, there were no differences between groups in the prevalence of HADS-defined anxiety (24% in both groups).

In a good-quality cohort study, women who were noncarriers had lower anxiety scores on the

STAI at 7 to 10 days followup (mean, 31.6 vs. 38.5 vs. 36.8, respectively; p=0.024) compared with women who were carriers and women who did not get tested, though all scores indicated high anxiety.[250] Four studies reported no differences in anxiety either over time[237,246] or between women who were carriers, noncarriers, and age-matched controls,[236,245] with all below the case cutoff threshold.

Depression

Only one good-quality prospective cohort study reported higher depression scores, as measured by the HADS, in women who did not get genetic testing, but had a family history of breast cancer, compared with women receiving positive BRCA test results (mean, 2.9 vs. 1.7, respectively; p<0.05), though scores did not reach the threshold for clinical depression.[240] Four studies reported no differences in depression either over time[235,246] or between women who were carriers, noncarriers, and age-matched controls,[236,245] with all scores below the case cutoff threshold. In a good-quality cohort study, women who were noncarriers had lower depression scores, as measured by the Beck Depression Inventory, at 4 months followup (mean, 3.6 vs. 6.2 vs. 6.4, respectively; p=0.024) compared with women who were carriers and women who did not get tested, though scores did not reach the threshold for clinical depression.[250]

Sleep Disturbances

A fair-quality case-control study reported more subjective sleep problems, as measured by the Pittsburgh Sleep Quality Index, in women who were carriers compared with women who were noncarriers and age-matched controls (mean, 7.29 vs. 3.94 vs. 4.21, respectively; p=0.013).[247] However, actual sleep duration, latency, and wakefulness, as measured by a wrist monitor, showed no differences between groups.

Other Outcomes

Two small (n=13 and n=7) descriptive case-series studies did not meet eligibility criteria, but provided outcomes relevant to harms to familial relationships.[251,252]

A study of women with true negative test results reported that they were relieved to find out they were not carriers, and several women described feeling particularly reassured that their children would also not have the mutation.[251] Most women (10/13 [67%]) believed their risk of developing breast or ovarian cancer continued to be slightly higher than that of the general population and therefore chose to undergo intensive screening. These women also decreased their communication about mutation status with other family members, especially those who were BRCA-positive.

A study of women with test results indicating the presence of BRCA mutations indicated that women were still grappling with how to live with their carrier status 3 years after disclosure of test results.[252] Some women felt comforted by other mutation carriers in the family, but felt less comforted by the noncarriers. Several women had undergone risk-reducing mastectomy, oophorectomy, or both, and although they felt assured knowing they had done everything they could to reduce their risks of developing cancer, they also felt a loss of their natural breasts and

ovarian hormones. This study also described that women struggled with what to tell their daughters, and how and when to tell them about their mutation status.

Risk Perception

A good-quality prospective cohort study reported an 18 percent increase in the number of women who perceived their risk of breast cancer to be high or very high 5 years after receiving a positive test result for a BRCA mutation versus before receiving results (p=0.016).[242] Women who were noncarriers had a corresponding 47 percent decrease (p<0.001). Also, 20 percent more women who were mutation carriers perceived their risk of ovarian cancer to be high or very high (p=0.007), while 27 percent of women who were noncarriers perceived their risk to be low (p<0.001).

Supplemental Information on the Impact of Genetic Testing on Family Members

Testing for BRCA mutations and disclosure of mutation status can have an impact beyond the patient in the clinician's office. While there are conflicting opinions and rulings on a clinician's ethical and legal duty to warn a patient's family about hereditary disease risk,[253] patients may want to inform family members themselves.[254,255] Studies indicate that most patients feel a responsibility to share their BRCA test results with family members in order to benefit them.[256,257]

A descriptive study of 162 women who were tested for BRCA mutations and 444 relatives indicated that 69.4 percent of tested women shared their test results with at-risk relatives, but more often with female (sisters or daughters) rather than male relatives (brothers and sons) (79.9% vs. 60.4%; p<0.001).[258] More women who tested positive for a BRCA mutation indicated that they had a difficult time explaining the results compared with those with true negative or indeterminate results (14.6% vs. 0% vs. 1.4%, respectively; p<0.001). In addition, women who tested positive were more likely to indicate that they and their relatives were upset when communicating the results compared with women who had true negative or indeterminate results (upset relatives, 52.4% vs. 10.0% vs. 7.4%, respectively; p<0.001; upset patient, 19.5% vs. 0% vs. 1.9%, respectively; p<0.001).

A descriptive study of 115 women who were BRCA mutation carriers reported that all participants disclosed test results to some at-risk relatives, and 88 percent disclosed to all at-risk relatives.[259] However, only 56.8 percent of at-risk relatives subsequently underwent testing, although female relatives were more likely to have testing compared with male relatives (73% vs. 49%, respectively; p<0.01).

Four descriptive studies focused on disclosure of BRCA test results to children. Two small studies indicated that women who were mutation carriers who disclosed their positive test results to their children did so because of their concern about passing along the gene.[260,261] In a study of 13 tested parents and 22 adult children, 77 percent of children felt the disclosure had no significant impact on their emotional health, while 18 percent reported a negative impact.[262] Only 31.8 percent of children had undergone BRCA testing by the time of the survey, but 87

percent of those who had not undergone testing indicated intention to do so. A small study of children ages 11 to 17 years who had mothers with BRCA mutations reported normal scores on anxiety and depression measures (STAI) after hearing of their mother's test results.[263] However, 70 percent of children had mothers with breast cancer, and 57 percent of them had worrisome thoughts about their mother's cancer that affected their feelings at least some of the time. Children who worried about their own cancer risk were more likely to be withdrawn (p=0.02) and have somatic problems (p=0.003), and children who worried about a family member's cancer risk were more likely to have thought problems (p=0.02).

Supplemental Information on the Effects of Direct-to-Consumer Marketing of BRCA Mutation Testing

Until the U.S. Supreme Court decision against DNA patents in June 2013,[264,265] Myriad Genetics held patents on the direct DNA sequencing of *BRCA1* and *BRCA2* mutations and was the exclusive provider of clinical testing in the United States.[266] Myriad allowed other laboratories to conduct direct DNA sequencing for research purposes under strict constraints. Testing for specific known mutations, including previously identified familial types and Ashkenazi Jewish founder mutations, does not require full sequence testing and has been provided by other laboratories. Although other types of genetic tests were patented in the United States, they were nonexclusively licensed. For example, genetic testing for familial colorectal cancer has been available from multiple laboratories.[267]

Myriad launched its initial direct-to-consumer advertising campaign in 2002, targeting potential patients in specific U.S. markets. Advertising included print and electronic media to raise awareness of breast cancer susceptibility genes and encourage women to speak to their physicians about testing. A study to determine the impact of the marketing campaign on patients and physicians was conducted by the Centers for Disease Control and Prevention.[268] This study surveyed randomly selected women from the community as well as family physicians, internists, obstetrician/gynecologists, and oncologists in 2003, comparing two pilot cities with marketing campaigns (Atlanta and Denver) with two control cities that had no marketing (Seattle and Raleigh-Durham).

In pilot cities, women reported increased awareness of the BRCA test ($p<0.05$) and seeing an advertisement for the test ($p<0.05$).[268] Cities did not differ by women's interests in having the test, overall knowledge about genetic testing for breast and ovarian cancer, and if they had ever talked to health care providers or friends/family about the test.[268] Physicians' knowledge did not differ between sites.[269] In pilot cities, there were increases in patients asking about testing (adjusted odds ratio [AOR], 2.1 [95% CI, 1.6 to 2.9]), asking for referrals (AOR, 1.6 [95% CI, 1.1 to 2.4]), and asking directly for testing (AOR, 2.1 [95% CI, 1.5 to 3.0]).[269] In pilot cities, 14 percent of physicians reported an increase in the number of times they ordered BRCA testing in the previous 6 months compared with 7 percent of physicians in control cities (AOR, 1.9 [95% CI, 1.2 to 3.1]).[269]

A telephone survey to assess the impact of direct-to-consumer marketing among women of varying genetic risk was conducted in 315 women enrolled in a registry of families with cancer in Denver, a Myriad marketing site.[270] In this study, high-risk women were more knowledgeable

about the test and more likely to recall media advertisements than low-risk women (60% vs. 39%; p<0.01). Approximately 40 percent of women were interested in testing and 10 percent had increased worry about cancer after viewing the advertisements. However, women across all risk groups overstated the benefits of testing, and equal numbers of high- and low-risk women thought they would benefit from testing (51% vs. 60%).

Another study in Denver surveyed 750 low-risk women, 100 high-risk women, and 180 primary care providers in a managed care organization.[271] Sixty-two percent of patient respondents described exposure to the Myriad advertisements, and 63 percent with exposure reported that the advertisements caused no anxiety. However, some women reported anxiety from the advertisements, including women with high levels of perceived breast cancer risk (AOR, 3.23 [95% CI, 1.35 to 7.73]) and Hispanic women (AOR, 4.19 [95% CI, 1.48 to 11.83]). Women who viewed the advertisements had greater knowledge about testing. Eighty-four percent of physicians reported that the advertisements caused no strain on the doctor-patient relationship, and 80 percent reported no effect on daily clinical practice.

A study of referrals to genetic counseling in the same managed care organization in Denver was compared with a similar organization in a nonmarketed city.[272] Results indicated a 244 percent increase in referrals during the marketing campaign compared with the previous year (p<0.001), although the proportion of referrals of high-risk women declined from 69 percent to 48 percent (p<0.001) during the campaign. No changes in practice were detected in the nonmarketed organization.

Myriad has recently launched a new campaign directly targeting mammography imaging centers and primary care, obstetrician/gynecology, and surgery practices. This strategy involves risk stratification using a simple checklist administered by a physician or nonphysician (e.g., mammography technician), patient consent, and specimen collection with subsequent testing by Myriad. Results are then sent to the ordering physician who follows up as needed. The impact of this approach has not yet been evaluated.

Key Question 4. Do Interventions Reduce the Incidence of BRCA-Related Cancer and Mortality in Women With Increased Risk?

Summary

No trials of the effectiveness of intensive screening for breast or ovarian cancer in women who are BRCA mutation carriers with cancer or mortality outcomes have been published. Six observational studies that reported test characteristics of breast and ovarian cancer screening are described. Overall, the sensitivity of screening for breast cancer with MRI was higher than with mammography (71% vs. 41%), while specificity was comparable (90% vs. 95%). Sensitivity of screening for ovarian cancer was 43 percent for TVUS and 71 percent for serum CA-125 testing, and specificity was 99 percent.

There are no trials of risk-reducing medications specifically in women who are BRCA mutation carriers. A systematic review and meta-analysis of four tamoxifen and two raloxifene placebo-controlled RCTs and one head-to-head trial (Study of Tamoxifen and Raloxifen Trial [STAR]) provided efficacy outcomes for women who had various risk levels. Trials were limited by heterogeneity, and data on doses, duration, and timing of use were lacking. Tamoxifen and raloxifene reduced invasive breast cancer by 30 to 68 percent compared with placebo (7 to 9/1,000 women over 5 years); tamoxifen had a greater effect than raloxifene in the STAR trial (5/1,000 women over 5 years). Reduction was greater in women with family history of breast cancer, but CIs were overlapping. Reduction was significant for ER-positive but not ER-negative breast cancer. Noninvasive breast cancer and mortality were not significantly reduced and did not differ between medications.

Four studies reported descriptive outcomes of risk-reducing mastectomy, one study reported outcomes after salpingo-oophorectomy, and three studies reported outcomes after oophorectomy. Comparison groups varied between studies, although results were consistent. Risk-reducing bilateral mastectomy reduced breast cancer by 85 to 100 percent in high-risk women and women who were mutation carriers; oophorectomy or salpingo-oophorectomy reduced breast cancer 37 to 100 percent and ovarian cancer 69 to 100 percent in high-risk women and women who were mutation carriers. Breast cancer–specific mortality was reduced by 81 to 100 percent after risk-reducing mastectomy in one study and all-cause mortality was reduced by 55 to 100 percent after risk-reducing salpingo-oophorectomy in another study.

Evidence

Intensive Screening

Breast Cancer. No studies from the previous review met inclusion criteria for the updated review. No RCTs of the effectiveness of intensive screening to reduce breast cancer incidence or mortality in women who are at increased risk were identified by searches. Four observational studies, including three prospective studies[273-275] and one retrospective analysis of a prospective study,[276] provided descriptive information about test characteristics of screening modalities (**Table 17**, **Appendix C10**). In these studies, prevalent cases were defined as women with cancer detected on the first round of screening and incident cases were those detected on subsequent rounds.[273,277,278]

The Dutch MRI Screening Study (MRISC), a prospective study, evaluated performance characteristics of breast cancer screening in 2,157 women with 15 percent or higher cumulative lifetime risks of breast cancer, including 594 women who were BRCA mutation carriers.[278] Screening included biannual clinical breast examinations and annual concurrent contrast enhanced MRI and mammography. Digital mammography replaced film during the study period. In this study, women were categorized by mutation status or as high- or moderate-risk based on their family histories and risk factors as applied to modified Claus tables. The average age of participants at study entry was 40 years, and they were followed for a mean of 4 years. There were 97 breast cancer cases (78 invasive, 19 ductal carcinoma in situ [DCIS]) detected in 94 women, including 78 screen-detected cancer cases (15 prevalent, 63 incident), six of which were

detected at risk-reducing mastectomy, and 13 interval cancer cases detected by the woman between screening rounds after initial negative results.

Analysis of results of 75 women with breast cancer indicated significantly higher sensitivity of MRI versus mammography (71% vs. 41%; p=0.0016). Both modalities had high specificity (MRI, 90%; mammography, 95%). Including only women with invasive cancer increased the sensitivity of MRI to 77 percent and decreased that of mammography to 36 percent (MRI vs. mammography, p=0.00005). In women who were *BRCA1* carriers, the sensitivity of MRI was 67 percent versus 25 percent for mammography (p=0.0129), and for *BRCA2*, 69 percent versus 62 percent (p=1.0). Additional comparisons of the sensitivity of modalities between risk groups and by carrier status were not statistically significant. At diagnosis, 80 percent of invasive tumors were 2 cm or less in size, 39 percent were grade 3, and 31 percent were node positive. Women who were *BRCA1* carriers were more likely to experience interval cancer, were younger at diagnosis, and had larger, higher grade tumors at diagnosis compared with other risk groups ($p<0.05$ for comparisons between all subgroups).

The Magnetic Resonance Imaging Breast Screening study was a prospective multicenter study conducted in the United Kingdom that evaluated screening of high-risk women using annual contrast enhanced MRI and mammography.[274] The study enrolled 649 women, including 120 who were BRCA mutation carriers, with a median age at entry of 40 years. The duration of followup varied, but each woman completed at least two annual screenings. Thirty-five cancer cases (29 invasive, six DCIS) were detected, including two interval cancer cases.

The sensitivity of screening all women using mammography plus MRI (94%) was higher than that of using either method alone (MRI, 77%; mammography, 40%), though specificity was reduced when the methods were combined (77%) compared with either MRI alone (81%) or mammography (93%) alone. Including only invasive cancer cases increased MRI sensitivity to 86 percent, reduced mammography sensitivity to 31 percent, and increased the sensitivity of combined methods to 97 percent.

In women who were *BRCA1* mutation carriers or were related to carriers, the sensitivity of screening with MRI alone (92%) or combined with mammography (92%) was higher than that of mammography alone (23%). However, the specificity of MRI alone (79%) or MRI plus mammography (74%) was less than that of mammography alone (92%). In women who were *BRCA2* mutation carriers or were related to carriers, the sensitivity of screening with MRI plus mammography (92%) was higher than that of either method alone (MRI, 58%; mammography, 50%). The specificity of mammography alone (94%) was higher than that of MRI alone (82%) or MRI plus mammography (78%). At diagnosis, invasive cancer cases were an average 15 mm in size, 66 percent were grade 3, and 19 percent were node positive.

A prospective study of 1,325 high-risk Italian women, including 48 who were BRCA mutation carriers, evaluated a breast cancer screening program of mammography, ultrasound, and clinical breast examinations.[273] MRI screening was introduced later in the study for women who were mutation carriers. Screening intervals varied by risk category, age, and modality and ranged between 6 months and 2 years. After a median followup of 55 months, 44 breast cancer cases (28 invasive, 16 DCIS) were detected, including 36 screen-detected cases and eight interval cases. In

four women who were mutation carriers with screen-detected breast cancer, the sensitivity of screening with mammography was 50 percent, ultrasound 75 percent, ultrasound plus mammography 75 percent, and MRI 100 percent. At diagnosis, 61 percent of invasive breast cancer cases were stage I, 64 percent were less than 15 mm in size, and 36 percent were node positive.

A retrospective chart review of a prospective study of 73 women at a single institution in the United States evaluated outcomes after screening using MRI alternating with mammography every 6 months in addition to six monthly clinical breast examinations.[276] Participants were mutation carriers or first-degree relatives at a high-risk cancer clinic with a median age of 44 years who had two screening cycles and were followed for a median of 2 years. Thirteen breast cancer cases (10 invasive, three DCIS) were detected in 11 patients. The sensitivity and specificity of MRI was 92 and 87 percent respectively.

Ovarian Cancer. The previous review included a descriptive study of TVUS screening in 1,610 women with family histories of ovarian cancer and reported that only six of 61 women with abnormal scans had ovarian cancer.[279] A recently published large U.S. screening RCT, the Prostate, Lung, Colorectal, and Ovarian Cancer Screening Trial, reported no mortality benefit of screening average-risk women ages 55 to 74 years with TVUS and serum CA-125 testing compared with usual care after a median followup of 12.4 years.[280] This trial did not report outcomes specifically for high-risk women, including those who were BRCA mutation carriers.

One new descriptive study identified in updated searches reported test characteristics of TVUS and serum CA-125 testing (**Appendix C10**).[281] A European prospective descriptive study evaluated the use of annual CA-125 measurement and TVUS from ages 30 to 35 years in women who were at increased risk. In 459 women who were BRCA carriers with complete data amounting to 1,116 annual screening visits, the sensitivity of serum CA-125 testing alone was 71 percent, TVUS alone was 43 percent, and combined modalities was 71 percent. Corresponding specificities were 99 percent for each modality alone and combined.[281] The positive predictive value was 33 percent for serum CA-125 testing alone, 20 percent for TVUS alone, and 23 percent for combined modalities. Three percent of women had abnormalities detected by one or both screening modalities, and seven ovarian cancer cases were diagnosed.

Risk-Reducing Medications

The previous review identified no trials that evaluated the use of risk-reducing medications specifically in women who are mutation carriers, although the National Surgical Adjuvant Breast and Bowel Project (NSABP P-1) trial of tamoxifen described results for 288 women who were mutation carriers and who developed breast cancer during the trial.[282] Of the eight women with breast cancer who had *BRCA1* mutations, five received tamoxifen and three received placebo (RR, 1.67 [95% CI, 0.32 to 10.70]). Of 11 women with breast cancer and *BRCA2* mutations, three received tamoxifen and eight received placebo (RR, 0.38 [95% CI, 0.06 to 1.56]). Also, 86 percent (6/7) of women with *BRCA1* mutations had ER-negative breast cancer, and 67 percent (6/9) with *BRCA2* mutations had ER-positive breast cancer.

The updated review identified no RCTs that evaluated use of risk-reducing medications

specifically in women who are BRCA mutation carriers, although several RCTs of women who had various levels of risk have been published and summarized in meta-analyses.[116,283] Four placebo-controlled trials of tamoxifen include the NSABP P-1 trial,[284] Royal Marsden trial,[285] Italian Randomized Tamoxifen Prevention Trial,[286] and the International Breast Cancer Intervention Study (IBIS-I).[287] Placebo-controlled trials of raloxifene include the Raloxifene Use for the Heart Trial (RUTH)[73] and the Multiple Outcomes of Raloxifene Evaluation trial, with its followup study, Continuing Outcomes Relevant to Evista.[288] The STAR[289] trial was a head-to-head trial that compared raloxifene with tamoxifen. Inclusion criteria varied between trials, duration of active treatment ranged from 4 to 8 years, and followup ranged from 6 to 13 years. Additional details of the trials are provided in **Appendix C11**. Trials meeting fair-quality criteria were limited by incomplete reporting of followup,[284,285,287] inadequate maintenance of comparable groups,[284,285,287] high (>30%) crossover between groups,[284] and low (<65%) numbers of participants completing all treatment years.[285,286]

Results of a published meta-analysis indicate that women randomized to either tamoxifen (RR, 0.70 [95% CI, 0.59 to 0.82]; 4 trials; 7 cases/1,000 women over 5 years) or raloxifene (RR, 0.44 [95% CI, 0.27 to 0.71]; 2 trials; 9/1,000 women) had reduced risks for invasive breast cancer compared with women randomized to placebo (**Table 18**).[116,283] Updated results of the head-to-head trial indicated greater risk reduction with tamoxifen compared with raloxifene (RR for raloxifene, 1.24 [95% CI, 1.05 to 1.47]; 5/1,000 women).[289] Tamoxifen and raloxifene reduced ER-positive but not ER-negative or noninvasive cancer in placebo-controlled trials, and had similar effects in the STAR trial. All-cause mortality was not reduced in placebo trials and was similar in the STAR trial.

Although no trials evaluated breast cancer incidence specifically in women who were BRCA mutation carriers, all trials evaluated breast cancer incidence by family history, except IBIS-I, in which 97 percent of participants reported some degree of family history.[287] No trials evaluated breast cancer or all-cause mortality outcomes based on familial risk. Trials defined a positive family history as breast cancer in any first-degree relative, except the Royal Marsden trial, which also included second-degree relatives.[285]

In women randomized to tamoxifen, invasive breast cancer risk was further reduced for those with the highest numbers of affected relatives in the NSABP P-1 (RR for no relatives, 0.54 [95% CI, 0.34 to 0.83]; RR for ≥3 relatives, 0.49 [95% CI, 0.16 to 1.34]), although CIs were overlapping[284] (**Figure 5**). The Royal Marsden trial reported similar findings (RR for 0–2 relatives, 0.51 [95% CI, 0.27 to 0.96]; RR for ≥3 relatives, 0.43 [95% CI, 0.19 to 0.95]).[285] The Italian trial reported increased breast cancer risk in women with familial risk using tamoxifen, but the risk estimate was not statistically significant (RR, 1.43 [95% CI, 0.65 to 3.15]).[286]

In women randomized to raloxifene, the Multiple Outcomes of Raloxifene Evaluation and Continuing Outcomes Relevant to Evista trials indicated a greater reduction in breast cancer risk in women with at least one affected first-degree relative (adjusted hazard ratio [HR] for no relatives, 0.55 [95% CI, 0.36 to 0.84]; HR for ≥1 relative, 0.16 [95% CI, 0.06 to 0.42])[288] (**Figure 6**). RUTH indicated no significant effect of family history.[73] The raloxifene trials were primarily designed to determine its effect on osteoporosis and heart disease outcomes and only a minority of participants reported family histories of breast cancer. In the STAR trial comparing

tamoxifen and raloxifene, the effect of family history was not statistically significant.[289]

Risk-Reducing Surgery

Mastectomy. Four studies met inclusion criteria; one from the previous review[290,291] and three from updated searches.[292-294] The prior evidence review included a retrospective descriptive study based on data from patients' medical records.[290,291] In women who underwent risk-reducing mastectomy, breast cancer was reduced by 92 percent in high-risk women compared with sister controls, and by 89.5 percent in moderate-risk women compared with Gail model-based expected incidence.[291] Postmastectomy breast cancer–related deaths were reduced by 81 percent in high-risk women compared with sister controls, and by 100 percent in moderate-risk women compared with expected rates.[290] When the high-risk group was evaluated for BRCA status, none of the 18 women who were mutation carriers developed postmastectomy breast cancer compared with the 4.5 (low-penetrance model) and 6.1 (high-penetrance model) cases that were expected.[295]

Since the prior review, three new prospective studies reported breast cancer outcomes after risk-reducing bilateral mastectomy[292-294] (**Table 19**, **Appendix C12**). Cohort studies met criteria for good-quality[294] or fair-quality,[292] and one descriptive study could not be rated for quality.[293] The fair-quality study was limited by a lack of information about groups at baseline, attrition, and followup.[292]

A study enrolling women from 22 North American and European centers evaluated outcomes for women with BRCA mutations.[292] During 2.7 years of followup, no women who had risk-reducing mastectomies were diagnosed with breast cancer compared with 34 of 585 (5.8%) women who did not have mastectomies.

Another study compared observed with expected breast cancer cases in women with BRCA mutations or who were otherwise considered at high risk. Results indicated that none of 307 women who had bilateral mastectomies were diagnosed with breast cancer, while 21.3 cases were expected.[293] In a study of women who were mutation carriers in Denmark, three of 96 (0.8% per person-year) women who underwent mastectomy were diagnosed with breast cancer versus 16 of 211 (1.7% per person-year) who did not (HR, 0.39 [95% CI, 0.12 to 1.36]), although the study was inadequately powered for this outcome.[294]

Salpingo-Oophorectomy or Oophorectomy. Four studies met inclusion criteria; one from the previous review[229] and three from updated searches.[185,292,296] The previous evidence review included a prospective cohort study of women from families with high ovarian cancer risk who had risk-reducing oophorectomy compared with first-degree relatives who were at similar risk and did not have surgery.[229] Eight ovarian cancer cases occurred in 346 relatives without surgery (2.3%) versus two cases of carcinomatosis in 44 women with surgery (4.5%). Also, 14 cases of breast cancer occurred in relatives without surgery (4.0%) versus three cases in women with surgery (6.8%). Mean followup time was not reported for this study, but person-years ranged from 460 to 1,665. This study met criteria for poor-quality and was limited by a lack of information about groups at baseline, methods for ascertaining exposures and outcomes, followup, and attrition.[229]

One new study of risk-reducing salpingo-oophorectomy[292] and two new studies of oophorectomy[185,296] in high-risk women and women who were mutation carriers met inclusion criteria (**Table 19**, **Appendix C12**). Two studies[185,292] met criteria for fair-quality and one was descriptive.[296] The fair-quality studies were limited by a lack of information about groups at baseline, attrition, and followup.[185,292]

In a prospective cohort study evaluating the outcomes of women who were BRCA mutation carriers at 22 North American and European centers, salpingo-oophorectomy was significantly associated with reduced incidence of ovarian or primary peritoneal cancer (1.3% vs. 5.8%; HR, 0.28 [95% CI, 0.12 to 0.69]).[292] In addition, salpingo-oophorectomy was associated with reduced breast cancer incidence (11.6% vs. 21.6%; HR, 0.54 [95% CI, 0.37 to 0.79]) and all-cause mortality (1.8% vs. 5.9%; HR, 0.45 [95% CI, 0.21 to 0.95]). Reductions in breast cancer–specific (0.5% vs. 2.3%; HR, 0.27 [95% CI, 0.05 to 1.33]) and ovarian cancer–specific mortality (0.7% vs. 2.5%; HR, 0.39 [95% CI, 0.12 to 1.29]) were not statistically significant.

In a prospective cohort study of women from families with known *BRCA1* mutation carriers, oophorectomy was associated with reduced breast cancer incidence (18% vs. 42%; HR, 0.38 [95% CI, 0.15 to 0.97]).[185] Risk reduction was most pronounced in women who had the procedure at a younger age.

A retrospective study compared observed versus expected breast cancer incidence rates in women who underwent oophorectomy.[296] In this study, oophorectomy was associated with reduced risks that were more pronounced in women who were younger than age 50 years and premenopausal at time of surgery (O/E = 1/3.9; RR, 0.26 [95% CI, 0.001 to 0.99]) compared with older postmenopausal women (O/E = 3/5.4; RR, 0.56 [95% CI, 0.11 to 1.33]).

Key Question 5. What Are the Potential Adverse Effects of Interventions to Reduce Risk for BRCA-Related Cancer?

Summary

For breast cancer screening, the adverse effects of intensive screening were described in three studies of physical harms and two studies of anxiety. Results indicated that false-positive rates, unnecessary imaging, and unneeded surgeries were higher in women undergoing intensive screening using MRI versus mammography. Most women experienced no anxiety after breast cancer screening with MRI, mammography, or clinical breast examination. Two studies described harms of ovarian cancer screening; one reported an unneeded diagnostic surgery rate of 55 percent in women who were mutation carriers screened with TVUS and serum CA-125 testing.

There are no trials of risk-reducing medications specifically in women who are BRCA mutation carriers. A systematic review and meta-analysis of four tamoxifen and two raloxifene placebo-controlled RCTs and one head-to-head trial provided adverse event outcomes for women who had various levels of risk. Trials were limited by heterogeneity and data on long-term effects were incomplete. Tamoxifen and raloxifene increased thromboembolic events compared with

placebo (4 to 7/1,000 women over 5 years) and tamoxifen had a greater effect than raloxifene (4/1,000 women over 5 years). Tamoxifen increased endometrial cancer compared with placebo (4/1,000 women over 5 years) and raloxifene (5/1,000 women over 5 years), and increased cataracts compared with raloxifene (15/1,000 women over 5 years). Both caused undesirable side effects in some women, such as vasomotor symptoms.

Case-series and before-after studies described surgical complications, physical effects, and distress measures related to risk-reducing surgery. Studies lacked important outcomes, enrolled small numbers of participants, and had no comparison groups. Some women experienced physical complications of surgery, had postsurgical symptoms, or changes in body image, while some women had improved anxiety.

Evidence

Intensive Screening

Breast Cancer. The previous review identified no studies with information about the harms of intensive screening for breast cancer. The updated review includes three studies, in four publications, reporting false-positive or false-negative results, unneeded procedures, or recall rates (**Table 20**, **Appendix C13**),[274,276,277,297] and two studies about discomfort, pain, or anxiety (**Table 21**, **Appendix C14**).[275,298]

In studies of false-positive or false-negative results, unneeded procedures, or recall rates, women with increased familial risk of breast cancer were recruited from the Netherlands, the United Kingdom, and the United States. Two studies used prospective designs,[274,277,297] and one retrospectively analyzed data from a completed prospective study.[276] Sample sizes ranged from 73 to 1,909, and 18 to 100 percent of participants were BRCA mutation carriers. Mean/median age at entry was 40 to 44 years, and mean/median followup was approximately 2 years or at least two annual scans by the time of analysis.[277,297]

Two studies reported false-positive rates of mammography compared with MRI.[276,297] The Dutch MRISC reported results by screening round, and defined the false-positive rate as the number of positive test results in women who did not have cancer. The false-negative rate was defined as the number of negative test results in women who had cancer. This study reported significantly higher false-positive rates for MRI compared with mammography in the first and subsequent imaging rounds (first round with prior mammography, 14% vs. 5.5%; subsequent rounds, 8.2% vs. 4.6%; $p<0.001$ for both rounds).[297] False-negative results for MRI were lower than for mammography, although numbers were small.

In a study of six monthly breast cancer screenings using MRI alternating with mammography, a result was considered a false-positive if initial findings on screening appeared suspicious, but followup clinical examination, imaging, or biopsy resulted in a final benign assessment. This study reported similar false-positive results for both modalities (MRI, 11%; mammography, 15%), and did not report false-negative findings.[276]

Two studies reported the number of unneeded additional imaging procedures or biopsies.[276,277]

These procedures were considered unneeded because final results were benign and women may never have undergone the procedures if the original screening test had not been performed. The Dutch MRISC determined the need for additional procedures using the Breast Imaging Reporting and Data System (BI-RADS) score from the screening examination. Women with BI-RADS scores of 3 (probably benign) or 0 (need additional imaging evaluation) underwent further evaluations using ultrasound with or without fine-needle aspiration or repeat mammography or MRI. Women with BI-RADS scores of 4 (suspicious abnormality) or 5 (highly suggestive of malignancy) underwent biopsy. Results indicated that 43 percent of women with unneeded biopsies had preceding screening MRI and 28 percent had mammography.[277]

A study that retrospectively analyzed data from a prospectively followed cohort of women who were BRCA mutation carriers or their first-degree relatives found that alternating MRI with mammography screening every 6 months yielded a greater proportion of unneeded imaging procedures (targeted ultrasound) in women screened with mammography (8/11) than with MRI (4/8).[276] However, rates of unneeded biopsies were similar (3/11 for mammography and 2/8 for MRI).

Recall rates for annual MRI were higher than for annual mammography in a descriptive study conducted in the United Kingdom that included women who were mutation carriers (MRI, 11% per woman-year; mammography, 3.9% per woman-year; combined, 13% per woman-year).[274] In this study, 245 of 279 recalls were for benign findings, amounting to 8.5 recalls per cancer detected.

A fair-quality prospective cohort study of women with a mean age of 40.9 years compared discomfort, pain, and anxiety of women undergoing intensive screening with annual mammography, MRI, and biannual clinical breast examinations with women only receiving biannual clinical breast examinations.[275] These outcomes did not differ between groups, as measured by the Medical Outcomes Study 36-Item Short Form (**Table 21**, **Appendix C14**).[275] Most women experienced no anxiety after each type of screening intervention (72% after mammography, 63% after MRI, 78% after clinical breast examination).

In a before-after study of MRI plus mammography, ultrasound, and clinical breast examination, women who were recalled reported higher anxiety scores compared with women who were not recalled at 4 to 6 weeks after screening (8.8 vs. 5.9, respectively; p=0.03).[298] These represent midrange scores, as measured by the HADS. Between-group differences were not significant by 6 months (7.1 vs. 5.9, respectively).

Ovarian Cancer. Two studies met inclusion criteria, one from the previous review[279] and one from updated searches.[281] A prospective descriptive study included in the previous review estimated false-positive results for TVUS when used for screening for ovarian cancer in 1,601 self-referred asymptomatic women with at least one relative who was diagnosed with ovarian cancer.[279] Forty-three percent of women were screened with only one ultrasound. In this study, 3.8 percent (61/1,601) of screened women had suspicious findings on TVUS and were referred to surgery. Cancer was detected in six of 61 referred cases, yielding a false-positive rate of 3.4 percent (95% CI, 2.6 to 4.5). Addition of color flow imaging to ultrasound reduced the number of false-positive cases from 55 to six.

The updated review identified a descriptive study conducted in the Netherlands that reported the number of unneeded diagnostic surgeries associated with ovarian cancer screening using annual serum CA-125 measurements and annual TVUS in 459 women who were BRCA mutation carriers[281] (**Appendix C13**). Abnormalities were detected in 9 percent (40/459) of women with complete data, which included 3 percent (38/1,116) of screening visits, as well as visits for symptomatic complaints. Of 26 diagnostic procedures, cancer was not detected in 67 percent (4/6) following abnormal CA-125 measurement compared with 100 percent (9/9) following abnormal TVUS findings. Combined modalities resulted in an unneeded diagnostic surgery rate of 55 percent (6/11).

Risk-Reducing Medications

No studies evaluated the adverse effects of risk-reducing medications specifically in women who are BRCA mutation carriers, although adverse effects were reported in several RCTs of women who had various levels of risk and have been summarized in meta-analyses.[116,283] Studies include four placebo-controlled trials of tamoxifen,[284-287] two placebo-controlled trials of raloxifene,[73,288] and a head-to-head RCT of tamoxifen versus raloxifene.[289] No adverse effect outcomes were provided specifically by mutation status or family history risk in these trials. Details of the trials are provided in **Appendix C11**. Fair-quality trials were limited by incomplete reporting of followup,[284,285,287] inadequate maintenance of comparable groups,[284,285,287] high (>30%) crossover between groups,[284] and low (<65%) numbers of participants completing all treatment years.[285,286]

In these trials, thromboembolic events were increased for tamoxifen (RR, 1.93 [95% CI, 1.41 to 2.64]; 4 trials; 4 cases/1,000 women over 5 years) and raloxifene (RR, 1.60 [95% CI, 1.15 to 2.23]; 2 trials; 7/1,000 women over 5 years) compared with placebo (**Table 22**).[116,283] Raloxifene caused fewer events than tamoxifen in STAR (RR, 0.77 [95% CI, 0.60 to 0.93]; 4/1,000 women over 5 years).[289] Coronary heart disease events or stroke were not increased in placebo-controlled trials, and did not differ in STAR, although women randomized to raloxifene had higher stroke mortality than placebo in RUTH (RR, 1.49 [95% CI, 1.00 to 2.24]).[299]

Tamoxifen caused more cases of endometrial cancer (RR, 2.13 [95% CI, 1.36 to 3.32]; 3 trials; 4/1,000 women over 5 years), and was related to more benign gynecologic conditions, surgical procedures (including hysterectomy), and uterine bleeding than placebo.[116,283] Raloxifene did not increase risk for endometrial cancer or uterine bleeding.[116,283] In the STAR trial, raloxifene caused fewer cases of endometrial cancer (RR, 0.55 [95% CI, 0.36 to 0.83]; 5/1,000 women over 5 years), hyperplasia, and procedures than tamoxifen.[289] Women using tamoxifen had more cataract surgeries than placebo in the NSABP P-1 trial.[284] Raloxifene did not increase risk for cataracts or cataract surgery compared with placebo, and caused fewer cataracts than tamoxifen in STAR (RR, 0.80 [95% CI, 0.72 to 0.95]; 15/1,000 women).[289]

Most common side effects were vasomotor symptoms and vaginal discharge, itching, or dryness for tamoxifen and vasomotor symptoms and leg cramps for raloxifene. In STAR, raloxifene users reported more musculoskeletal problems, dyspareunia, and weight gain, while tamoxifen users had more gynecological problems, vasomotor symptoms, leg cramps, and bladder control symptoms.[289]

Risk-Reducing Surgery

Mastectomy. The prior review found no studies that met inclusion criteria for the physical harms of mastectomy, though it described a series of 112 high-risk women, including 79 who were mutation carriers, undergoing risk-reducing mastectomy with immediate reconstruction. Twenty-one percent had physical complications, including hematomas, contracture, or implant rupture.[300]

Four descriptive studies about surgical complications, physical effects, or distress related to risk-reducing surgery met inclusion criteria for the updated review.[301-305] Three studies reported information on physical harms of risk-reducing mastectomy.

In a case-series of 122 women who had undergone mastectomy, 64.4 percent reported postsurgical symptoms of numbness, pain, tingling, infection, swelling, breast hardness, bleeding, organizing hematoma, failed reconstruction, breathing problems, thrombosis, and pulmonary embolism.[301] In a study of pain after surgery using the Health-Related Quality of Life tool, there were no significant differences between women's scores obtained before mastectomy and either 6 months or 1 year postmastectomy.[302]

A case-series from the Karolinska University evaluated the physical effects of risk-reducing mastectomy and immediate breast reconstruction in 59 high-risk women.[303] Questionnaires were sent to study subjects at least 2 years after the mastectomy and at least 1 year after any corrective procedures. Eleven patients had postoperative infections and three of them needed implant extraction, four reported hematomas, two needed revisions of flap necrosis, and 35 required corrective procedures. Of the 55 patients who completed the questionnaires, 48 reported postmastectomy pain and discomfort. Of these, five required occasional pain medication and 12 reported that pain affected their daily lives.

Four descriptive studies, in five publications, provided data about distress due to mastectomy to reduce risk for BRCA-related cancer in women who were at increased risk because of family history or BRCA mutation (**Table 23**, **Appendix C14**).[301-305]

A before-after study enrolled 90 high-risk women who had risk-reducing bilateral mastectomies, including 41 percent (37/90) *BRCA1* mutation carriers, 14 percent (13/90) *BRCA2* mutation carriers, 29 percent (26/30) with 50 percent lifetime risk, and 9 percent (98/90) with 25 percent lifetime risk. Results indicated significant decreases in anxiety scores, as measured by the HADS, 6 months and 1 year after surgery compared with before surgery (mean, 3.80 vs. 3.83 vs. 5.59, respectively; p=0.0004).[302,304] The study also reported decreased pleasure in sexual activity, as measured by the pleasure subscale of the Sexual Activity Questionnaire (SAQ), 1 year after surgery compared with 6 months after surgery and before surgery (mean, 11.18 vs. 12.21 vs. 12.28, respectively; p=0.005). Depression scores, body image concerns, or any other portion of the SAQ were not significantly different.

A case-series study of 59 women undergoing risk-reducing mastectomy compared with a reference sample of 1,725 women from a previous study of women considering risk-reducing mastectomy reported no significant differences on any psychological or sexual activity measures.[303] These measures also did not differ in a separate case-series of women undergoing

risk-reducing mastectomy that compared women younger versus older than age 50 years.[301]

A descriptive case-series study, utilizing semistructured interviews, described physical and psychological effects in 13 women 10 years after risk-reducing mastectomy. Most women reported that their family lives were unchanged (8/13 [62%]), although 39 percent (5/13) reported a negative effect on their relationship with their spouse, due to decreased sensation and changed body appearance.[305] Most women considered the cosmetic results positive (10/13 [77%]) and most had discussed breast cancer risk with their daughters (10/11 [91%]).

Salpingo-Oophorectomy. The prior review found no studies that met inclusion criteria, though it included a descriptive study of risk-reducing salpingo-oophorectomy in women who were mutation carriers that included 70 percent of participants with personal histories of breast cancer. Four out of 80 women who underwent salpingo-oophorectomy without hysterectomy experienced complications of wound infection, bladder perforation, small bowel obstruction, and uterine perforation.[79]

Only one new study was identified for the updated review. A before-after study of women who were mutation carriers with a mean age of 47.5 years included 47 women with personal histories of breast cancer and 67 women without. Most women reported significant worsening of vasomotor symptoms ($p<0.01$), as measured by the Menopause-Specific Quality of Life-Intervention scale, and decreased sexual functioning ($p<0.05$), as measured by the SAQ, after risk-reducing salpingo-oophorectomy.[306]

CHAPTER 4. DISCUSSION

Summary of Review Findings

A summary of the findings of the systematic review and meta-analysis is provided in **Table 24**. No studies directly addressed the overarching question regarding the effectiveness of risk assessment, genetic counseling, and genetic testing in reducing cancer incidence and mortality (key question 1).

Several studies of the accuracy of methods to assess familial risk for BRCA-related cancer by nongenetics specialists met inclusion criteria for key question 2a, but no studies met criteria for key question 3a regarding potential adverse effects (**Figure 7**). Although various clinical criteria for referral to genetic counseling have been developed, their accuracy in predicting mutation or cancer risk has not been evaluated. A published systematic review of studies of 13 general breast cancer risk models, such as the Gail model, indicated that they are modest predictors of individual risk (c-statistic, 0.55 to 0.65). Ten studies evaluated the accuracy of five familial risk models that predict risk specifically for BRCA mutations and are intended to guide referrals to genetic counseling. These include the FHAT, Manchester Scoring System, RST, PAT, and FHS-7. Results indicated high accuracy (c-statistic, >0.80), although some models have only been evaluated in single studies. Reference standards and study designs varied across studies, limiting comparisons between models. Risk was most often based on self-reported information; thus, the accuracy of risk models was limited by the accuracy of reported family history in each study.

A new systematic review and several new RCTs and cohort, case-control, and before-after studies of distress, accuracy of risk perception, and intention for genetic testing evaluated benefits and harms of genetic counseling (key questions 2b and 3b). No studies reported increased measures of breast cancer worry after women received genetic counseling; seven studies reported decreased worry, while one study reported no changes. Also, no studies reported significant increases in anxiety or depression after receiving genetic counseling, while three studies reported significant decreases and three reported no changes. In most studies, anxiety and depression scores were below clinical thresholds.

Eight new studies reported that the accuracy of a woman's perception of her breast cancer risk improved after genetic counseling. Two new studies reported decreased intention to undergo genetic testing after genetic counseling. The new studies expand and support the results of 11 studies included in the previous evidence review (**Figure 7**). Studies were limited by differences in their designs and measures, use of dissimilar comparison groups, and enrollment of small numbers of women from specialty clinics.

Key question 2c concerns how consistently and accurately BRCA mutation status predicts risk for BRCA-related cancer (clinical validity). To address this question, 31 new cohort, cross-sectional, and descriptive studies were combined with 39 earlier studies for meta-analysis estimates of the prevalence and penetrance of BRCA mutations in various groups of women (**Figure 8**). Prevalence varied by population, including 0.2 to 0.3 percent in unselected women; 1.8 percent for *BRCA1* and 1.3 percent for *BRCA2* in women with breast cancer; 6 percent in

women with breast cancer onset at age 40 years or younger; 4.4 percent for *BRCA1* and 5.6 percent for *BRCA2* in women with ovarian cancer; and 13.6 percent for *BRCA1*, 7.9 percent for *BRCA2*, and 19.8 percent for combined *BRCA1* and *BRCA2* in women with high-risk families. In Ashkenazi Jewish women, prevalence was 2.1 percent in unselected populations and 10.2 percent in those with high-risk families.

In high-risk women with positive test results, risk for breast cancer to age 70 years included 46 to 70 percent for *BRCA1* and 50 to 71 percent for *BRCA2*; risk for ovarian cancer was 41 percent for *BRCA1* and 17 percent for *BRCA2* (**Figure 8**). In Ashkenazi Jewish women, risk to age 75 years was 34 percent for breast cancer and 21 percent for ovarian cancer. No estimates are available for women with variants of uncertain significance. In women with uninformative negative test results, the SIR for breast cancer was 3.81 (95% CI, 3.06 to 4.75). In women with true negative test results, the SIR for breast cancer was 1.13 (95% CI, 0.81 to 1.58). Estimates for ovarian cancer were highly heterogeneous. Limitations included differences between laboratory techniques for research and clinical care, lack of studies outside of high-risk populations, and bias in estimates from women or families with cancer.

Studies of potential adverse effects of genetic testing (key question 3c) reported that breast cancer worry and anxiety increased for women with positive results and decreased for others, although results differed (**Figure 8**). Risk perception improved after receiving test results. Studies were limited by high loss to followup and differences between comparison groups. Other relevant outcomes were not studied, including false-negative or false-positive results, genetic discrimination, and insurability.

Interventions to reduce the incidence of BRCA-related cancer and mortality in women with increased risk include intensive screening, risk-reducing medications, and risk-reducing surgery (key question 4). No trials evaluated the effectiveness of intensive screening. Although no trials of risk-reducing medications specifically in women who are BRCA mutation carriers were available, several RCTs that included women with various levels of risk are relevant. Tamoxifen and raloxifene reduced invasive breast cancer by 30 to 68 percent compared with placebo, and tamoxifen had a greater effect than raloxifene in a head-to-head trial (**Figure 9**). Results suggested that reduction was greater in women with more relatives with breast cancer, but CIs overlapped. Reduction was significant for ER-positive but not ER-negative breast cancer. Noninvasive breast cancer and mortality were not significantly reduced and did not differ between medications. Trials were limited by heterogeneity and data were lacking on doses, duration, and timing of use.

For high-risk women and women who are mutation carriers, observational studies indicated that risk-reducing bilateral mastectomy reduced breast cancer by 85 to 100 percent, and oophorectomy or salpingo-oophorectomy reduced breast cancer by 37 to 100 percent and ovarian cancer by 69 to 100 percent. Breast cancer–specific mortality was reduced by 81 to 100 percent after risk-reducing mastectomy in one study, and all-cause mortality was reduced by 55 to 100 percent after risk-reducing salpingo-oophorectomy in another. Comparison groups varied between studies, although results were consistent.

Studies of the potential adverse effects of intensive screening for breast cancer (key question 5)

indicated that false-positive rates, unnecessary imaging, and unneeded surgery were higher in women undergoing intensive screening using MRI compared with mammography (**Figure 9**). In one study, most women experienced no anxiety after breast cancer screening with MRI, mammography, or clinical breast examination. Studies of ovarian cancer screening reported high unneeded diagnostic surgery rates after screening with TVUS and serum CA-125 testing.

Trials of risk-reducing medications indicated that tamoxifen and raloxifene increased thromboembolic events compared with placebo and tamoxifen had a greater effect than raloxifene. Tamoxifen increased endometrial cancer and cataracts. Both caused undesirable side effects for some women, such as vasomotor symptoms.

Case-series and before-after studies described surgical complications, physical effects, and distress measures related to risk-reducing surgery. Some women experienced physical complications of surgery, postsurgical symptoms, or changes in body image, while some women had improved anxiety. Studies lacked important outcomes, and the few available studies had small numbers of participants and no comparison groups.

Limitations

Limitations of this review include using only English-language articles and studies applicable to the United States, although this focus improves its relevance to the USPSTF recommendation. Also, the number, quality, and applicability of studies evaluated in the evidence review varied widely. Limitations of studies specific to each key question are briefly described in **Table 24**.

Most studies in this review were conducted in highly-selected samples of women, many with preexisting breast or ovarian cancer, from high-risk groups, or from previously identified kindreds. How the results of studies based on these highly-selected women in research settings translate to a general screening population is unknown. In some cases, data to determine penetrance came exclusively from one study, and when multiple studies were available, they were heterogeneous. Estimates may therefore be unreliable. Most studies used research laboratory techniques to detect clinically significant mutations that differ from the DNA sequencing available clinically. The clinical significance of mutations was determined by each study, and was based on likely functional significance and/or previous evidence of increased cancer risk.

Data are not available to determine the optimal age at which to test and how age at testing influences benefits and harms. Whether testing for BRCA mutations reduces cause-specific or all-cause mortality and improves quality of life is unknown. The harms associated with receiving a false-negative test result or a result indicating mutations of unknown significance are not known.

The systematic review focused on five key questions that limited its scope. Several relevant issues were not addressed. These include the impact of modifier genes on estimates of penetrance[307-311] and estimates for cancer susceptibility genes other than *BRCA1* and *BRCA2*.[312-315] The prevalence of *BRCA1* and *BRCA2* mutations outside of U.S. or European populations was

also not evaluated. Indications for testing in women who have previously been diagnosed with breast or ovarian cancer, or estimation of their risk of contralateral breast cancer,[201,316-319] were not considered because the review focused on women without cancer. For example, women with triple-negative (i.e., HER2-negative, ER-negative, and PR-negative) breast cancer may be more likely to carry *BRCA1* mutations.[320] Also, the review did not consider indications for use of the BRCA Rearrangement Test as an adjunct to standard clinical testing, an emerging practice in the United States. The clinical utility of genetic testing is determined by outcomes following testing. Clinical utility was not explicitly included in the key questions, although the review considered use of risk-reducing interventions after genetic testing. Most studies relating to clinical utility are descriptive case-series and important outcomes are lacking. Finally, men were not included in the scope of this review except as family members of the women under evaluation.

Evidence of harms often relied on observational studies with designs that lacked quality rating criteria. Existing studies show that most women do not experience adverse effects from BRCA risk assessment, counseling, and testing. However, the long-term impact is unknown because most studies followed patients for less than 1 year. Studies used several types of measures and scales that limited comparisons between studies and prohibited meta-analysis. Measures of anxiety or depression often lacked clinical thresholds, and when available, few studies reported results based on the number of individuals who met them. No studies measured genetic discrimination as a harm of testing.

Treatment effects are influenced by several factors that were not evaluated in studies. The effectiveness of salpingo-oophorectomy in reducing risk for breast cancer depends on the age at which the procedure is performed, and it becomes less effective when performed after menopause. However, it is not clear how and when the benefit/harm ratio shifts for individuals facing this decision. Also, the type of risk-reducing intervention selected by women who are mutation carriers may depend on the specific mutation; for example, women with *BRCA1* mutations have a higher risk of ovarian cancer than those with *BRCA2* mutations. Medications are most effective in reducing risk for ER-positive breast tumors, although they have not been specifically evaluated in women with BRCA mutations. The proportion of ER-positive tumors varies from 28 percent in women with *BRCA1* mutations to 63 percent in women with *BRCA2* mutations. How these factors influence patient decisionmaking and eventual clinical outcomes is unknown.

Emerging and Future Research

In order to determine the appropriateness of risk assessment and testing for BRCA mutations in primary care, more information is needed about mutation prevalence and impact in the general population. Research has focused on highly-selected women in referral centers and generally reported short-term outcomes. Issues such as access to testing; effectiveness of screening approaches, including risk stratification; use of system supports; and patient acceptance and education require additional study. Who should perform risk assessment and genetic counseling services, how it should be done, and what skills are needed are unresolved questions. Trials comparing types of providers and protocols could address these issues. What happens after patients are identified as high-risk in clinical settings is also unknown. The consequences of

genetic testing for individuals and their relatives require more study. Well-designed investigations that use standardized measures and enroll subjects who reflect the general population, including minority women, are needed.

An expanded database or registry of patients who receive genetic counseling and testing for BRCA mutations would provide essential information about predictors of cancer, response to interventions, and other modifying factors. Traditionally, all clinical testing through direct DNA sequencing in the United States was done by a single private laboratory, and patient data were inaccessible. Developing a centralized accessible database with key variables to address these issues as testing practices change in the wake of the recent U.S. Supreme Court decision on DNA patents[265] would be a major advance in this field. Additional data from women of varying socioeconomic, racial, and ethnic groups are needed. Currently available risk prediction tools and interventions may not apply to these populations.

Additional research on interventions is needed. Without effectiveness trials of intensive screening, practice standards have preceded supporting evidence. For example, while intensive screening with annual TVUS and serum CA-125 testing is recommended for high-risk women, there are no trials of screening effectiveness, and a descriptive study of 3,532 European women who were at increased risk of ovarian cancer, receiving TVUS and serum CA-125 testing, and followed for up to 16 years indicated no stage shifts in disease incidence.[321] Trials of risk-reducing medications in women who are mutation carriers that include aromatase inhibitors, evaluation of the effect of age at intervention on outcomes, and measurement of long-term outcomes are also needed. Comparisons of salpingo-oophorectomy versus more limited surgery would inform current practice. Studies of factors related to acceptance of risk-reducing interventions based on genetic information would be useful, such as determining if cancer incidence in relatives is reduced because they adopt risk-reducing interventions. This information could improve patient decisionmaking and lead to better health outcomes.

Conclusions

Risk assessment by nongenetics specialists using familial risk models to determine individual risks for BRCA mutations can accurately guide referrals for genetic counseling. Comprehensive risk evaluations by genetic counselors provide estimates of individual risks for mutations and identify optimal candidates for genetic testing. Genetic counseling reduces distress, improves patients' risk perception, and reduces their intentions for genetic testing. Results of genetic testing provide estimates of an individual's chances of developing BRCA-related cancer depending on the specific test results. Women with positive test results have a 34 to 71 percent chance of developing breast cancer and 17 to 41 percent chance of developing ovarian cancer by age 70 years. Estimates for women with variants of uncertain significance are not available. Women with uninformative negative results have nearly a four-fold increase in risk for breast cancer; those with true negative results have no increased risk for breast cancer, while estimates for ovarian cancer are uncertain.

Although intensive screening for breast and ovarian cancer with MRI, TVUS, and serum CA-125 testing are recommended by experts for women who are mutation carriers, their effectiveness has

not been evaluated. Intensive breast cancer screening with MRI increases sensitivity, but also causes more false-positive results and procedures; screening for ovarian cancer is not accurate and leads to more procedures. Tamoxifen and raloxifene reduce risk for breast cancer in women with varying levels of risk, but increase risk for thromboembolic events. Tamoxifen also increases risk for endometrial cancer. Risk-reducing mastectomy and salpingo-oophorectomy are effective in reducing breast and ovarian cancer in women who are mutation carriers and high-risk women.

The process of familial risk assessment by nongenetics specialists, referral and evaluation by genetic counselors, genetic testing, and use of intensive screening and risk-reducing medications and surgeries is complex. Each step of the pathway requires careful interpretation of information, consideration of future risks, and shared decisionmaking before moving on to the next step. Services must be well integrated and highly individualized in order to optimize benefits and minimize harms for patients as well as their families. Additional studies are necessary to better inform practice.

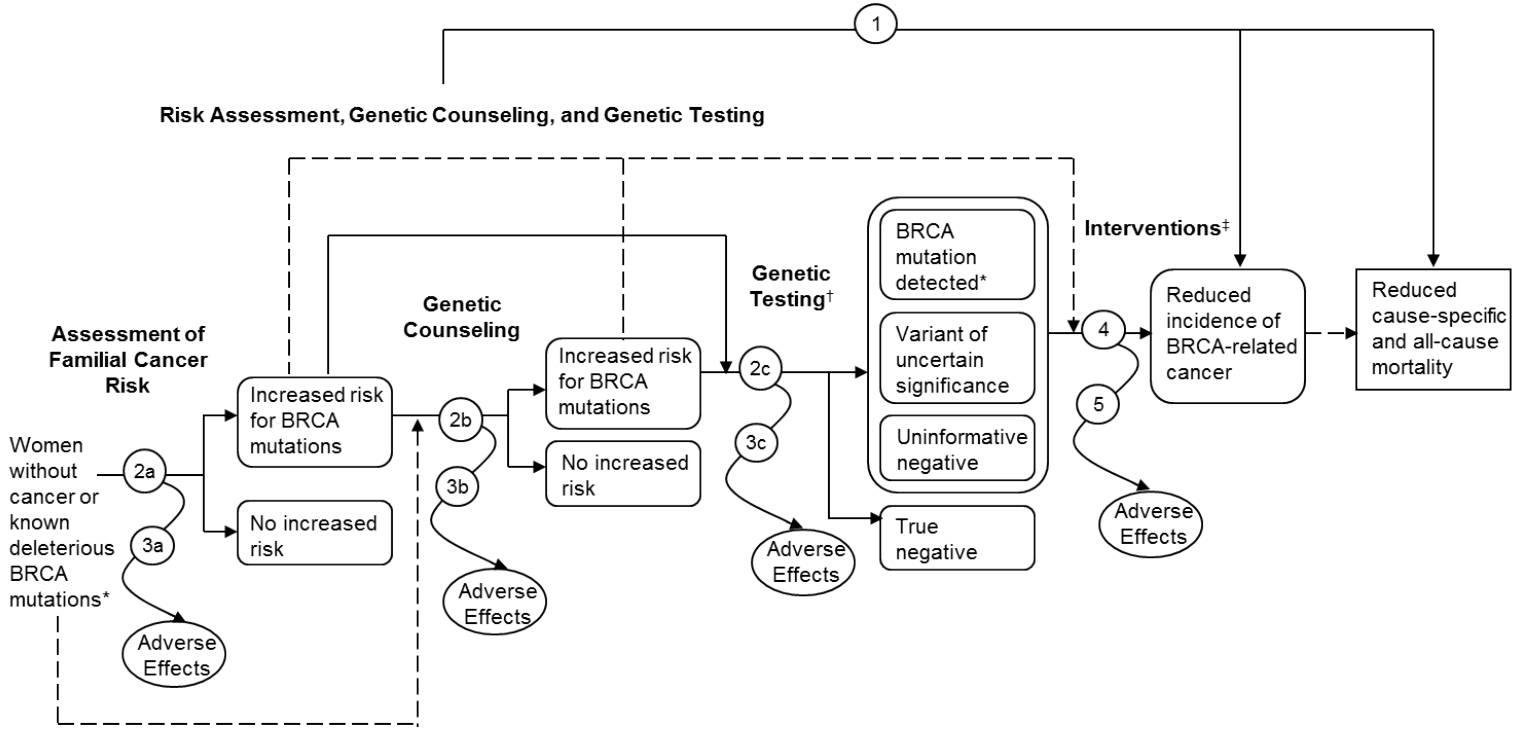
Figure 1. Analytic Framework and Key Questions



Key Questions

1. Does risk assessment, genetic counseling, and genetic testing lead to reduced incidence of BRCA-related cancer and reduced cause-specific and all-cause mortality?
2a. What is the accuracy of methods to assess familial cancer risk for BRCA-related cancer when performed by a nongenetics specialist in a clinical setting?
2b. What are the benefits of genetic counseling in determining eligibility for genetic testing for BRCA-related cancer?
2c. What is the clinical validity of genetic testing for deleterious mutations in women with increased risk for BRCA-related cancer?
3. What are the potential adverse effects of a) risk assessment, b) genetic counseling, and c) genetic testing?
4. Do interventions reduce the incidence of BRCA-related cancer and mortality in women with increased risk?
5. What are the potential adverse effects of interventions to reduce risk for BRCA-related cancer?

* Clinically significant mutations of *BRCA1*, *BRCA2*, or related syndromes.
† Testing may be done on the unaffected woman, her relative with cancer, or relative with highest risk, as appropriate.
‡ Interventions include increased early detection through intensive screening (earlier and more frequent mammography, breast magnetic resonance imaging), risk-reducing medications (tamoxifen, raloxifene), and risk-reducing surgery (mastectomy, salpingo-oophorectomy).

Uninformative negative test = no known mutation in relatives, none detected in patient; True negative test = known mutation in relatives but none detected in patient.

Figure 2. Included Studies of Prevalence and Penetrance

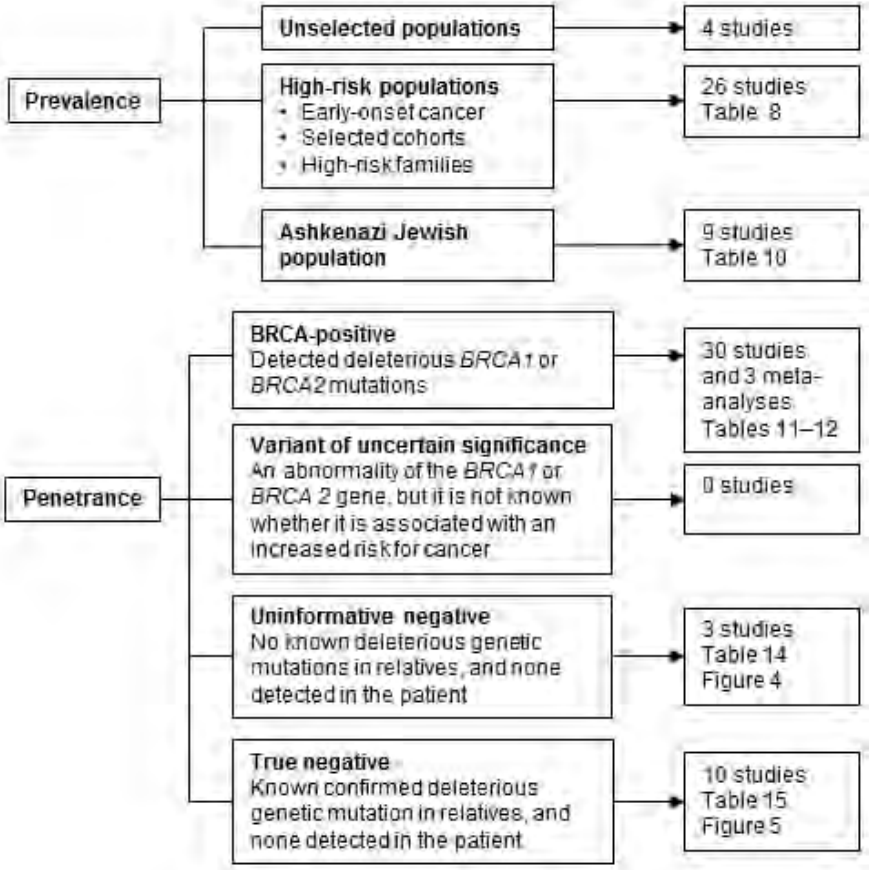


Figure 3. Meta-Analysis of Studies of Breast and Ovarian Cancer Incidence in Women With Uninformative Negative Results

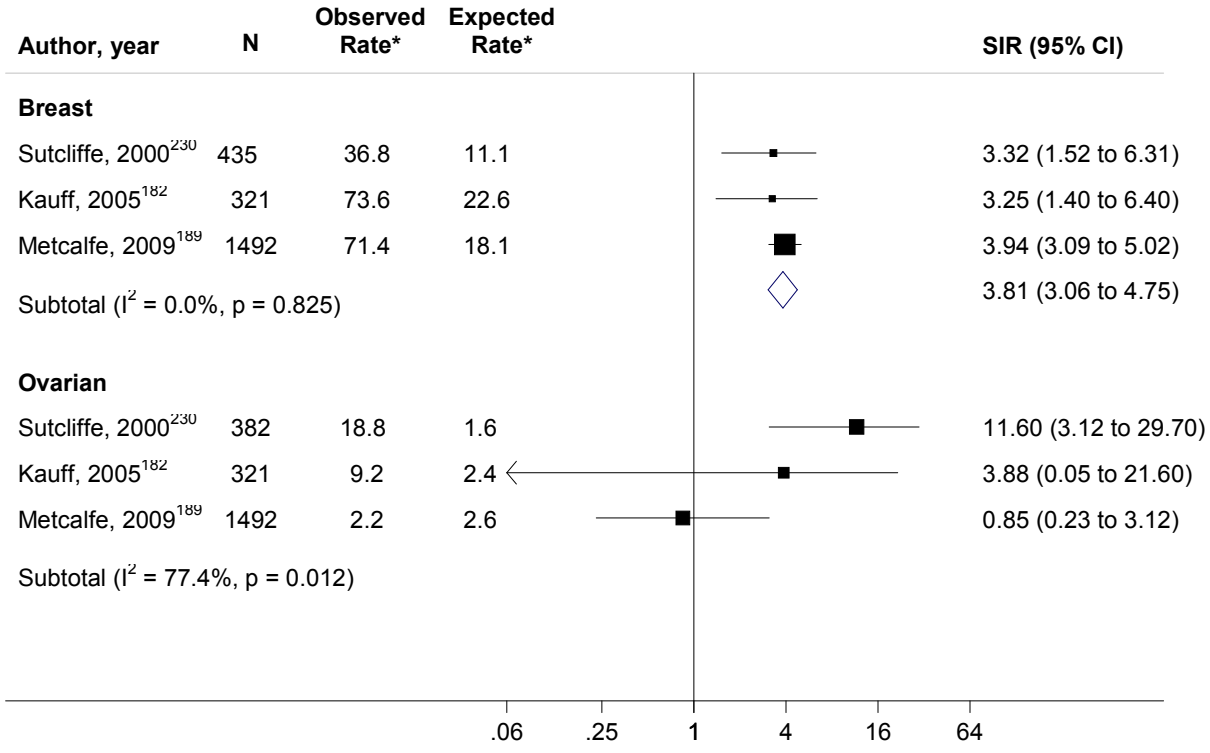
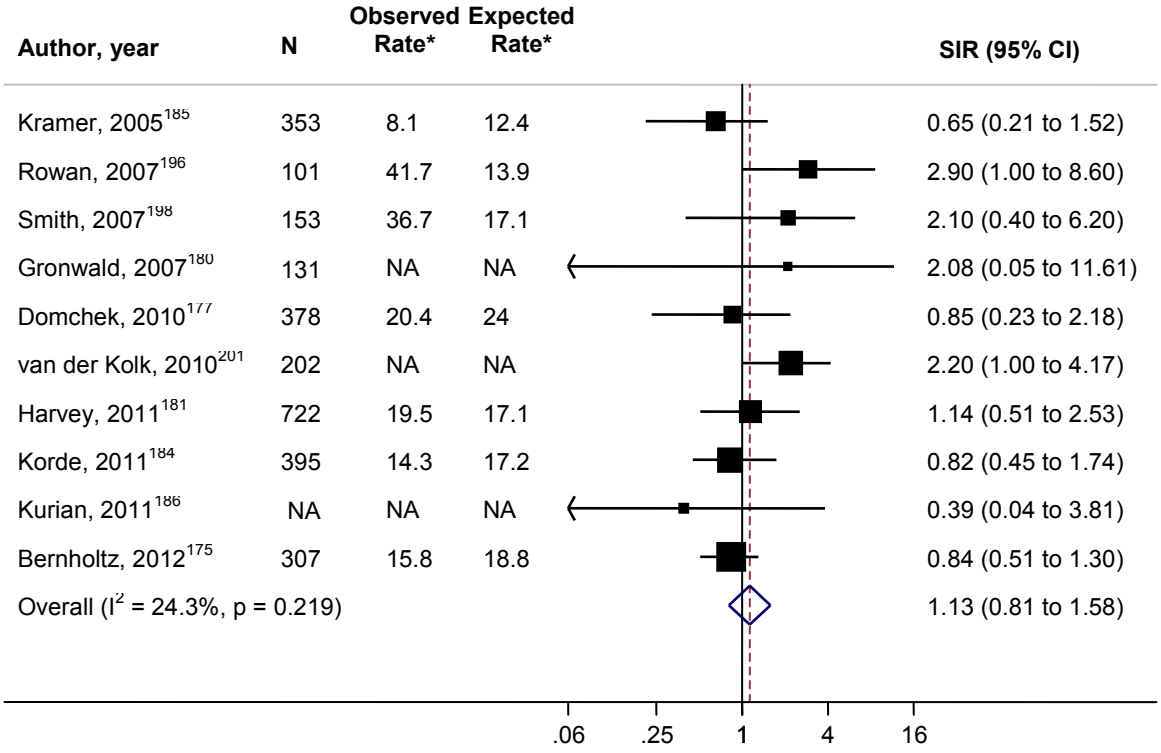


*Per 10,000 person-years.

Abbreviations: CI = confidence interval; SIR = standardized incidence ratio.

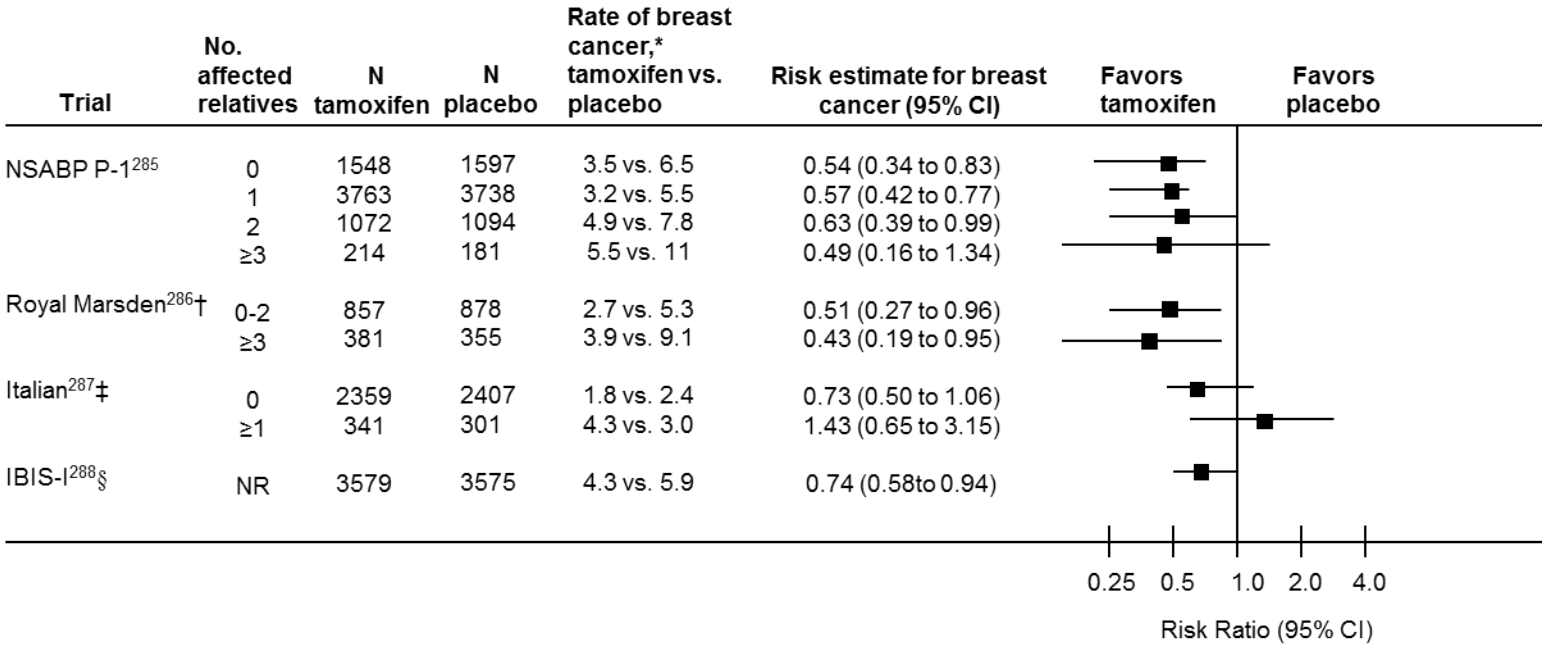
Figure 4. Meta-Analysis of Studies of Breast Cancer Incidence in Women With True Negative Results



*Per 10,000 person-years.

Abbreviations: CI = confidence interval; NA = not applicable; SIR = standardized incidence ratio.

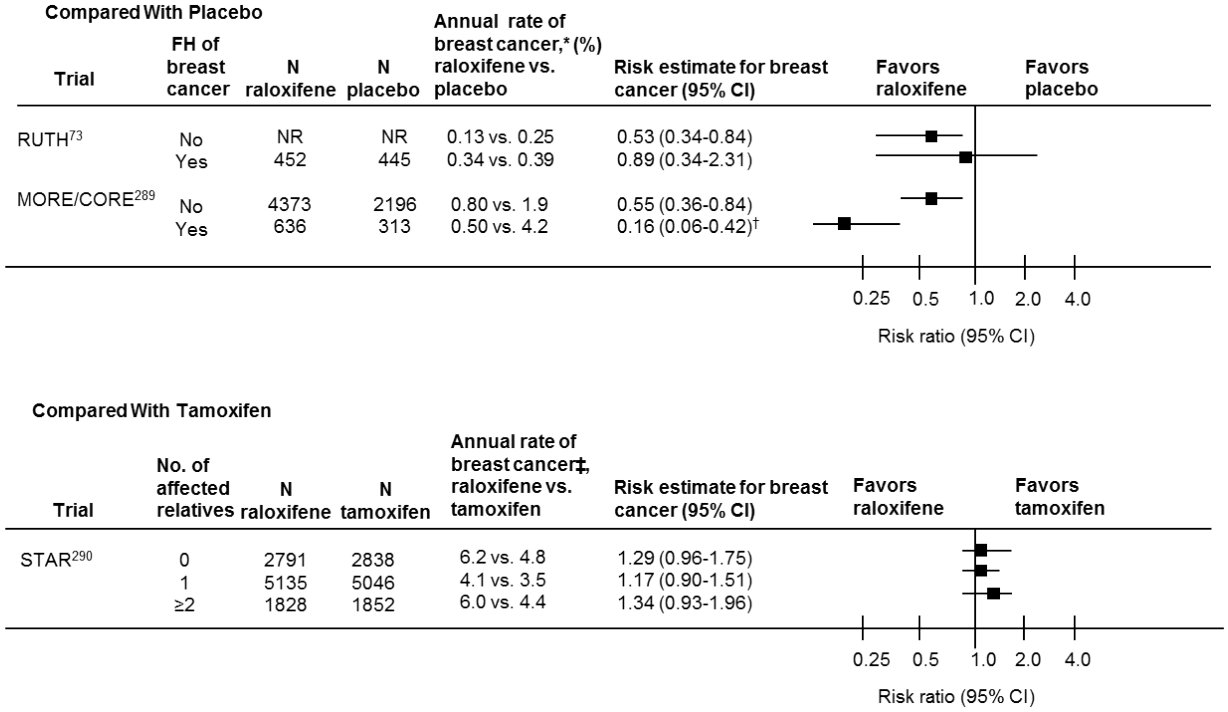
Figure 5. Invasive Breast Cancer Risk Reduction With Tamoxifen Use, by Family History



* Per 1,000 women-years.
† Analysis restricted to ER-positive tumors.
‡ Type of breast cancer not reported.
§ Results not presented by family history (97% of participants had some family history).

Abbreviations: CI = confidence interval; IBIS-I = International Breast Cancer Intervention Study; Italian = Italian Randomized Tamoxifen Prevention Trial; NSABP P-1 = National Surgical Adjuvant Breast and Bowel Project P-1 Trial.

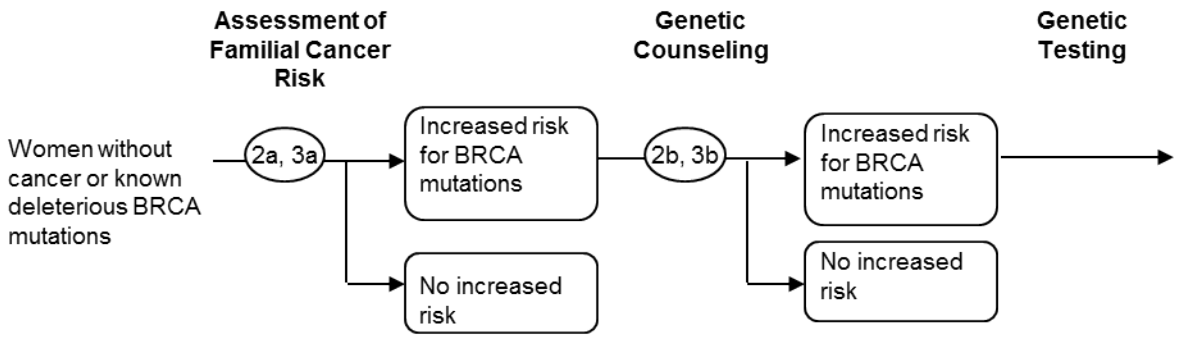
Figure 6. Invasive Breast Cancer Risk Reduction With Raloxifene Use, by Family History



* Per 10,000 women-years.
† Adjusted for age, estradiol level.
‡ Per 1,000 women-years.

Abbreviations: CI = confidence interval; CORE = Continuing Outcomes Relevant to Evista Trial; FH = family history; MORE = Multiple Outcomes for Raloxifene Evaluation Trial; NR = not reported; RUTH = Raloxifene Use for the Heart Trial; STAR = Study of Tamoxifen and Raloxifene Trial.

Figure 7. Summary of Key Questions 2a, 3a and 2b, 3b

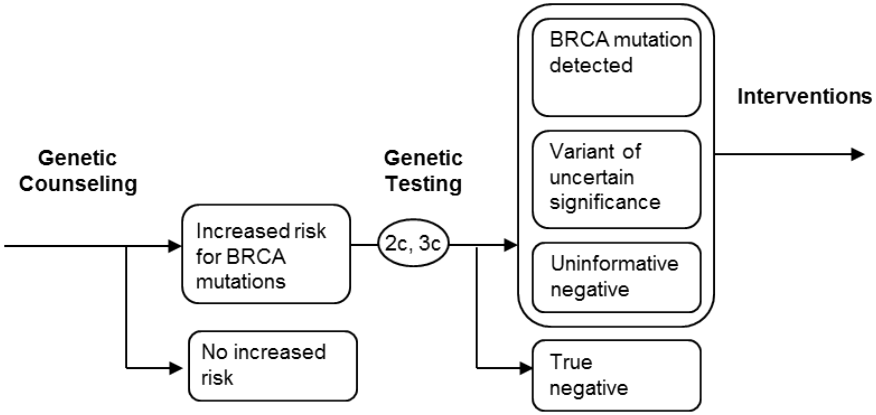


KQ 2a. Accuracy of Risk Assessment	
Risk Models	**Discriminatory Accuracy (c statistic)**
Referral criteria	No studies
General risk models	0.55–0.65 for breast cancer risk; models do predict mutation risk
Family history models	>0.80 for mutation risk
KQ 3a. Adverse Effects of Risk Assessment	
No studies	

KQs 2b, 3b. Benefits and Adverse Effects of Genetic Counseling			
	Number of Studies		
Measure	**Increase**	**Decrease**	**NS**
Breast cancer worry	0	8	9
Anxiety	0	5	8
Depression	0	1	6
Risk accuracy	15	2	5
Intention to test	1	4	0

NS = differences between counseled/noncounseled groups or before/after counseling are not statistically significant.

Figure 8. Summary of Key Questions 2c and 3c



KQ 2c. Clinical Validity of Genetic Testing

Population	Mutation Prevalence
Unselected	0.2%–0.3%
High-risk	
Breast or ovarian cancer onset ≤40 yrs	*BRCA1*: 4.3% *BRCA2*: 2.9% Combined: 6.0%
Breast cancer cohort	*BRCA1*: 1.8% *BRCA2*: 1.3%
Ovarian cancer cohort	*BRCA1*: 4.4% *BRCA2*: 5.6%
Family history of breast or ovarian cancer	*BRCA1*: 13.6% *BRCA2*: 7.9% Combined: 19.8%
Ashkenazi Jewish	
Unselected	*BRCA1*: 1% *BRCA2*: 1% Combined: 2.1%
Family history of breast or ovarian cancer	*BRCA1*: 6.4% *BRCA2*: 1.1% Combined: 10.2%

Test Result	Chance of Cancer (mutation penetrance)
Positive	% to age 70 or 75 yrs
1 person tested	*BRCA1*: 46% BC; 41% OC *BRCA2*: 50% BC; 17% OC
>1 person tested	*BRCA1*: 70% BC; 46% OC *BRCA2*: 71% BC; 23% OC
Ashkenazi Jewish	Combined: 34% BC; 21% OC
Variant of Unknown Significance	No studies
Negative	Standardized incidence rate
Uninformative	Breast: 3.81 (3.06–3.32) Ovarian: 0.85–11.6
True	Breast: 1.26 (0.79–2.01) Ovarian: 0–4.6

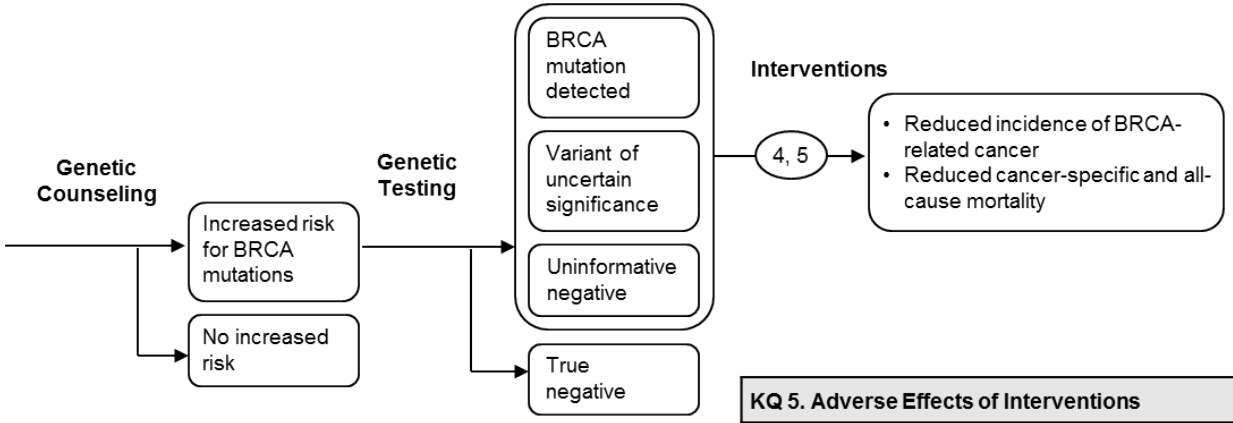
KQ 3c. Adverse Effects of Genetic Testing

Measure	Number of Studies		
	Increase	Decrease	NS
Breast cancer worry	4	1	0
Anxiety	5	3	4
Depression	1	1	4

NS = Differences between counseled/noncounseled groups or before/after counseling are not statistically significant.

Abbreviations: BC = breast cancer; OC = ovarian cancer.

Figure 9. Summary of Key Questions 4 and 5



KQ 4. Benefits of Interventions	
Intervention	**Risk Reduction**
Intensive Screening	No effectiveness studies
Risk-Reducing Medications	
Invasive breast cancer	30%–68%*
Ovarian cancer	No significant reduction
Mortality	No significant reduction
Risk-Reducing Surgery	
Breast cancer	RRM: 85%–100%; RRSO: 37%–100%†
Ovarian cancer	RRSO: 69%–100%
Mortality	RRM: 81%–100% breast cancer; RRSO: 55%–100% all-cause

KQ 5. Adverse Effects of Interventions	
Intervention	**Rates**
Intensive Screening (per episode or year)	
False-positive	4.6%–15% mammogram; 8.2%–14% MRI; 3.4% TVUS
Recall	3.9% mammogram; 11% MRI
Unneeded biopsy	27%–28% mammogram; 25%–43% MRI; 100% TVUS‡; 67% CA-125‡
Risk-Reducing Medication (over 5 years)	
Venous thrombosis	0.4%–0.7%
Endometrial cancer	Tamoxifen: 0.4%
Risk-Reducing Surgery	
Complications	RRM: 3%–59%; RRSO: no studies
Symptoms	RRM: 64%–87%; RRSO: no studies
Quality of life	RM: decrease anxiety; sexual RRSO: decrease sexual

* Risk reduction for all women; analysis by family history was similar.
† Includes studies of oophorectomy alone.
‡ Includes some women with symptoms.

Abbreviations: CA-125 = cancer antigen-125; MRI = magnetic resonance imaging; RRM = risk-reducing mastectomy; RRSO = risk-reducing salpingo-oophorectomy; TVUS = transvaginal ultrasound.

Table 1. Types of Clinical Testing for BRCA Mutations in the United States[96]

Test	Description	Approximate cost (U.S. $)*
Comprehensive testing	Gene sequencing of the entire length of both *BRCA1* and *BRCA2* and a five-site rearrangement panel of specific large-scale rearrangements.	>$3000
Single site testing	One specific gene mutation when the mutation in the family has already been identified.	$475
Multisite panel	Three specific gene changes common among Ashkenazi Jewish ancestry.	$575
BRCA Rearrangement Test	Large-scale rearrangements within the BRCA genes that would not have been detected through comprehensive testing.	$700

*Reflects costs prior to the recent U.S. Supreme Court decision against DNA patents.

Table 2. Recommendations of Other Groups

Organization, year	Recommendations
American Society of Clinical Oncology, 2010[327]	ASCO recommends genetic testing when: 1) there is personal or family history suggestive of genetic cancer susceptibility, 2) the test can be adequately interpreted, and 3) the results will aid in diagnosis or medical management of the patient or family members at hereditary risk of cancer. ASCO recommends genetic testing only when pre- and post-test counseling is included.
American Congress of Obstetricians and Gynecologists, 2009[323]	For patients who are likely to have hereditary breast and ovarian cancer syndrome, ACOG recommends further genetic risk assessment for women who have more than a 20%–25% chance of having an inherited predisposition to breast or ovarian cancer. ACOG also suggests genetic risk assessment may also be appropriate for patients with a 5%–10% chance of having hereditary risk. Recommended screening and prevention plans are based on individual risk factors and family history.
American Society of Human Genetics, 1994[322]	Testing should initially be offered and performed on an investigational basis by appropriately trained health care professionals who have a therapeutic relationship with the patient and are fully aware of the genetic, clinical, and psychological implications of testing, as well as of the limitations of existing test procedures. Linkage analysis is recommended for select high-risk families, if it will provide for more refined counseling than is currently available from family history alone. It is premature to offer population screening, until the risks associated with specific *BRCA1* mutations are determined.
National Comprehensive Cancer Network, 2012[50]	NCCN recommends risk assessment and counseling if the hereditary breast and/or ovarian cancer syndrome testing criteria are met. Genetic testing is recommended if criteria are met (see **Appendix A1**).
European Society for Medical Oncology, 2011[324]	In all cases in which a patient may be referred for BRCA testing, the ESMO Guidelines Working Group recommends informed consent and genetic counseling be completed first. Carriers should be encouraged to advise close family members to obtain genetic counseling.
National Society of Genetic Counselors, 2012[326]	Genetic testing should be offered to individuals with a personal or family history suggestive of an inherited cancer syndrome; when the test can be adequately interpreted; if testing will influence medical management of the patient or relatives; when potential benefits outweigh potential risks; if testing is voluntary; and when the individual seeking testing or their legal proxy can provide informed consent.
Society of Gynecologic Oncologists Education Committee, 2007[325]	The SGO Education Resource Panel for Hereditary Cancers believes that individuals with a personal risk of having an inherited predisposition to cancer of greater than approximately 20%–25% should undergo genetic risk assessment. It also believes that it is reasonable to offer genetic risk assessment to any individual with greater than approximately 5%–10% chance of having an inherited predisposition to cancer. Genetic testing for cancer predisposition requires informed consent that should include pretest education and counseling concerning the risks, benefits, and limitations of testing, including the implications of both positive and negative genetic test results.

Table 3. Risk Stratification Models

Model	Included variables						Calibration expected/observed cases (95% CI)*	Discriminatory accuracy c-statistic (95% CI)*
	Age, *y*	Menarche age, *y*	Age at birth of first child, *y*	First-degree relatives with breast cancer, *n*	Previous breast biopsy, *n*	Other factors		
Gail Model Variations								
Gail-2 5-year risk	<50; ≥50	≥14; 12–13; ≤12	<20; 20–24; 25–29 or none; ≥30	0; 1; ≥2	Bx: 0; 1; ≥2 AH: 0; ≥1	Not included	1.03 (0.88 to 1.21);[126] 0.94 (0.89 to 0.99);[132] 0.96 (0.84 to 1.17);[127] 0.79;[123] 1.12[121]	0.55 (0.51 to 0.60);[117] 0.60;[126] 0.58 (0.56 to 0.60);[119] 0.58;[132] 0.59 (0.54 to 0.63);[127] 0.60;[122] 0.61 (0.60 to 0.62)[135]

Chlebowski 5-year risk	50–59; 60–69; 70–79	≥14; 12–13; ≤12	<20; 20–24; 25–29 or none; ≥30	0; ≥1	Bx: 0; 1; ≥2	BMI, menopause age, HT use and duration, race, alcohol use, parity, breastfeeding, smoking status, physical activity	Not reported	0.61 (0.59 to 0.63);[123] 0.62 (0.60 to 0.64) (ER+);[123] 0.53 (0.47 to 0.58) (ER-)[123]
Chlebowski-simplified 5-year risk	<50; ≥50	Not included	Not included	0; ≥1	Bx: 0; 1; ≥2	Not included	Not reported	0.58 (0.56 to 0.60) (ER+)[123]

* For invasive breast cancer, other outcomes are specifically indicated.
† Invasive and noninvasive breast cancer.
‡ BI-RADS categories include: 0 = unknown; 1 = entirely fat; 2 = scattered fibroglandular densities; 3 = heterogeneously dense; 4 = extremely dense.
§ Includes an Italian population and used incidence rates from the Italian Multicenter case-control study of Diet and Breast Cancer and from Italian cancer registries.

Abbreviations: AH = atypical hyperplasia; BCSC = Breast Cancer Surveillance Consortium; BI-RADS = Breast Imaging Reporting and Data System; BMI = body mass index; Bx = biopsy; CI = confidence interval; DCIS = ductal carcinoma in situ; ER- = estrogen receptor negative; ER+ = estrogen receptor positive; HT = hormone therapy; LCIS= lobular carcinoma in situ; PR- = progesterone receptor negative; PR+ = progesterone receptor positive.

Table 4. Familial Risk Stratification Models to Predict Individual Risk for Deleterious BRCA Mutations in Primary Care Settings

Model	Data collection and calculation	Relatives with breast and ovarian cancer	Other factors	Reference standard	Performance characteristics for predicting risk for BRCA mutations
Ontario Family History Assessment Tool (FHAT)[142,144-146]	Clinical scoring tool; referral threshold of 10 is equivalent to a 2-fold relative risk for breast or ovarian cancer	1st-, 2nd-, 3rd-degree	Age at diagnosis; bilateral breast cancer; breast and ovarian cancer in same person; male breast cancer; colon and prostate cancer	BRCAPRO; Claus	Sensitivity 91%–94%; specificity 15%–51%; PPV 31%; c statistic 0.68–0.83
Manchester Scoring System[56,139,141,144-146]	Clinical scoring tool; referral if ≥2 positive responses	1st-, 2nd-, 3rd-degree	Type of cancer (breast, ovarian, pancreatic, or prostate), affected family members, and age at diagnosis	BRCAPRO; Myriad II; BOADICEA; FHAT	Sensitivity 58%–93%; specificity 33%–71%; c statistic 0.75–0.80
Referral Screening Tool (RST)[140]	Clinical scoring tool; referral if ≥2 positive responses	1st-, 2nd-degree	Breast cancer at age ≤50 (self or relatives); ovarian cancer at any age (self or relatives); ≥2 breast cancer cases at age >50 on same side of family; male breast cancer; Jewish ancestry	BRCAPRO; Myriad II; BOADICEA; FHAT	Sensitivity 81%; specificity 92%; PPV 0.80; NPV 0.92; c statistic 0.87
Pedigree Assessment Tool (PAT)[143]	Clinical scoring tool; score ≥8 was optimal threshold	1st-, 2nd-, 3rd-degree	Breast cancer at age ≤50 or >50; ovarian cancer at any age; male breast cancer; Ashkenazi Jewish ancestry	Myriad II	Sensitivity 100%; specificity 93%; PPV 0.63; NPV 1.00; c statistic 0.96 (compared with Gail 5-year 0.39; Gail lifetime 0.59)
FHS-7[138]	Clinical scoring tool; one positive response was threshold	1st-degree with breast or ovarian cancer	Any relatives with breast cancer at age ≤50; bilateral breast cancer; breast and ovarian cancer in same person; male breast cancer; ≥2 relatives with breast and/or ovarian cancer; ≥2 relatives with breast and/or colon cancer	Claus; Gail; Tyrer-Cuzick; Penn II	Sensitivity 88%; specificity 56%; PPV 0.63; NPV 1.00; c statistic 0.96

Abbreviations: BOADICEA = Breast and Ovarian Analysis of Disease Incidence and Carrier Estimation Algorithm; NPV = negative predictive value; PPV = positive predictive value.

Table 5. Studies of Genetic Counseling

Abbreviations: BSI = Brief Symptom Inventory; CWS = Cancer Worry Scale; GHQ = General Health Questionnaire; HADS = Hospital Anxiety and Depression Scale; IES = Impact of Event Scale; NR = not reported; NSI = nonstandard instrument; PAS = Psychiatric Assessment Schedule; PPC = Perceived Personal Control; SPIKES = Setting, Patient's perception, Invitation, Knowledge, Exploring/Empathy, Strategy/Summary; STAI = State-Trait Anxiety Inventory; VAS = Visual Analog Scale.

Table 6. Types of Genetic Counseling Provided in Included Studies

Author, year	Setting	Provider of genetic counseling	Components of genetic counseling
Current report			
Armstrong et al, 2005[148]	Not reported	Not reported	Genetic counseling not specified.
Bennett et al, 2008[150]	Cancer Genetics Service Center	Genetic counselor	Women with family history of breast/ovarian cancer referred by general practitioner or other medical specialists into the service. After assessment of information in family health questionnaire by genetic specialists, individual genetic risk of developing familial breast and ovarian cancer was calculated as a percentage of lifetime risk and stratified into high, moderate, and population risk levels. Women considered high risk for breast/ovarian cancer were offered counseling, genetic testing, and annual mammography; woman at moderate risk were offered annual mammography.
Bennett et al, 2009[149]	Cancer Genetics Service Center	Genetic counselor	See Bennett 2008.
Bloom et al, 2006[151]	Telephone counseling	Master's level counselor	Telephone counseling session included: establishment of rapport and determination of special concerns, emotional readiness, risk notification by providing modified Gail model lifetime risk estimate and discussing in terms of pretest self-assessment of risk, deescalation of tension regarding breast cancer checkup, evaluation of coping skills, reinforcement of problem solving and coping skills, information on health protective behaviors, early detection through American Cancer Society screening, and information on genetic testing when requested.
Bowen et al, 2006[152]	University	Psychologist, genetic counselor	**Group psychological counseling:** Psychologist led four 2-hour, weekly sessions of 5 to 6 women per group, with each session including a 20-min group cohesion activity followed by 1 of 4 major intervention components: risk assessment and perception, education, stress management, and problem solving and social support. **Individual genetic counseling:** Genetic counselor provided 1-hour counseling sessions and sessions covered several topics, including participant's family background, breast cancer risk assessment, *BRCA1* and *BRCA2* mutations in the Ashkenazi Jewish population, nongenetic risk factors for breast cancer, and breast screening.
Brain et al, 2011[153]	Not reported	Clinician	Women with a family history of breast cancer receive a specialist genetic assessment service. Control group received general risk level (low/population, moderate, or high) based on age, reproductive history, and minimal family history; intervention group received a specific percentage based on Claus model based on detailed family pedigree; genetic testing was available to women in intervention group at high risk (≥25% risk).
Braithwaite et al, 2005[154]	Not reported	Clinical nurse specialist	**Risk counseling:** Received pedigree with information from family history and assessed risk as low, moderate, or high based on GRACE guidelines; participants were mailed letters summarizing content afterward. **GRACE:** Completed pedigrees in GRACE and assessed their risk, learning their risk assessment and how to manage their risk; received a numerical estimate of lifetime risk, a visual display of cumulative risk with general population as comparator, and a qualitative description; clinical nurse specialists then offered to book mammography and arrange meetings with geneticists, where appropriate.

Table 6. Types of Genetic Counseling Provided in Included Studies

Author, year	Setting	Provider of genetic counseling	Components of genetic counseling
Fry et al, 2003[155]	Familial Breast Cancer Clinic	Genetics consultant and specialist breast surgeon; geneticist and genetics nurse specialist	**Standard (regional) service:** Self-report family history and baseline questionnaire completed by all women; genetics consultant and genetics nurse specialist assigned categorical risk via Cancer Research Campaign. Women at low risk received a letter; women at moderate or high risk were offered an appointment at familiar breast cancer clinic where a genetics consultant discussed risk status and breast surgeon discussed risk management. Where appropriate, clinical exams and mammography were included in the appointment. Patients' general practitioners received summary data, and patients received followup questionnaires 4 weeks and 6 months later. **Novel (community-based) service:** All women sent an appointment for a community-based clinic near their residence. Meetings run by genetics nurse specialist where family history collected and compared to published criteria (Cancer Research Campaign) to determine risk. Women at low risk offered information, reassurance, and discharged. Women at increased risk (moderate or high) were offered an appointment at a regional center with a geneticist and genetics nurse specialist, and asked to complete followup questionnaires at 4 weeks and 6 months.
Gurmankin et al, 2005[156]	University breast and ovarian cancer risk evaluation program	Health care provider	**Precounseling interview:** Assessed patient's breast cancer risk perception, BRCA mutation risk perception, worry about breast cancer, family history of cancer, breast cancer risk reduction behaviors, and demographic information. **Postcounseling interview:** Assessed patient's breast cancer risk, BRCA mutation risk, recall of actual risk information, and worry about breast cancer.
Helmes et al, 2006[157]	Not reported	Board certified genetic counselor	**In-person counseling:** Review of family history, discussion of breast cancer risk, and education about breast cancer genes; discussed genetic testing considerations, including implications of results, testing strategies, potential risks and benefits of test, costs and psychological effects of test; gave information packet with personal risk information comparing woman's risk with average woman's risk, personal computer-drawn 3-generation pedigree, brochures on self-breast exams, Pap test, and mammography; genetics visual aids, and list of community resources. **Telephone counseling:** Information packet was sent in the mail with instructions to open at the beginning of the telephone counseling, which was identical in content and structure to in-person counseling.
Hopwood et al, 2004[158]	Cancer genetic service centers	Genetic counselor	Genetic counseling prior to testing varied by participating center, but offered or recommended some of the following: risk estimation (based on molecular genetic analysis or more often on family history), genetic risk counseling, clinical exam, screening/surveillance for early tumor detection (mammography, endoscopy), information on preventive strategies (surgery, diet), family planning advice, and referral for psychological assessment/support.
Kelly et al, 2008[159]	Not reported	Genetic counselor	Review of family cancer history, personal risk factors for breast and ovarian cancer, mechanisms of cancer inheritance, meaning of a positive and negative test result, and risks and benefits associated with testing.
Matloff et al, 2006[160]	Not reported	Certified genetic counselor	Personalized letter summarizing patient data.
Mikkelsen et al, 2007[161]	University clinical departments	Physicians	Information on incidence of sporadic breast cancer, genetics, inheritance patterns, and estimated personal lifetime risk of inherited cancer.
Mikkelsen et al, 2009[162]	University clinical departments	Physicians	Information on incidence of sporadic breast cancer, genetics, inheritance patterns, and estimated personal lifetime risk of inherited cancer.

Table 6. Types of Genetic Counseling Provided in Included Studies

Author, year	Setting	Provider of genetic counseling	Components of genetic counseling
Pieterse et al, 2011[163]	Department of medical genetics	Clinical geneticists, residents in clinical genetics, genetic counselors	Session topics included family's occurrence of breast and other cancers, inheritance, and criteria on probability of inherited breast cancer, and the likelihood of hereditary breast cancer running in the family was estimated.
Roshanai et al, 2009[164]	University cancer genetic clinic	Specialist nurse	Included pedigree explanation, Buckman's Breaking Bad News model to inform at-risk relatives, pamphlet, videotape, copies of pedigree, and medical records.
Prior report			
Bowen et al, 2002[57]	Not reported	Genetic counselor or trained health counselor	**Individual genetic counseling**: Telephone contact with genetic counselor to review pedigree information and one 2-hour session following protocol based on standard genetic practice, with a letter sent to participant within 2 weeks summarizing the session. **Group psychosocial counseling:** Group of 4–6 participants met for four 2-hour sessions with trained health counselor, participants received risk assessment sheet, personalizing the group discussion to her own risk status, main topics: risk assessment, perception, screening, stress management and problem solving, social support.
Bowen et al, 2004[62]	Not reported	Genetic counselor or trained health counselor	**Individual genetic counseling**: Telephone contact with genetic counselor to review pedigree information and one 2-hour session following protocol based on standard genetic practice, with a letter sent to participant within 2 weeks summarizing the session. **Group psychosocial counseling:** Group of 4–6 participants met for four 2-hour sessions with trained health counselor, participants received risk assessment sheet, personalizing the group discussion to her own risk status, main topics: risk assessment, perception, screening, stress management and problem solving, social support.
Brain et al, 2002[166]	Not reported	Clinical geneticist and genetic nurse specialist	Breast cancer surveillance, option to enter UK Tamoxifen Prevention Trial, annual surgical followup with surveillance and advice, genetic risk assessment and counseling.
Burke et al, 2000[58]	Unclear	Genetic counselor	Adapted genetic counseling protocol for women with intermediate risk included precounseling telephone call gathering a complete family history, in-person genetic counseling session discussing breast cancer risk factors, focusing on issues relevant to the participant, reviewed pedigree information, communicated likelihood of mutation in participant's family, risk estimate sheet given to participant based on the Gail and Claus models and National Cancer Institute statistics for average risk, information about genetic testing, recommendations for breast cancer screening, and a followup letter summarizing the genetic counseling session.
Cull et al, 1998[59]	Breast cancer family clinic	Geneticist and breast surgeon	Individual meeting with geneticist to discuss individual risk and with breast surgeon to discuss risk management, participants either received a copy of the educational video about 10 days before the clinic consultation or took the video home after the postclinic assessment.
Hopwood et al, 1998[167]	Family history clinics	Unclear	Family history consultation, not otherwise described.
Lerman et al, 1996[168]	Comprehen-sive cancer centers	Genetic counselor	Discussion of individual factors contributing to elevated risk, presentation of individualized risk data, recommendations for annual mammography and clinical breast exams, and instruction in breast self-exam.

Table 6. Types of Genetic Counseling Provided in Included Studies

Author, year	Setting	Provider of genetic counseling	Components of genetic counseling
Lerman et al, 1999[60]	Hospital and cancer center	Oncology nurses or genetic counselor	**Education only:** Topics discussed included individual risk factors for breast and ovarian cancer and patterns of inheritance for breast and ovarian cancer susceptibility, subjects given qualitative estimates of risk of developing breast and ovarian cancer, and pedigrees reviewed, potential benefits, limitations, and risks of genetic testing for inherited breast and ovarian cancer susceptibility reviewed. **Education plus counseling:** Provided the same education and materials described above and subjects were guided through questions exploring personal issues related to cancer and genetic testing, discussed the emotional impact of having a family history of cancer, psychosocial implications of genetic testing for inherited breast and ovarian cancer susceptibility, anticipated reactions to positive and negative test result, and intentions to communicate test results to family members and friends.
Lobb et al, 2004[169]	Not reported	Clinical geneticists, oncologist, genetic counselors	Counselors provided counseling at their discretion and study was to assess the different aspects of counseling, which included information giving concerning: breast cancer genetics, genetic testing, family history and risk, prophylactic surgery, breast cancer prevention, screening and management; communication style including: facilitating patient involvement, facilitating understanding, patient centeredness and partnership building, and supportive and counseling communications.
Watson et al, 1998[171]	Hospitals	Clinical geneticist	Consultation provided information on pedigree based on risk calculation and information regarding management options based on risk level, with instructions offered on self-exam and clinical exam, with the intervention group also receiving an audiotape of the consultation to take home.
Watson et al, 1999[172]	Genetic counseling centers	Clinical geneticists	Not described.

Table 7. Standardized Measures Used to Assess Distress

Measure	Abbreviation	Description
Beck Depression Inventory[334]	BDI	A 21-question, multiple choice, self-report inventory for measuring the severity of depression. Scores of 0 to 9 indicate minimal depression, 10 to 18 mild depression, 19 to 29 moderate depression, and 30 to 63 severe depression.
Beck Hopelessness Scale[351]	BHS	A 20-item scale to quantify hopelessness, with scores ranging from 0 to 20 and a score above 9 indicating suicidal ideations.
Body Image after Breast Cancer[333]	BIBC	A 53-item questionnaire to assess the long-term impact of breast cancer on body image in 6 key areas: vulnerability, body stigma, limitations, body concerns, transparency, arm concerns.
Body Image Scale[341]	BIS	A 10-item questionnaire for assessing body image changes in patients with cancer.
Brief Symptom Inventory[339]	BSI	A 53-item self-reported psychological symptom scale.
Center for Epidemiologic Studies-Depression[348]	CES-D	Measures symptoms of depression on a 20-item scale with scores ranging from 0 to 60; scores above 15 indicating high levels of depressive symptoms.
Coping Orientation to Problems Experienced Scale[338]	COPE	Covers 14 coping strategies as potential responses to stressors.
Decision Regret Scale[337]	DRS	A 5-item questionnaire to measure dissatisfaction or misgiving after making a medical decision.
DUKE Social Support Questionnaire[345]	DUKE-SSQ	Used to measure access to and satisfaction with social support on 8 items with scores ranging from 1 to 5. Affective subscale (DUKE-SSQ-A) includes items 1, 2, and 8; confident subscale (DUKE-SSQ-C) includes items 3-7.
Emotional Approach Coping Scale[350]	None	A 52-item questionnaire to measure both problem solving (items 1-20) and emotion-based (items 21-32) coping strategies. An additional 4 questions pertain to alcohol and drug use.
EuroQoL-5 Dimensions[343]	EQ-5D	A short, self-reported questionnaire designed to evaluate an individual's state of overall health in 5 areas: mobility, self-care, usual activities, pain/discomfort, anxiety/depression.
General Health Questionnaire[342]	GHQ	A 60-item questionnaire to screen individuals for psychiatric disorders, scores are given as means and scores above 3 indicate disorders; a 30-item version of the same questionnaire uses a threshold of 6 to indicate general psychological distress.
Health-Related Quality of Life[330]	HR-QOL	A 14-item self-report questionnaire to assess an individual's quality of life based on healthy days (items 1-4), activity limitations (items 5-9), and symptoms (items 10-14).
Hospital Anxiety and Depression Scale[335]	HADS	A 14-item self-report scale for the detection of depression and anxiety in hospitalized patients. Scores range from 1 to 21, interpreted as normal (0 to 7), mild (8 to 10), moderate (11 to 14), and severe (15 to 21). Subscales for anxiety (HADS-A) and depression (HADS-D).
Impact of Events Scale[356]	IES	A 17-item questionnaire to measure an individual's level of distress in relation to a specific event or condition. Scores range from 0 to 75; scores 9 to 25 indicate moderate difficulties and above 26 indicate clinical adaptation difficulties. Several variations are also used: Impact of Events Scale-Revised (IES-R) 22-items (items A-V); Impact of Events Subscale-Intrusive Events (IES-I) (items A, B, C, F, I, N, P, T); Impact of Events Subscale-Avoidance (IES-A) (items E, G, H, K, L, M, Q, V); Impact of Events Subscale-Hyperarousal (IES-H) (items D, J, O, R, S, U).
Lerman Breast Cancer Worry Scale[336]	CWS or LCWS	A 3-item questionnaire to measure how frequently an individual worries about getting breast cancer and the impact of worrying on mood and performance of daily activities. A 6-item version of the same questionnaire has scores ranging from 6 to 24; higher scores mean greater levels of worry.
Medical Coping Modes Questionnaire[349]	MCMQ	A 19-item self-report questionnaire to quantify coping styles into 1 of 4 categories: confrontive, avoidant, resigned, nondominant.

Table 7. Standardized Measures Used to Assess Distress

Measure	Abbreviation	Description
Medical Outcomes Study 36-Item Short Form[344] Swedish Short Term-36 Health Survey[353]	SF-36 or MOS SF-36	A 36-question health questionnaire for measuring health and well-being in 8 core areas: physical functioning, role limitations due to physical health, bodily pain, general health perceptions, vitality, social functioning, role limitations due to emotional problems, mental health. The Swedish Short Term-36 Health Survey is one of many variations.
Menopause-Specific Quality of Life Questionnaire[346]	MENQOL	A 29-item self-administered questionnaire to assess health-related quality of life postmenopause.
Multidimensional Fatigue Symptom Inventory-Short Form[352]	MFSI-SF	A 30-item questionnaire to measures perceived sleep disturbance.
Pittsburgh Sleep Quality Index[340]	PSQI	A measure of subjective sleep disturbance in clinical populations.
Post-Traumatic Growth Inventory[332]	PTGI	An instrument for assessing positive outcomes reported by persons who have experienced traumatic events.
Sexual Activity Questionnaire[354]	SAQ	A 3-section self-reported questionnaire to assess sexual functioning, including hormonal status, reasons for sexual inactivity, sexual functioning.
State-Trait Anxiety Inventory[331]	STAI	Measures an individual's current anxiety feelings. Scores range from 10 to 40. Scores above 22 indicate high anxiety.
Symptom Checklist-90[347]	SCL-90	A 90-question self-reported questionnaire to assess psychological status in the following categories somatization, obsessive-compulsive, interpersonal sensitivity, depression, anxiety, hostility, phobic anxiety, paranoid ideation, psychoticism.
Visual Analogue Scale[355]	VAS	Any of a number of pain self-assessment tools where subjects indicate their level of pain in response to a continuous visual scale (no pain to worst pain ever experienced).

*Based on followup to censoring date.
†*BRCA1* carriers evaluated in group including those with and without surgery.
‡*BRCA2* carriers evaluated in group including those with and without surgery.
§Total at-risk time in surgery group was 378.7 years vs. 934.6 years in the no surgery group.
‖Expected incidence based on life tables.
¶Study included women with prior breast cancer; only data on women with no prior breast cancer included in evidence review.
**Total number of women with *BRCA1/2* mutation, regardless of breast cancer history; study did not provide the number of women with a mutation and no prior history of breast cancer.
†† Oophorectomy performed.
‡‡ Families testing positive for *BRCA1* mutation; families had multiple breast and ovarian cancer cases prior to testing.
§§ Expected incidence based on Gail model.
‖ ‖ One first-degree relative with breast cancer before age 50 years or one first-degree relative with ovarian cancer at any age and at least one other first- or second-degree relative with either diagnosis at any age.
¶¶One first-degree relative with breast cancer at any age.
***Based on control group of sisters.
†††Subgroup of high-risk group.
‡‡‡Based on high-penetrance model.
§§§Based on low-penetrance model.
‖ ‖ ‖Incidence includes postoophorectomy ovarian carcinomatosis.
¶¶¶Followup for ovarian cancer incidence was 1665 person-years for no surgery group, 460 person-years for surgery group; followup for breast cancer incidence was 1587 person-years for no surgery group, 484 person-years for surgery group.

Abbreviations: CI = confidence interval; HR = hazard ratio; NA = not applicable; NR = not reported; RR = relative risk.

Table 20. Harms of Intensive Screening for Breast Cancer Using Mammography vs. MRI in High-Risk Women

Author, year	N (*BRCA1/2*) # of cancer cases	Age at entry, y	Screening interval Followup, y	False-positive rate	False-negative, n	Recall rates	Unneeded* additional exams or imaging Unneeded* biopsy
Kriege et al, 2004[277] Kriege et al, 2006[297] Dutch MRISC study	1909 (14/4) 39 *BRCA1* 45 *BRCA2*	Mean, 40	Annual, same-day Mean, 2.7	n=39 cancers First imaging round (prior mammography): 5.5% vs. 14%; p<0.001 Subsequent imaging rounds: 4.6% vs. 8.2%; p<0.001	n=39 cancers First imaging round (prior mammography): 12 vs. 1 Subsequent imaging rounds: 12 vs. 4	NR	n=45 cancers Exams†: 207 vs. 420 Biopsy: 28% (7/25‡) vs. 43% (24/56‡)
Leach et al, 2005[274] MARIBS study	649 (13/6) 33	Median, 40	Annual, same-day Variable followup, ≥2 scans	NR	NR	279 recalls overall 3.9% vs. 11% per woman-year Combined tests: 13% per woman-year 245/279 recalls for benign findings 8.5 recalls per cancer detected	All study arms§ Ultrasound: 38% (93/245) Core biopsy: 13% (32/245) FNA: 19% (47/245) Surgery: 3% (7/245) 0.21 benign biopsies per cancer detected
Le-Petross et al, 2011[276]	73 (51/49) 13	Median, 44	Biannual, alternating mammography with MRI Median, 2	15% (11/73) vs. 11% (8/73)	NR	NR	Imaging: 73% (8/11) vs. 50% (4/8) Biopsy: 27% (3/11) vs. 25% (2/8) Imaging plus biopsy: 0% vs. 25% (2/8)

*Women who were diagnosed as cancer free.
†Additional investigation included ultrasound ± fine needle biopsy or repeat mammography or repeat MRI.
‡Women with BIRADS ≥3 on mammography or MRI.
§Results not reported by imaging arm.

Abbreviations: BIRADS = Breast Imaging Reporting and Data System; FNA = fine needle aspiration; MARIBS = Magnetic Resonance Imaging Breast Screening; MRI = magnetic resonance imaging; MRISC = Magnetic Resonance Imaging Screening Study; NA = not applicable; NR = not reported.

Table 21. Distress Due to Intensive Screening for Breast Cancer in Women Who Are Mutation Carriers

Author, year, quality rating	N, study design	Mutation status	Comparison	Measures of distress	Anxiety	Depression	Sexual activity	Body image	General QOL
Rijnsburger et al, 2004[275] Fair	288; prospective cohort and pre-post	35 *BRCA1/2* mutation positive	A) CBE (n=287) B) CBE + mammography (n=134) C) CBE + MRI (n=109)	SF-36, EQ-5D, VAS, SCL-90	0	NR	NR	NR	0
Spiegel et al, 2011[298] NA	55; pre-post	*BRCA1:* 30/55 (54.5%) *BRCA2:* 25/55 (45.5%)	A) Recall examinations (n=18) B) No recall examinations (n=37)	HADS, WIS	X increase A vs. B*	0	NR	NR	0

X = statistically significant difference; 0 = studied but not significant.
*At 4 to 6 weeks after screening only, returned to baseline levels by 6 months.

Abbreviations: CBE = clinical breast examination; EQ-5D = EuroQoL-5 Dimensions; HADS = Hospital Anxiety and Depression Scale; MRI = magnetic resonance imaging; NA = not applicable; NR = not reported; QOL = quality of life; SCL-90 = Symptom Checklist-90; SF-36 = Short-Form 36-Item Health Survey; VAS = Visual Analogue Scale; WIS = Breast Cancer Worry Interference Scale.

Table 22. Results of Trials of Risk-Reducing Medications: Adverse Effects[115,116]

	Raloxifene vs. tamoxifen		Tamoxifen vs. placebo			Raloxifene vs. placebo		
Outcome	Risk ratio (95% CI)	Events reduced/ increased, *n* (95% CI)*	Risk ratio (95% CI) (Trials, *n*)†	Placebo rate (SE)‡	Events reduced/ increased, *n* (95% CI)*	Risk ratio (95% CI) (Trials, *n*)†	Placebo rate (SE)‡	Events reduced/ increased, *n* (95% CI)*
Thromboembolic events§	0.75 (0.60 to 0.93)‖	4 (1 to 7) more tamoxifen	1.93 (1.41 to 2.64) (4)	0.91 (0.19)	4 (2 to 9) more tamoxifen	1.60 (1.15 to 2.23) (2)	2.34 (0.25)	7 (2 to 15) more raloxifene
Deep vein thrombosis	0.72 (0.54 to 0.95)‖	3 (1 to 5) more tamoxifen	1.45 (0.89 to 2.37) (2)			1.91 (0.87 to 4.23) (2)		
Pulmonary embolus	0.80 (0.57 to 1.11)‖		2.69 (1.12 to 6.47) (2)	0.19 (0.07)	2 (0.1 to 6) more tamoxifen	2.19 (0.97 to 4.97) (2)		
Coronary heart disease events	1.10 (0.85 to 1.43)¶		1.00 (0.79 to 1.27) (4)			0.95 (0.84 to 1.06) (2)		
Stroke	0.96 (0.64 to1.43)¶		1.36 (0.89 to 2.08) (4)			0.96 (0.67 to 1.38) (2)		
Endometrial cancer	0.55 (0.36 to 0.83)‖	5 (2 to 9) more tamoxifen	2.13 (1.36 to 3.32) (3)	0.75 (0.15)	4 (1 to 10) more tamoxifen	1.11 (0.65 to 1.89)** (3)		
Cataracts	0.80 (0.72 to 0.95)‖	15 (8 to 22) more tamoxifen	1.25 (0.93 to 1.67)†† (3)			0.93 (0.84 to 1.04) (2)		

*Numbers of events increased for harms compared with placebo or other comparator per 1000 women, assuming 5 years of use.
†If meta-analysis.
‡Per 1000 women. Estimated from a meta-analysis of rates from the placebo groups from the same trials included in the risk ratios.
§ Includes deep vein thrombosis and pulmonary embolus.
‖ Updated results from the Study of Tamoxifen and Raloxifene (STAR), 2010.
¶Initial results from STAR, 2006.
** Updated meta-analysis.
††The risk ratio for cataracts was significantly increased in the NSABP P-1, 1998 (574 vs. 507 events; RR, 1.14 [95% CI, 1.01 to 1.29]).

Abbreviations: CI = confidence interval; NR = not reported; SE = standard error.

Table 23. Distress Due to Risk-Reducing Surgery

Author, year	N, study design	Mutation status	Comparison	Measures of distress	Anxiety	Depression	Sexual activity	Body image	General QOL
Mastectomy									
Brandberg et al, 2008[302] Brandberg et al, 2012[304]	90; pre-post	37/90 (41.1%) *BRCA1* 13/90 (14.4%) *BRCA2* 2/90 (2.2%) unknown mutation	A) Before surgery (n=81) B) 6 months after (n=71) C) 1 year after (n=65)	NSI, SAQ, BIS, HADS, SF-36	X decrease B & C vs. A	0	X* decrease C vs. A & B	0	NR
Gahm et al, 2010[303]	1784; case-series	NR	A) Surgery (n=59) B) Control (n=1725)	NSI, SF-36, DRS	NR	NR	NR	NR	0
Metcalfe et al, 2004[301]	60; case-series	21.7% *BRCA1/2*	A) Age <50 years (n=46) B) Age ≥50 years (n=14)	BSI, BIBC, IES, SAQ	0	NR	0	NR	NR
Salpingo-oophorectomy									
Finch et al, 2011[306]	67; pre-post	*BRCA1* or *BRCA2*	A) Before surgery B) After surgery	MENQOL, SAQ	NR	NR	X decrease B vs. A	NR	NR

X = statistically significant difference; 0 = studied but not significant.
*For pleasure subscale of SAQ only.

Abbreviations: BIBC=Body Image after Breast Cancer; BIS = Body Image Scale; BSI=Brief Symptom Inventory; DRS=Decision Regret Scale; HADS=Hospital Anxiety and Depression Scale; IES=Impact of Events Scale; MENQOL=Menopause-Specific Quality of Life-Intervention; NSI=not standard instrument; NR = not reported; QOL=quality of life; SAQ=Sexual Activity Questionnaire; SF-36 = Short-Form 36-Item Health Survey.

Table 24. Summary of Evidence

Studies, *n*	Design	Limitations	Consistency	Applicability	Overall quality	Findings
Key Question 1. Does risk assessment, genetic counseling, and genetic testing lead to reduced incidence of BRCA-related cancer and reduced cause-specific and all cause mortality?						
No studies	NA	NA	NA	NA	NA	NA
Key Question 2a. What is the accuracy of methods to assess familial cancer risk for BRCA-related cancer when performed by a nongenetics specialist in a clinical setting? Key Question 3a. What are the potential adverse effects of risk assessment?						
Systematic review of 13 general risk models; 10 studies of 5 familial risk models; no studies of the accuracy of referral criteria or adverse effects of risk assessment.	Diagnostic accuracy; cohort; case-control	Reference standards and study designs varied across studies; risk was based on self-reported information.	Consistent	High	Good	General risk models that predict risk for breast cancer, such as the Gail, are modest predictors for individuals (c-statistic, 0.55 to 0.65). Familial risk models (FHAT, Manchester, RST, PAT, and FHS-7) predict risk for BRCA mutations, are intended to guide referrals to genetic counseling, and have high accuracy (c-statistic, >0.80).
Key Question 2b, 3b. What are the benefits and potential adverse effects of genetic counseling for determining eligibility for genetic testing for BRCA-related cancer?						
16 studies of distress, accuracy of risk perception, and intention for genetic testing.	RCT, cohort, case-control, before-after	Noncomparable comparison groups; small studies; outcome measures varied.	Consistent	High	Fair	Counseling decreased cancer worry, anxiety, and depression; increased the accuracy of risk perception; and decreased intention for mutation testing.
Key Question 2c. What is the clinical validity of genetic testing for deleterious mutations in women with increased risk for BRCA-related cancer?						
32 new and 38 earlier studies provided data for meta-analysis estimates to determine the likelihood of BRCA mutations in women in specific risk populations (prevalence) and their chances of developing breast or ovarian cancer based on results of genetic testing (penetrance).	Cohort, cross-sectional, descriptive studies	Studies are heterogeneous; laboratory techniques differed; no studies outside high-risk populations; bias in estimates; no studies in women with variants of uncertain significance.	Consistent	Moderate	Fair	Prevalence is 0.2%-0.3% in general populations: 3% women with breast cancer, 6% women with breast cancer onset age ≤40, 10% women with ovarian cancer, and 20% high-risk families; for Ashkenazi Jewish women, 2% in unselected populations and 10% high-risk families. Positive test results indicate risks for breast cancer to age 70 of 46%-70% for *BRCA1* and 50%-71% for *BRCA2*; for ovarian cancer, 41%-46% for *BRCA1* and 17%-23% for *BRCA2*; in Ashkenazi Jewish women, 34% for breast cancer and 21% for ovarian cancer. Uninformative negative test results are associated with increased risk for breast cancer (SIR, 3.81 [95% CI, 3.06 to 4.75]), while true negative results are not (SIR, 1.13 [95% CI, 0.81 to 1.58]); estimates for ovarian cancer were highly heterogeneous.
Key Question 3c. What are the potential adverse effects of genetic testing?						
13 studies of distress measures and risk perception	Cohort; case-control; before-after	No studies of other outcomes; high loss to followup; comparison groups and measures varied.	Mixed	High	Fair	Breast cancer worry and anxiety increased for women with positive results and decreased for others, although results differed across studies. Risk perception improved after receiving test results.

Table 24. Summary of Evidence

Studies, *n*	Design	Limitations	Consistency	Applicability	Overall quality	Findings
Key Question 4. Do interventions reduce the incidence of BRCA-related cancer and mortality in women with increased risk?						
Intensive screening: no effectiveness studies	NA	NA	NA	NA	NA	NA
Risk-reducing medications: systematic review; 6 placebo-controlled trials (4 tamoxifen, 2 raloxifene) and 1 head-to-head trial (STAR)	RCT	No results for BRCA mutation carriers; trials are heterogeneous and data are lacking on doses, duration, and timing of use.	Consistent	Moderate	Good	Tamoxifen and raloxifene reduced invasive breast cancer by 30%-68% compared with placebo; reduction was greater for women with family history of breast cancer, but confidence intervals were overlapping. Reduction was significant for ER+ but not ER- cancer. Noninvasive breast cancer and mortality were not significantly reduced.
Risk-reducing surgery: 4 studies of mastectomy and 3 of oophorectomy or salpingo-oophorectomy	Cohort	Comparison groups varied.	Consistent	High	Fair	For high-risk women and mutation carriers, mastectomy reduced breast cancer 85%-100% and breast cancer mortality 81%-100%; salpingo-oophorectomy reduced breast cancer 37%-100%, ovarian cancer 69%-100%, and all-cause mortality 55%-100%.
Key Question 5. What are the potential adverse effects of interventions to reduce risk for BRCA-related cancer?						
Intensive screening: 3 studies of physical harms of breast cancer screening and 2 studies of anxiety; 1 study of physical harms of ovarian cancer screening	Cohort	No RCTs; screening intervals and false-positive calculations varied between studies; some studies lacked within-cohort comparison groups.	Consistent	High	Poor	False-positive rates, unnecessary imaging, and unneeded surgeries were higher for women undergoing intensive screening for breast and ovarian cancer. Most women experienced no anxiety after screening with MRI, mammography, or clinical breast examination, although women recalled had transient anxiety.
Risk-reducing medications: no studies provided results by mutation status; 1 systematic review; 6 placebo-controlled trials (4 tamoxifen, 2 raloxifene) and 1 head-to-head trial	RCT	No results for BRCA mutation carriers; trials are heterogeneous and data on long-term effects are incomplete.	Consistent	High	Good	Tamoxifen and raloxifene increased thromboembolic events compared with placebo. Tamoxifen increased endometrial cancer and cataracts compared with raloxifene. Both caused undesirable side effects for some women.
Risk-reducing surgery: 5 studies of complications, physical effects, or distress	Case-series; before-after studies	Lack of studies; small numbers of participants; no comparison groups.	NA	Low	Poor	Some women experienced physical complications of surgery, had postsurgical symptoms, or changes in body image. Some women had improved anxiety.

Abbreviations: BC = breast cancer; FHAT = Family History Assessment Tool; MRI = magnetic resonance imaging; NA = not applicable; OC = ovarian cancer; PAT = Pedigree Assessment Tool; RCT = randomized, controlled trial; RST = Referral Screening Tool; SIR = standardized incidence rate; STAR = Study of Tamoxifen and Raloxifene.

Appendix A1. Referral Criteria, Adapted From National Comprehensive Cancer Network Guidelines[50]

Table 1. Criteria for Further Genetic Risk Evaluation

a) Unaffected individual and a family history of ≥1 of these:	≥2 breast primaries, either in 1 individual or 2 different individuals from the same side of family (maternal or paternal)
	≥1 ovarian cancer primary from the same side of the family (maternal or paternal)
	First- or second-degree relative with breast cancer age ≤45 years
	A combination of breast cancer with ≥1 of the following: thyroid cancer, sarcoma, adrenocortical carcinoma, endometrial cancer, pancreatic cancer, brain tumor, diffuse gastric cancer, dermatologic manifestations and/or marocephaly, or leukemia/lymphoma on the same side of the family (especially if early-onset)
	A known mutation in a breast cancer susceptibility gene within the family
	Male breast cancer
b) Individuals at increased risk, may have modified inclusion (e.g., Ashkenazi Jewish with above at any age)	

- One or more of these criteria is suggestive of hereditary breast/ovarian cancer (HBOC) syndrome that warrants further personalized risk assessment, genetic counseling, and management. The maternal and paternal sides should be considered independently. Other malignancies reported in some HBOC families include prostate and melanoma.
- Individuals with limited family history, such as less than 2 first- or second-degree female relatives or female relatives surviving beyond age 45 years in either lineage, may have an underestimated probability of familial mutation.
- For the purposes of these guidelines, invasive and ductal carcinoma in situ breast cancer should be included.
- Close blood relatives include first-, second-, and third-degree relatives.
- For the purposes of these guidelines, fallopian tube and primary peritoneal cancer are included. Ovarian/fallopian tube/primary peritoneal cancer are component tumors of hereditary nonpolyposis colorectal cancer/Lynch syndrome; be attentive for clinical evidence of this syndrome.
- Two breast primaries include bilateral (contralateral) disease or 2 or more clearly separate ipsilateral primary tumors either synchronously or asynchronously.

Table 2. Criteria for Genetic Testing for HBOC Syndrome

a) Individual from a family with a known deleterious *BRCA1* or *BRCA2* mutation	
b) Personal history of breast cancer and ≥1 of these:	Diagnosed at age ≤45 years
	Diagnosed at age ≥50 years with ≥1 close blood relatives with breast cancer at age 50 years and/or ≥1 close blood relatives with epithelial ovarian cancer at any age
	2 breast primaries when first breast cancer diagnosis occurred at age ≤50 years
	Diagnosed at age ≤60 years with a triple negative breast cancer
	Diagnosed at age ≤50 years with a limited family history
	Diagnosed at any age, with ≥2 close blood relatives with breast and/or epithelial ovarian cancer at any age
	Diagnosed at any age with ≥2 close blood relatives with pancreatic cancer at any age
	Close male blood relative with breast cancer
	Individual of ethnicity associated with higher mutation frequency (e.g., Ashkenazi Jewish)
	Personal history of epithelial ovarian cancer
	Personal history of male breast cancer
	Personal history of pancreatic cancer at any age with ≥2 close blood relatives with breast and/or ovarian cancer and/or pancreatic cancer at any age
c) No personal history of breast cancer, but ≥1 of these:	First- or second-degree blood relative meeting any of the above criteria
	Third-degree blood relative with breast cancer and/or ovarian cancer with ≥2 close blood relatives with breast cancer (≥1 with breast cancer at age ≤50 years) and/or ovarian cancer

- Testing of unaffected family members should only be considered when no affected family member is available, and then the unaffected family member with the highest probability of mutation should be tested. Significant limitations of interpreting test results should be discussed.
- Testing for Ashkenazi Jewish founder-specific mutation(s) should be performed first. Full sequencing may be considered if ancestry also includes nonAshkenazi Jewish relatives or other HBOC criteria are met. Founder mutations exist in other populations.

Appendix A1. Referral Criteria, Adapted From National Comprehensive Cancer Network Guidelines[50]

- Individuals with limited family history, such as less than 2 first- or second-degree female relatives or female relatives surviving beyond age 45 years in either lineage, may have an underestimated probability of familial mutation.
- For the purposes of these guidelines, invasive and ductal carcinoma in situ breast cancer should be included.
- Close blood relatives include first-, second-, and third-degree relatives.
- For the purposes of these guidelines, fallopian tube and primary peritoneal cancer are included. Ovarian/fallopian tube/primary peritoneal cancer are component tumors of hereditary nonpolyposis colorectal cancer/Lynch syndrome; be attentive for clinical evidence of this syndrome.
- Two breast primaries include bilateral (contralateral) disease or 2 or more clearly separate ipsilateral primary tumors either synchronously or asynchronously.

Appendix A2. Definitions of Terms Used in Systematic Review

Term or Phrase	Definition
BRCA-related cancer	Predominantly breast, ovarian, fallopian tube, and peritoneal
Genetic counseling	A service delivered by a qualified health professional that provides a comprehensive evaluation of familial risk for inherited disorders using kindred analysis and other methods, patient education, discussion of the benefits and harms of genetic testing, interpretation of results after testing, and discussion of management options
True negative test	Known confirmed deleterious genetic mutation in relatives, and none detected in the patient
Uninformative negative test	No known deleterious genetic mutations in relatives, and none detected in the patient
Variant of uncertain significance	An abnormality of the *BRCA1* or *BRCA2* gene, but it is not known whether it is associated with an increased risk for cancer
Analytic validity*	Technical test performance measured by analytic sensitivity and specificity, reliability, and assay robustness
Clinical validity*	The test's ability to accurately and reliably predict the future disorder measured by clinical sensitivity and specificity, and predictive values of positive and negative tests that take into account the disorder prevalence
Clinical utility*	Balance of benefits and harms when the test is used to influence patient management. For risk assessment, clinical utility is determined by improved health outcomes based on prevention or early detection strategies

*Defined by the Centers for Disease Control and Prevention Evaluation of Genomic Applications in Practice and Prevention (EGAPP) Working Group for tests of risk assessment/susceptibility (*Genet Med.* 2009;11:3-14).

Appendix B2. Inclusion and Exclusion Criteria

	Include	Exclude
Population	Asymptomatic adult (age 18 years or older) women with a family history of breast and/or ovarian cancer	Men, children, women with prior history of breast and/or ovarian cancer, no family history of breast and/or ovarian cancer
Interventions	Risk assessment, genetic counseling, and genetic testing for deleterious *BRCA1* or *BRCA2* mutations, interventions primarily aimed at reducing the risk of BRCA-related cancer in women with deleterious mutations: intensive screening (e.g., earlier and more frequent mammography, breast magnetic resonance imaging), use of medications (e.g., tamoxifen, raloxifene), and risk-reducing surgery (e.g., mastectomy, oophorectomy)	Surveillance, referral practices, testing for polymorphisms
Outcomes	Invasive breast cancer, invasive ovarian cancer, other BRCA-related cancer (fallopian tube, peritoneal), mortality (all cause, cancer-specific). Harms include inaccurate risk assessment; inappropriate testing; false-positive and false-negative results; adverse impact on the patient's relationships with family; false reassurance; incomplete testing; misinterpretation of the test result; anxiety; cancer worry; immediate and long-term harms associated with breast imaging, risk-reducing medications, and risk-reducing surgery; and ethical, legal, and social implications	Increased detection, predictors of adherence, uptake of screening or risk-reducing interventions
Study types and designs	Randomized, controlled trials; prospective and retrospective cohort studies; case-control studies; cross-sectional studies (for harms); systematic reviews; and meta-analyses	Case reports

Randomized, Controlled Trials (RCTs) and Cohort Studies

Criteria:

- Initial assembly of comparable groups: RCTs—adequate randomization, including concealment and whether potential confounders were distributed equally among groups; cohort studies—consideration of potential confounders with either restriction or measurement for adjustment in the analysis; consideration of inception cohorts
- Maintenance of comparable groups (includes attrition, cross-overs, adherence, contamination)
- Important differential loss to follow-up or overall high loss to follow-up
- Measurements: equal, reliable, and valid (includes masking of outcome assessment)
- Clear definition of interventions
- Important outcomes considered
- Analysis: adjustment for potential confounders for cohort studies, or intention-to-treat analysis for RCTs; for cluster RCTs, correction for correlation coefficient

Definition of ratings based on above criteria:

Good: Meets all criteria: Comparable groups are assembled initially and maintained throughout the study (follow-up at least 80 percent); reliable and valid measurement instruments are used and applied equally to the groups; interventions are spelled out clearly; important outcomes are considered; and appropriate attention to confounders in analysis.

Fair: Studies will be graded "fair" if any or all of the following problems occur, without the important limitations noted in the "poor" category below: Generally comparable groups are assembled initially but some question remains whether some (although not major) differences occurred in follow-up; measurement instruments are acceptable (although not the best) and generally applied equally; some but not all important outcomes are considered; and some but not all potential confounders are accounted for.

Poor: Studies will be graded "poor" if any of the following major limitations exists: Groups assembled initially are not close to being comparable or maintained throughout the study; unreliable or invalid measurement instruments are used or not applied at all equally among groups (including not masking outcome assessment); and key confounders are given little or no attention.

Case Control Studies

Criteria:

- Accurate ascertainment of cases
- Nonbiased selection of cases/controls with exclusion criteria applied equally to both
- Response rate
- Diagnostic testing procedures applied equally to each group
- Measurement of exposure accurate and applied equally to each group
- Appropriate attention to potential confounding variable

***Definition of ratings based on criteria above*:**

Good: Appropriate ascertainment of cases and nonbiased selection of case and control participants; exclusion criteria applied equally to cases and controls; response rate equal to or greater than

80 percent; diagnostic procedures and measurements accurate and applied equally to cases and controls; and appropriate attention to confounding variables.

Fair: Recent, relevant, without major apparent selection or diagnostic work-up bias but with response rate less than 80 percent or attention to some but not all important confounding variables.

Poor: Major selection or diagnostic work-up biases, response rates less than 50 percent, or inattention to confounding variables.

Systematic Reviews

Criteria:

- Search dates reported?
- Search methods reported?
- Comprehensive search?
- Inclusion criteria reported?
- Selection bias avoided?
- Validity criteria reported?
- Validity assessed appropriately?
- Methods used to combine studies reported?
- Findings combined appropriately?
- Conclusions supported by data?

Definitions of ratings based on above criteria:

Good: Meets all criteria: reports comprehensive and reproducible search methods and results; reports pre-defined criteria to select studies and reports reasons for excluding potentially relevant studies; adequately evaluates quality of included studies and incorporates assessments of quality when synthesizing data; reports methods for synthesizing data and uses appropriate methods to combine data qualitatively or quantitatively; conclusions supported by the evidence reviewed.

Fair: Studies will be graded fair if they fail to meet one or more of the above criteria, but the limitations are not judged as being major.

Poor: Studies will be graded poor if they have a major limitation in one or more of the above criteria.

Watson et al, 1999[170]	Unclear	Yes	Yes	No	Yes	Yes	No	Yes	Good

Appendix C3. Quality Ratings for Case-Control Studies

Author, year	Did study attempt to enroll all or random sample of cases using predefined criteria?	Were controls derived from the same population as the cases?	Were groups comparable at baseline on key prognostic factors?	Were enrollment rates similar in cases and controls invited to participate?	Did study use accurate methods for identifying outcomes?	Did study use accurate methods for ascertaining exposures and potential confounders?	Did study perform appropriate statistical analyses on potential confounders?	Quality
Armstrong et al, 2005[148]	Yes	No	No	No	Yes	Yes	Yes	Good
Dagan and Shochat, 2009[237] Shochat and Dagan, 2010[248]	Yes	Unclear	Matched	No	Yes	Yes	Yes	Fair

Appendix C4. Quality Rating for Systematic Review

Author, year	Search dates	Search methods reported	Comprehensive search	Inclusion criteria reported	Selection bias avoided	Validity criteria reported	Validity assessed appropriately	Methods used to combine studies reported	Findings combined appropriately	Conclusions supported by data	Quality rating
Smerecnik et al, 2009[165]	2000 to 2007	Yes	Yes	Yes	Yes	No	Not reported	No	Not reported	Yes	Fair

Appendix C5. Familial Risk Assessment Models

Ontario Family History Assessment Tool (FHAT)[142]

Risk Factor		Points
Breast and ovarian cancer	Mother	10
	Sibling	7
	2nd/3rd degree relative	5
Breast cancer relatives	Parent	4
	Sibling	3
	2nd/3rd degree relative	2
	Male relative (add to above)	2
Breast cancer characteristics	Onset age 20-29	6
	Onset age 30-39	4
	Onset age 40-49	2
	Pre (peri) menopausal	2
	Bilateral/multifocal	3
Ovarian cancer relatives	Mother	7
	Sibling	4
	2nd/3rd degree relative	3
Ovarian cancer onset age	<40	6
	40-60	4
	>60	2
Prostate cancer onset	Age <50	1
Colon cancer onset	Age <50	1
Family Total	**Referral**	**≥10**

Referral with score ≥10 corresponds to doubling of lifetime risk for breast cancer (22%).

Manchester Scoring System[141]

Risk Factor (age of onset for relative in direct lineage)	*BRCA1* Score	*BRCA2* Score
Female breast cancer		
<30	6	5
30-39	4	4
40-49	3	3
50-59	2	2
≥60	1	1
Male breast cancer		
<60	5*	8†
≥60	5*	5†
Ovarian cancer		
<60	8	5
≥60	5	5
Pancreatic cancer	0	1
Prostate cancer		
<60	0	2
≥60	0	1
Total individual genes	**10**	**10**
Total for combined=15		

Probability of ≥10% chance of *BRCA1* or *BRCA2* mutation individually or combined.
*If *BRCA2* tested.
†If *BRCA1* tested.

Appendix C5. Familial Risk Assessment Models

Referral Screening Tool (RST)[143]

History of breast or ovarian cancer in the family? If yes, complete checklist.		
Risk Factor	**Breast cancer age ≤50**	**Ovarian cancer at any age**
Yourself		
Mother		
Sister		
Daughter		
Mother's side		
Grandmother		
Aunt		
Father's side		
Grandmother		
Aunt		
≥2 cases of breast cancer after age 50 on the same side of the family		
Male breast cancer at any age in any relative		
Jewish ancestry		

Referral if ≥2 checks in table.

Pedigree Assessment Tool (PAT)[144]

Risk Factor	**Score for every family member with breast or ovarian cancer diagnosis, including 2nd/3rd degree**
Breast cancer at age ≥50	3
Breast cancer at age <50	4
Ovarian cancer at any age	5
Male breast cancer at any age	8
Ashkenazi Jewish heritage	4
Total	

Score ≥8 is the optimal referral threshold.

FHS-7[145]

1. Did any of your 1st degree relatives have breast *or* ovarian cancer?
2. Did any of your relatives have bilateral breast cancer?
3. Did any man in your family have breast cancer?
4. Did any woman in your family have breast *and* ovarian cancer?
5. Did any woman in your family have breast cancer before the age of 50 years?
6. Do you have 2 or more relatives with breast *and/or* ovarian cancer?
7. Do you have 2 or more relatives with breast *and/or* bowel cancer?

One positive response initiates referral.

Appendix C6. Evidence Table of Genetic Counseling

Author, year Quality	Subcategory	Purpose	Study type	N	Country	Population/setting
Current report						
Armstrong et al, 2005[148] Good	Cancer worry Attitudes	To assess the association between race and use of genetic counseling for *BRCA1/2* testing in women at risk of carrying a *BRCA1/2* mutation and to evaluate the potential contributions of socioeconomic characteristics about genetic testing, and interactions with primary care physicians to this association	Case-control	Eligible: NR Enrolled: NR Randomized: NR Analyzed: 408 (217 cases, 191 controls)	U.S.	Visit to University of Pennsylvania Health System Cases: women from reference population who presented for genetic counseling, mean age 42.5 years, 29% Jewish Controls: random sample of women from reference population, mean age 53.1 years, 11% Jewish
Bennett et al, 2008[150] NA	Psychological	To examine the relationship between measures of anxiety and depression and a number of variables identified to be associated with distress	Before and after	Eligible: 367 Enrolled: 319 Analyzed: 128	U.K.	Women referred for genetic risk assessment to a large Cancer Genetics Service for Wales (CGSW) center
Bennett et al, 2009[149] NA	Cancer worry Psychological	To explore the relationship between a number of factors hypothesized to be associated with the frequency of intrusive worries close to the time women were informed of their genetic risk for developing breast and/or ovarian cancer	Before and after	Eligible: 221 Enrolled: 221 Analyzed: 128	U.K.	Women referred for genetic risk assessment to a large Cancer Genetics Service for Wales (CGSW) center
Bloom et al, 2006[151] Poor	Risk perception Cancer worry Health behaviors	To compare women in a telephone counseling intervention to controls and determine whether perceived risk would be more consistent with objective risk and whether there would be reduction in breast cancer worries, improvement in health protective behaviors, and an increase in breast cancer screening	RCT	Eligible: NR Enrolled: 163 Randomized: 163 (80 in intervention, 83 in control) Analyzed: 149 (71 in intervention, 78 in control)	U.S.	Sisters of women diagnosed with breast cancer at age ≤50; predominantly Euro-American and well educated; substantial majority receive regular breast cancer screening
Bowen et al, 2006[152] Fair	Risk perception Cancer worry Interest in genetic testing	To test the efficacy of 2 counseling methods in Ashkenazi Jewish women with average or moderately increased risk of breast cancer	RCT	Eligible: 347 Enrolled: 221 Randomized: 221 (68 to psychosocial counseling, 77 to genetic counseling, 75 to control) Analyzed: 96% followup rate	U.S.	Ashkenazi Jewish women from the greater Seattle area; mean age of 47 years; 100% Ashkenazi Jewish

Appendix C6. Evidence Table of Genetic Counseling

Author, year Quality	Subcategory	Purpose	Study type	N	Country	Population/setting
Brain et al, 2011[153] NA	Cancer worry	To provide 6-year followup on women in TRACE study and the predictors of long-term cancer worry, perceived risk, and health behaviors	Before and after	Eligible: 545 Enrolled: 384 Analyzed: 263	U.K.	Women who took part in the TRACE study
Braithwaite et al, 2005[154] Fair	Risk perception	To examine the acceptability of the GRACE prototype to women with a family history of breast cancer and test the hypothesis that GRACE would perform as well as the nurse counselor at improving women's risk perceptions without causing adverse emotional reactions	RCT	Eligible: 89 Enrolled: 72 Randomized: 72 (38 to GRACE, 34 to clinical nurse specialist) Analyzed: 58	U.K.	Women with a family history of breast cancer recruited through newspaper ads and posters
Fry et al, 2003[155] Fair	Perceived risk Cancer worry	To compare the psychological outcomes of 2 models of breast cancer genetics services	RCT	Eligible:574 Enrolled:373 Analyzed: 244	Scotland	Women referred by GP for breast cancer genetic risk counseling
Gurmankin et al, 2005[156] NA	Risk perception	To examine the risk perception derived from a risk communication with a health care provider during genetic counseling for breast cancer and *BRCA1/2* mutation risks	Before and after	Eligible: NR Enrolled: 58 Analyzed: NR	U.S.	New patients at university cancer evaluation program; mean age of 46 years; most were white and had some college education or more
Helmes et al, 2006[157] Fair	Cancer worry Risk perception	To assess whether women participating in either in-person or telephone counseling sessions would have a more accurate perception of their personal breast cancer risk, increase their intentions for breast screening, have reduced levels of cancer worry, and have less interest in genetic testing	RCT	Eligible: 898 Enrolled: 340 Randomized: 340 (104 to the in-person arm, 121 to the telephone arm, 115 to control) Analyzed: 335 (102 in the in-person arm, 119 in the telephone arm, 114 control arm)	U.S.	Physicians network in Washington Mean age, 40.7 years
Hopwood et al, 2004[158] NA	Cancer worry Psychological factors	To assess changes in risk perception, psychological distress, health care behaviors, and use of health care resources; to assess satisfaction with services, to describe regional variations in outcomes	Before and after	Eligible: 271 Enrolled: 256 Analyzed: 234 (1 month), 202 (12 month), 192 (precounsel, 1 and 12 months)	U.K.	Cancer genetic services centers Age range, 49-52 years

Appendix C6. Evidence Table of Genetic Counseling

Author, year Quality	Subcategory	Purpose	Study type	N	Country	Population/setting
Kelly et al, 2008[159] NA	Risk perception	To examine change in subjective risk of ovarian cancer over time in response to genetic counseling and testing in the short- and long-term; discrepancy between subjective and objective estimates of ovarian cancer risk; and new methods for conceptualizing subjective risk derived from the Common Sense Model	Before and after	Eligible: 78 Enrolled: 78 (40 to no personal history of breast cancer, 38 to personal history) Analyzed: NR	U.S.	Women were recruited from the community Mean age, 48.64 years
Matloff et al, 2006[160] Fair	Risk perception	To examine if a personalized risk assessment and genetic counseling intervention would affect knowledge, risk perception, and decisionmaking in a group of women who had 1 FDR with breast cancer compared with a control group	RCT	Eligible: NR Enrolled: NR Randomized: 64 (32 in each group) Analyzed: 54 completed 1 month followup (28 control and 26 intervention), 48 completed 6 month followup (25 control and 23 intervention)	U.S.	Women recruited through advertisements in New Haven, CT
Mikkelsen et al, 2007[161] Fair	Risk perception	To explore the impact of genetic counseling on perceived personal lifetime risk of breast cancer, the accuracy of risk perception, and possible predictors of inaccurate risk perception 1 year following counseling	Prospective cohort	Eligible: 3257 (568 in counseling group, 689 in reference group 1, 2000 in reference group 2) Enrolled: 1971 (319 in counseling group, 381 in comparison group 1, and 1271 in group 2) Analyzed: 1602 (213 in counseling group, 319 in comparison group 1, and 1070 in group 2)	Denmark	Danish women at risk of hereditary breast and ovarian cancer
Mikkelsen et al, 2009[162] Fair	Psychological factors Cancer worry Quality of life changes	To clarify the psychosocial impact of genetic counseling for hereditary breast and ovarian cancer	Prospective cohort	Eligible: 3257 (568 in counseling group, 689 in reference group 1, 2000 in reference group 2) Enrolled: 1971 (319 in counseling group, 381 in comparison group 1, and 1271 in group 2) Analyzed: 1602 (213 in counseling group, 319 in comparison group 1,	Denmark 2007	Danish women at risk of hereditary breast and ovarian cancer

Appendix C6. Evidence Table of Genetic Counseling

Author, year Quality	Subcategory	Purpose	Study type	N	Country	Population/setting
				and 1070 in group 2)		
Pieterse et al, 2011[163] NA	Risk perception accuracy, correct knowledge, perceived personal control, generalized state anxiety, and cancer-related distress	To assess changes in cognitions (accurate risk perception, correct knowledge, perceived personal control) and distress (state anxiety, cancer-related stress reactions) from before to immediately and 6 months after concluding breast cancer genetic counseling in female counselees, and whether changes in cognitions and distress were similar in affected versus unaffected women	Before and after	Eligible: 204 Enrolled: 77 Randomized: N/A Analyzed: 77	The Netherlands	Women seeking counseling for hereditary cancer at University Medical Center in the Netherlands, surveys exchanged through the mail
Roshanai et al, 2009[164] Fair	Risk perception Psychological factors	To investigate the effect of an informational intervention on counselees' knowledge, risk perception, communication of information to at-risk relatives and satisfaction with the service	RCT	Eligible: 210 Randomized: 163 (85 in intervention, 78 in control group) Analyzed: 147 at precounseling (73 in intervention, 74 in control); 144 for risk perception (71 in intervention, 73 in control); 147 2 weeks postcounseling (73 in intervention, 74 in control); 139 at 8 months postcounseling (68 in intervention, 71 in control)	Sweden	Swedish women visiting a university cancer genetic clinic, mainly referred due to breast cancer or family history of breast, ovarian or colorectal cancer (groups separated for analysis)

Appendix C6. Evidence Table of Genetic Counseling

Author, year Quality	Subcategory	Purpose	Study type	N	Country	Population/setting
Prior report						
Bowen et al, 2002[57] Fair	Interest in genetic testing	To test the effects of breast cancer risk on interest in genetic testing in women who have a family history of breast cancer	RCT	Eligible: 561 Enrolled: 357 Randomized: 357 (120 to genetic counseling, 114 to psychosocial group, 123 to delayed counseling) Analyzed: 317 (105 to genetic counseling, 103 to psychosocial, 109 to delayed counseling)	U.S.	Women recruited from the Seattle area; see Bowen et al, 1999. All volunteered after seeing a notice, hearing about the study from a network, or through a relative with cancer
Bowen et al, 2004[62] Fair	Cancer worry Psychological factors Risk perception	To test the effects of 2 types of breast cancer risk counseling (group psychosocial or individual genetic) on perceived risk, negative affect, and worry about breast cancer	RCT	Eligible: 561 Enrolled: 354 Randomized: 354 (118 genetic counseling arm, 114 psychosocial counseling arm, 122 delayed intervention arm) Analyzed: 348 (117 genetic counseling arm, 110 psychosocial counseling arm, 121 delayed intervention arm)	U.S.	Recruitment from among family members with breast cancer and through notices in local electronic and print outlets. Recruitment completed in 8 months. Women with a range of actual breast cancer risk levels were included
Brain et al, 2002[166] Good	Psychological factors	To compare the psychological impact of a multidisciplinary specialist genetics service with surgical provision in women at high risk and lower risk of familial breast cancer	RCT	Eligible: 1,000 Enrolled: 740 Randomized: 735 (369 control, 366 trial) Analyzed: 653 (315 control, 338 trial)	Wales	Welsh women with family history of breast cancer referred to breast cancer clinic by doctor in 18-month trial period (1996 to 1997). Randomized to trial (n=366) or control group (n=369)
Burke et al, 2000[58] Fair	Cancer worry Risk perception	To assess whether modified traditional genetic counseling causes women with an intermediate risk of breast cancer to have a more realistic view of their risk, of genetic testing, and to decrease breast cancer worry	RCT	Eligible: 793 Enrolled: 356 Randomized: 243 (120 to genetic counseling, 123 to control group) Analyzed: 237 (116 to genetic counseling, 121 to control group)	U.S.	Sources for solicitation include women who live within 60 miles of Seattle: 2 studies at Fred Hutchinson Cancer Research Center, an oncologist's practice at University of Washington, mass media announcements

Appendix C6. Evidence Table of Genetic Counseling

Author, year Quality	Subcategory	Purpose	Study type	N	Country	Population/setting
Cull et al, 1998[59] Good	Psychological factors Risk perception	To evaluate use of video for education on the genetic basis of breast cancer and on strategies for breast cancer risk management in a breast cancer family clinic	RCT	Eligible: 159 Enrolled: 144 Randomized: 128 (66 to video before group, 62 to video after) Analyzed: 95 (53 to video before group, 42 to video after group)	U.K.	A consecutive series of women newly referred to the breast cancer family clinic were invited by mail to participate; 24% of the video before and 30% of the video after group were referred by another hospital clinic; 1 subject in each group had been referred from another genetic clinic. The remaining were referred by GPs
Hopwood et al, 1998[167] Fair	Psychological factors	To understand psychological support needs for women at high genetic risk for breast cancer	Cohort	Eligible: 176 Enrolled: 174 Analyzed: 158	England	All were consecutive first-time attendees at the Family History Clinics (Manchester, U.K.)
Lerman et al, 1996[168] Fair	Cancer worry Risk perception	To study effect of individualized breast cancer risk counseling	RCT	Eligible: 438 Enrolled: 227 Randomized: 227 (group randomization NR) Analyzed: 200 (90 to risk counseling, 110 to control group)	U.S.	Subjects identified by relatives under treatment for breast cancer at either Fox Chase Cancer Center or Duke Comprehensive Cancer Center
Lerman et al, 1999[60] Fair	Cancer worry Interest in genetic testing	To investigate racial differences in response to 2 alternate pretest education strategies for *BRCA1* genetic testing: a standard education model and an education plus counseling model	RCT	Eligible: 581 Enrolled: 364 Randomized: 364 (group randomization NR) Analyzed: 298 (157 to education only, 141 to education plus counseling)	U.S.	Subjects were recruited from 2 cancer centers (Georgetown University Medical Center or Washington Hospital Center)
Lobb et al, 2004[169] Good	Psychological factors	To examine the effect of different consultant communication styles on a variety of outcomes	Longitudinal	Eligible: NR for unaffected group Enrolled: NR for unaffected group Analyzed: 89	Australia	Women from high-risk breast cancer families attending their first consultation before genetic testing
Watson et al, 1998[171] Good	Cancer worry Psychological factors Risk perception	To look at recall of risk information after genetic counseling and to determine impact of receiving an audiotape of the genetic consultation on level of recall, cancer-related worry, and uptake of risk management methods	RCT	Eligible: 135 Enrolled: 115 Randomized: 115 (60 cases, 55 controls) Analyzed: 107 (56 cases, 51 controls)	U.K.	First-time attendees at the cancer family clinics of 2 London hospitals: Royal Marsden, Sutton and London, and St. George's Hospitals

Appendix C6. Evidence Table of Genetic Counseling

Author, year Quality	Subcategory	Purpose	Study type	N	Country	Population/setting
Watson et al, 1999[170] Good	Psychological factors	To investigate perception of genetic risk and the psychological effects of genetic counseling in women with a family history of breast cancer	Prospective cohort	Eligible: 303 Enrolled: 282 Analyzed: 282	England	First-time genetic clinic attendees recruited from 4 South London genetic counseling centers (Royal Marsden NHS Trust Hospital [2 separate clinics], Mayday University Hospital, and St. Georges' Hospital)

Author, year Quality	Demographics	Inclusion/exclusion criteria	Risk level definition
Current report			
Armstrong et al, 2005[148] Good	Cases vs. controls Mean age (years): 42.5 (range, 19-66) vs. 53.1 (range, 20-89) Race/ethnicity: African American: 7.4% vs. 29% Asian American: 3.3% vs. 3.2% White: 85% vs. 66% Hispanic: 0% vs. 2.1% Other: 4.6% vs. 0% Religious heritage: Jewish: 29% vs. 11% Christian: 52% vs. 60% Other: 13% vs. 13% NR: 5.9% vs. 16%	Inclusion: Women ages 18-80 years seeing a primary care physician within the University of Pennsylvania Health System in the 3 years prior to the start of the study, with FDR or SDR with a breast or ovarian cancer diagnosis Exclusion: Personal diagnosis of breast or ovarian cancer, identified as being unable to participate because of illness or mental incapacity by their primary care physician Controls: Previously participated in *BRCA1/2* genetic counseling	FDR or SDR with a breast or ovarian cancer diagnosis
Bennett et al, 2008[150] NA	Mean age, 43.3 years	Inclusion: Women undergoing assessment for risk of breast/ovarian cancer at the CGSW and who completed followup questionnaires Exclusion: Did not complete risk assessment process before the end of the study	23% low risk 45% moderate risk 31% high risk
Bennett et al, 2009[149] NA	Mean age, 44.3 years (SD, 10.81; range, 18-76)	Inclusion: Women undergoing assessment for risk of breast/ovarian cancer at the CGSW and who completed followup questionnaires Exclusion: Did not complete risk assessment process before the end of the study	30/128 (23.4%) at population risk 61/128 (47.7%) at moderate risk 37/128 (28.9%) at high risk
Bloom et al, 2006[151] Poor	Mean age, 47.4 years (SD, 7.2) 77% Euro-American 6.1% African American 9.2% Latina 8.0% Asian/Other	Inclusion: Not reported Exclusion: Prior breast cancer	All had ≥1 FDR (sister) with breast cancer diagnosis at age ≤50

Appendix C6. Evidence Table of Genetic Counseling

Author, year Quality	Demographics	Inclusion/exclusion criteria	Risk level definition
Bowen et al, 2006[152] Fair	Mean age, 47 years	Inclusion: Women ages 18-74 years with ≥1 Ashkenazi Jewish ancestor who lived within 60 miles of Seattle Exclusion: Personal history of breast or ovarian cancer, family history consistent with an autosomal dominant inheritance of breast cancer predisposition	≥1 Ashkenazi Jewish ancestor
Brain et al, 2011[153] NA	Mean age, 42.3 years (SD, 8.22)	Inclusion: Women who took part in TRACE study and were approved by physician to be contacted Exclusion: NR	Moderate risk not otherwise described
Braithwaite et al, 2005[154] Fair	GRACE (n=37) vs. counseling (n=34) Age (years): 18-34: 62.2% vs. 67.6% 35-49: 27% vs. 20.6% ≥50: 10.8% vs. 11.8% Ethnicity: White: 91.9% vs. 94.1% Other: 8.1% vs. 5.8%	Inclusion: Having ≥1 FDR or SDR with breast cancer Exclusion: Personal history of breast cancer	All had ≥1 FDR or SDR with breast cancer
Fry et al, 2003[155] Fair	Mean age (SD) Standard service: 37.3 (9.4) Novel service: 39.1 (9.6)	Inclusion: Women who lived in the region and were able to give informed consent and complete a baseline questionnaire Exclusion: Women who were symptomatic or diagnosed with breast and/or ovarian cancer, or women who had previously consulted with another clinic about their family history of cancer	Criteria for significantly increased risk: Having a FDR with breast cancer diagnosis before age 40; having 2 FDRs or SDRs on the same side of the family with breast cancer diagnosis before age 60 or with ovarian cancer; having 3 FDRs or SDRs on the same side of the family with breast or ovarian cancer; having a FDR with breast cancer in both breasts; and having a male relative with breast cancer
Gurmankin et al, 2005[156] NA	Mean age of 45.9 years (SD, 10.5) 88% White 10% Black 2% Other 42% Ashkenazi Jewish	Inclusion: Females only Exclusion: Health care provider indicated they were too ill to participate	NR

Appendix C6. Evidence Table of Genetic Counseling

Author, year Quality	Demographics	Inclusion/exclusion criteria	Risk level definition
Helmes et al, 2006[157] Fair	Mean age (years): In-person counseling: 39.9 (SD, 9.2) Telephone counseling: 40.4 (SD, 9.7) Delayed counseling: 41.8 (SD, 10.1)	Inclusion: Women ages 18-64 years within 60 miles of research institute, planning to live in area for 1 year, spoke English, telephone in home, covered by commercial health insurance plan Exclusion: Women with personal history of breast/ovarian cancer, personal history of genetic counseling or testing for cancer risk	14.7% had family history of breast cancer
Hopwood et al, 2004[158] NA	Average across all 5 cancer genetics services: Mean age, 41 years (range, 22-72) 94% Female 2% Ethnic minority	Inclusion: Women seen at a cancer genetics services center Exclusion: Women who had been diagnosed with cancer, age <18 years	NR
Kelly et al, 2008[159] NA	Mean age, 48.64 years (SD, 12.69) 100% Ashkenazi Jewish women	Inclusion: Ashkenazi Jewish women with personal or family histories suggestive of an inherited predisposition to breast and/or ovarian cancer Exclusion: Prior history of ovarian cancer, men, women having prophylactic oophorectomies	≥1 Ashkenazi Jewish grandparent
Matloff et al, 2006[160] Fair	Mean age, 49 years (range, 41-55) 21% Ashkenazi Jewish	Inclusion: Women age ≥40 years with ≥1 FDR with breast cancer, had gone through natural menopause Exclusion: Taking menopausal therapy, having had cancer, atypical hyperplasia, or LCIS, being a known carrier of a *BRCA1/2* mutation, having heart disease, women with family history that placed them at >10% risk of carrying a mutation	≥1 FDR with breast cancer
Mikkelsen et al, 2007[161] Fair	Median age (years): Counseling: 39 (range, 18-72) Group 1: 56 (range, 28-76) Group 2: 45 (range, 18-75)	Inclusion: Women age ≥18 years who attended an initial genetic counseling session for breast or ovarian cancer Exclusion: Women affected with breast or ovarian cancer at baseline or who developed cancer during the followup period	NR
Mikkelsen et al, 2009[162] Fair	Median age (years): Counseling: 39 (range, 18-72) Group 1: 56 (range, 28-76) Group 2: 45 (range, 18-75)	Inclusion: Women age >18 years who attended an initial genetic counseling session for breast or ovarian cancer Exclusion: Women affected with breast or ovarian cancer at baseline or who developed cancer during the followup period	NR

Appendix C6. Evidence Table of Genetic Counseling

Author, year Quality	Demographics	Inclusion/exclusion criteria	Risk level definition
Pieterse et al, 2011[163] NA	Age ≥18 years	Inclusion: Patients sought counseling for hereditary cancer; were first among their 1st- and 2nd-degree relatives to request counseling; were first-time attendees; and age >18 years Exclusion: NR	Seeking counseling for hereditary cancer
Roshanai et al, 2009[164] Fair	Female: 90.5% (n=133) Male: 9.5% (n=14) Median age, females (years): 56 (range, 23-84)	Inclusion: Women age ≥18 years; able to read, write, and speak Swedish Exclusion: Suffered from any mental illness	Risk estimated by geneticist: Intervention n (%) vs. control n (%) ≤20%: 5 (15) vs. 3 (23) 21%-40%: 29 (72.5) vs. 37 (77) >40%: 3 (9) vs. 1 (4)
Prior report			
Bowen et al, 2002[57] Fair	Psychological counseling arm: Mean age, 41.9 years (SD, 11.3) 90% White, nonHispanic 3.5 % White, Hispanic 0.9% African American 2.6% Asian or Pacific Islander 1.8% Native American 0.9% Multiracial Genetic counseling arm: Mean age, 42.8 years (SD, 11.8) 94% White, nonHispanic 0.0% White, Hispanic 0.8% African American 1.7% Asian or Pacific Islander 1.7% Native American 1.7% Multiracial Control arm: Mean age, 42.4 years (SD, 11.5) 93% White, nonHispanic 0.0% White, Hispanic 2.5% African American 3.3% Asian or Pacific Islander 0.0% Native American 0.8% Multiracial	Inclusion: Women ages 18-74, lived within 60 miles of research center, agreed to participate in counseling and complete questionnaires, and had ≥1 relative affected by breast cancer Exclusion: Lack of family history of breast cancer, age outside the 18-74 range, >1 close relative affected by breast cancer, living outside the catchment area and lack of interest in completing the study	Family history: Close relatives affected by breast cancer included grandmothers, mothers, sisters, and aunts Risk level: Gail and Claus scores, along with population data
Bowen et al, 2004[62] Fair	Mean age, years (SD) Genetic counseling: 42.6 (11.8) Psychosocial counseling: 42.1 (11.4) Delayed intervention: 42.5 (11.5)	Inclusion: Women ages 18-74 with ≥1 relative with breast cancer, no personal history of breast or ovarian cancer, no family history consistent with a BRCA mutation for breast cancer risk, living within 60 mile radius of research center, willingness to complete research activities and completed and returned baseline questionnaire Exclusion: NR	Family history: Self-report of any family history of breast cancer Risk level: Calculated by use of Gail and Claus models, along with population data

Appendix C6. Evidence Table of Genetic Counseling

Author, year Quality	Demographics	Inclusion/exclusion criteria	Risk level definition
Brain et al, 2002[166] Good	Mean age, years (SD) Low vs. moderate vs. high risk Control group: 48.6 (10.25) vs. 40.5 (9.13) vs. 39.2 (7.33) Trial group: 52.9 (7.75) vs. 41.6 (8.52) vs. 33.7 (8.19)	Inclusion: Women with a 1st-degree female relative diagnosed with breast cancer before age 50 years or with bilateral breast cancer diagnosed at any age, ≥2 FDRs with breast cancer, or a FDR and SDR with breast cancer Exclusion: Personal history of breast cancer, previously received genetic counseling, or was not a resident of Wales	Family history risk definition: 1st-degree female relative diagnosed with breast cancer before age 50; 1st-degree female relative with bilateral breast cancer at any age; ≥2 FDRs with breast cancer; or a FDR and SDR with breast cancer. Risk definition: In trial group, risk was assessed on detailed pedigree data collected and analyzed by geneticist using Claus model. In control group, surgical assessment of risk was based on info collected on age, reproductive history, and minimal family history
Burke et al, 2000[58] Fair	Genetic counseling arm: Average age, 43 years (SD, 12) 94% White Control group arm: Average age, 42 years (SD, 12) 93% White	Inclusion: Women ages 18-74, lived within 60 miles of Seattle, and had ≥1 biological relative who has been diagnosed with breast cancer Exclusion: A personal history of breast or ovarian cancer and a family history indicative of autosomal dominant inheritance of breast cancer	Intermediate family history of breast cancer: ≥1 biological relative with breast cancer but whose pedigree suggests a low likelihood of autosomal dominant transmission. Family history indicative of autosomal dominant inheritance of breast cancer: ≥2 1st-degree or 1 1st- and 1 2nd-degree relative with either breast cancer before age 50 or ovarian cancer at any age, or ≥2 paternal 2nd-degree relatives with either breast cancer before age 50 or ovarian cancer at any age. The Claus model showed that these women would have ≥20% breast cancer risk by age 79
Cull et al, 1998[59] Good	Mean age, 39 years (SD, 8)	NR	NR
Hopwood et al, 1998[167] Fair	Mean age, 36.19 years (range, 22.63-46.35)	Inclusion: Women ages 18-45 living within a 25 mile radius of the FHC with risk ≥2-fold greater than the population for breast cancer Exclusion: NR	Risk was ≥2-fold greater than the population for breast cancer (i.e., 1:6 lifetime risk or greater as assessed using the Claus model)

Appendix C6. Evidence Table of Genetic Counseling

Author, year Quality	Demographics	Inclusion/exclusion criteria	Risk level definition
Lerman et al, 1996[168] Fair	18% ages 35-40 years 41% ages 41-49 years 42% age ≥50 years 90% White 10% Black	Inclusion: Women age ≥35 years and a family history of breast cancer Exclusion: A personal history of cancer and younger than age 35 years	≥1 FDR with breast cancer; breast cancer risk estimates for individual women were calculated using subject's Gail model variables and estimated the lifetime probability of developing breast cancer, 95% CIs, and the estimated lifetime risk for a woman of the same age with the lowest risk of disease
Lerman et al, 1999[60] Fair	24% Black 34% age <40 years 66% age ≥40 years 76% White 41% age <40 years 59% age ≥40 years	Inclusion: Caucasian and African American women with a family history of breast cancer or ovarian cancer Exclusion: Personal history of cancer (except basal cell or squamous cell skin cancer)	≥1 FDR affected with breast cancer and/or ovarian cancer
Lobb et al, 2004[169] Good	Mean age, 38.7 years (range, 19-60)	Inclusion: Women attending their first consultation before genetic testing with no prior testing for or carrier of *BRCA1* or *BRCA2* Exclusion: Unable to give informed consent, age <18 years, showed evidence of severe mental illness, and nonfluent in English	NR
Watson et al, 1998[171] Good	Median age, 37 years (range, 28-56) for participants from the Royal Marsden Hospital Median age, 41 years (range, 23-71) for participants from St. George's Hospital	Inclusion: Women with a family history of breast cancer, first visit to genetic clinic, never having been clinically affected with cancer, no known mental illness, and age ≥18 years Exclusion: NR	NR
Watson et al, 1999[170] Good	Median age, 37 years (range, 19-76)	Inclusion: Women with a family history of breast cancer, never clinically affected by cancer, no known serious mental illness, age ≥18 years, and able to complete a questionnaire Exclusion: NR	Breast cancer risk calculated using CASH model based on the number of breast cancer cases in 1st- and 2nd-degree relatives, age of family members at disease onset, and age of woman presenting for genetic counseling

Author, year Quality	Interventions	Measures	Duration of followup
Current report			
Armstrong et al, 2005[148] Good	A) Genetic counseling prior to testing, otherwise not described B) Controls		1999-2003 Not applicable

Appendix C6. Evidence Table of Genetic Counseling

Author, year Quality	Interventions	Measures	Duration of followup
Bennett et al, 2008[150] NA	CGSW referral guidelines and BRCAPRO risk calculation model	Medical Coping Modes Questionnaire (MCMQ, scale NR) Impact of Events Scale (IES, subscales 0 to 28) DUKE Social Support Questionnaire (DUKE-SSQ, scale 1 to 5) Hospital Anxiety and Depression Scale (HADS, subscales 0 to 21) Perceived health Quality of Life	Year NR 1 week following risk notification
Bennett et al, 2009[149] NA	CGSW referral guidelines and BRCAPRO risk calculation model	Impact of Events Scale (IES, subscales 0 to 28) Medical Coping Modes Questionnaire (MCMQ, scale NR) DUKE Social Support Questionnaire (DUKE-SSQ, scale 1 to 5)	Year NR Approximately 5 to 7 weeks
Bloom et al, 2006[151] Poor	A) Telephone counseling from a master's level counselor within 2 weeks; breast cancer worries measured by 4-point Likert scale; perceived risk measured on 5-point scale; rating chances of diagnosis (0%-100%). Telephone counseling session included establishment of rapport and determination of special concerns, emotional readiness; risk notification by providing modified Gail model lifetime risk estimate and discussing in terms of her pretest self-assessment of risk; deescalation of tension regarding breast cancer checkup; evaluation of coping skills, reinforcement of problem solving and coping skills; information on health protective behaviors; early detection through American Cancer Society screening; and information on genetic testing when requested. B) Delayed telephone counseling following the posttest	NSI: 3-item measure of breast cancer worry: perceived risk of breast cancer, health behaviors, and breast cancer sreening	1999-2002 6 months
Bowen et al, 2006[152] Fair	A) Group psychosocial counseling: psychologist led four 2-hour, weekly sessions of 5 to 6 women per group. Each session included 20-minute group cohesion activities followed by 1 of 4 major intervention components: risk assessment and perception, education, stress management, and problem solving and social support. B) Individual genetic counseling: genetic counselor provided 1-hour counseling sessions, individually. Sessions covered several topics, including participant's family background, breast cancer risk assessment, *BRCA1/2* mutations in the Ashkenazi Jewish population, nongenetic risk factors for breast cancer, and breast screening. C) Delayed counseling: no counseling, served as control	NSI: Continuous scale of 0-100 to assess risk perception BSI: 53-item self-reported psychological symptom scale	Year NR 6 months
Brain et al, 2011[153] NA	A) Claus model B) Generalized risk level based on age, reproductive history, and minimal family history	Cancer Worry Scale-Revised (CWS-R, scale 6 to 24) Perceived risk (single item scale, 1 to 5)	Year NR 6 years

Appendix C6. Evidence Table of Genetic Counseling

Author, year Quality	Interventions	Measures	Duration of followup
Braithwaite et al, 2005[154] Fair	Both interventions were 1 session; cognitive outcomes assessed at baseline, postclinic, and at 3 months A) Risk counseling arm: Clinical nurse specialist undertook counseling sessions and drew pedigree with information from family history and assessed risk as low, moderate, or high based on GRACE guidelines. Participants were mailed letters summarizing content afterward B) GRACE: Participants completed their pedigrees in GRACE and assessed their risk, learning their risk assessment and how to manage their risk. They received a numerical estimate of lifetime risk; a visual display of cumulative risk with general population as comparator; and a qualitative description. Clinical nurse specialists then offered to book mammography and arrange meetings with geneticists, where appropriate	NSI: Measured attitude, perceived benefit, risk perception, and satisfaction and risk communication on a likert scale STAI: Measures an individual's current anxiety feelings HADS: 14-item self-report scale for the detection of depression and anxiety in hospitalized patients	Year NR 3 months
Fry et al, 2003[155] Fair	Standard (regional) service: Self-report family history and baseline questionnaire; genetics consultant and genetics nurse specialist assigned categorical risk via Cancer Research Campaign. Women at low risk receive infomative letter; women at moderate/high risk offered appointment at familial breast cancer clinic where a genetics consutant discusses risk status and breast surgeon discusses risk management. Where appropriate, clinical exams and mammography included. Patients' GPs receive summary data, and patients receive followup questionnaires 4 weeks and 6 months later Novel (community-based) service: Women sent an appointment for a community-based clinic near their residence. Meetings run by genetics nurse specialist where family history collected and compared to published criteria (Cancer Research Campaign) to determine risk. Women at low risk offered information, reassurance, and discharged. Women at moderate/high risk offered appointment at a regional center with a geneticist and genetics nurse specialist, and asked to complete followup questoinnaires at 4 weeks and 6 months	Cancer Worry Scale (scale 5 to 24) GHQ-30	6 months
Gurmankin et al, 2005[156] NA	A) Precounseling interview assessed patient's breast cancer risk perception, *BRCA1/2* mutation risk perception, worry about breast cancer, family history of cancer, breast cancer risk reduction behaviors, and demographic information B) Postcounseling interview assessed patient's breast cancer risk, *BRCA1/2* mutation risk, recall of actual risk information, worry about breast cancer, completion of the Spielberger Trait Anxiety Inventory (20-80 score range) and	STAI: Measures an individual's current anxiety feelings NSI: Scale of 0 to 100 to assess risk perception Scale of 1 to 7 to asses cancer worry	October 2002 to February 2004 1 week

Appendix C6. Evidence Table of Genetic Counseling

Author, year Quality	Interventions	Measures	Duration of followup
	the Life Orientation Test-Revised (0-32 measure of optimism)		
Helmes et al, 2006[157] Fair	A) In-person counseling: board-certified genetic counselor conducted counseling consisting of a review of family history, discussion of breast cancer risk, and education about breast cancer genes. Also discussed genetic testing considerations, including implications of results, testing strategies, potential risks and benefits of test, cost of test, and psychological effects of test. Information packet was provided that contained personal risk information comparing the woman's risk with average woman's risk; personal computer-drawn 3-generation pedigree; brochures on self-breast exams, Pap smear, and mammography; genetics visual aids; list of community resources; and cover letter B) Telephone counseling: information packet was sent in the mail with instructions to open at the beginning of the telephone counseling, which was identical in content and structure to in-person counseling. C) Control group did not receive counseling	NSI: Scale of 0 to 100 to assess risk perception Scale of 1-4 to measure intention to obtain breast cancer screening 4-item questionnaire to assess interest in genetic testing	Year NR 3 months
Hopwood et al, 2004[158] NA	A) Genetic counseling, otherwise not described	NSI: 5-response category assement of perceived cancer risk GHQ: 60-item questionnaire to screen individuals for psychiatric disorders	Year NR At 1 month and 1 year following precounseling
Kelly et al, 2008[159] NA	A) Genetic counseling included review of family cancer history, personal risk factors for breast and ovarian cancer, mechanisms of cancer inheritance, meaning of a positive and negative test result, and risks and benefits associated with testing	CWS: 3-item questionnaire to measure how frequently an individual worries about getting breast cancer	Year NR 6 months
Matloff et al, 2006[160] Fair	A) Counseling session with personalized letter summarizing patient data B) Controls who received no counseling	NSI: Reviewed detailed information about menopause, the risks and benefits of each menopasue therapy option, and a disease risk factor assessment	August 2002 to January 2004 6 months
Mikkelsen et al, 2007[161] Fair	A) Genetic counseling: information on incidence of sporadic breast cancer, genetics, inheritance patterns, and estimated personal lifetime risk of inherited cancer B) Comparison group 1: women referred for mammography C) Comparison group 2: random sample of women	IES: 17-item questionnaire to measure an individual's level of distress in relation to a specific event or condition	2003-2004 1 year
Mikkelsen et al, 2009[162] Fair	A) Genetic counseling: information on incidence of sporadic breast cancer, genetics, inheritance patterns, and estimated personal lifetime risk of inherited cancer B) Comparison group 1: women referred for mammography C) Comparison group 2: random sample of women	HADS: 14-item self-report scale for the detection of depression and anxiety in hospitalized patients	2003-2004 1 year

Appendix C6. Evidence Table of Genetic Counseling

Author, year Quality	Interventions	Measures	Duration of followup
Pieterse et al, 2011[163] NA	A) First session topics included family's occurrence of breast and other cancers, inheritance, and criteria on probability of inherited breast cancer. Likelihood of hereditary breast cancer running in family was estimated. Genetic testing was offered to counselees or affected relatives when they had an a priori chance (≥10%) of carrying BRCA gene. Counselees eligible for testing informed of medical consequences and options. Periodic surveillance recommended to all counselees at increased risk (>20%). Counselees and referring physician receive summary letter about genetic and risk information. Counselors distributed postcounseling questionnaire after last session and asked participants to complete it within a day. 6 months later, counselees were sent a followup questionnaire. All 3 of these questionnaires assessed cognitions and distress. Counselors completed a questionnaire after counselee's last visit. Counseling spanned 1 to 4 visits over 6 to 24 months; STAI, IES, and VAS were used to measure anxiety levels	VAS: Any of a number of pain self-assessment tools where subjects indicate their level of pain in response to a continuous visual scale NSI: Scale of 0 to 100 to assess risk perception Scale of 0 to 7 to assess hereditary breast cancer knowledge PPC: Construct reflecting the degree to which a person believes that a situation is under their control STAI: Measures an individual's current anxiety feelings IES: 17-item questionnaire to measure an individual's level of distress in relation to a specific event or condition	24 months (6 months after last counseling session)
Roshanai et al, 2009[164] Fair	A) Genetic counseling from specialist nurse: pedigree explanation; Buckman's Breaking Bad News model to inform at-risk relatives; pamphlet, videotape, copies of pedigree and medical records B) Control group received standard care given at the clinic: genetic counseling from a specialist nurse, no additional information, and no help in identifying at-risk relatives	SPIKES: A 6-step protocol for delivering bad news HADS: 14-item self-report scale for the detection of depression and anxiety in hospitalized patients	2003-2005 At 2 weeks and at 8 months postcounseling
Prior report			
Bowen et al, 2002[57] Fair	A) IGC: Phone call to review pedigree information followed by a single 2-hour counseling session. Subject given information on her own risk for breast cancer using Gail and Claus scores along with population data. Information given on genetic testing, current knowledge about nonhereditary risk factors, and current screening techniques. Summary letter provided B) PGC: Four 2-hour group meetings with 4 to 6 women led by a health counselor. Included: risk assessment and perception, education, stress management, problem solving and social support. Personal risk for breast cancer, interpretation, and appropriate screening provided privately to subjects. C) CG: Offered choice of counseling modality after the final followup	NSI: 3-item questionnaire to assess awareness, candidacy, and interest in genetic testing Tolerance for ambiguity assessed using a questionnaire derived from previous research 5-point response scale to beliefs about genetic testing	Years: 6 months

Appendix C6. Evidence Table of Genetic Counseling

Author, year Quality	Interventions	Measures	Duration of followup
Bowen et al, 2004[62] Fair	Telephone screening survey to determine eligibility followed by mailed baseline survey. Those who returned completed surveys were randomized to individual genetic counseling (IGC), group psychosocial counseling (PC), or a delayed intervention control group (CG) A) IGC: Telephone contact with genetic counselor to review pedigree information. One 2-hour session following protocol based on standard genetic practice. Letter sent to participant within 2 weeks summarizing the session B) PC: Group of 4 to 6 participants met for four 2-hour sessions with trained health counselor. Each participant received her own risk assessment sheet, personalizing the group discussion to her own risk status. Main topics: risk assessment and perception, screening, stress management and problem solving, and social support C) CG: Offered counseling following study completion. For ICG and PC, brief survey on reactions to counseling within 4 weeks of last counseling contact. Mailed second assessment 6 months after randomization, with a reminder call and offer of phone completion to those who did not return survey after 2 weeks	NSI: 4-item questionnaire to assess risk perception Survey to assess reactions to counseling	Years: 6 months
Brain et al, 2002[166] Good	A) Control group: 1) breast cancer surveillance; 2) surgical assessment of individual breast cancer risk; 3) option to enter U.K. Tamoxifen Prevention Trial; and 40 annual surgical followup with surveillance and advice B) Trial group: components 1, 3, and 4 of control group with genetic risk assessment and counseling	STAI: Measures an individual's current anxiety feelings NSI: 3-item scale to assess interest in genetic testing	Years: Immediately
Burke et al, 2000[58] Fair	Random assignment to 3 groups: individual genetic counseling (120 women), psychosocial group counseling (113 women, reported elsewhere [Bowen 1999]), control (123 women) A) Adapted genetic counseling protocol for women with intermediate risk included precounseling telephone call, baseline questionnaire, individual genetic counseling session, immediate followup questionnaire, 6 month followup questionnaire, mailed summary letter B) Control group was offered group counseling following completion of the study	NSI: Questionnaire to assess breast cancer worry, opinions on genetic testing, and risk perception	Year NR 6 months

Appendix C6. Evidence Table of Genetic Counseling

Author, year Quality	Interventions	Measures	Duration of followup
Cull et al, 1998[59] Good	A) Subjects sent information about study with initial clinic appointment 4 weeks before the appointment. They were asked to return baseline questionnaires and forms within 2 weeks if wanting to participate. Those who did so were randomized either to the Video Before group, and were sent a copy of the educational video about 10 days before the clinic consultation, or to the Video After group, taking the video home after the postclinic assessment. B) Clinic consultation: individual meeting with geneticist to discuss individual risk and with breast surgeon to discuss risk management. Clinicians noted session length and rated assessment of it. Postclinic assessment included completion of instruments. Followup assessment by mail 4 weeks later	NSI: 12-response category assessment of risk perception 4-point scale to assess genetic risk Multiple choice questionnaire to assess objective risk STAI: Measures an individual's current anxiety feelings GHQ: 30-item questionnaire to screen individuals for psychiatric disorders	Year NR 1 month following clinic consultation
Hopwood et al, 1998[167] Fair	A) Postal questionnaire prior to counseling B) At attendance for risk counseling, women were asked to complete GHQ together with several other self-report measures C) Questionnaires completed again at 3, 6, 9, and 12 months later D) Three months after Family History Consultation, home visit conducted with research interviews, including administration of the Psychiatric Assessment Schedule. Additional structured questions assessed attitude to risk information, reaction, and concerns about cancer	NSI: 5-item questionnaire to assess risk perception GHQ: 60-item questionnaire to screen individuals for psychiatric disorders PAS: Semistructured clinical interview designed for use with respondents who have learning disability	3, 6, 9, and 12 months following genetic counseling
Lerman et al, 1996[168] Fair	A) Study group: 1) discussion of individual factors contributing to elevated risk, 2) presentation of individualized risk data, 3) recommendations for annual mammography and clinical breast exams, 4) instruction in breast self-exam B) Control group: 1) interview assessment of current health practices, 2) age-specific recommendations for variety of cancer screening tests, 3) encouragement to quit smoking, 4) suggestions for reducing dietary fat to ≤30%, 5) recommendations for regular aerobic exercise	IES: 17-item questionnaire to measure an individual's level of distress in relation to a specific event or condition	Year NR 3 months

Appendix C6. Evidence Table of Genetic Counseling

Author, year Quality	Interventions	Measures	Duration of followup
Lerman et al, 1999[60] Fair	A) Education only: topics discussed included individual risk factors for breast and ovarian cancer and patterns of inheritance for breast and ovarian cancer susceptibility. Subjects given qualitative estimates of their risk of developing breast and ovarian cancer. Pedigrees were reviewed. Potential benefits, limitations, and risks of genetic testing for inherited breast and ovarian cancer susceptibility also reviewed. B) Education plus counseling: provided the same education and materials described above. Subjects guided through a set of questions that explored personal issues related to cancer and genetic testing. Subjects discussed the emotional impact of having a family history of cancer, psychosocial implications of genetic testing for inherited breast and ovarian cancer susceptibility, anticipated reactions to a positive and negative test result, and intentions to communicate test results to family members and friends	IES: 17-item questionnaire to measure an individual's level of distress in relation to a specific event or condition	Year NR 1 month
Lobb et al, 2004[169] Good	A) Self-administered questionnaires were mailed 2 weeks before and 4 weeks after their genetic consultation. Consultations were taped and retained for analysis. Questionnaires included Breast Cancer Genetics Knowledge, Expectations, Perceived Risk, IES, HADS, and Satisfaction with Genetic Counseling Scale B) Women came to the center for their genetic consultation. The consultation was recorded, analyzed, and coded to capture 10 aspects of genetic counseling. Not all counselors incorporated all aspects, and this was the basis for the study	NSI: Scale of 0 to 7 to assess genetic clinic expectations Scale of 0 to 9 to assess information sought Scale of 0 to 100 to assess risk perception IES: 15-item scale measuring intrusion and avoidance responses in relation to a specific stressor HADS: 14-item self-report scale for the detection of depression and anxiety in hospitalized patients	4 weeks
Watson et al, 1998[171] Good	All subjects were referred for genetic counseling with a clinical geneticist who provided a consultation (randomized at clinic immediately after consultation to minimize bias), including pedigree based on risk calculation and information regarding management options based on risk level. All were part of consultation A) Consultation plus audiotape group offered instructions on self-exam and clinical exam and received an audiotape of the consultation B) Consultation-only group offered instructions on self-exam and clinical exam	GHQ-12: 12-item questionnaire to screen individuals for psychiatric disorders CWS: 3-item questionnaire to measure how frequently an individual worries about getting breast cancer VAS: Any of a number of pain self-assessment tools where subjects indicate their level of pain in response to a continuous visual scale	Year NR 6 months

Appendix C6. Evidence Table of Genetic Counseling

Author, year Quality	Interventions	Measures	Duration of followup
Watson et al, 1999[170] Good	A) Self-administered questionnaires given at genetic clinic immediately, pre-, and post-genetic consultation, and by postal survey at 1-, 6-, and 12-month followup	NSI: Lifetime risk perception assess as a 1 in x odds ratio Relative risk assessed on a 5-point scale Breast cancer incidence assessed as 1 in x GHQ: 12-item questionnaire to screen individuals for psychiatric disorders IES: 17-item questionnaire to measure an individual's level of distress in relation to a specific event or condition STAI: Measures an individual's current anxiety feelings	Years: 12 months

Author, year Quality	Results	Conclusions	Funding source
Current report			
Armstrong et al, 2005[148] Good	<u>Logistic regression model of association between race and use of genetic counseling: OR (95% CI)</u> African American (vs. white): 0.28 (0.09 to 0.89) Increased age: 0.97 (0.93 to 0.99) Increased probability of BRCA mutation: 1.25 (1.10 to 1.42) Increased risk perception for breast cancer: 2.88 (1.98 to 4.21) Increased risk perception for ovarian cancer: 1.56 (1.02 to 2.38) Increased ovarian cancer worry: 1.56 (1.02 to 2.38) Belief that testing leads to discrimination: 0.74 (0.57 to 0.96) Increased belief that testing provides reassurance: 1.60 (1.15 to 2.23) Gynecologist discussed BRCA testing: 1.79 (1.02 to 3.13) PCP discussed BRCA testing: 1.93 (1.00 to 3.74) NS associations: marital status, education, income, health insurance, increased breast cancer worry, belief that testing provides information, belief that testing creates anxiety, and number of visits to gynecologist or PCP	African Americans are less likely to undergo genetic counseling than whites. Women who believe testing is likely to lead to discrimination were not likely to undergo genetic counseling. Older women were less likely to undergo genetic counseling than younger women. Women with an increased risk perception for either breast or ovarian cancer were likely to undergo genetic counseling.	The American Cancer Clinical Research Training Grant and the Robert Wood Johnson Generalist Physician Faculty Scholar Award

Appendix C6. Evidence Table of Genetic Counseling

Author, year Quality	Results	Conclusions	Funding source
Bennett et al, 2008[150] NA	**Baseline vs. followup after risk assessment** Mean scores (SE) HADS-D: 4.44 (3.77) vs. 4.05 (3.85); NS HADS-A: 8.02 (4.56) vs. 7.03 (4.41); NS IES-I: 13.17 (10.57) vs. 7.76 (8.95); p<0.001 IES-A: 12.19 (10.78) vs. 8.45 (9.61); p<0.01 Perceived health, quality of life (scale, 0 to 100): 76.74 (20.10) vs. 77.96 (17.68); p<0.05 DUKE-SSQ (scale not described): 27.15 (11.93) vs. 24.97 (11.02); p<0.01 **Correlations between key independent variables and HADS-A vs. HADS-D** Age, level or risk assigned, and MCMQ-confrontation were NS IES-I: 0.703 (p<0.01) vs. 0.448 (p<0.01) IES-A: 0.636 (p<0.01) vs. 0.365 (p<0.01) DUKE-SSQ-confidant: 0.364 (p<0.01) vs. 0.493 (p<0.01) DUKE-SSQ-affective: 0.375 (p<0.001) vs. 0.411 (p<0.01 Perceived health: -0.493 (p<0.01) vs. -0.664 (p<0.01) Hopeless about getting cancer: 0.389 (p<0.01) vs. 0.366 (p<0.01) Hopeless about health: 0.374 (p<0.01) vs. 0.197 (p<0.05) Control over getting cancer: -0.372 (p<0.01) vs. 0.175 (NS) MCMQ-avoidance: 0.429 (p<0.001) vs. 0.271 (p<0.01) MCMQ-acceptance-resignation: 0.383 (p<0.01) vs. 0.206 (p<0.05) Neuroticism: 0.265 (p<0.01) vs. 0.193 (p<0.05)	Following risk status disclosure, women did not have changes in their level of anxiety or depression, as measured by the HADS; their intrusive thoughts and avoidance of intrusive thoughts declined after notification, while their perceived quality life of health and satisfaction increased. This indicates the level or risk disclosed does not negatively impact women's psychological well-being.	NR
Bennett et al, 2009[149] NA	**Baseline vs. followup after risk assessment** IES-I (estimated from graph) High risk: 12.5 vs. 7.8 (p<0.001) Moderate risk: 12.5 vs. 7.9 (p<0.001) Low risk: 11.8 vs. 8.2 (p<0.001) Between-group differences were NS (p=0.694) IES-A (estimated from graph) High risk: 13.1 vs. 8.3 (p<0.05) Moderate risk: 10.6 vs. 8.9 (p<0.05) Low risk: 10 vs. 11.3 (p<0.05) Between-group differences for low vs. moderate and high risk was significant (p<0.05) **Key variables associated with IES intrusion scores** Cognitive response Control over risk for cancer: -0.279 (p<0.001) Hopelessness about developing cancer: 0.412 (p<0.001) Emotional response to risk information Hopeful: -0.331 (p<0.001) Relieved: -0.278 (p<0.001) Calm: -0.506 (p<0.001)	Levels of worry fell among all women following risk assessment, regardless of risk status assignment. Only women with low (population) risk had high frequencies of avoidance after risk assessment. Intrusive worries were associated with a lack of confidant support and a confrontive coping response.	NR

Appendix C6. Evidence Table of Genetic Counseling

Author, year Quality	Results	Conclusions	Funding source
	Anxious: 0.438 (p<0.001) Social support Confidant support: 0.232 (p<0.01) Affective support: 0.208 (p<0.05) Coping Confrontation: 0.284 (p<0.001) Avoidance: 0.442 (p<0.001) Acceptance-resignation: 0.391 (p<0.001) Variables not associated with IES intrusion scores: age, risk status, and surprised emotional response to risk information Similar results were found for IES avoidance scores		
Bloom et al, 2006[151] Poor	Women overestimated their risk of breast cancer by an average of 25 percentage points; proportion of women underestimating risk was larger in women with perceived lower risk (40%) than those who perceived it as the same (16%), higher (10%), or much higher (5%) than the risk of other women (p=0.009) Women reduced their overestimation more if the initial overestimate was higher (p<0.0001); intervention effect was significant only in women age ≥50 years (p=0.004)	Telephone counseling appears to reduce risk overestimates in women with higher than average risk and to promote healthy behaviors in sisters of women with breast cancer.	Grant 4EB-5800 from the California Breast Cancer Research Program
Bowen et al, 2006[152] Fair	**A vs. B vs. C (results at followup)** Perceived risk (scale, 0% to 100%): 18 (SD, 16) vs. 18 (SD, 16) vs. 32 (SD, 23); p<0.001 for both counseling groups vs. control Cancer worry (scale, 4 to 16): 5.2 (SD, 1.5) vs. 4.9 (SD, 1.1) vs. 6.1 (SD, 1.9); p<0.001 for both counseling groups vs. control Awareness of genetic testing (range from 1=almost nothing to 4=a lot): 2.6 (SD, 0.7) vs. 2.6 (SD, 0.7) vs. 2.2 (SD, 0.7); p<0.001 for both counseling groups vs. control Interest in having genetic testing (range from 1=definitely not to 4=definitely yes): 2.4 (SD, 0.9) vs. 2.4 (SD, 0.9) vs. 2.8 (SD, 0.8); p<0.01 for both counseling groups vs. control Candidacy judgment (range from 1=definitely not to 4=definitely yes): 2.0 (SD, 0.8) vs. 2.0 (SD, 0.8) vs. 2.6 (SD, 0.8); p<0.05 for both counseling groups vs. control Fear of stigma (scale range unclear, higher score indicates higher fear of stigma): 3.4 (SD, 1.1) vs. 3.4 (SD, 1.1) vs. 3.3 (SD, 1.2); no significant difference between groups Access to genetic testing (scale range unclear, higher score indicates more unrestricted access): 3.8 (SD, 1.4) vs. 3.9 (SD, 1.4) vs. 4.3 (SD, 1.4); p<0.05 for both counseling groups vs. control Information flow (scale range unclear, higher score indicates more restrictions on information flow): 2.0 (SD, 1.1) vs. 2.1 (SD, 1.0) vs. 1.9 (SD, 0.9); p<0.05 for both counseling groups vs. control	Counseling, either group or individual, reduced cancer worry, lowered inflated risk perceptions, and decreased interest in genetic testing. Included in Smerecnik 2009 review.	National Human Genome Research Institute grant HG01190

Appendix C6. Evidence Table of Genetic Counseling

Author, year Quality	Results	Conclusions	Funding source
Brain et al, 2011[153] NA	**A vs. B** Mean perceived risk after risk assessment: 3.83 (SD, 0.51) vs. 3.97 (SD, 0.38); p=0.01 All other outcomes were NS between groups	Women's cancer worry decreased over time regardless of intervention group, though there was a significant effect immediately after risk assessment, this effect was gone by 9 months followup.	Wales Office for Research and Development in Health and Social Care
Braithwaite et al, 2005[154] Fair	**A vs. B** Mean baseline cancer worry (scale, 1 to 4): 1.92 vs. 1.81 Mean baseline STAI-state anxiety (scale, 20 to 80): 35.73 vs. 40.00 (p<0.01) Perceptions of risk information Participants were positive about risk information from both interventions on credibility, trustworthiness, accuracy, clarity, and helpfulness. Nurse counseling scored significantly higher than GRACE for all; significant differences in participants' satisfaction with risk information. Clinical nurse specialist arm was "very satisfied" with risk information (p<0.01)	No significant differences between GRACE and nurse counseling in risk perception or cancer worry. Nurse counseling was superior to GRACE on patient attitudes and satisfaction indicators.	Cancer Research U.K. (CUK), grant no. C1345/A169
Fry et al, 2003[155] Fair	**A (standard) vs. B (novel)** Cancer worry Baseline: 11.5 (3.2) vs. 11.3 (3.0) 4 weeks: 10.3 (2.4) vs. 10.2 (2.7) 6 months: 9.9 (2.5) vs. 9.7 (2.7) GHQ-30 total score: median (IQR) Baseline: 2 (9) vs. 2 (7.3) 4 weeks: 1 (8) vs. 2 (8.5) 6 months: 0 (4) vs. 0 (5) GHQ-30 case-level distress: n (%) Baseline: 66 (36) vs. 58 (31) 4 weeks: 32 (21) vs. 27 (22) 6 months: 29 (21) vs. 28 (23)	All women experienced a significant reduction in CWS scores, with greatest reductions from baseline to 4 weeks (p<0.000) and a smaller, but still significant, reduction from 4 weeks to 6 months (p=0.003). Women experienced a significant drop in case-level distress from baseline to 4 weeks (p=0.004), but there were no other significant differences in numbers of women with case-level distress between trial arms or time points.	Chief Scientists's Office and Cancer Research U.K.
Gurmankin et al, 2005[156] NA	Mean breast cancer risk perception: 44% Risk perception change from baseline: +17% (p<0.001) Accuracy of recall Risk information patients recalled was higher than risk communicated to them (+6% p=0.02 vs. 8% p=0.001) Patients' belief in recall was positive for breast cancer, showing postcounseling risk perceptions higher than risk information they recalled being told (+9% p=0.001)	Patients' breast cancer risk perceptions following risk communication were higher than corresponding actual risk communicated to them (+19% p<0.001). Inaccurate risk perception (high or low) can lead patients to make different medical decisions than they would with accurate risk perception. They could engage in interventions or experience unnecessary stress if perceived risks are inaccurately high.	The American Cancer Society and a Robert Wood Johnson Faculty Scholar Award

	p=0.07 for A vs. C)		
Mikkelsen et al, 2009[162] Fair	**A vs. B vs. C** HADS-A score decreased from baseline to 1 year: 4.7% (95% CI, -3.5 to 12.8) vs. 2.5% (95% CI, -4.5 to 9.5) vs. 1.1% (95% CI, -2.3 to 4.7); decrease in anxiety in group 1 was in women in nonsystematic screening (7.0% [95% CI, -4.1 to 18.1]), with a slight increase in women in systematic screening (1.1% [95% CI, -7.5 to 9.8]) Baseline vs. 2-weeks followup vs. 6-months followup vs. 12-months followup Cancer-specific distress: 52% vs. 50% vs. 41% vs. 41% Comparing women referred for mammography vs. no genetic counseling (41% to 35%) or to a random sample from the general population (from 32% to 30%) with no counseling. More women with genetic counseling experienced decrease in cancer-specific distress; difference statistically significant when compared to general population (p=0.006) and subgroup of women with mammography screening (p=0.05).	An 11% (95% CI, 1.4 to 20.8) decrease in cancer-specific distress in genetic counseling group from baseline to 1-year followup exceeded decrease in groups 1 and 2, with significance in group 2 (p=0.006) and subgroup of group 1 in systematic screening (p=0.05).	Danish Cancer Society, Grant Number PP 02 010, the Center of Innovation and Development in Nursing Education in the County of Aarhus and Aarhus University Research Foundation, and the Danish Nurses' Organization
Pieterse et al, 2011[163] NA	Risk perception accuracy: N (%) Precounseling vs. immediately postcounseling vs. 6-months postcounseling Underestimation: 1 (3) vs. 5 (16) vs. 8 (24) Correct estimation: 0 (-) v. 10 (32) vs. 6 (18) Overestimation: 29 (97) vs. 16 (52) vs. 19 (57) Total number of counselees: 3 (unaffected group)	Counseling educates women on lifetime breast cancer risk; correct knowledge on breast cancer genetics decreased over time. Benefits gained immediately after counseling seem to remain over time.	Dutch Cancer Society supported original study (Grant number NIVEL 1999-2090); author supported by a post-doctoral fellowship from the Dutch Cancer Society.
Roshanai et al, 2009[164] Fair	The only significant difference between intervention and control was immediately after counseling and at 2 weeks, when controls showed more accurate estimation of risk; groups showed the same results at 8-months followup. No significant difference for anxiety or depression between control and intervention at any time point; both groups significantly decreased over time (p<0.01).	At 8-months followup, 74% of counselees in control and intervention groups had informed relatives; 96% of relatives of intervention counselees and 89% of relatives of controls reported being informed. The majority (75% of intervention relatives and 67% of controls) reported receiving sufficient information.	The Swedish Cancer Society
Prior report			
Bowen et al, 2002[57] Fair	Counseling on risk slightly changed levels of interest in genetic testing in women with a family history. Those who participated in counseling were less interested in genetic testing and less likely to view themselves as good candidates. Stigma and access beliefs about genetic testing were related to the effect of counseling on whether women thought they should participate in testing. As women gained more information, they were slightly less likely to want to participate in testing.	Individual counseling was more predictive of women's increased awareness than psychosocial group counseling.	The National Cancer Institute and the National Human Genome Institute (HG01190)

Appendix C6. Evidence Table of Genetic Counseling

Author, year Quality	Results	Conclusions	Funding source
Bowen et al, 2004[62] Fair	Women's perceived risk for breast cancer decreased by 50% for the 2 counseling groups relative to control ($p<0.01$). Cancer worry decreased in both counseling groups by 1 scale point ($p<0.05$). There were no differential effects of counseling type on perceived risk or cancer worry. Women in psychosocial counseling experienced more anxiety change than those in the other groups. Depression was not impacted by study group.	Some women reported high levels of attendance and satisfaction with counselors and counseling; women in the genetic counseling arm reported more frequently talking about concerns than did women in psychosocial groups. Perceived risk and worry can be reduced with both types of short-term interventions.	The National Human Genome Institute, the National Cancer Institute, and the National Office for Research on Women's Health (HG/CA01190)
Brain et al, 2002[166] Good	State anxiety: Significant main effect of time, with decreased anxiety from baseline to followup ($p=0.03$). Breast cancer worry: Significant overall reduction from baseline to followup. Significant interaction between risk information and time. Decline in women at low risk ($t(106)$, 5.92; $p<0.001$) and moderate risk ($t(443)$, 12.13; $p<0.001$), but not at high risk. Satisfaction: Significantly lower in high-risk group ($p<0.001$). Perception of risk: Marginally significant trend to increased perceived risk in high-risk women in the trial group. Interest in genetic testing: Effect of risk information not significant.	Specialists other than geneticists might provide assessment of breast cancer risk, reassuring those at reduced risk and targeting high-risk women for specialist genetic counseling and testing services. Low-risk women: Anxiety and cancer concerns were reduced with personal risk information. High levels of satisfaction, whether or not information based on detailed genetic analysis. High-risk women: Risk information, even unfavorable, does not appear to create significant anxiety. Concerns about breast cancer risk remained and they were less satisfied with consultation in either group. Implication: Breast cancer worry may impact quality of life for women who recognize they are at high risk.	The Medical Research Council, National Assembly for Wales, NHS R&D (Wales), and Imperial Cancer Research Fund. Dr. Gray is supported by Tenovus, a cancer charity
Burke et al, 2000[58] Fair	Significant differences between counseling and control groups in mean perceived risk of breast cancer ($F=27.9$; $p<0.009$). Significant differences over time in perceived risk for the counseling group ($F=65.9$; $p<0.001$). Interaction between group and time for perceived risk was significant ($F=50.6$; $p<0.001$). Low overestimators of breast cancer risk reduced risk estimates by an average of 19 percentage points after counseling, compared with high overestimators who reduced risk estimates by an average of 36 percentage points ($F=13.41$; $p<0.00001$). After counseling, those who perceived themselves as candidates for testing decreased from 82% to 60%; interest in testing was reduced from 91% to 60%. 82 (70%) liked the counseling very much. 65 (56%) found the counseling very useful and 26 (22%) found it moderately useful. After receiving risk estimates, 39 (33%) were a lot less worried and 37 (32%) were a little less worried.	Most participants saw a benefit to counseling and afterward had a more accurate understanding of their risk. Counseling reduced interested in genetic testing.	The National Institutes of Health (HGO1190)

Appendix C6. Evidence Table of Genetic Counseling

Author, year Quality	Results	Conclusions	Funding source
Cull et al, 1998[59] Good	Duration of Consultation: VB group spent less time with surgeon (mean, 11.8 min vs. 14.6; p< 0.05), but their time with geneticist was not significantly shorter. Risk Assessment: No significant difference between VB or VA in accuracy of estimate at baseline. VB retained accuracy from clinic to followup. VA were more likely to underestimate at followup (p<0.05). Understanding of Risk Information: Subjective: at baseline and at followup, no significant difference. Objective: VB had higher scores (p<0.01) and a higher proportion of correct responses to more items. Followup: no significant differences after adjusting for education level (t=0.34). Emotional Distress: No significant difference in groups in anxiety or distress levels. Use of Video and Family Discussion: VB: 94% watched video at least 1 time from start to finish. 76% reported it offered new information. VA: 41/42 who gave followup data watched the video at least once and 41% of them said it gave new information. In both VA and VB, most (66% and 65%, respectively) watched it alone and most discussed it with a partner.	Women who saw the video before their clinic visit were not deterred from attending. Compliance with the study and satisfaction with the clinic visit were higher among those who viewed the video beforehand.	The NHS R&D (Cancer) Programme and the Imperial Cancer Research Fund
Hopwood et al, 1998[167] Fair	GHQ scores: Compliance at baseline was 85% (n=34) and 94% at 3 months (n=148). Prevalence of psychological distress, with a cutoff score of >5, was 31% at baseline and 26% at 3 months. An examination of the 4 subscales of GHQ showed that 9.7% scored a ≥5 on the somatic scale, 14% on the anxiety subscale, and 3% each on the depression and suicidal ideation subscales at baseline. At 3 months, proportions were 12%, 15%, 6.8%, and 3.4%, respectively. When analysis was restricted to 105 women with evaluable assessments on all occasions, prevalence was 31% and 25%, respectively. Baseline scores compared with precounseling risk estimates showed no significant difference (p=0.087). Significant differences between psychological distress and perceived risk postcounseling (p=0.0053). Women with accurate risk knowledge postcounseling had significantly lower scores than those who underestimated (p=0.0034) or who overestimated (p=0.0447). Psychiatric Assessment Schedule: Psychiatric disorder was confirmed in 21 (13.3%) of the study participants at 3 months. Most women had multiple concerns, but none reported risk counseling as a precipitant for their distress. Estimation of risk: Prior to risk counseling, 10% accurately estimated risk of breast cancer, while 50% accurately estimated after (p=0.0000). More women continued to overestimate (17%) than underestimate (11%). In general, giving women an accurate estimate of their probability of breast cancer when they perceived it to be much lower did not appear to trigger	Prevalence rate for psychological distress when measured by a self-report questionnaire was double that ascertained by psychiatric interview, which is regarded as the gold standard. Interview data suggests that psychiatric morbidity was not apparently caused by the genetic counseling. This suggests that routine genetic risk consultations do not facilitate disclosure of distress or unresolved grief, and the use of a screening instrument together with a second-stage assessment interview should be explored further.	The Cancer Research Campaign

Author, year Quality	Results	Conclusions	Funding source
	clinical anxiety or depression.		
Lerman et al, 1996[168] Fair	Breast cancer preoccupation: IES average score on measure of breast cancer preoccupation was 6.9 + 0.71 (mean + SE). No significant baseline difference in risk comprehension between groups; however, significant change in risk comprehension at 3-months followup due to movement in risk counseling group from overestimation to accurate or underestimation.	Among women with less formal education, counseling led to significant reductions in distress by the 3-months followup, suggesting a possible increased adherence to mammography.	Public Health Service grants ROICA57767 and K07CAOI604 from the National Cancer Institute, National Institutes of Health, Department of Health and Human Services
Lerman et al, 1999[60] Fair	Genetic testing intention: Family history and baseline genetic testing intentions both made significant independent contributions to 1-month genetic testing intentions. Women with stronger family history of cancer had greater increases in intentions. Only in African Americans, education plus counseling led to greater increases in intentions than education only (p=0.003). IES scores: All groups evidenced a reduction in distress from baseline to 1 month. However, this decrease, although not a significant difference, was smallest among African American women who received education plus counseling.	Overall: African American women were found to differ significantly from Caucasian women in the effects of the interventions on testing intentions and provision of a blood sample. Effects were independent of socioeconomic status and referral mechanism.	The National Institutes of Mental Health and National Human Genome Research Institute grant MH/HG54435
Lobb et al, 2004[169] Good	Anxiety: Women who had more aspects of genetic testing discussed had a decrease in anxiety after 4 weeks (p=0.03). Women receiving a letter summarizing their consultation had lower anxiety (p=0.012) and a trend toward less anxiety about breast cancer (p=0.089). Women who received ≥4 supportive communications were more anxious about breast cancer (p=0.000). Depression: Women whose consultants facilitated understanding more had a decrease in depression (p=0.052). Risk Accuracy: Women receiving a letter summarizing their consultation had increased risk accuracy (p=0.023).	Women who understood what was being presented to them had decreased depression. This can imply that women may feel overwhelmed with the amount of information they receive and may feel worse if they are not helped to understand it. Providing a written summary of the consultation helped with accurate risk perception.	The University of Sydney Cancer Research Fund
Watson et al, 1998[171] Good	CWS scores: For both groups, median score was 11 (range, 6-22) (95% CI, 10-12 for cases and 95% CI, 10-11 for controls); mean, 11.14 (SD, 3.23) for cases and mean, 11.39 (SD, 3.37) for controls. Scores fell in subjects given a tape of consultation from a median of 11 at baseline to 10 at 1 month, then 9 at 6 months. Relative risk scores: At 1-month followup, 41% accurately recalled their risk of developing cancer, 25% overestimated, 11% underestimated, 23% didn't know/didn't remember. Results suggest that risk figure, regardless of accuracy, doesn't reflect more general view about risk compared with average women. When rRisk figure was given as odds ratio compared with other formats (percentage or descriptive terms), 71% were accurate in recall compared with 25% when given in other formats. Risk questionnaire scores: Usefulness of information rated on a visual analog scale. Average ratings were high, ranging from 8.5 (population	Overall: GHQ-12 scores: For combined groups, median score was 1 (range, 0-11). 36 subjects had a score indicative of psychological morbidity (>3) at baseline and 31 at 1-month and 6-month followup.	NR

Appendix C6. Evidence Table of Genetic Counseling

Author, year Quality	Results	Conclusions	Funding source
	risk) to 9.1 (risk of gene in family). Risk of gene in family, lifetime risk, and risk before age 50 were rated significantly more useful than population risk, risk of no cancer by age 50, and risk of disease over next 5 years. Medical management uptake: No significant correlation between cancer worry change scores and either level of breast clinical exam (p=0.8) or mammography (p=0.8); no difference between cases and controls for rate of self-exam, doctor exam, or mammography at 6-month followup; no difference between groups for other health behaviors unaffected by whether consultation tape was received or not.		
Watson et al, 1999[170] Good	GHQ: One third had notable levels of distress. There was no statistically significant change in general mental health at each followup compared with precounseling level. Cancer Anxiety and Helplessness/IES: No statistically significant changes in levels of cancer-specific distress. Followup assessment revealed that 13% (35/268) had received some psychological intervention during the 12 months since attending the clinic. Of these, 7% (n=19) had received psychotropic medication, 4% (n=10) had engaged in psychological counseling, and 2% (n=6) had received both forms of intervention. Levels of state anxiety: Anxiety levels at precounseling were at similar levels to those reported in healthy women attending for breast cancer screening (mean, 38.7), with a significant downward shift immediately postcounseling (mean, 35.2; p<0.001). Perception of risk: Specific figures about risk, provided within genetic counseling, tend not to be remembered. Continual overestimators may be worrying unnecessarily and excessively about breast cancer risk and underestimators appear undisturbed by the information that their risk is greater than they thought. Underestimators were not significantly different from the rest of the sample in terms of their scores for intrusive and avoidant thoughts about breast cancer risk when assessed precounseling. However, at 12 months, their scores were significantly lower than the rest on each of the scales (avoidance, p=0.02; intrusion, p=0.006), indicating that in the long term they are less likely to report having intrusive thoughts about breast cancer risk. High levels of cancer-specific distress were found in pregenetic counseling, with 28% reporting that they worried about breast cancer "frequently or constantly" and 18% worry about breast cancer as a "severe or definite" problem. Following genetic counseling, levels of cancer-specific distress were unchanged. General mental health remained unchanged over time (33% psychiatric cases were detected pregenetic counseling, and 27% 12 months after genetic counseling).	High levels of cancer-related worry compare unfavorably to previously gathered data on general population risk samples. Genetic counseling does not alleviate cancer-specific distress in a substantial minority of women; this contradicts previous U.S. findings. A single counseling session may not shift worries in some women. General levels of psychological morbidity unaffected by genetic counseling. Substantial minority of women who do not benefit from counseling and continue to overestimate risk, and worry was unrelieved. Study highlights problems with genetic counseling (e.g., some women continue to overestimate risk despite being told otherwise). Anxiety is not alleviated by genetic counseling, and women who continue to overestimate their risk and worry about breast cancer are likely to go on seeking unnecessary screening. Prevalence high-risk					
Beristain et al, 2007[174]	NA	NR	Individuals with suspicious personal or family history.	Cases met 1 of the following criteria: 1) patients without family history of breast and/or ovarian cancer, but showing early onset breast cancer (age <40); 2) patients from families with 2 cases of female breast cancer, 1 diagnosed at age <50; 3) patients of families with ≥3 cases of female breast cancer; 4) patients from families with ≥1 case of breast cancer or ovarian cancer in association with ≥1 case of male breast cancer; 5) patients from families with ≥1 cases of ovarian cancer or breast and ovarian cancer in the same individual; 6) patients from families with ≥2 cases of ovarian cancer. Each index case was the youngest individual affected with breast and/or ovarian cancer alive in each family.	Basque Country, Spain
Konecny et al, 2011[183]	NA	High-risk clinics	Individuals referred for genetic analysis on the basis of family history.	Families were included if they met any of the following criteria: 1) the presence of ≥2 patients with diagnosed breast or ovarian cancer among the direct relatives and ≥1 case diagnosed at age <45; 2) the presence of bilateral breast or ovarian cancer among the direct relatives diagnosed at any age; 3) occurrence of duplex breast and ovarian cancer in ≥1 patient diagnosed at any age; 4) the presence of sporadic breast or ovarian cancer diagnosed at age <35 years; 5) the presence of ≥1 case of male breast cancer diagnosed at any age.	Slovakia
Nanda et al, 2005[193]	NA	Genetics clinic	Families presenting to high-risk clinic.	Families with ≥2 cases of breast cancer, ovarian cancer, or both among FDRs and SDRs. Families were excluded if any individual had previously been tested for a *BRCA1* or *BRCA2* mutation.	U.S.: University of Chicago, Mayo Clinic, Rush University, UCSF
Neuhausen et al, 2009[194]	Breast Cancer Family Registry	Population and clinic-based family registries	Probands and their families recruited through population and clinic-based registries.	Population-based families from the California Breast CFR recruited case probands <65 years at diagnosis; <70 years at diagnosis from the Ontario Breast CFR; and case probands stratified by age from the Australian Breast CFR. Clinic-based families from the Philadelphia and New York Breast CFRs recruited affected and unaffected probands with a family history of breast and/or ovarian cancer; families with ≥3 cases of breast or ovarian cancer, especially if ≥1 occurred before age 45, were recruited to the Utah Breast CFR; and affected and unaffected probands with ≥2 affected relatives were recruited to the Australian Breast CFR. Ashkenazi Jewish women with a personal or family history of breast cancer were recruited through the New York, Philadelphia, Ontario and Australian Breast CFRs.	U.S., Canada, Australia

Author, year	Data source/ parent study	Setting	Population	Inclusion/exclusion criteria	Country
Seymour et al, 2008[197]	Cancer Prevention Units in the Forli-Cesena and Ravenna provinces of north-central Italy	Genetics clinic	Women undergoing breast checkups who completed a questionnaire on family history.	Healthy or affected individuals from families meeting 1 of the following criteria: 1) ≥1 relative diagnosed with a) BC at age <36 years, b) BC and OC in the same patient at any age, c) bilateral BC at age <51 years, d) male BC at any age, e) OC of fallopian tube cancer at age <46 years; or 2) a) 2 relatives diagnosed with BC at age <51 years, b) 1 relative with BC at age <51 years and 1 relative with bilateral BC at any age, c) 1 relative with BC at age <51 years and 1 relative with OC or fallopian tube cancer at any age, d) 2 relatives diagnosed with OC of fallopian tube cancer at any age; or 3) ≥3 relatives diagnosed with BC at any age.	Italy
Tamboom et al, 2010[199]	Estonian Cancer Registry	North Estonia Medical Centre's Centre of Oncology and the Hematology and Oncology Clinic of Tartu University Hospital	Early onset, familial, and predictive cases.	Early onset cases were identified if diagnosed with breast cancer <45 years. Early onset cases with a familial history of breast or ovarian cancer were classified as familial cases. Familial cases were identified as individuals with breast or ovarian cancer, including early onset, with ≥1 relative with these cancers. Predictive testing cases included individuals with high-risk families (≥2 relatives diagnosed with breast or ovarian cancer) who did not have breast or ovarian cancer themselves.	Estonia
Tommasi et al, 2005[200]	Dipartimento Donna of the National Cancer Institute of Bari, Italy	Surgical department	Women with a first diagnosis of breast cancer undergoing surgery.	A preliminary investigation of cancer syndromes was performed by a surgeon and the patients eligible for genetic counseling were referred.	Italy
Vaziri et al, 2001[202]	Familial Cancer Registry of the Cleveland Clinic Foundation	Clinic	Breast and breast-ovarian cancer families recruited through the registry.	An affected proband with ≥2 family members with cancer; 2 of whom must have either breast cancer (<50 years) or ovarian cancer; and ≥1 with breast, ovarian, colon, prostate or pancreatic cancer. Cases must be present in ≥2 generations.	U.S.
Weitzel et al, 2005[319]	City of Hope's Cancer Screening & Prevention Program Network	High-risk clinics; Hereditary Cancer Registry	All patients presenting for genetic cancer risk assessment.	Probands of Hispanic origin who enrolled in the registry between October 1998 and October 2004 and underwent testing. Participants with Hispanic origin only on 1 parental side were eligible if that side was significant for a history of breast cancer.	Hispanic; U.S.
Unselected populations (Ashkenazi Jewish)					
Metcalfe et al, 2010[191]	NA	Article published in a national newspaper in May 2008	Ashkenazi or Sephardic Jews.	Women who self identified as (Ashkenazi or Sephardic) Jewish, who were between the ages of 25 and 80 years, and who resided in Ontario. Not selected on the basis of family or personal history of cancer.	Ontario, Canada

Appendix C7. Evidence Table of Prevalence of *BRCA1* and *BRCA2* Mutations

Author, year	Study design	Primary risk measure	Comparison group	Family history/risk level definition	N
Prevalence high-risk					
Beristain et al, 2007[174]	Post intervention series	Prevalence	NA	See inclusion/exclusion criteria	236 index cases
Konecny et al, 2011[183]	Post intervention series	Prevalence	NA	See inclusion/exclusion criteria	585 families
Nanda et al, 2005[192]	Post intervention series	Prevalence	NA	NR	155 families

Appendix C8. Evidence Table of Penetrance of BRCA-Related Cancer

Author, year	Data source/ parent study	Setting	Population	Inclusion/exclusion criteria
BRCA uncertain or uninformative				
Kauff et al, 2005[182]	Memorial Sloan Kettering Cancer Center	Genetics clinic	BRCA mutation negative site-specific breast cancer kindreds with a living female proband. All probands, 1st-, and 2nd-degree relatives age >18 years at the time that BRCA test results were transmitted to the proband.	Probands were included if the kindred had ≥3 cases of breast cancer in the same lineage, 1 of the breast cancers in a kindred was diagnosed when the patient was age <50 years, no ovarian cancer was present anywhere in the lineage, and BRCA mutation screening did not detect a deleterious or unclassified missense mutation in the proband's *BRCA1* or *BRCA2* gene. If the proband reported her heritage to be exclusively Ashkenazi, testing negative for the 3 Ashkenazi founder mutations was sufficient for inclusion. The proband was defined as the youngest living individual with breast cancer in the kindred who had personally undergone BRCA mutation testing. If the family had no member who had both been diagnosed with breast cancer and had undergone genetic testing, the proband was defined as the first unaffected individual in the kindred who underwent testing.
Metcalfe et al, 2009[189]	NA	Genetics clinic	All female FDRs of the breast cancer cases age >18 years at the time the pedigree was drawn.	Inclusion: In database of families who have received testing for *BRCA1/2* at 1 of 2 Canadian centers between 1993 and 2003, ≥1 woman affected with breast cancer had been tested and was found not to carry a *BRCA1* or *BRCA2* mutation.
BRCA true negative				
Bernholtz et al, 2012[175] **[True negative group only]**	Israeli Cancer Registry	Oncogenetics unit, Sheba medical center	Jewish, female mutation carriers and their family members referred for oncogenetic counseling.	High-risk status was assigned based on: 1) FDR with breast and ovarian cancer, 2) FDR with bilateral breast cancer and ≥1 breast cancer diagnosed at age <50 years, 3) 1st- or 2nd-degree male relative who developed breast cancer, 4) FDRs or SDRs with ovarian cancer, 5) 3 FDRs or SDRs diagnosed with breast cancer at any age, or 6) 1 FDR and 1 SDR with breast cancer diagnosed at age <50 years. Excluded if nonJewish origin and/or unwillingness to participate.
Domchek et al, 2010[177]	Memorial Sloan Kettering Cancer Center and University of Pennsylvania	Genetics clinic	Women who do not carry a known family mutation in *BRCA1* or *BRCA2*.	Women who had genetic testing at the University of Pennsylvania or Memorial Sloan Kettering Cancer Center who agreed to participate in research were considered for inclusion. Women were eligible if they were a close relative of an individual with a known deleterious *BRCA1* or *BRCA2* mutation, had undergone genetic testing for the known family mutation in *BRCA1* or *BRCA2*, had ≥1 followup since having genetic testing, had no prior cancer diagnosis at the time of their genetic testing (apart from in situ cervical cancer or nonmelanoma skin cancer), and had not undergone bilateral mastectomy prior to genetic testing or subsequent to genetic testing.
Gronwald et al, 2007[180]	NA	18 hospitals in Poland	Women who do not carry a known family mutation in *BRCA1* or *BRCA2.*	The probands were unselected breast cancer patients diagnosed before age 50 years who were found to carry a *BRCA1* or *BRCA2* mutation. Living sisters of probands were included in this study if they received genetic testing for the family mutation.

Appendix C8. Evidence Table of Penetrance of BRCA-Related Cancer

Author, year	Data source/ parent study	Setting	Population	Inclusion/exclusion criteria
Harvey et al, 2011[181]	Australian Cancer Incidence and Mortality data	1 of 16 family cancer clinics in Australia and New Zealand; Kathleen Cuningham Foundation Consortium for Research into Familial Breast Cancer (kConFab)	Women who were blood relatives of mutation carriers who tested negative for the known mutation in their family.	Women were eligible if they were 1) blood relatives (not married to) of mutation carriers with a known pathogenic, large deletion, or splice site mutation in *BRCA1* or *BRCA2*; 2) had tested negative for the known mutation in their family; 3) had no personal history of cancer at enrollment (other than in situ cervical carcinoma or nonmelanoma skin cancer); and 4) had not had risk-reducing surgery before enrollment in kConFab.
Korde et al, 2011[184]	NCI cohort	NR	Mutation negative women in families with known deleterious *BRCA1/2* mutations.	All bloodline individuals within 3 degrees of relatedness to a known mutation carrier. Excluded because of missing date of birth or because researchers had not had contact with the individual or a family member within ≥3 degrees of relatedness.
Kramer et al, 2005[185] **[Mutation Negative Group Only]**	NCI	Families participating in research studies	Self or physician-referred families.	Analysis was restricted to 23 families with a known *BRCA1* mutation out of a larger cohort of 60 HBOC families.
Kurian et al, 2011[186]	BCFR	Population-based cancer registries	Women with incident breast cancer and their female 1st-degree family members, including mothers and full sisters.	Inclusion: Northern California site: Diagnosed with breast cancer at age <65 years through the Greater Bay Area Cancer Registry. Ontario site: Diagnosed at age <70 years through the Ontario Cancer Registry. These 2 sites recruited all patients diagnosed between ages 18 and 34 years or having a family history of cancer suggestive of increased genetic susceptibility, and a random sample of patients without these features. Australian site: All women diagnosed from age 18 to 39 years and random samples of women diagnosed from age 40 to 59 years through the Victorian and New South Wales Cancer Registries. Most probands were enrolled between 1996 and 2000; from 2001 and 2009, contributing sites recruited families with specific criteria of interest, including oversampling of racial and ethnic minorities.
Rowan et al, 2007[196]	NA	Familial breast cancer center	Women who do not carry a known family mutation in *BRCA1* or *BRCA2*.	Inclusion: Resident in Ontario, Canada ages 30 to 70 years. A FDR or SDR with a documented *BRCA1* or *BRCA2* mutation, the participant being negative for this mutation, and no history of breast, ovarian, or other cancer at the date of disclosure of the participant's genetic test result.

Appendix C8. Evidence Table of Penetrance of BRCA-Related Cancer

Author, year	Data source/ parent study	Setting	Population	Inclusion/exclusion criteria
Smith et al, 2007[198]	M6-ICE Study	Genetics clinic	Women who do not carry a known family mutation in *BRCA1* or *BRCA2*	Families were identified from those being tested for *BRCA1/2* mutations in specialist genetic clinics, and detailed 3-generation family history was elicited. Families were only included if a *BRCA1/2* mutation was identified. Patients were only included if they have breast or ovarian cancer and tested negative for the family mutation.
van der Kolk et al, 2010[201] **[Testing Negative Group Only]**	University Medical Center Groningen	Genetics clinic	Women who do not carry a known family mutation in *BRCA1* or *BRCA2*	Screening is carried out if the family history meets 1 of the following: 1) 1 breast cancer case at age <35 years, 2) 2 breast cancer cases in 1st-degree relatives with 1 case at age <50 years, 3) ≥3 FDRs with breast cancer in 2 successive generations, 4) the occurrence of breast and ovarian cancer in FDRs, and 5) the occurrence of male breast cancer.
BRCA positive-single				
Chen et al, 2006[122]	Cancer Genetics Network	282 Ashkenazi Jewish families were population-based, the remainder were from genetics clinics	Families presenting to high-risk clinic.	Families were recruited from 8 centers including: Georgetown University, University of Pennsylvania, Duke University, Johns Hopkins University, Baylor College of Medicine, MD Anderson Cancer Center, University of Texas Southwestern Medical School, and Huntsman Cancer Institute. Criteria for inclusion varied across centers, but most families had a positive family history of breast or ovarian cancer. On average, there were >3 diagnoses of breast or ovarian cancer per family. There were 282 Ashkenazi Jewish families recruited at Baylor that were population-based.
Finkelman et al, 2012[179] **[Prospective participants only]**	Prevention and Observation of Surgical End Points (PROSE) Consortium	22 international centers in the PROSE consortium	Jewish and nonJewish women with a confirmed disease-associated *BRCA1/2* mutation.	Participants were excluded if they did not have a confirmed disease-associated *BRCA1/2* mutation or if they had a mutation in both *BRCA1* and *BRCA2.* For BC analysis, participants were excluded if they had BC or were censored before ascertainment, or if they were missing necessary data to determine followup. For OC analyses, participants were excluded if they had OC or were censored before ascertainment, or if they were missing necessary data to determine followup.
Lubinski et al, 2012[187]	26 centers in Canda, United States, and Poland	Clinical centers	Unaffected women with a *BRCA1* mutation.	A woman was eligible if she was a carrier of a deleterious mutation in *BRCA1*, was between age 25 and 65 years at baseline, and if she did not have a prior mastectomy or known diagnosis of breast or ovarian cancer.
Marroni et al, 2004[188]	NA	Clinical centers	Families receiving BRCA testing.	Eligibility criteria for genetic testing varied across centers and within centers over time; families with multiple cases of breast or ovarian cancer or early-onset cancer cases were preferentially selected.

Appendix C8. Evidence Table of Penetrance of BRCA-Related Cancer

Author, year	Data source/ parent study	Setting	Population	Inclusion/exclusion criteria
Metcalfe et al, 2010[190]	Hereditary Breast Cancer Clinical Study Group	33 centers in 6 countries	Women who were known to be carriers of a deleterious mutation in *BRCA1* or *BRCA2*.	A woman was eligible if molecular analysis established that she was a carrier of a deleterious mutation in *BRCA1* or *BRCA2*. For estimation of breast cancer risk: Ages 25 to 65 years at the time of completion of the baseline questionnaire, did not have breast cancer or a prophylactic mastectomy at or before baseline, and had been followed for ≥2 years after baseline. Followed until development of breast cancer, prophylactic mastectomy, or death, whichever occurred first. For ovarian cancer risk estimation: Ages 25 to 65 years at baseline, no ovarian cancer diagnosis or prophylactic oophorectomy at baseline, ≥2 years of followup. Followed until the development of ovarian or fallopian tube cancer, prophylactic oophorectomy, death, or date of last followup, whichever occurred first.
Risch et al, 2006[1895]	Ontario Cancer Registry	Registry for ovarian cancer	All patients diagnosed with invasive and borderline ovarian cancer.	All patients diagnosed from January 1, 1995 to December 31, 1999 with invasive ovarian cancer and from January 1, 1995 to December 31, 1997 with borderline ovarian tumors. Ages 20 to 79 years and resident in Ontario at the time of diagnosis of a new primary tumor.
BRCA positive-multi				
Al-Mulla et al, 2009[172]	NA	NR	Patients and their family members in moderate- or high-risk families.	Moderate- or high-risk families.
Antoniou et al, 2006[173]	INHERIT BRCAs	Network of referring physicians	Families with family history suggestive of a genetic component.	Family meets ≥1 of the following criteria: 1) ≥4 individuals with breast and/or ovarian cancer diagnosed at any age in FDRs or SDRs, 2) 3 FDRs affected with breast and/or ovarian cancer at any age, or 3) deleterious mutation already identified in the *BRCA1/2* genes. 8 additional families that did not meet those criteria were recruited when the analysis of pedigrees was suggestive of a genetic component (e.g., monozygotic twins affected with breast cancer at an early age; 4 related individuals with early-onset breast cancer; 1 case of male breast cancer plus a women affected with early breast cancer). Age >18 years and mentally competent.
Evans et al, 2008[178]	NA	Genetics clinic	Families presenting to high-risk clinic.	Families were identified from those being tested for *BRCA1/2* mutations in specialist genetic clinics, and detailed 3-generation family history was elicited. Families were only included if a *BRCA1* or *BRCA2* mutation was identified.
Kramer et al, 2005[185] **[Mutation Carrier Group Only]**	NCI	Families participating in research studies	Self- or physician-referred families.	Analysis was restricted to 23 families with a known *BRCA1* mutation out of a larger cohort of 60 HBOC families.

Appendix C8. Evidence Table of Penetrance of BRCA-Related Cancer

Author, year	Data source/ parent study	Setting	Population	Inclusion/exclusion criteria
Milne et al, 2008[192]	NA	Genetics clinic	Families testing positive for deleterious mutations in *BRCA1* or *BRCA2*.	Families were selected for mutation testing if they contained ≥3 cases of breast or ovarian cancer in the same family line, ≥2 FDRs diagnosed with breast cancer before age 50 years, ≥1 case of breast cancer and 1 case of ovarian or bilateral breast cancer in the same family line, ≥1 woman with both breast and ovarian cancer, and/or ≥1 case of male breast cancer. Once a mutation was identified in the family, the family was eligible only if ≥1 other member was tested for the family mutation.
van der Kolk et al, 2010[201] **[Mutation Carriers Group Only]**	University Medical Center Groningen	Genetics clinic	Families presenting to high-risk clinic.	Screening is carried out if the family history meets 1 of the following inclusion criteria: 1) 1 breast cancer case at age <35 years, 2) 2 breast cancer cases in FDRs with 1 case at age <50 years, 3) ≥3 FDRs with breast cancer in 2 successive generations, 4) the occurrence of breast and ovarian cancer in FDRs, and 5) the occurrence of male breast cancer.

van der Kolk et al, 2010[201] **[Testing Negative Group Only]**	Probands and some family members. Noncarriers were defined as women who tested negative for a known familial mutation in either *BRCA1* or *BRCA2*.	Observed vs. expected BC in *BRCA1* group: 5 vs. 2.5; age- and period-adjusted SIR, 2.0 (95% CI, 0.7 to 4.7) OC in *BRCA1* group: 0 vs. 0.3; age- and period-adjusted SIR, 0 (95% CI, 0 to 12) BC in *BRCA2* group: 4 vs. 1.6; age- and period-adjusted SIR, 2.5 (95% CI, 0.7 to 6.3) OC in *BRCA2* group: 0 vs. 0.2; age- and period-adjusted SIR, 0 (95% CI, 0 to 20.4)	NR	Cancer status was reported by the family. Cancer cases were confirmed by hospital or pathology records or else through a first degree family member.	DCIS was included as breast cancer. Information was collected on age, cancer status, vital status, and prophylactic surgery.	NA
BRCA positive-single						
Chen et al, 2006[122]	Proband	*BRCA1* carriers vs. *BRCA2* carriers Cumulative BC risk at age 70: 0.46 (95% CI, 0.39 to 0.54) vs. 0.43 (95% CI, 0.36 to 0.51) Cumulative OC risk at age 70: 0.39 (95% CI, 0.30 to 0.50) vs. 0.22 (95% CI, 0.14 to 0.32)	NR	NR	It is not clear if information was collected on prophylactic surgery or vital status.	The retrospective likelihood approach was used.
Finkelman et al, 2012[179] **[Prospective participants only]**	Proband	BC vs. OC *BRCA1*, 185delAG (ref nonCJM): HR, 1.23 (95% CI, 0.87 to 1.73) vs. 0.97 (95% CI, 0.58 to 1.63) *BRCA1*, 5382insC (ref nonCJM): HR, 1.53 (95% CI, 0.96 to 2.45) vs. 0.61 (95% CI, 0.27 vs. 1.38) *BRCA2*, 6174delT (ref nonCJM): HR, 0.35 (95% CI, 0.18 to 0.69) vs. 1.34 (95% CI, 0.48 to 3.73) Jewish (ref nonJewish): HR, 0.76 (95% CI, 0.56 to 1.01) vs. 0.93 (95% CI, 0.59 to 1.46) RRSO (ref no): HR, 0.62 (95% CI, 0.47 to 0.83) vs. 0.08 (95% CI, 0.04 to 0.16) No significant difference in BC hazard reduction from RRSO was observed in specific CJM carriers (joint Wald test; p=0.61).	NR	NR	Information was collected on prophylactic surgery, age, cancer status, and vital status.	Cumulative incidence of cancer based on method adapted from Antoniou et al, 2003.

Appendix C8. Evidence Table of Penetrance of BRCA-Related Cancer

Author, year	Who was tested?	Results/conclusions	Quality considerations			
			Definition of clinically significant	How was cancer status ascertained?	Confounders	Method
Lubinski et al, 2012[187]	Proband	North America vs. Poland Cumulative incidence: 15.9% (95% CI, 12.0 to 19.8) vs. 12.1% (95% CI, 8.0 to 16.2) Average annual risk of BC: 2.4% (95% CI, 1.8 to 2.9) vs. 1.7% (95% CI, 1.2 to 2.1) Penetrance to age 70: 71.7% vs. 48.6% Penetrance to age 70 after adjusting for oophorectomy: 76.3% vs. 57.5% Residence in Poland vs. North America: adjusted HR, 0.54 (95% CI, 0.34 to 0.86); p=0.01 Adjusted for oophorectomy, age at study entry, age of menarche, parity (0, 1, 2, 3, 4+), oral contraceptive use (ever/never), tamoxifen use (ever/never), hormone replacement therapy (ever/never), smoking (ever/never), regular alcohol use (ever/never), and family history (number of FDRs and SDRs with BC).	NR	Cancer status was reported by the proband and 70% were confirmed with pathology reports.	Information was collected on prophylactic surgery, age, cancer status, and vital status.	Theoretical penetrance curves up to age 70, for age-specific cancer rates calculated based on 5-year intervals.
Marroni et al, 2004[188]	Probands. Not reported if other family members tested.	Penetrance (*BRCA1* vs. *BRCA2*) BC by age 50: 27% (95% CI, 20 to 34) vs. 26% (95% CI, 18 to 34) BC by age 70: 39% (95% CI, 27 to 52) vs. 44% (95% CI, 29 to 58) OC by age 50: 14% (95% CI, 7 to 22) vs. 3% (95% CI, 0 to 7) OC by age 70: 43% (95% CI, 21 to 66) vs. 15% (95% CI, 4 to 26)	NR	Cancer status was reported by family members for FDRs and SDRs of the proband.	It is not clear if information was collected on prophylactic surgery	Parameter estimates are based on the retrospective likelihood, the likelihood of the genetic data (the observed test results) conditional on the phenotype. Obtained penetrance estimates via a Metropolis-Hastings Markov Chain Monte Carlo

Appendix C8. Evidence Table of Penetrance of BRCA-Related Cancer

Author, year	Who was tested?	Results/conclusions	Quality considerations			
			Definition of clinically significant	How was cancer status ascertained?	Confounders	Method
						(MCMC) method implemented in BRCAPRO.
Metcalfe et al, 2010[220]	Proband	0 FDRs vs. 1 FDR vs. ≥2 FDRs diagnosed with BC at age ≤50 years *BRCA1* penetrance for BC by age 70: 56% vs. 57% vs. 72% *BRCA2* penetrance for BC by age 70: 38% vs. 46% vs. 85% 0 FDRs vs. 1 FDR vs. ≥2 FDRs diagnosed with OC *BRCA1* penetrance for OC by age 70: 39% vs. 55% vs. 68%	NR	Cancer status was reported by the proband.	Information was collected on age, cancer status, prophylactic surgery, and vital status.	Age and mutation specific cancer rates were calculated for the 2 sites of cancer for 5-year intervals. Based on these rates, penetrance curves were constructed by applying the observed cancer rates annually to a theoretical cohort of healthy women from age 25 to 70 years.

Appendix C8. Evidence Table of Penetrance of BRCA-Related Cancer

Author, year	Who was tested?	Results/conclusions	Quality considerations			
			Definition of clinically significant	How was cancer status ascertained?	Confounders	Method
Risch et al, 2006[1895]	Proband	*BRCA1* vs. *BRCA2* Cumulative incidence for BC by age 80: 90% (95% CI, 77 to 97) vs. 41% (95% CI, 26 to 60) Cumulative incidence for OC by age 80: 24% (95% CI, 15 to 38) vs. 8.4% (95% CI, 3.9 to 17)	Founder mutations; shortened, non-functional proteins; substitutions producing premature termination codons; mutations reported previously as documented in the BIC database or elsewhere.	Investigators reviewed pathology reports to determine eligibility for the proband. Family history information was reported by the proband through telephone interview.	It is not clear if information was collected on prophylactic surgery	Cumulative incidence of cancer to age 80 years for all cancer sites was based on Ontario general population age-specific incidence and mortality data. The DevCan computer program was used to calculate cancer site specific incidence according to mutation status. The sum of the incidence to age 80 years for the 3 groups (non carriers, *BRCA1* carriers, and *BRCA2* carriers) totaled the population incidence.
BRCA positive-multi						
Al-Mulla et al, 2009[172]	Probands and their family members.	Median age at onset for BC (years) 185delAG mutation in exon 2: 55 4184delTCAA mutation in exon 11: 47 Exon 13 duplication: 41	NR	Not clear.	Information was collected on age, cancer status, and vital status.	Cox proportional hazards regression adjusting for clustering within families using robust standard errors by the method of Lin and Wei.

Appendix C8. Evidence Table of Penetrance of BRCA-Related Cancer

Author, year	Who was tested?	Results/conclusions	Quality considerations			
			Definition of clinically significant	How was cancer status ascertained?	Confounders	Method
Antoniou et al, 2006[173]	Families were included that had ≥1 mutation carrier identified and ≥1 further family member had DNA testing after the mutation carrier was identified.	Cumulative risk (*BRCA1* vs. *BRCA2*) BC by age 50: 20% (95% CI, 0 to 45) vs. 21% (95% CI, 0 to 55) BC by age 70: 72% (95% CI, 0 to 93) vs. 75% (95% CI, 0 to 97) OC by age 50: 1% (95% CI, 0 to 10) vs. 0.4% (95% CI, 0 to 2) OC by age 70: 38% (95% CI, 0 to 78) vs. 49% (95% CI, 0 to 81)	NR	Cancer status of family members was reported by the proband. In most instances, the diagnoses of breast and/or ovarian cancer were confirmed by examining a pathology report.	It was not reported whether prophylactic surgery was collected.	Penetrance parameters were estimated by maximum likelihood using a modified segregation analysis implemented in MENDEL.
Evans et al, 2008[178]	Index case and some family members. Testing is offered to all blood relatives. Where possible, all affected women with breast/ovarian cancer are tested.	*BRCA1* vs. *BRCA2* Penetrance of BC to age 70: 68% (95% CI, 65 to 71) vs. 75% (95% CI, 72 to 78) Risk of OC to age 70: 60% (95% CI, 65 to 71) vs. 30% (95% CI, 26 to 35) There was evidence of a strong cohort effect with women born after 1940 having a cumulative risk of 22% for breast cancer by age 40 years compared to 8% in women born before 1930 (p=0.0005).	NR	Cancer status of family members was reported by the proband for 1st, 2nd, and 3rd degree relatives. All cases of breast or abdominal cancers are confirmed by means of hospital/pathology records, cancer registries, or death certification.	Information was collected on age, cancer status, prophylactic surgery, and vital status. DCIS was included as breast cancer.	Penetrance analysis was performed by including all mutation positive individuals and appropriate numbers of untested FDRs on a proportional basis.
Kramer et al, 2005[185] **[Mutation Carrier Group Only]**	All women in the family who agree to testing. Women were inferred positive based on having a child who was found to carry the mutation. Women were inferred negative based on having a parent that tested negative for the family mutation. A total of 451/673 (67%) had a known or inferred genotype.	Risk of BC (SE) *BRCA1* carriers at age 50: 0.44 (0.07) *BRCA1* carriers at age 70: 0.76 (0.08) 10-year BC risk (SE) in mutation carriers BC free with intact ovaries vs. same who have undergone oophorectomy At age 40 years: 0.32 (0.13) vs. 0.11 (0.10) At age 50 years: 0.28 (0.14) vs. 0.19 (0.12) At age 60 years: 0.25 (0.18) vs. 0.14 (0.13)	NR	Cancer status was initially reported by family members by questionnaire. Reported cancers were confirmed through death certificates, medical records, pathology reports, and central review of pathology slides.	Information was collected on prophylactic surgery, age, cancer status, and vital status.	Cumulative, age specific probabilities of developing breast cancer were estimated using the Kaplan-Meier product-limit method, with age as the time variable, modified to account for late entry. Analysis was repeated with oophorectomy as a censoring

Appendix C8. Evidence Table of Penetrance of BRCA-Related Cancer

Author, year	Who was tested?	Results/conclusions	Quality considerations			
			Definition of clinically significant	How was cancer status ascertained?	Confounders	Method
						event. A Cox proportional hazards model incorporated oophorectomy as a time-dependent covariate to estimate the effect oophorectomy on the incidence of breast cancer. To provide estimate of the absolute risk of breast cancer by age in mutation carriers, oophorectomy was treated as time-fixed covariate as defined at the beginning of a given age interval. Followup time was divided into 10 year intervals. A competing risks model (with death as the competing risk) was then used to estimate the 10 year cumulative incidence.
Milne et al,	Probands and ≥1	*BRCA1*	Deleterious if	Cancer status was	Information was	Penetrance

Author, year Quality	Subcategory	Purpose	Study type	N	Country	Population/Setting
Current report						
Arver et al, 2004[235] NA	Psychological	To prospectively evaluate the psychological consequences during the 1st year following pre-symptomatic testing with respect to anxiety, depression, and QOL in self-referred individuals tested for breast/ovarian or colon cancer genes known in their families.	Before and after	Eligible: NR Enrolled: 66 Analyzed: 63 at week 1 and 2 months, 61 at 6 months, 59 at 12 months	Sweden	Clinical Genetic Unit, Karolinska University Hospital, Stockholm
Dagan and Shochat, 2009[236] Fair Same population as Shochat and Dagan, 2010[247]	Psychological Cancer worry	To investigate the association between *BRCA1/2* status and HR-QOL in Ashkenazi asymptomatic women.	Case-control	Eligible: 152 (39 carriers, 77 noncarriers, 36 controls) Enrolled: 73 (17 carriers, 20 noncarriers, 36 controls) Analyzed: 73 (17 carriers, 20 noncarriers, 36 controls)	Israel	Rambam Health Care Campus oncogenetic clinic
Ertmanski et al, 2009[237] NA	Psychological	To predict which women might suffer from abnormally high levels of anxiety and depression after receiving a positive genetic test result.	Before and after	Eligible: NR Analyzed: 56	Poland	Women seeking genetic testing at cancer genetics center in Poland. Women who tested positive for BRCA were included in analysis.
Foster et al, 2007[238] Fair	Cancer worry	To assess long-term impact of genetic testing for breast/ovarian cancer predisposition in a clinical cohort.	Prospective cohort	Eligible: NR Analyzed: 154	U.K.	Recruited from 9 U.K. centers between 1997 and 2000
Geirdal et al, 2005[240] Good Same population as Geirdal and Dahl, 2008[239]	Psychological	To explore psychological distress in women at risk of FBOC and HNPCC cancer and without access to genetic testing, and to compare them with mutation carriers and with healthy women from the general population.	Prospective cohort	Eligible: 10,321 (253 FBOC, 10,000 normal controls, 68 *BRCA1* mutation carriers) Enrolled: 10,244 (176 FBOC, 10,000 normal controls, 68 *BRCA1* mutation carriers) Analyzed: 10,244 (176 FBOC, 10,000 normal controls, 68 *BRCA1* mutation carriers)	Norway	Section for Genetic Counseling, Department of Cancer Genetics, The Norwegian Radium Hospital
Geirdal and Dahl, 2008[239] Good Same population as Geirdal et al, 2005[240]	Psychological	To examine how coping strategies used by women with FBOC were associated with caseness of anxiety disorder and to explore if a similar pattern of associations were observed in the carrier group.	Prospective cohort	Eligible: 333 (253 FBOC, 80 *BRCA1* mutation carriers) Enrolled: 242 (174 FBOC, 68 *BRCA1* mutation carriers) Analyzed: 242 (174 FBOC, 68 *BRCA1* mutation carriers)	Norway	Section for Genetic Counseling, Department of Cancer Genetics, The Norwegian Radium Hospital

Appendix C9. Evidence Table of Distress After Genetic Testing

Author, year Quality	Subcategory	Purpose	Study type	N	Country	Population/Setting
Graves et al, 2012[241] NA	Psychological	To examine long-term psychosocial outcomes in a large U.S. sample.	Case-series	Eligible: 655 Enrolled: 464 Analyzed: 107 (unaffected)	U.S.	Women at the Lombardi Comprehensive Cancer Center Familial Cancer Registry
Julian-Reynier et al, 2011[242] Good	Risk perception	To describe the sequences of preventive decisions made by women up to 5 years after disclosure of their test results and the surveillance/surgical options chosen by various age groups.	Prospective cohort	Eligible: 331 Analyzed: 246	France	French Cancer Genetic Network
Kinney et al, 2005[243] Poor	Psychological	To evaluate the effect of receiving genetic test results on general and cancer-specific psychological distress in African Americans at high risk for carrying a deleterious *BRCA1* mutation.	Prospective cohort	Eligible: NR Analyzed: 52	U.S.	Members of a high-risk African American kindred that was identified previously with the *BRCA1* mutation
Low et al, 2008[244] Fair	Psychological	To examine the relationship between mutation carrier status, personal cancer history, and the potential positive impact of genetic testing.	Prospective cohort	Eligible: NR Analyzed: 47	U.S.	UCLA Familial Cancer Registry and Genetic Evaluation Program
Metcalfe et al, 2012[249] NA	Psychological	To report on cancer-related distress levels, uptake of cancer risk reduction options, and the resulting breast and ovarian cancer risk in Jewish women 2 years after receiving a postive BRCA mutation result.	Before and after	Eligible: 22 Enrolled: 19 Analyzed: 17	Canada	Jewish women responding to a newspaper ad
Reichelt et al, 2004[245] Good	Psychological	To examine the short-term psychological impact of receiving definite results concerning *BRCA1* mutation status in a clinical setting.	Prospective cohort	Eligible: 301 Enrolled: 244 Analyzed: 209	Norway	Unit of Medical Genetics, The Norwegian Radium Hospital
Reichelt et al, 2008[246] NA	Psychological	To examine the levels of psychological and cancer-specific distress at 18 months after getting genetic test results in women with demonstrated *BRCA1* mutations and to explore associations with baseline characteristics.	Before and after	Eligible: NR Analyzed: 181	Norway	Section for Hereditary Cancer, Department of Medical Genetics, Rikshospitalet-Radiumhospitalet Medical Center, Oslo, Norway

Appendix C10. Evidence Table of Intensive Screening Interventions

Author, year Quality	Design	Purpose	Population/ setting	Inclusion/exclusion criteria	Risk level definitions
Breast cancer					
Cortesi et al, 2006[273] NA Modena Study Group for Familial Breast and Ovarian Cancer participants	Prospective cohort (Expected incidence ratio derived from registry data)	To describe the results of an intensive surveillance program and document effectiveness of the program in selecting individuals at risk of breast cancer	Italy Women with increased risk of breast cancer	Inclusion Women age >18 years with *BRCA1/2* mutations discovered through genetic testing or increased risk for breast cancer relative to the general population based on Gail model, Claus tables, and modified BRCAPro model (adapted to the Italian population) and study defined criteria: ≥3 relatives diagnosed with breast or ovarian cancer in 2 different generations; ≥1 of these 3 relatives must be FDR of 1 of the other 2, in case of male interposition, a relationship of different degree is allowed; ≥1 breast cancer diagnosed at age <35 years regardless of family history; ≥1 breast cancer and 1 ovarian cancer in the same woman, regardless of family history; ≥1 male breast cancer, regardless of family history; 1 sporadic breast cancer or ovarian cancer Exclusion Women with symptoms suggestive of breast cancer; women with a personal history of breast cancer	Risk level was defined by Gail model, Claus tables, modified BCAPRO model, and study defined criteria (see Inclusion). Carrier (Gail model lifetime risk of 50%-85%): presence of mutant BRCA genes. High-risk (Gail model lifetime risk of 30%-50%): ≥3 relatives with breast cancer (or ovarian cancer) in 2 different generations; 1 breast/ovarian cancer case is a FDR of the other 2; ≥1 case has been diagnosed at age <40 years or with bilateral breast cancer; breast cancer diagnosed at age <35 years, regardless of family history; breast and ovarian cancer in same woman, regardless of family history. Intermediate risk (Gail model lifetime risk of 18%-29%): male breast cancer, regardless of family history. Slightly increased risk (Gail model lifetime risk of 6%-18%): breast/ovarian cancer without any of the described criteria.
Leach, 2005[274] NAMARIBS study	Prospective cohort, one-arm	To compare contrast enhanced MRI with mammography for breast cancer screening in women genetically predisposed to breast cancer	U.K. Women attending 1 of 22 participating centers in the U.K. with increased breast cancer risk	Inclusion Asymptomatic women ages 35 to 49 years fulfilling 1 of the following: known carrier of a deleterious *BRCA1/2* or TP53 mutation; FDR of someone with 1 of these deleterious mutations; strong family history of breast or ovarian cancer or both; or family history consistent with classic Li-Fraumeni syndrome. Aim was to include women whose affected FDRs had ≥60% chance of being a *BRCA1/2* mutation carrier or women with an annual risk of at least 0.9%. Exclusion Women with previous breast cancer, those with any cancer such that prognosis was <5 years, participants who had predictive genetic testing during study and whose results were negative, women who developed cancer during study period.	Known carrier of a deleterious *BRCA1/2* or TP53 mutation; FDR of someone with 1 of these deleterious mutations; strong family history of breast or ovarian cancer or both; or family history consistent with classic Li-Fraumeni syndrome.

Appendix C10. Evidence Table of Intensive Screening Interventions

Author, year Quality	Design	Purpose	Population/ setting	Inclusion/exclusion criteria	Risk level definitions
Le-Petross et al, 2011[276] NA	Retrospective analysis of prospective cohort, one-arm	To investigate the efficacy of alternating screening mammography and breast MRI every 6 months in women with a genetically high risk of developing breast cancer for breast cancer detection	United States Women at increased genetic risk of breast cancer at single institution	Inclusion Women age ≥18 years, having undergone alternating screening mammography and breast MRI every 6 months at study institution, either confirmed *BRCA1/2* carriers or FDR of confirmed *BRCA1/2* carrier. Exclusion Women with history of breast cancer, who had calculated lifetime risk of breast cancer >20%, or who did not undergo a screening MRI, women who used chemoprevention or underwent bilateral prophylactic mastectomy, those with metastatic disease, undergoing treatment, or high BMI preventing MRI, women lost to followup, or died during original trial.	Based on BRCA status.
Rijnsburger et al, 2010[278] See also Kriege et al, 2004[277] NA Dutch MRISC study	Prospective cohort (Registry data/data from another prospective study used for cancer characteristics comparison)	To evaluate the long-term results of the Dutch MRI Screening (MRISC) study, including separate analyses of *BRCA1/2* mutation carriers and survival results	The Netherlands Women with increased familial or genetic predisposition for breast cancer attending academic and/or cancer centers at 6 sites	Inclusion Women ages 25 to 75 years with cumulative lifetime risk of breast cancer ≥15% due to genetic or familial predisposition (women could be tested before age 25 years if family member diagnosed before age 30). Exclusion Women with symptoms suggestive of breast cancer or who had a personal history of breast cancer; women proven not to have a mutation in a family with a proven mutation.	Based on cumulative lifetime risk determined using modified Claus tables: *BRCA1/2* carriers, or other mutations: 50%-85% risk. High-risk: 30%-50% risk. Moderate risk (no documented gene mutation): 15%-30% risk.
Ovarian Cancer					
Hermsen et al, 2007[281] NA	Prospective cohort, one-arm (staging compared to 2 external comparison groups; unscreened family members with cancer, combined data from multiple studies)	To assess efficacy of annual gynecological screening, accounting for compliance to protocol	The Netherlands Women with BRCA mutation screened at 6 University Family Cancer Clinics	Inclusion Women with *BRCA1/2* mutation screened at 1 of participating centers. Exclusion Women with symptoms at first visit, who had only 1 visit, or who were found to have cancer at first screening visit.	Based on BRCA status.

Appendix C10. Evidence Table of Intensive Screening Interventions

Author, year Quality	N	Baseline Demographics	Screening method and interval	Scoring criteria
Breast cancer				
Cortesi et al, 2006[273] NA Modena Study Group for Familial Breast and Ovarian Cancer participants	1325 enrolled 48 mutation carriers (37 *BRCA1* and 11 *BRCA2*) 674 high risk 257 intermediate risk 346 slightly increased risk	Mean age at surveillance (range), years Carrier: 42 (20-75) High-risk: 42 (15-75) Intermediate risk: 43 (19-67) Slightly increased risk: 40 (18-75)	From 1994 to September 2000 all women underwent: A) Mammography B) Ultrasonography C) CBE D) Transvaginal ultrasound and serum CA 125 levels Testing interval varied by assessed risk (see below). From October 2000 mutation carrier surveillance modified to include: E) CE MRI BRCA risk: Started at age 25 with annual mammography and MRI, biannual CBE and ultrasound plus transvaginal ultrasound and serum CA 125 levels. High risk: Started at age 30 with mammography every 2 years until age 36 and then annually, biannual CBE and ultrasound plus annual transvaginal ultrasound and serum CA 125 levels. Intermediate risk: Started at age 30 with mammography every 2 years until age 40 and then annually, biannual CBE and ultrasound plus annual transvaginal ultrasound and serum CA 125 levels. Slightly increased risk: Started at age 30 with 1 mammogram < 40 years, then every 18 to 24 months, and annual CBE and ultrasound. Note: if possible, all exams performed on the same day during the 2nd week of the menstrual cycle in premenopausal women; additional investigation using fine needle aspiration or core biopsy performed as required.	
Leach, 2005[274] NAMARIBS study	649 analyzed 82 (13%) with known *BRCA1* mutation 38 (6%) with known *BRCA2* mutation	Median age at entry, years: 40 (range, 31-55; only 1 woman age >50 years)	All women underwent: A) Annual mammography from age 35 years (or younger if FDR developed cancer at age <35 years) B) Annual CE MRI Note: if possible, exams done on same day, between days 6 and 16 of menstrual cycle. Note: In women with equivocal results, high specificity MRI exam or repeat screening MRI done 2 to 6 weeks later, followed by ultrasound, fine needle aspiration, localization, and tissue sampling by conventional methods as appropriate. Note: 93% of mammographic examinations were 2-view, 7% 1-view.	Scoring system based on morphological and dynamic contrast uptake characteristics validated against histology (area under receiver operator curve=0.88 [95% CI, 0.83-0.94]) and diagnostic accuracy tested using subset of present study and 100 symptomatic cases (sensitivity, 91% [95% CI, 83-96]; specificity, 81% [95% CI, 79-83]). Note: All scoring was double reported; in statistical analysis, scoring system was paired to BIRADS as follows: for MRI; score of B, suspicious = BIRADS 0, 3, or 4 and score of A, malignant = BIRADS 5; for mammography; score M3, indeterminate = BIRADS 0-3, M4, suspicious = BIRADS 4, and M5, malignant = 5.

Appendix C10. Evidence Table of Intensive Screening Interventions

Author, year Quality	N	Baseline Demographics	Screening method and interval	Scoring criteria
Le-Petross et al, 2011[276] NA	321 screened 73 analyzed (37 [51%] *BRCA1*, 36 [49%] *BRCA2*)	Median age at entry, years: 44 (range, 23-75) Mean age at diagnosis, years: 51 (range, 43-64)	All women underwent CBE every 6 months plus: A) Mammography every 6 months alternating with B) MRI every 6 months Note: Ultrasound used to evaluate abnormal screen findings, biopsy as required.	BIRADS
Rijnsburger et al, 2010[278] See also Kriege et al, 2004[277] NA Dutch MRISC study	2275 enrolled 2157 analyzed (422 *BRCA1*, 172 *BRCA2*, 5 other mutation, 1069 high risk, 489 moderate risk)	Mean age at entry, years: Cohort: 40.1 (range, 19-75) *BRCA1*: 38.7 *BRCA2*: 40.0 High risk: 40.8 Moderate risk: 40.0	All women underwent: A) Biannual CBE B) Annual mammography C) Annual contrast enhanced MRI Note: Both imaging investigations performed on same day or time period when possible, between day 5 and 15 of menstrual cycle. Note: When 1 of the examinations reported "probably benign finding" or "need additional imaging evaluation" (BI-RADS 3 or 0), further investigation undertaken by ultrasonography. Malignancy diagnosis based on histological findings.	BIRADS
Ovarian Cancer				
Hermsen et al, 2007[281] NA	883 (683 *BRCA1*, 200 *BRCA2*) 459 for analysis of screening/ compliance (data available for all screen visits)	Median age, years: *BRCA1*: 40 (range, 21-76) *BRCA2*: 44 (range, 25-77)	All women underwent: A) Annual serum CA-125 measurement B) Annual TVUS Starting at age 35 years or 5 years earlier than youngest diagnosed ovarian cancer in the family Note: Biannual screens were done in some centers during the study period, but this was not systematically adopted.	CA-125: >35kU1-1 abnormal if resulted in extra screen visit or diagnostic operation. TVUS: Abnormal or normal.

Author, year Quality	Duration/ Followup	Outcome: Test characteristics	Cancer incidence
Breast Cancer			
Cortesi et al, 2006[273] NA Modena Study Group for Familial Breast and Ovarian Cancer participants	1992-2005 Median, 55 months (range, 1-151 months)	44 breast cancers detected; 64% (n=28) invasive, 36% (n=16) DCIS 36 screen-detected Carriers: n=5 cancers (4 invasive, 1 DCIS) High risk: n=23 (14 invasive, 9 DCIS) Intermediate risk: n=11 (8 invasive, 3 DCIS) Slightly increased risk: n=5 (2 invasive, 3 DCIS) <u>Sensitivity, A vs. B vs. A+B vs. E</u> All: 78% (28/36) vs. 50% (18/36) vs. 97% (35/36) vs. 100% (4/4) Carriers: 50% (2/4) vs. 75% (3/4) vs. 75% (3/4) vs. 100% (4/4) High risk: 90% (19/21) vs. 52% (11/21) vs. 100% (21/21) Intermediate risk: 50% (4/8) vs. 450% (4/8) vs. 100% (8/8) Slightly increased risk: 100% (3/3) vs. 0% (0/3) vs. 100% (3/3)	Breast cancer incidence in study population vs. expected incidence All: SIR, 4.9 (95% CI, 1.6-7.6), p<0.001 Carriers: SIR, 20.3 (95% CI, 3.1-83.9), p<0.001 High-risk: SIR, 4.5 (95% CI, 1.5-8.3), p<0.001 Intermediate risk: SIR, 7.0 (95% CI, 2.0-17.1), p=0.0018 Slightly increased risk: SIR not significantly increased Note: SIR=ratio of observed to expected number of cancers; expected number of cancers based on Modena Cancer Registry rates from 1998 to 2002 in 5-year age groups from 25 to >85 years; observed women-years at risk were multiplied by expected cancer incidence to estimate total number of cancers expected.

Appendix C10. Evidence Table of Intensive Screening Interventions

Author, year Quality	Duration/ Followup	Outcome: Test characteristics	Cancer incidence
Leach, 2005[274] NAMARIBS study	Study recruitment 1997-2003 Variable screening episodes per individual but screening continued until each women had at least 2 annual scans (in 2004)	**All cancers (n=35)** Sensitivity (95% CI), A vs. B 40% (24-58) vs. 77% (60-90), p=0.01 A plus B: 94% (81-99) Specificity (95% CI), A vs. B 93% (92-95) vs. 81% (80-83), p<0.0001 A plus B: 77% (75-79) PPV (95% CI), A vs. B 10% (5.8-17) vs. 7.3% (4.9-10) NPV (95% CI), A vs. B 99% (98-99) vs. 99% (99-100) Area under receiver operator curve, A vs. B 0.70 (0.68-0.72) vs. 0.85 (0.84-0.87), p=0.035 **Excluding DCIS (n=6)** Sensitivity (95% CI), A vs. B 31% (15-51) vs. 86% (68-96), p=0.0009 A plus B: 97% (82-100) ***BRCA1* carriers or relative with *BRCA1* mutation (n=139)** Sensitivity (95% CI), A vs. B 23% (5-54) vs. 92% (64-100), p=0.004 A plus B: 92% (64-100) Excluding 1 DCIS case: 25% (5.5-57) vs. 100% (74-100) Specificity (95% CI), A vs. B 92% (88-94) vs. 79% (75-83), p<0.0001 A plus B: 74% (69-78) PPV (95% CI), A vs. B 9.1% (1.9-24) vs. 14% (7.2-23) ***BRCA2* carriers or relative with *BRCA2* mutation (n=86)** Sensitivity (95% CI), A vs. B 50% (21-79) vs. 58% (28-84), p=1.0 A plus B: 92% (62-100) Excluding 3 DCIS cases: 33% (7.5-70) vs. 67% (30-93), p=0.45 Specificity (95% CI), A vs. B 94% (91-97) vs. 82% (77-87), p=0.0001 A plus B: 78% (72-83) PPV (95% CI), A vs. B 9.1% (1.9-24) vs. 14% (7.2-23) Note: Anonymous testing was restricted to women with breast cancer so that women with BRCA-positive relatives but no breast cancer themselves were not tested; sensitivities refer only to tested mutation carriers, specificities are only preliminary estimates. **Incident screens (n=15 cancers, n=1217 noncancers); observed incidence rate was 1.9% per year** Sensitivity (95% CI), A vs. B Any cancer: 40% (16-68) vs. 80% (52-96), p=0.11	15 incident cancers, observed incidence rate was 1.9% per year

Breast Cancer				
Cortesi et al, 2006[273] NA Modena Study Group for Familial Breast and Ovarian Cancer participants	Staging: 61% (n=17) stage I; 25% (n=7) stage II; 7% (n=2) stage III; 7% (n=2) stage IV Size: 29% (n=8) <10 mm in diameter; 36% (n=10) were 10-15 mm in diameter; 32% (n=9) >15 mm in diameter; 1 was inflammatory breast cancer Nodal status: 36% (n=10) node positive Interval cancers: n=8, all identified with CBE; interval cancer rate, 1.3 per 1000; diagnosed with CBE only (n=4); CBE plus ultrasound (n=3); CBE plus ultrasound plus mammography (n=1); time interval from last negative screen to diagnosis ranged from 1 to 14 months DCIS: Screening sensitivity for DCIS increased with age; low rate (65%) in women <50 years; high rate (93%) in oldest age group	Post treatment, 4 recurrences and 3 deaths (2 for disease progression, 1 from heart failure). Actuarial 5 year survival rate was 93%.	Rate of cancer detected in women at high risk for breast cancer was significantly higher than expected in an age-matched general population. Results support increased screening surveillance program to identify and monitor high-risk individuals.	Italian consortium for Hereditary Breast and Ovarian Cancer; COFIN-MURST 2003-2005; Faondazione Cassa di Risparmio di Modena; Associazione Angela Serra per la ricerca sul Cancro
Leach, 2005[274] NAMARIBS study	Grade: 10% (3/29) grade 1; 24% (7/29) grade 2; (66%) 19/29 grade 3 Size: 38% (11/29) were <10 mm in greatest dimension; 14% (4/29) were 10-14 mm in greatest dimension; 17% (5/29) were 15-19 mm; 31% (9/29) were ≥20 mm in greatest dimension; average tumor size = 15 mm Nodal status: 81% (21/26) cancers node-negative Interval cancers: n=2 (1 considered benign on MRI and 1 considered benign on mammography; method of detection NR)	NR	Contrast-enhanced MRI is more sensitive than mammography for breast cancer detection in women with familial risk for breast cancer. Specificity was acceptable for both. Detected tumors were small and mostly node negative, suggesting that annual screening with mammography and contrast-enhanced MRI would detect most tumors in this risk group.	Grant from U.K. Medical Research Council; MRI cost paid from subvention funding for research from U.K. National Health Service
Le-Petross et al, 2011[276] NA	Size on MRI: Mean, 14 mm (range, 1-30 mm) Nodal status: 9% (1/11) women node-positive Interval cancers: n=0	NR	Screening women at increased genetic risk of breast cancer by alternating mammography with MRI every 6 months has a higher cancer yield than	NR

Appendix C10. Evidence Table of Intensive Screening Interventions

Author, year Quality	Outcome: Cancer characteristics Interval cancers	Outcome: Disease-free survival Mortality	Conclusions	Funding source
			studies that screened using both modalities at the same time point.	
Rijnsburger et al, 2010[278] See also Kriege et al, 2004[277] NA Dutch MRISC study	<u>Characteristics of detected breast cancer (includes 78 screen-detected cancers and 11 interval cancers)</u> Tumor size: 40% (30/76) <1 cm, 39% (29/76) 1-2 cm, 20% (15/76) >2 cm; p1=0.003, p2=0.0045 Nodal status negative: 69% (50/72); p1=0.42, p2=1 Histology: 29% (21/72) grade 1, 32% (23/72) grade 2, 39% (28/72) grade 3; p1<0.001, p2=0.15 p1=overall comparison between subgroups p2=comparison between *BRCA1* and *BRCA2* Note: Age at diagnosis, number of interval cancers, and estrogen and progesterone receptor status significantly different between subgroups <u>Number of interval cancers (total, invasive, DCIS)</u> *BRCA1*: 10/35, 10/31, 0/4 *BRCA2*: 1/18, 1/18, 0/5 Other mutation: 0/0, 0/0, 0/0 High risk: 1/27, 1/23, 0/4 Moderate risk: 1/16, 0/11, 1/5 Total: 13/97, 12/78, 1/19 Note: denominator includes 6 breast cancers detected at prophylactic mastectomy <u>Kriege 2004 breast cancer characteristics, study group vs. control 1 vs. control 2 (based on 50 screen-detected cancers in study group, 1500 in control group 1, and 45 in control group 2)</u> Number of DCIS: 6 vs. 120 vs. 0 Invasive tumor size ≤1 cm: 19/44 vs. 193/1380 vs. 5/45; p<0.001 vs. control 1, p<0.04 vs. control 2 Nodal status negative: 28/44 vs. 657/1380 vs. 17/45; p<0.001 vs. control 1, p=0.001 vs. control 2 Histological grade 1: 19/44 vs. 99/1380 vs. 4/45; p<0.001 vs. control 1, p=0.01 vs. control 2 Note: Control 1 = National Cancer Registry data of women with breast cancer diagnosed in 1998; Control 2 = participants diagnosed with breast cancer between 1996 and 2002 participating in a prospective study of gene mutation.	<u>Disease-free and overall survival in 89 patients</u> 11/93 patients with breast cancer had relapse, 7/11 were mutation carriers 5 patients had distant metastasis, all were mutation carriers 4 patients died, 3/31 (9.7%) *BRCA1* and 1/16 (6.3%) *BRCA2* Cumulative metastasis-free and overall survival at 6 years in 43 mutation carriers with invasive cancer were 84% and 93%; other groups had 100% cumulative survival	Sensitivity of MRI superior to mammography for detection of breast cancer in women at increased risk. *BRCA1*-associated cancers have younger age at diagnosis, lower mammographic sensitivity, high number of interval cancers, low number of DCIS, and unfavorable tumor size at diagnosis.	Dutch government; Cancer Genomics Center

Author, year Quality	Outcome: Cancer characteristics Interval cancers	Outcome: Disease-free survival Mortality	Conclusions	Funding source
Ovarian Cancer				
Hermsen et al, 2007[281] NA	Stage: 80% (8/10) stage III/IV (4/5 incident, 4/5 interval cancers) vs. 77% (20/26) in unscreened family members with cancer Interval cancers: n=5	After mean followup of 28 months from diagnosis: 3/15 cases died of ovarian cancer	Annual screening with TVUS and serum CA-125 is an ineffective method for detecting ovarian cancer in women at increased risk due to family history.	Biocare Foundation

*Incident plus interval cancer.

Abbreviations: BIRADS = Breast Imaging- Reporting and Data System; BMI = body mass index; CA-125 = cancer antigen-125; CBE = clinical breast examination; CE = contrast enhanced; CI = confidence interval; DCIS = ductal carcinoma in situ; FDR = first-degree relative; MRI = magnetic resonance imaging; MRISC = Magnetic Resonance Imaging Screening Study; NA = not applicable; NPV = negative predictive value; NR = not reported; PPV = positive predictive value; SIR = standardized incidence ratio; TP53 = tumor protein 53; TVUS = transvaginal ultrasound; US = ultrasound.

Appendix C11. Evidence Table of Risk-Reducing Medications

Trial Quality	Design	Purpose	Intervention	Country/population/ setting	Inclusion/exclusion criteria
Tamoxifen vs. placebo					
IBIS-I[287] Fair See also Cuzick 2002[328]	RCT	To report the updated analysis of IBIS-I, focusing on the period after active treatment was completed	Oral tamoxifen 20 mg/day or placebo Groups directly compared, no expected incidence rates but baseline risk assessed using complex model for 10-year risk of ≥5%	United Kingdom (60% of participants), Europe, Australia, and New Zealand (37% of participants) Women at increased risk of breast cancer Recruited from family history clinics, relatives of women with breast cancer, breast screening centers, general practitioners, and the media	Inclusion Women had to have risk factors for breast cancer indicating ≥2-fold RR if they were ages 45 to 70 years, 4-fold RR if ages 40 to 44 years, or 10-fold RR if ages 35 to 39 years. Specifically, women were eligible from age 45 years if they had 1) mother or sister diagnosed with breast cancer before age 50 years, 2) 2 FDRs or SDRs with breast cancer at any age, or 3) FDR with breast cancer at any age, and were nulliparous or had previous hyperplastic benign lesion. Women were eligible from age 40 years if they had 1) atypical ductal or lobular hyperplasia, 2) FDR with bilateral breast cancer at any age, 3) 2 FDRs or SDRs with breast cancer, 1 of whom was diagnosed before age 50 years. Women were eligible from age 35 years if they had either 1) lobular carcinoma in situ or 2) 2 FDRs with breast cancer, both diagnosed before the age of 50 years. Any woman with estimated 10-year risk of ≥5% based on complex model was eligible after approval by study chairman. Exclusion Women with any previous invasive breast cancer, aside from nonmelanoma skin cancer, previous deep vein thrombosis or pulmonary embolism, current users of anticoagulants, or those wishing to become pregnant.
NSABP P-1[284] Fair See also Fisher et al, 1998[71]	RCT	To update the findings from the NSABP P-1 Trial after 7 years of followup	Oral tamoxifen 20 mg/day vs. placebo Note: 2 groups compared directly, no expected incidence rates	United States and Canada Women at increased risk for breast cancer Recruited through 133 clinical centers	Inclusion Women at increased risk for breast cancer due to 1) age ≥60 years, 2) ages 35 to 59 years with 5-year predicted risk of ≥1.66% by Gail model, 3) history of lobular carcinoma in situ, as well as 10 years of life expectancy, no clinical or mammographic evidence of breast cancer, not pregnant and not planning on becoming pregnant during study, normal white blood cell and platelet counts, normal hepatic and renal function, available for followup, have undergone endometrial sampling. Exclusion Women who had taken hormone replacement therapy, oral contraception, or androgens within 3 months of randomization; history of DVT or pulmonary embolism.

Appendix C11. Evidence Table of Risk-Reducing Medications

Trial Quality	Design	Purpose	Intervention	Country/population/ setting	Inclusion/exclusion criteria
Royal Marsden[285] Fair See also Powles et al, 1998[70]	RCT	To identify any long-term prevention of breast cancer associated with tamoxifen treatment after 20 years of followup of the Royal Marsden trial	Oral tamoxifen 20 mg/day or placebo Note: 2 groups compared directly, no expected incidence rates	United Kingdom Women at increased risk of breast cancer Recruited from breast clinics at Royal Marsden Hospital	Inclusion Healthy women ages 30 to 70 years, with no clinical or screening evidence of breast cancer; at increased risk of breast cancer because of family history; with 1) ≥1 FDR age <50 years at breast cancer diagnosis, 2) 1 FDR with bilateral breast cancer, or 3) 1 FDR with breast cancer diagnosed at any age plus ≥1 other affected FDR or SDR with breast cancer; personal history of benign breast biopsy and FDR with breast cancer and those using hormone replacement therapy also eligible. Exclusion Women with history of any cancer, DVT, or pulmonary embolism; risk of pregnancy; or using oral contraceptives.
Italian Randomized Tamoxifen Prevention[286] Fair See also Veronesi et al, 1998[72]	RCT	To update the results of the Italian Randomized Tamoxifen Prevention Trial after 11 years of followup, focusing on the occurrence of breast cancer	Oral tamoxifen 20 mg/day vs. placebo Note: 2 groups compared directly, no expected incidence rates	Italy (97% of patients), South America, Greece Healthy women at average risk for breast cancer Recruited via national advertising and through gynecologists	Inclusion Healthy women ages 35 to 70 years who had a hysterectomy for reasons other than neoplasm. Exclusion Women with severe concurrent illness or history of cardiac disease, endometriosis, and suspected or certain previous DVT.
Raloxifene vs. placebo					
RUTH[73] Good See also Barrett-Connor et al, 2006[299]	RCT	To provide further details about breast cancer incidence by tumor characteristics, duration of treatment, and subgroup in the RUTH trial	Oral raloxifene 60 mg/day vs. placebo Note: 2 groups compared directly, no expected incidence rates (5-year risk of invasive breast cancer at baseline based on Gail model)	Multinational Postmenopausal women at increased risk of coronary events Recruited through 177 sites in 26 countries, including the U.S.	Inclusion Women age ≥55 years; ≥1 year from final menstrual period; with documented coronary heart disease or increased risk for coronary heart disease based on risk factors (older age, diabetes, hypertension, smoking, hyperlipidemia). Exclusion Women suspected of having breast cancer or those with a history of breast cancer; recent myocardial infarction, coronary artery bypass grafting or percutaneous coronary angioplasty, or severe heart failure; history of venous thromboembolism; recent unexplained uterine bleeding; life expectancy <5 years; chronic liver or renal disease; recent use of oral or transdermal estrogens or current use of sex hormones or SERMs.

Appendix C11. Evidence Table of Risk-Reducing Medications

Trial Quality	Design	Purpose	Intervention	Country/population/ setting	Inclusion/exclusion criteria
MORE and CORE[288] Good See also Cummings et al, 1999[74]	RCT	To assess the effect of raloxifene, indicated for osteoporosis treatment and prevention, on invasive breast cancer in subgroups of postmenopausal women by defined risk factors for breast cancer	MORE: Oral raloxifene 60 or 120 mg/day vs. placebo CORE: Oral raloxifene 60mg/day vs. placebo Note: 5-year predicted risk based on the modified Gail model score at baseline of CORE trial per each woman's risk factors	Multinational Postmenopausal women with osteoporosis Recruited from 180 clinical centers in 25 countries, including the U.S.	Inclusion Women age ≤80 years; ≥2 years postmenopausal; with documented osteoporosis. Exclusion Women with a history of breast cancer, invasive endometrial cancer, stroke, or venous thromboembolism in the preceding 10 years. Note: only eligibility requirement for CORE was to have been enrolled in MORE trial.
Tamoxifen vs. raloxifene					
STAR[289] Good See also Vogel et al, 2006[329]	RCT	To update the findings from the STAR trial	Oral tamoxifen 20 mg/day vs. oral raloxifene 60 mg/day Note: expected breast cancer incidence rates based on Gail model of risk per woman's risk factors	United States and Canada Women with increased risk for breast cancer Recruited from nearly 200 clinical centers	Inclusion Women age ≥35 years; postmenopausal; 5-year predicted breast cancer risk ≥1.7% (per Gail model); not taking tamoxifen, raloxifene, hormone therapy, oral contraceptives, or androgens for ≥3 months before randomization; not currently on warfarin or cholestyramine; no history of stroke, transient ischemic attack, pulmonary embolism, or DVT; no atrial fibrillation; no uncontrolled diabetes or uncontrolled hypertension; no psychiatric condition that would interfere with adherence; performance status that would not restrict normal activity; no history of previous malignancy except basal cell or squamous cell carcinoma of the skin, carcinoma in situ of the cervix, or LCIS of the breast.

Appendix C11. Evidence Table of Risk-Reducing Medications

Trial Quality	Assignment/attrition	Demographics	Surveillance	Duration/follow up
Tamoxifen vs. placebo				
IBIS-I[287] Fair See also Cuzick 2002[328]	Tamoxifen vs. placebo 7154 randomized: 3579 vs. 3575 4861 (68%) completed 5 years of treatment: 2287 (64%) vs. 2574 (72%) Approximately 85% of women returned ≥1 questionnaire during posttreatment followup	Tamoxifen vs. placebo Mean (SD) age, years: 50.7 (7.0) vs. 50.8 (6.7) 3913 (55%) ages 45 to 54 years Family history: 6939 (97%) of women reported some family history of breast cancer Cuzick 2002 FDR with breast cancer at age ≤50 years: 1689/3573 (47%) vs. 1744/3566 (49%) FDR with bilateral breast cancer: 579/3573 (16%) vs. 601/3566 (17%) ≥2 FDRs or SDRs with breast cancer: 2204/3573 (62%) vs. 2206/3566 (62%)	During treatment, women followed every 6 months by clinic visit or phone call. Compliance measured by pill counts at each 6 month visit. Posttreatment, followed by annual mailed questionnaire for women in U.K. and Europe or annual clinic visits for women in Australia and New Zealand.	5 years of treatment Median followup was 95.6 months
NSABP P-1[284] Fair See also Fisher et al, 1998[71]	Tamoxifen vs. placebo 57,641 approached 14,453 agreed to be medically evaluated for eligibility 13,954 met eligibility requirements 13,388 randomized; 6681 vs. 6707 13,207 had followup and were included in analysis; 6597 vs. 6610 Note: withdrawal rate between year 6 and 7 of followup was higher in the placebo vs. tamoxifen group, resulting in different amounts of information for groups during this period	Age distribution at randomization: 39% ages 35-49 years 31% ages 50-59 years 30% age ≥60 years FDRs with breast cancer, n (tamoxifen vs. placebo): None: 1548 (26%) vs. 1597 (24%) 1: 3763 (57%) vs. 3738 (57%) 2: 1072 (16%) vs. 1094 (17%) ≥3: 214 (3.2%) vs. 181 (2.7%)	NR	5 years of treatment Mean followup was 6.2 years
Royal Marsden[285] Fair See also Powles et al, 1998[70]	2508 consented 14 withdrew consent prior to randomization 1250 randomized to tamoxifen, 12 excluded from analysis (all previous DCIS) 1238 analyzed 1244 randomized to placebo, 11 excluded from analysis (10 previous DCIS, 1 invasive cancer) 1233 analyzed Note: self-reported compliance was 8% less in the tamoxifen arm vs. placebo (p=0.002); difference seen at 1 year and remained constant over treatment period	Tamoxifen vs. placebo Median age, years (range): 47 (31-70) vs. 47 (30-70) Age <50 years: n=774 vs. 749 FDRs or SDRs with breast cancer, n: 0/not known: 8 vs. 10 1: 373 vs. 372 2: 476 vs. 496 3: 257 vs. 228 4: 81 vs. 82 ≥5: 43 vs. 45 Note: no significant differences between groups	Followup visits every 6 months with clinical breast exam and assessment for acute toxicity. Data forms completed at each visit. Medical problems and changes to family history were recorded at each visit. Mammography done annually.	8 years of treatment Median followup was 158 months

Appendix C11. Evidence Table of Risk-Reducing Medications

Trial Quality	Assignment/attrition	Demographics	Surveillance	Duration/follow up
Italian Randomized Tamoxifen Prevention[286] Fair See also Veronesi et al, 1998[72]	Tamoxifen vs. placebo 13,419 recruited 4,989 refused 1499 ineligible 527 not contactable 996 missing 5408 randomized: 2700 vs. 2708 2119 withdrew: 1085 vs. 1034 (56 for ineligibility, 99 due to major changes in protocol, 394 for major adverse events, 1407 voluntarily, 154 lost to followup, 9 deaths) 3289 completed 5 years of treatment: 1615 vs. 1674	Median age at entry: 51 years FDRs with breast cancer, n: None: 2359 (87%) vs. 2407 (89%) ≥1: 341 (13%) vs. 301 (11%) Note: no differences between groups on any baseline characteristics	During treatment, women had a physical and blood tests every 6 months and mammography annually. After trial completion, or in case of dropout, women were followed annually. Information about major endpoints (death, adverse events, cancer diagnosis) continuously collected.	Mean duration of treatment, 4.2 years Mean followup, 9.1 years (cancers other than breast endpoint) 11.2 years (breast cancer endpoint)
Raloxifene vs. placebo				
RUTH[73] Good See also Barrett-Connor et al, 2006[299]	Raloxifene vs. placebo 10,101 enrolled and randomized: 5044 vs. 5057 Completed 5 years of followup: 4060 (80%) vs. 3979 (79%) Note: 71% of placebo and 70% of raloxifene group took 70% of study medication based on pill counts	Raloxifene vs. placebo Mean age at baseline, years (SD): 67.5 (6.6) vs. 67.5 (6.7) Family history of breast cancer, n: 452 (9.8%) vs. 445 (9.7%) Note: no differences between groups on any baseline characteristics Note: Unable to determine number without family history per group because of missing values not accounted for	Breast cancer risk assessment at baseline. Clinical breast exam at baseline and every 2 years after. Mammogram within 1 year of randomization and every 2 years after. Participants attended study visits or contacted by telephone semiannually to assess adherence, adverse events, and outcomes of interest.	Median exposure to drug was 5.05 years Median followup, 5.6 years (analysis of data collected before February 2006)
MORE and CORE[288] Good See also Cummings et al, 1999[74]	7705 randomized in MORE: 2557 to raloxifene 60 mg/day, 2572 to raloxifene 120 mg/day, 2567 to placebo 4011 enrolled in CORE: 2725 to raloxifene 60 mg/day, 1286 to placebo	Characteristics at beginning of MORE Age ≥65 years, n (%): 4621/7705; 2563 (60%) of combined raloxifene groups; 1550 (60%) of placebo group Age <65 years, n (%): 3084 total; 2058 (40%) of combined raloxifene groups; 1026 (40%) of placebo group Family history of breast cancer, n (%): 949/7705; 636 (13%) of combined raloxifene groups; 313 (12%) of placebo group Note: no significant differences between groups at baseline in MORE or CORE	MORE: Mammograms at baseline, 2, 3, 4 years and optional at year 1. Biannual study visits for clinical breast exam and questions about breast cancer diagnosis, biopsy, surgery since last visit. CORE: Mammograms within 1 year of study entry and at 2 and 4 years. Annual study visits for clinical breast exam and questions about breast cancer diagnosis, biopsy, surgery since last visit.	4 years of treatment in MORE, 4 years in CORE (median time from end of MORE to enrollment in CORE, 10.6 months (range, 2.6-62 months); mean time from randomization in MORE to end of CORE, 7.8 years (includes period between trials)

Appendix C11. Evidence Table of Risk-Reducing Medications

Trial Quality	Assignment/attrition	Demographics	Surveillance	Duration/follow up
Tamoxifen vs. raloxifene				
STAR[289] Good See also Vogel et al, 2006[329]	184,460 screened; 88,092 excluded for breast cancer risk <1.7% 96,368 had breast cancer risk ≥1.7%; 20,616 consented to screening for medical eligibility 20,168 met eligibility criteria; 421 did not want to participate 19,747 randomized; 9872 assigned to tamoxifen; 9875 assigned to raloxifene 19,471 original analysis (274 lost to followup; 146 in tamoxifen group, 128 in raloxifene group; 2 excluded for bilateral mastectomy prior to randomization) 19,490 update analysis; 9736 in tamoxifen group; 9754 in raloxifene group (followup collected on 20 women missing from original; 1 excluded due to breast cancer diagnosis before randomization) Note: adherence to 5 years of therapy was within study limits; since unblinding (April 2006), women who had not completed 5-year course of tamoxifen were offered option to switch to raloxifene for remaining portion of treatment course, which 879 women did	Characteristics at entry of women included in the STAR update analysis Mean age, years: 58.5 (SD 7.4) Age distribution: 9% <50 years; 50% ages 50-59 years; 32% ages 60-69 years; 8.8% age ≥70 years FDRs with breast cancer, n (%); tamoxifen vs. raloxifene: None: 2838 (29) vs. 2791 (27) 1: 5046 (52) vs. 5135 (53) 2: 1532 (16) vs. 1561 (16) ≥3: 320 (3.3) vs. 267 (2.7)	Followup occurred at 6 months after treatment initiation and every 6 months thereafter for 5 years. After 5 years, followup occurred annually. Biannual clinical breast exam and annual mammography. Annual gynecological examinations, complete blood count, routine serum chemistry tests. Outcomes assessed at each visit and verified with medical reports when applicable.	Mean duration of treatment was 43.5 months (SD, 20.7) for tamoxifen group and 46.8 months (SD, 20.0) for raloxifene group Median followup, 81 months (analysis cutoff March 2009)

Trial Quality	Results	Conclusions	Funding source
Tamoxifen vs. placebo			
IBIS-I[287] Fair See also Cuzick 2002[328]	Number of events and rate of breast cancers; tamoxifen vs. placebo: Total breast cancers: 142 vs. 195; rate,* 4.97 vs. 6.82; RR, 0.73 (95% CI, 0.58-0.91) Invasive breast cancers: 124 vs. 168; rate,* 4.34 vs. 5.88; RR, 0.74 (95% CI, 0.58-0.94) DCIS: 17 vs. 27; rate,* 0.60 vs. 0.94; RR, 0.63 (95% CI, 0.32-1.20)	Risk reducing effect of tamoxifen persists after ≥10 years of followup in a cohort of women, in which 97% reported some family history of breast cancer.	Cancer Research United Kingdom; National Health and Medical Research Council Australia

Appendix C11. Evidence Table of Risk-Reducing Medications

Trial Quality	Results	Conclusions	Funding source
NSABP P-1[284] Fair See also Fisher et al, 1998[71]	Tamoxifen vs. placebo Number and rates* of invasive breast cancer by number of FDRs with breast cancer: None: 33 vs. 62; rate,* 3.48 vs. 6.47; difference, 2.99; RR, 0.54 (95% CI, 0.34-0.83) 1: 73 vs. 124; rate,* 3.16 vs. 5.52; difference, 2.36; RR, 0.57 (95% CI, 0.42-0.77) 2: 32 vs. 52; rate,* 4.91 vs. 7.84; difference, 2.93; RR, 0.63 (95% CI, 0.39-0.99) ≥3: 7 vs. 12; rate,* 5.48 vs. 11.24; difference, 5.76; RR, 0.49 (95% CI, 0.16-1.34)	In women with FDRs with breast cancer, tamoxifen reduced the incidence of invasive breast cancer versus placebo; statistically significant reduction of risk for those with 1 or 2 FDRs with breast cancer, nonsignificant with ≥3 relatives	National Cancer Institute; U.S. Department of Health and Human Services
Royal Marsden[285] Fair See also Powles et al, 1998[70]	Tamoxifen vs. placebo Invasive ER-positive breast cancer events and rate* by family history, number of relatives: 0-2: 14 vs. 28; rate, 2.7 vs. 5.3; HR, 0.51 (95% CI, 0.27-0.96); p=0.04 ≥3: 9 vs. 19; rate, 3.9 vs. 9.1; HR, 0.43 (95% CI, 0.19-0.95); p=0.04 P for interaction (between tamoxifen and placebo, after adjusting for menopausal status at randomization, HT use during treatment) = 0.004	In women with a family history of breast cancer (FDRs or SDRs with breast cancer), less invasive ER-positive breast cancer observed in tamoxifen arm than in placebo arm; statistically significant	National Health Service; Cancer Research U.K.
Italian Randomized Tamoxifen Prevention[286] Fair See also Veronesi et al, 1998[72]	Tamoxifen vs. placebo Number and rates of breast cancer by number of FDRs with breast cancer: None: 46 vs. 64; rate,* 1.75 vs. 2.41; difference, 0.66; RR, 0.73 (95% CI, 0.50-1.06) ≥1: 16 vs. 10; rate,* 4.29 vs. 3.00; difference, -1.29; RR, 1.43 (95% CI, 0.65-3.15)	In women with ≥1 FDR with breast cancer, more breast cancer observed in tamoxifen arm than in placebo arm; not statistically significant difference	Italian National Research Council; Italian Foundation for Cancer Research; American-Italian Cancer Foundation; Italian League Against Cancer
Raloxifene vs. placebo			
RUTH[73] Good See also Barrett-Connor et al, 2006[299]	Raloxifene vs. placebo Number of cases (annualized rate†, %) of invasive breast cancer by family history: No: 29 (0.13) vs. 53 (0.25); HR, 0.53 (95% CI, 0.34-0.84) Yes: 8 (0.34) vs. 9 (0.39); HR, 0.89 (95% CI, 0.34-2.31) P for interaction=0.34	In women with a family history of breast cancer (FDR with breast cancer), raloxifene reduced the incidence of invasive breast cancer versus placebo; nonsignificant reduction	Eli Lilly and Company

Appendix C12. Evidence Table of Risk-Reducing Surgery

Author, year Quality	Design	Purpose	Sample size	Population/setting	Demographics
Salpingo-oophorectomy or oophorectomy vs. no oophorectomy					
Domchek et al, 2010[292] Fair	Prospective cohort	To assess the relationship of RRM or RRSO with cancer outcomes.	Eligible: 2482 Analyzed: 1458 with no prior breast cancer (935 *BRCA1*, 523 *BRCA2*)	1974-2008 U.K., Europe, and North America Women from 22 centers in the PROSE consortium	NR
Kramer et al, 2005[185] Fair Note: only oophorectomy performed	Prospective cohort	To assess whether population differences in oophorectomy prevalence might significantly influence breast cancer penetrance estimates in *BRCA1* mutation families.	Eligible: 673 (98 *BRCA1* positive, 23 from *BRCA1* families)	Year: NR U.S. Women from self-referred and physician-referred families affected by hereditary breast/ovarian cancer with a *BRCA1* mutation and participating in ongoing studies at the National Cancer Institute	NR Mean, 2.7 cases of breast cancer and 3.0 cases of ovarian cancer per family diagnosed before ascertainment
Olson et al, 2004[296] NA Note: only oophorectomy performed	Retrospective cohort	To estimate the potential risk reduction of breast cancer for women who underwent oophorectomy and had a family history of breast cancer but unknown BRCA status.	Eligible: 851 Analyzed: 634	1970-1994 U.S./review of Mayo Clinic Surgical Index Followup survey completed by patient or surrogates (if patient deceased)	Surrogate respondent vs. self-respondent Age at surgery, years (n): 21-30: 1 (4%) vs. 16 (3%) 31-40: 1(4%) vs. 88 (14%) 41-50: 11 (41%) vs. 319 (53%) 51-60: 14 (52%) vs. 184 (30%) Age at questionnaire response (followup) of self-respondents, years (n): 31-40: 9 (1%) 41-50: 48 (8%) 51-60: 172 (28%) 61-70: 231 (38%) 71-80: 124 (20%) 81-90: 20 (3%) Deceased: n=30
Mastectomy vs. no mastectomy					
Domchek et al, 2010[292] Fair	Prospective cohort	To assess the relationship of RRM or RRSO with cancer outcomes.	Eligible: 2482 Analyzed: 1458 with no prior breast cancer (935 *BRCA1*, 523 *BRCA2*)	1974-2008 U.K., Europe, and North America Women from 22 centers in the PROSE consortium	NR
Evans et al, 2009[293] NA	Prospective cohort	To assess effectiveness of risk-reducing surgery in women at high risk of breast cancer, including carriers and noncarriers of *BRCA1/2* mutation.	Eligible: 550 Enrolled: 314 women with no prior breast cancer	1987-1992 Europe Multidisciplinary family history clinics established at 10 centers	Mean age of women undergoing mastectomy at Manchester site, years: 41 (range, 21-60) Age range at all sites, years: 21-72

Appendix C12. Evidence Table of Risk-Reducing Surgery

Author, year Quality	Design	Purpose	Sample size	Population/setting	Demographics
Skytte et al, 2011[294] Good	Prospective cohort	To compare incidence of breast cancer after RRM in healthy BRCA mutation carriers versus nonoperated mutation carriers and background population.	Eligible: 307 with mutation (201 *BRCA1*, 106 *BRCA2*)	January 1996-February 2008 Denmark Women from clinical genetics departments at multiple sites with mutation status diagnosed	Median age at entry into study, years: 36.2 (range, 17.9-86.3) Mean age at group entry, years (mastectomy vs. no mastectomy): 37.1 vs. 37.7 <40 years: 64/96 (67%) vs. 127/211 (60%) Note: age at group entry = age at mastectomy for mastectomy group and age at BRCA diagnosis for no mastectomy group
Prior Report					
Mastectomy					
Hartmann et al, 1999[290]	Retrospective cohort	To define the effect of RRM on incidence of breast cancer and risk of death from breast cancer	Eligible: 639 Analyzed: 639	1960-1993 U.S.; Mayo Clinic medical records of women who underwent RRM	Mean age at surgery, 42 (range, 18-79)
Hartmann et al, 2001[291]	Retrospective cohort	To report the effect of RRM on breast cancer risk in *BRCA1/2* carriers identified from a high-risk cohort	18 *BRCA1/2*	*BRCA1/2* mutation carriers undergoing RRM and enrolled as high-risk participants in prior study (Hartmann 1999)	Mean age at surgery, 41 (range, 20-75)
Oophorectomy					
Struewing et al, 1995[229]	Prospective cohort	To determine the incidence of post-oophorectomy carcinomatosis and quatify the effectiveness of risk-reducing surgery	Eligible: 16 families Analyzed: 12 families (390 1st-degree relatives of breast or ovarian cancer cases)	Women with high genetic risk of ovarian cancer and oophorectomy matched to high-risk women who did not undergo surgery from National Cancer Institute, Creighton University, and U.K.	NR

Appendix C12. Evidence Table of Risk-Reducing Surgery

Author, year Quality	Inclusion/exclusion criteria	Risk definition	Followup
Salpingo-oophorectomy or oophorectomy vs. no oophorectomy			
Domchek et al, 2010[292] Fair	Inclusion Women with *BRCA1/2* mutations, no prior ovarian cancer, no salpingo-oophorectomy at time of ascertainment, and minimum 6 months followup. Exclusion Women with cancer diagnosis within first 6 months of followup, women who had RRM prior to ascertainment excluded from all breast cancer end points, and women with occult ovarian cancer during RRSO excluded from ovarian cancer end points.	BRCA status	Patients followed until end of 2009. Median followup was 3.65 years for those who had surgery and 4.29 years for those who did not. **Oophorectomy & breast cancer outcomes:** *BRCA1* followed mean 4.7 years to censoring *BRCA2* followed mean 4.7 years to censoring **Oophorectomy & ovarian cancer outcomes:** *BRCA1* followed mean 5.6 years to censoring *BRCA2* followed mean 5.8 years to censoring
Kramer et al, 2005[185] Fair Note: only oophorectomy performed	Inclusion Female, bloodline family member from *BRCA1*-positive family, no history of breast cancer before ascertainment, no history of bilateral mastectomy, age ≥20 years by study closing date. Exclusion Breast cancer diagnosed before family ascertainment and families with variants of uncertain significance.	BRCA status	Mean followup: 16.5 years; 11,105 person-years of observation Mean followup per patient (years) *BRCA1* positive: 14.1 *BRCA1* negative: 17.6 *BRCA1* unknown: 15.8
Olson et al, 2004[296] NA Note: only oophorectomy performed	Inclusion Women age <60 years with bilateral oophorectomy during study dates. Exclusion Women who had hysterectomy alone or only had 1 ovary removed, had prophylactic mastectomy at any time, or had any history of cancer prior to surgery, aside from nonmelanoma skin cancer.	High risk ≥1 1st-degree relative with breast cancer at age <50 or 1 1st-degree relative with ovarian cancer at any age and ≥1 other 1st- or 2nd-degree relative with either diagnosis at any age. Moderate risk Only 1 1st-degree relative with breast cancer at any age. Low risk No breast or ovarian cancer family history	N/A
Mastectomy vs. no mastectomy			
Domchek et al, 2010[292] Fair	Inclusion Women with *BRCA1/2* mutations, no prior ovarian cancer, no salpingo-oophorectomy at time of ascertainment, and minimum 6 months followup. Exclusion Women with cancer diagnosis within first 6 months of followup, women who had RRM prior to ascertainment excluded from all breast cancer end points, and women with occult ovarian cancer during RRSO excluded from ovarian cancer end points.	BRCA status	Patients followed until end of 2009. Median followup was 3.65 years for those who had surgery and 4.29 years for those who did not. **Mastectomy & breast cancer outcomes:** *BRCA1* followed mean 2.7 years to censoring *BRCA2* followed mean 2.5 years to censoring

Appendix C12. Evidence Table of Risk-Reducing Surgery

Author, year Quality	Inclusion/exclusion criteria	Risk definition	Followup
Evans et al, 2009[293] NA	Inclusion Eligible for bilateral RRM if lifetime breast cancer risk in excess of 25% or eligible for unilateral RRM if already had a diagnosis of in situ or invasive breast cancer in the contralateral breast. Paris center offered surgery to *BRCA1/2* carriers only. Exclusion NR	Lifetime risk of breast cancer >25% based on family history with or without mutation status or diagnosis of breast cancer in contralateral breast	Followup in all women with RRM, years: Median, 7.5; Mean, 6.1; 3,334 women-years Followup in women undergoing bilateral RRM: 2,155 women-years (Manchester site, 1,274 women-years) Followup in control women: 2,438 women-years
Skytte et al, 2011[294] Good	Inclusion *BRCA1/2* mutation positive and women who did not have mastectomy or salpingo-oophorectomy prior to study. Exclusion Diagnosis of breast or ovarian cancer before BRCA testing and women who opted for risk-reducing surgery before receiving test result.	BRCA status	Median time from study entry to mastectomy: 7.7 years Total at-risk time in mastectomy group: 378.7 years Total at-risk time in no mastectomy group: 934.6 years
Prior Report			
Mastectomy			
Hartmann et al, 1999[290]	Inclusion Women with a family history of breast cancer who had bilateral RRM Exclusion Breast cancer detected in surgically treated breast; surgery for augmentation of reduction High-risk comparison group inclusion Sisters of high-risk subjects were recruited to the study	High risk ≥2 1st-degree relatives with breast cancer; 1 1st-degree relative and ≥2 2nd- or 3rd-degree relatives with breast cancer; 1 1st-degree relative with breast cancer before age 45 years and 1 other relative with breast cancer; 1 1st-degree relative with breast cancer and ≥1 relatives with ovarian cancer; 2 2nd- or 3rd-degree relatives with breast cancer and ≥1 with ovarian cancer; 1 2nd- or 3rd-degree relative with breast cancer and ≥2 with ovarian cancer; ≥3 2nd- or 3rd-degree relatives with breast cancer; 1 1st-degree relative with bilateral breast cancer; breast cancer in male family members Moderate risk Women who did not meet these criteria	Median, 14 years; with a minimum of 2 years for 99% of the subjects.
Hartmann et al, 2001[291]	Inclusion Women with *BRCA1/2* mutations who had bilateral RRM mastectomy	BRCA status	13.1 years

Appendix C12. Evidence Table of Risk-Reducing Surgery

Author, year Quality	Inclusion/exclusion criteria	Risk definition	Followup
Oophorectomy			
Struewing et al, 1995[229]	Inclusion: Families with ≥3 cases of ovarian cancer or ≥2 cases of ovarian cancer and ≥1 case of breast cancer before age 50. Exclusion: Families fitting criteria for Lynch Syndrome II.	Results presented by those with an affected 1st-degree relative and those with an affected 2nd-degree relative	Surgery vs. no surgery Ovarian cancer incidence 1st-degree relative: 460 vs. 1665 person-years 2nd-degree relative: 106 vs. 2123 person-years Breast cancer incidence 1st-degree relative: 484 vs. 1587 person-years 2nd-degree relative: 106 vs. 2131 person-years

Author, year Quality	Results	Conclusions	Funding source
Salpingo-oophorectomy or oophorectomy vs. no oophorectomy			
Domchek et al, 2010[292] Fair	Number of cancer cases in women with no history of breast cancer; surgery vs. no surgery Risk-reducing salpingo-oophorectomy and ovarian or primary peritoneal cancer risk Total: 6/465 (1.3%) vs. 63/1092 (5.8%); HR, 0.28 (95% CI, 0.12-0.69) *BRCA1*: 6/342 (1.8%) vs. 49/661 (7.4%); HR, 0.31 (95% CI, 0.12-0.82) *BRCA2*: 0/123 vs. 14/431 (3.2%); HR N/A Note: HR adjusted for year of birth, oral contraceptive use, and stratified by center Risk-reducing salpingo-oophorectomy and breast cancer risk Total: 39/336 (12%) vs. 223/1034 (22%); HR, 0.54 (95% CI, 0.37-0.79) *BRCA1*: 32/236 (14%) vs. 129/633 (20%); HR, 0.63 (95% CI, 0.41-0.96) *BRCA2*: 7/100 (7%) vs. 94/401 (23%); HR, 0.36 (95% CI, 18.1-82.7) Note: HR adjusted for year of birth and stratified by center Risk-reducing salpingo-oophorectomy and all-cause mortality Total: 8/447 (1.8%) vs. 60/1011 (5.9%); HR, 0.45 (95% CI, 0.21-0.95) *BRCA1*: 8/327 (2.4%) vs. 43/608 (7.1%); HR, 0.52 (95% CI, 0.24-1.14) *BRCA2*: 0/120 vs. 17/403 (4.2%); HR N/A Note: HR adjusted for year of birth and stratified by center Risk-reducing salpingo-oophorectomy and breast cancer–specific mortality Total: 2/441 (0.5%) vs. 22/973 (2.3%); HR, 0.27 (95% CI, 0.05-1.33) *BRCA1*: 2/321 (1.0%) vs. 16/581 (2.8%); HR, 0.30 (95% CI, 0.06-1.53) *BRCA2*: 0/120 vs. 6/392 (1.5%); HR N/A Note: HR adjusted for year of birth and stratified by center Risk-reducing salpingo-oophorectomy and ovarian cancer–specific mortality Total: 3/442 (0.7%) vs. 24/975 (2.5%); HR, 0.39 (95% CI, 0.12-1.29) *BRCA1*: 3/322 (0.9%) vs. 20/585 (3.4%); HR, 0.46 (95% CI, 0.08-2.72) *BRCA2*: 0/120 vs. 4/390 (1.0%); HR N/A Note: HR adjusted for year of birth, oral contraceptive use, and stratified by center	Among a cohort of women with BRCA mutations, RRSO was associated with a lower risk of ovarian cancer, first diagnosis of breast cancer, all-cause mortality, breast cancer–specific mortality, and ovarian cancer–specific mortality.	Public Health Service; University of Pennsylvania Cancer Center; Cancer Genetics Network; Marjorie Cohen Research Fund; SPORE grant from the Dana-Farber/ Harvard Cancer Center; U.S. Department of Defense; Utah Cancer Registry; Utah State Department; Nebraska State Cancer and Smoking-Related Diseases Research Program grants; Cancer Research U.K. Grant; National Cancer Institute; Dr. Olopade received funding as the Doris Duke Distinguished Clinical Scientist; Dr. Eeles received funding from the National Institute for Health Research

Appendix C12. Evidence Table of Risk-Reducing Surgery

Author, year Quality	Results	Conclusions	Funding source
Kramer et al, 2005[185] Fair Note: only oophorectomy performed	Number of breast cancer cases; oophorectomy vs. no oophorectomy *BRCA1* positive (n=98): 6/33 (18%) vs. 27/65 (42%); HR, 0.38 (95% CI, 0.15 to 0.97); p=0.043 *BRCA1* negative (n=353): 1/34 (2.9%) vs. 4/319 (1.3%); HR NR *BRCA1* status unknown (n=222): 0/18 vs. 5/204 (2.5%); HR NR Absolute risk reduction in women who had oophorectomy was most prominent when surgery was done at a younger age (<40 years), figure representation	In a cohort of *BRCA1* mutation carriers from multiple-case families, oophorectomy was associated with decreased risk of breast cancer; affect was strongest in younger women; oophorectomy status affects breast cancer penetrance	Intramural Research Program of National Cancer Institute; funding source not specifically reported
Olson et al, 2004[296] NA Note: only oophorectomy performed	Expected vs. observed number of cancer cases <u>Age of surgery <60 years</u> High risk (n=55): 5.4 vs. 3; RR, 0.56 (95% CI, 0.11-1.33) Moderate risk (n=193): 10.9 vs. 9; RR, 0.83 (95% CI, 0.38-1.44) <u>Age of surgery <50 years</u> High risk (n=41): 3.9 vs. 1; RR, 0.26 (95% CI, 0.001-0.99) Moderate risk (n=130): 7.7 vs. 5; RR, 0.65 (95% CI, 0.21-1.32) <u>Age of surgery <60 years and premenopausal before surgery</u> High risk (n=52): 5.1 vs. 3; RR, 0.59 (95% CI, 0.12-1.41) Moderate risk (n=186): 10.4 vs. 7; RR, 0.67 (95% CI, 0.27-1.24) <u>Age of surgery <50 years and premenopausal before surgery</u> High risk (n=40): 3.8 vs. 1; RR, 0.26 (95% CI, 0.00-1.00) Moderate risk (n=126): 7.4 vs. 3; RR, 0.41 (95% CI, 0.08-0.98)	The number of observed breast cancers in women in the cohort was lower than expected for nearly all levels of risk, and especially for those age <50 years and premenopausal prior to surgery	Fraternal Order of the Eagles and the National Cancer Institute
Mastectomy vs. no mastectomy			
Domchek et al, 2010[292] Fair	Number of cancer cases in women with no history of breast cancer; surgery vs. no surgery <u>Risk-reducing mastectomy and risk of first occurrence of breast cancer</u> Total: 0/75 vs. 34/585 (5.8%) *BRCA1*: 0/43 vs. 19/372 (5.1%) *BRCA2*: 0/32 vs. 15/213 (7.0%)	In a cohort of women with BRCA mutations, RRM was associated with a lower risk of breast cancer	Public Health Service; University of Pennsylvania Cancer Center; Cancer Genetics Network; Marjorie Cohen Research Fund; SPORE grant from Dana-Farber/Harvard Cancer Center; U.S. Department of Defense; Utah Cancer Registry; Utah State Department; Nebraska State Cancer and Smoking-Related Diseases Research Program grants; Cancer Research U.K. Grant; National Cancer Institute; Dr. Olopade funded as the Doris Duke Distinguished Clinical Scientist; Dr. Eeles received funding from the National Institute for Health Research

Appendix C12. Evidence Table of Risk-Reducing Surgery

Author, year Quality	Results	Conclusions	Funding source
Evans et al, 2009[293] NA	Manchester (mastectomy vs. no mastectomy): RRM: 179 vs. 0 Breast cancers expected based on life tables: 12.12 vs. 20.8 Cancers diagnosed: 0 vs. 21 All sites: RRM: 307 per Table 2 (314 per text [p. 256]) Expected cancers: 21.30 Cancers diagnosed: 0	Risk-reducing surgery is highly effective	NR
Skytte et al, 2011[294] Good	Number of breast cancer cases (incidence per person-year); mastectomy vs. no mastectomy: 3/96 (0.8%) vs. 16/211 (1.7%); HR, 0.394 (95%CI, 0.115-1.355); p=0.14 Note: 3/3 women with breast cancer in the mastectomy group and 12/16 women in no mastectomy group were *BRCA1*-positive Note: All women diagnosed with cancer in mastectomy group had also had bilateral salpingo-oophorectomy; 1 woman diagnosed with breast cancer on date of mastectomy, contributed to the "no mastectomy" group at risk time and cancer incidence Adjusting for age did not change significance (HR, 0.455; p=0.224) Effect of age was significant (p=0.008); in both groups, 1-year age difference associated with 4.2% increase in breast cancer risk Annual incidence of breast cancer after mastectomy by carrier status: 1.1% for *BRCA1* (n=67); 0 for *BRCA2* (n=29)	Study of 307 healthy *BRCA1/2* carriers suggests bilateral RRM reduces risk of breast cancer but does not completely eliminate it. Study size too small to show a significant difference	NR
Prior Report			
Mastectomy			
Hartmann et al, 1999[290]	Overall: 425 subjects were classified moderate risk, 214 subjects high risk. 95% were alive at the time of the study. 7 were diagnosed with breast cancer (4 moderate risk, 3 high risk); all cases occurred after subcutaneous mastectomy. Cancer Diagnosis: 37 in the moderate-risk group (based on Gail model estimates) and 53 in the high-risk group (based on the high-risk comparison group) were expected to develop breast cancer had they not had mastectomy. RRM reduced risk in the moderate-risk group by 89.5% (p<0.001) and in the high-risk group by 90%-94% (depending on adjusted analysis). 2 women in the high-risk group were diagnosed with ovarian cancer. Death Reduction: 10 in the moderate-risk group (based on Gail model estimates) and 31 in the high-risk group (based on the high-risk comparison group) were expected to die from breast cancer had they not had mastectomy. Death was reduced in the moderate-risk group by 100% (no deaths) (95% CI, 70-100) and in the high-risk group by 81%-94% (depending on adjusted analysis) (2 deaths).	In women with high risk of breast cancer on the basis of family history, RRM can significantly reduce the incidence of breast cancer	U.S. Department of Defense; National Cancer Insitute; Donaldson Charitable Trust
Hartmann et al, 2001[291]	Risk Reduction: Easton model (a high-penetrance model), 6.1 cases were expected; Struewing model (a low-penetrance model), 4.5 cases. Mastectomy resulted in risk reduction of 89.5% or 100% for the Easton model (95% CI, 41.4-99.7 and CI, 68-100) and 85% or 100% for the Struewing model (95% CI, 15.6-99.6 and CI, 54.1-100).	Risk-reducing mastectomy is associated with a substantial reduction in the incidence of breast cancer in known *BRCA1/2* mutation	NR

Appendix C12. Evidence Table of Risk-Reducing Surgery

Author, year Quality	Results	Conclusions	Funding source
		carriers	
Oophorectomy			
Struewing et al, 1995[229]	Surgery vs. no surgery *Preliminary Analysis from National Cancer Insititute only* <u>Ovarian cancer incidence</u> 1st-degree relative: 2/44 vs. 8/346 2nd-degree relative: 0 vs. 1 Note: Incidence includes post-oophorectomy ovarian carcinomatosis <u>Breast cancer incidence</u> 1st-degree relative: 3/44 vs. 14/346 2nd-degree relative: 0 vs. 3	Findings suggest that there is a finite risk of post-oophorectomy carcinomatosis. Preliminary analysis suggests a statistically nonsignificant protective effect of surgery for ovarian cancer	NR

Abbreviations: CI = confidence interval; HR = hazard ratio; MRI = magnetic resonance imaging; NA = not applicable; NR = not reported; RR = relative risk; RRM = risk-reducing mastectomy; RRSO = risk-reducing salpingo-oophorectomy; PROSE = Prevention and Observation of Surgical Endpoints.

Appendix C13. Evidence Table of Harms of Intensive Screening

Author, year Quality	Subcategory	Study design	Country/population/ setting	Inclusion/exclusion criteria	Risk level definition
Breast cancer screening					
Kriege et al, 2004[277] NA Dutch MRISC study	Physical harms of increased screening	Prospective cohort (breast cancer characteristics compared to registry data and women with breast cancer from another prospective cohort study)	The Netherlands Women with increased familial or genetic predisposition for breast cancer attending academic and/or cancer centers at 6 sites	Inclusion Cumulative lifetime risk of breast cancer >15% due to genetic or familial predisposition according to modified Claus tables; age at entry between 25 and 70 years (could be tested at before age 25 if family member diagnosed before age 30 years) Exclusion Women with symptoms suggestive of breast cancer or personal history of breast cancer; women proven not to have a mutation in a family with a proven mutation	Cumulative lifetime risk of breast cancer >15% due to genetic or familial predisposition according to modified Claus tables
Kriege et al, 2006[297] NA Dutch MRISC study	Physical harms of increased screening	Prospective cohort (breast cancer characteristics compared to registry data and women with breast cancer from another prospective cohort study)	The Netherlands Women with increased familial or genetic predisposition for breast cancer attending academic and/or cancer centers at 6 sites	Inclusion Cumulative lifetime risk of breast cancer >15% due to genetic or familial predisposition according to modified Claus tables, age at entry between 25 and 70 years (could be tested at before age 25 if family member diagnosed before age 30 years), no previous breast cancer or symptoms suspicious for breast cancer Exclusion Women with symptoms suggestive of breast cancer or personal history of breast cancer; women proven not to have a mutation in a family with a proven mutation	Cumulative lifetime risk of breast cancer >15% due to genetic or familial predisposition according to modified Claus tables
Leach et al, 2005[274] NAMARIBS study	Physical harms of increased screening	Prospective cohort, one-arm	U.K. Women attending 1 of 22 participating centers in the U.K. with increased breast cancer risk	Inclusion Asymptomatic women aged 35-49 years fulfilling 1 of the following: known carrier of a deleterious *BRCA1*, *BRCA2*, or TP53 mutation; FDR of someone with 1 of these deleterious mutations; strong family history of breast or ovarian cancer or both; or family history consistent with classic Li-Fraumeni syndrome. Aim was to include women whose affected FDRs had ≥60% chance of being a *BRCA1* or *BRCA2* mutation carrier or women with an annual risk of ≥0.9% Exclusion Women with previous breast cancer, those with any cancer such that prognosis was <5 years, participants who had predictive genetic testing during study and whose results were negative, women who developed cancer during study period	Known carrier of a deleterious *BRCA1*, *BRCA2*, or TP53 mutation; FDR of someone with 1 of these deleterious mutations; strong family history of breast or ovarian cancer or both; or family history consistent with classic Li-Fraumeni syndrome

Appendix C13. Evidence Table of Harms of Intensive Screening

Author, year Quality	Subcategory	Study design	Country/population/ setting	Inclusion/exclusion criteria	Risk level definition
Le-Petross et al, 2011[276] NA	Physical harms of increased screening	Retrospective analysis of prospective cohort study, one-arm	U.S. Women at increased genetic risk of breast cancer at single institution	Inclusion Women age ≥18 years, having undergone alternating screening mammography and breast MRI every 6 months at study institution, either confirmed *BRCA1/2* carriers or FDR of confirmed *BRCA1/2* carrier Exclusion Women with history of breast cancer, who had calculated lifetime risk of breast cancer >20%, or who did not undergo a screening MRI, women who used chemoprevention or underwent bilateral prophylactic mastectomy, those with metastatic disease, undergoing treatment, or high BMI preventing MRI, women lost to followup, or died during original trial	Based on BRCA status or FDR of BRCA mutation carrier
Ovarian cancer screening					
Hermsen et al, 2007[281] NA	Physical harms of increased screening	Prospective cohort, one-arm (Staging compared to 2 external comparison groups; unscreened family members with cancer, combined data from multiple studies)	The Netherlands Women with BRCA mutation screened at 6 University Family Cancer Clinics	Inclusion Women with *BRCA1/2* mutation screened at 1 of participating centers Exclusion Women with symptoms at first visit, who had only 1 visit, or who were found to have cancer at first screening visit	Based on BRCA status
Prior report					
Bourne et al, 1993[279] NA	Physical harms of increased screening	Prospective cohort, one-arm	U.K. Self-referred asymptomatic women with a close relative diagnosed with ovarian cancer	Inclusion Women age ≥25 years with ≥1 close relatives who had developed ovarian cancer; symptomless	Based on pedigree/pattern of inheritance

Appendix C13. Evidence Table of Harms of Intensive Screening

Author, year Quality	N	Demographics	Duration/followup	Screening method and interval
Breast cancer screening				
Kriege et al, 2004[277] NA Dutch MRISC study	Enrolled: 1952 Analyzed: 1909 n=358 mutation carriers (276 *BRCA1*, 77 *BRCA2*, 1 both *BRCA1/2*, 2 PTEN, and 2 TP53), n=1052 high risk, n=499 moderate risk	Mean age at entry, years: 40 (range, 19-72)	1999-2003 Median, 2.9 years (mean, 2.7; range, 0.1-3.9 years)	A) Biannual CBE B) Annual mammography C) Annual contrast enhanced MRI Note: When 1 of the examinations reported as "probably benign finding" or "need additional imaging evaluation" (BI-RADS 3 or 0), further investigation undertaken by ultrasonography ± fine needle aspiration, or mammography or repeated MRI; when 1 of the examinations reported as "suspicious abnormality" or "highly suggestive of malignancy" (BI-RADS 4 or 5), cytologic or histologic evaluation of biopsy specimen performed; when results of imaging were negative but clinical breast exam was uncertain or suspicious, additional investigations performed
Kriege et al, 2006[297] NA Dutch MRISC study	Analyzed: 1909 n=358 mutation carriers (276 *BRCA1*, 77 *BRCA2*, 1 both *BRCA1* and *BRCA2*, 2 PTEN, and 2 TP53), n=1052 high-risk, n=499 moderate risk	Mean age at entry, years: 40 (range, 19-72)	1999-2003 Median, 2.9 years (mean, 2.7; range, 0.1-3.9 years)	A) Biannual CBE B) Annual mammography C) Annual contrast enhanced MRI Note: When 1 of the examinations reported as "probably benign finding" or "need additional imaging evaluation" (BI-RADS 3 or 0), further investigation undertaken by ultrasonography ± fine needle aspiration, or mammography or repeated MRI; when 1 of the examinations reported as "suspicious abnormality" or "highly suggestive of malignancy" (BI-RADS 4 or 5), cytologic or histologic evaluation of biopsy specimen performed; when results of imaging were negative but clinical breast exam was uncertain or suspicious, additional investigations performed
Leach et al, 2005[274] NAMARIBS study	649 n=82 (13%) with known *BRCA1* mutation n=38 (6%) with known *BRCA2* mutation	Median age at entry, years: 40 (range, 31-55; only 1 woman age >50 years)	Study recruitment 1997-2003 Variable screening episodes per individual but screening continued until each women had ≥2 annual scans (in 2004)	A) Annual mammography from age 35 years (or younger if FDR developed cancer at age <35 years) B) Annual CE MRI Note: In women with equivocal results, high specificity MRI exam done 2-6 weeks later (followed by ultrasound, fine needle aspiration, localization, and tissue sampling by conventional methods, as appropriate)
Le-Petross et al, 2011[276] NA	Screened: 321 Analyzed: 73 (37 [51%] *BRCA1*, 36 [49%] *BRCA2*)	Median age at entry, years: 44 (range, 23-75)	Records from 1997-2009 Median followup, 2 years (range, 1-6 years) Mean followup from suspicious finding to diagnosis, 1.7 years (range, 1-3 years)	All women underwent: A) Mammography every 6 months B) MRI every 6 months Note: imaging was performed on an alternating basis, women had clinical breast exam every 6 months, ultrasound used to evaluate abnormal mammographic or MRI findings, biopsy as required

		NS difference over time on any portion of impact on areas of life measures, any portion of BIS, and any subscales of SF-36.		
Finch et al, 2011[306] NA	October 2002 to June 2008 1 year	Women experienced a significant worsening of vasomotor symptoms ($p<0.01$) and a decrease in sexual function ($p<0.05$)	Women had worse vasomotor symptoms and decrease in sexual functioning.	Toronto Fashion Show, Kristi Piia Callum Memorial Fellowship in Ovarian Cancer Research, and University of Toronto Open Fellowship
Gahm et al, 2010[303] NA	2004-2006 Mean followup of 29 months (range, 24-49)	A vs. B **Mean SF-36 subscales (estimated from graph)** Physical functioning: 94 vs. 89; p=NS Role functioning: 86 vs. 85; p=NS Bodily pain: 87 vs. 72; p=0.002 General health: 79 vs. 77; p=NS Vitality: 68 vs. 68; p=NS Social functioning: 90 vs. 89; p=NS Role emotional: 80 vs. 85; p=NS Mental health: 80 vs. 80; p=NS **Pain and discomfort questionnaire responses after RRM** 38/55 (69%) pain in breasts 20/55 (36%) pain affected sleep 12/55 (22%) pain affected daily activities 39/55 (71%) discomfort in breasts 48/55 (87%) pain or discomfort in breasts No association between pain and age (OR, 0.99; p=0.771); pain and complication (OR, 0.60; p=0.538); or pain and reoperation (OR, 3.72; p=0.110) Pain or discomfort not related with negative effects in sexual outcomes ($p>0.05$ for both) **Postoperative complications** 11/59 (18.6%) had infections 3/59 (5.1%) required implant extraction 4/59 (6.8%) had hematoma 2/59 (3.4%) required acute operative evacuation 2/59 (3.4%) had revision of flap necrosis 35/59 (59%) had corrective surgical procedures 24/59 (41%) had procedure involving implant pockets **Sexuality questionnaire responses after RRM** 25/55 (45%) totally lost sexual sensations 22/55 (40%) substantially impaired sexual sensations 38/55 (69%) negative change in sexual importance of breasts 41/55 (75%) negative change in sexual enjoyment of breasts 32/55 (58.2%) no change in sexual intercourse Sexual attractiveness changes varied substantially	Women who had RRM had less bodily pain than the reference group, but no other differences on the SF-36. Most women who had RRM experienced pain, discomfort, and decrease in sexual enjoyment, attractiveness, and enjoyment. However, almost all women felt the choice was a good one and would make the same decision.	None

Appendix C14. Evidence Table of Psychological and Sexual Functioning Harms of Interventions

Author, year Quality	Duration of followup	Results	Conclusions	Funding source
		Regret scale responses after RRM 52/55 (94.5%) agreed the decision was right 51/55 (92.7%) would make the same decision again 48/55 (87.3%) said it was a wise decision		
Metcalfe et al, 2004[301] NA	January 1991 to June 2000 Mean time between surgery and questionnaire of 52.2 months (SD, 32.3)	97% were satisfied or extremely satisfied with decision to have RRM **Mean scales (SD) for whole group after RRM** IES-I: 8.44 (8.11); 4/57 (7.0%) scored above clinical cut-off, of these all (100%) had a strong family history of breast cancer and 3/4 (75%) had a mother who died from breast cancer IES-A: 8.79 (8.53); 5/57 (8.8%) scored above clinical cut-off, 3/5 (60%) had a strong family history of breast cancer, 1/5 (20%) had a BRCA mutation, and 1/5 (20%) had a mother who died of breast cancer Sexual activity, pleasure: 12.25 (4.72) Sexual activity, discomfort: 1.97 (2.13) Sexual activity, habit: 1.22 (0.66) BIBC, vulnerability: 2.43 (0.81) BIBC, body concerns: 3.09 (0.99) BIBC, body stigma: 2.33 (0.89) BIBC, transparency: 2.19 (0.79) **Age <50 years vs. ≥50 years** Mean scales (SD) IES-I: 9.07 (8.57) vs. 6.31 (6.10); p=NS IES-A: 8.61 (9.03) vs. 9.38 (6.85); p=NS Sexual activity, pleasure: 12.75 (4.70) vs. 10.25 (4.56); p=NS Sexual activity, discomfort: 1.78 (2.12) vs. 2.88 (2.03); p=NS Sexual activity, habit: 1.18 (0.64) vs. 1.42 (0.79); p=NS BIBC, vulnerability: 2.38 (0.80) vs. 2.60 (0.87); p=NS BIBC, body concerns: 3.12 (1.03) vs. 2.99 (0.86); p=NS BIBC, body stigma: 2.27 (0.91) vs. 2.52 (0.81); p=NS BIBC, transparency: 2.26 (0.86) vs. 1.97 (0.46); p=NS **Postsurgical symptoms** 38 (64.4%) of women reported postsurgical symptoms: numbness (27), pain (7), tingling (7), infection (7), swelling (2), breast hardness (2), bleeding (1), organizing hematoma (1), failed reconstruction (1), breathing complications (1), thrombosis (1), pulmonary embolism (1) 18 women reported only 1 symptom, 15 women reported 2 symptoms, and 5 women reported 3 symptoms as a result of surgery. No difference in reporting of postsurgical symptoms based on time elapsed since mastectomy.	Most women were happy with their decision to have RRM. For most women, the surgery did not cause high levels of distress and there was no correlation with age.	NR

Appendix C14. Evidence Table of Psychological and Sexual Functioning Harms of Interventions

Author, year Quality	Duration of followup	Results	Conclusions	Funding source
Rijnsburger et al, 2004[275] Fair	2000-2002 1-4 weeks after screening	A vs. B vs. C Experienced no pain after screening: 92.6% vs. 14.3% vs. 88.0%; p=NR Experienced no discomfort after screening: 91.5% vs. 30.8% vs. 54.6%; p=NR Experienced no anxiety after screening: 77.9% vs. 72.4% vs. 63.0%; p=NR **Before screening (T0) vs. day of screening (T1) vs. after screening (T2)** Mean VAS: 81.9 vs. 79.0 vs. 80.7; p<0.01 T0 vs. T1 and p<0.05 T1 vs. T2 **Before screening vs. after screening (A, B, and C groups combined) vs. reference group (Dutch general population)** Mean on SF-36 subscales; p=NS for before and after screening Physical functioning: 89.9 vs. 89.4 vs. 86.3; p<0.01 for reference group vs. before screening Role-physical: 85.7 vs. 84.1 vs. 77.6; p<0.01 for reference group vs. before screening Bodily pain: 82.4 vs. 83.0 vs. 72.8; p<0.01 for reference group vs. before screening General health perceptions: 76.4 vs. 77.3 vs. 72.2; p<0.01 for reference group vs. before screening Vitality: 67.1 vs. 68.9 vs. 64.8; p=NS Social functioning: 87.7 vs. 87.9 vs. 83.5; p<0.01 for reference group vs. before screening Role-emotional: 85.2 vs. 88.1 vs. 80.1; p<0.05 for reference group vs. before screening Mental health: 76.8 vs. 77.7 vs. 74.4; p<0.05 for reference group vs. before screening Mean SCL-90: 17.5 vs. 17.1 vs. 18.7; p<0.05 for reference group vs. before screening Mean ED-5D utility score (compared to Swedish reference group): 0.88 vs. 0.88 vs. 0.85; p<0.01 for reference group vs. before screening	Women who received MRI experienced less pain and discomfort than those who received mammography. Women in screening showed better health-related quality of life per the SF-36 than the reference group.	Health Care Insurance Board, the Netherlands
Spiegel et al, 2011[298] NA	Years NR 6 months	**Before screening vs. 4-6 weeks after screening vs. 6 months after screening** Mean HADS-A (SD): 7.15 (4.2) vs. 6.85 (4.5) vs. 6.31 (3.9); NS Mean HADS-D (SD): 2.65 (3.6) vs. 2.60 (3.5) vs. 2.60 (3.5); NS Mean WIS (SD): 10.27 (4.2) vs. 11.07 (4.9) vs. 10.44 (4.7); NS **A vs. B 4-6 weeks after screening** Mean HADS-A (SD): 8.8 (5.2) vs. 5.9 (3.9); p=0.03 Mean HADS-D (SD): 3.3 (4.3) vs. 2.2 (3.1); NS Mean WIS (SD): 13.6 (6.4) vs. 9.8 (3.5); NS **A vs. B 6 months after screening** Mean HADS-A (SD): 7.1 (3.8) vs. 5.9 (4.0); NS Mean HADS-D (SD): 3.1 (4.3) vs. 2.3 (3.1); NS Mean WIS (SD): 12.4 (6.3) vs. 9.4 (3.2); NS	Women who were recalled for examinations after screening had increased anxiety 4-6 weeks after screening, but by 6 months all scores returned to baseline levels.	Canadian Breast Cancer Research Alliance grant #012345 and private donation from Florence and Maury Rosenblatt

Appendix C14. Evidence Table of Psychological and Sexual Functioning Harms of Interventions

Author, year Quality	Duration of followup	Results	Conclusions	Funding source
Wasteson et al, 2011[305] NA	Years NR Median, 10 years (range, 9-12)	**Affects 10 years after RRM with reconstruction** 8/13 (61.5%) stated family life unchanged 4/13 (30.8%) stated positive affect on family life 5/13 (38.5%) stated negative affect on relationship with spouse (due to decreased sensation and changed body appearance) 10/13 (76.9%) considered cosmetic results positive 10/11 (90.9%) had discussed breast cancer risk with daughters	Most women stated positive affects 10 years after RRM with reconstruction.	NR

NCCN Guidelines Version 2.2014 Updates
Genetic/Familial High-Risk Assessment: Breast and Ovarian

Updates in Version 2.2014 of the NCCN Guidelines for Genetic/Familial High-Risk Assessment: Breast and Ovarian from Version 1.2014 include:

Breast and Ovarian Cancer Genetic Assessment:
BR/OV-2
- **A link to the new multi-gene testing section was added: "See Multi-Gene Testing (GENE-1)"**
- **Footnote "l" was added: "In some cases, multi-gene testing may be a preferable way to begin testing over the single-gene testing process."**

Hereditary Breast and Ovarian Cancer Syndrome:
HBOC-2
- **Genetic testing: "Consider multi-gene testing, if appropriate" was added. Also for LIFR-2 and COWD-2.**

Multi-Gene Testing
GENE-1
- **The multi-gene testing section is new to the Guidelines and includes:**
  - **An overview of multi-gene testing**
  - **Points in favor of multi-gene testing**
  - **Limitations in the use of multi-gene testing**
  - **Issues to consider in assessing a positive multi-gene test result for less characterized genes**
  - **General recommendations**

NCCN Guidelines Version 2.2014 Updates
Genetic/Familial High-Risk Assessment: Breast and Ovarian

NCCN Guidelines Index
Genetics Table of Contents
Discussion

Updates in Version 1.2014 of the NCCN Guidelines for Genetic/Familial High-Risk Assessment: Breast and Ovarian from Version 4.2013 include:

Breast and Ovarian Cancer Genetic Assessment:

BR/OV-1

- An affected individual
  - 6th bullet was modified: "≥1 family member on same side of family with a combination of breast cancer and ≥1 of the following (especially if early onset): pancreatic cancer, ~~aggressive~~ prostate cancer (Gleason score ≥7)..." (Also for an unaffected individual)
- An unaffected individual
  - 3rd and 4th bullet, "(maternal or paternal)" was removed from "same side of family."

BR/OV-2

- Detailed medical and surgical history
  - 1st bullet was modified by adding: "Any personal cancer history *(eg, age, type, laterality)*."
- Focused physical exam was revised to include: "conducted by *qualified clinician* ~~physician or nurse~~."

Hereditary Breast and/or Ovarian Cancer Syndrome Testing Criteria:

HBOC-1

- 2nd bullet, this section for "Personal history of breast cancer + one or more of the following" was reorganized by age.
  - 2nd sub-bullet, the 3rd tertiary bullet was revised by adding: "*An unknown or* limited family history."
  - 4th sub-bullet, the 4th tertiary bullet was revised: "≥2 close blood relatives with pancreatic cancer *and*/or ~~aggressive~~ prostate cancer (Gleason score ≥7) at any age."
- 5th bullet modified by removing "aggressive" from "prostate cancer."
  - A new sub-bullet was added: "For pancreatic cancer, if Ashkenazi Jewish ancestry, only one additional affected relative is needed."
- After criteria, "If HBOC testing criteria not met" was clarified by adding: "*consider testing for other hereditary syndromes.*" Then text after this was clarified by adding, "If criteria for other *hereditary syndromes not met, then* cancer screening as per NCCN Screening Guidelines."
- Footnote "a" was combined with another footnote and revised as: "*Meeting one or more of these criteria warrants further personalized risk assessment, genetic counseling, and often genetic testing and management. The probability of mutation detection associated with these criteria will vary based on family structure.* Individuals with *unknown* or limited family history/structure, such as fewer than 2 first- or second-degree female relatives having lived beyond age 45 in either lineage, may have an underestimated probability of familial mutation *detection. The likelihood of mutation detection may be very low in families with a large number of unaffected female relatives. Clinical judgment should be used to determine the appropriateness of genetic testing.* The maternal and paternal sides should be considered independently."

HBOC-2

- Footnote "n" was modified by removing: "If all affected family members are deceased, consider testing of paraffin-derived DNA from deceased relatives, if DNA is obtainable."

HBOC-A 1 of 2

- HBOC syndrome management for women
  - 3rd bullet, the previous recommendation, "Annual mammogram and breast MRI screening starting at age 25 y, or individualized based on earliest age of onset in family," was replaced by:
    - Breast screening
      - Age 25–29 y, annual breast MRI screening (preferred) or mammogram if MRI is unavailable or individualized based on earliest age of onset in family.
      - Age >30–75 y, annual mammogram and breast MRI screening.
      - Age >75 y, management should be considered on an individual basis.
- Footnote "3" was revised by removing: "The best screening strategy for woman age 25-30 is uncertain with some data suggesting that mammogram be added to MRI only after age 30."
- Footnote "5" was modified: "Given the high rate of occult neoplasms,...*See NCCN Guidelines for Ovarian Cancer for treatment of findings.*"

HBOC-A 2 of 2

- HBOC syndrome management for men
  - 4th bullet, "Consider prostate cancer screening starting at age 40 y" was replaced by,
    - Starting at age 40:
      - Recommend prostate cancer screening for *BRCA2* carriers
      - Consider prostate cancer screening for *BRCA1* carriers
  - Footnote "8" was added: "There are only limited data to support breast imaging in men."

National Comprehensive Cancer Network®

NCCN Guidelines Version 2.2014 Updates
Genetic/Familial High-Risk Assessment: Breast and Ovarian

NCCN Guidelines Index
Genetics Table of Contents
Discussion

Updates in Version 1.2014 of the NCCN Guidelines for Genetic/Familial High-Risk Assessment: Breast and Ovarian from Version 4.2013 include:

Li-Fraumeni Syndrome:

LIFR-1

- Early-age-onset breast cancer criteria was revised: "Individual with breast cancer ≤35 y ~~with a negative BRCA1/BRCA2 test~~, *TP53 testing can be ordered concurrently with BRCA1/2 testing or as a follow-up test after negative BRCA1/2 testing.*"

LIFR-A

- Breast cancer risk for women
  - 3rd bullet, the previous recommendation, "Annual mammogram and breast MRI screening starting at age 20-25 y, or individualized based on earliest age of onset in family" was replaced by:
    - Breast screening
      - Age 20–29 y, annual breast MRI screening (preferred) or mammogram if MRI is unavailable or individualized based on earliest age of onset in family.
      - Age >30–75 y, annual mammogram and breast MRI screening.
      - Age >75y, management should be considered on an individual basis.
- Other cancer risks
  - 3rd bullet was modified: "Therapeutic RT for cancer should be *avoided when possible* ~~used with caution~~."
  - 6th bullet was revised as: "Discuss option to participate in novel screening approaches using technologies ~~within clinical trials when possible~~..."
  - Footnote was removed: "Given theoretical concerns with harmful effects of radiation exposure in LFS, for patients age 20-30 y, annual MRI-only screening may be sufficient based on physician's discretion."

Cowden Syndrome/PTEN Hamartoma Tumor Syndrome:

COWD-1

- "PTEN hamartoma tumor syndrome" (PHTS) was added to "Cowden syndrome."
- Footnote "c" reference was updated to: "Pilarski R, Burt R, Kohlmann W, Pho L, Shannon KM, Swisher E. Cowden syndrome and the PTEN Hamartoma Tumor Syndrome: Systematic review and revised diagnostic criteria. J Natl Cancer Inst 2013;105:1607-1616."

COWD-2

- For no known familial *PTEN* mutation
  - After test outcomes for "Not tested or no mutation found" and "Variant of unknown significance found (uninformative)," the algorithm choices are now "Meets CS/PHTS diagnostic criteria (See COWD-3)" and "Does not meet CS/PHTS diagnostic criteria (See COWD-3)."

COWD-3

- A new page titled, "Revised PTEN Hamartoma Tumor Syndrome Clinical Diagnostic Criteria" was added to the guidelines.

COWD-A

- Cowden syndrome/PHTS management for women
  - 4th bullet was modified as: "For endometrial cancer screening, encourage patient education and prompt response to symptoms ~~and participation in a clinical trial to determine the effectiveness and necessity of screening modalities~~. *Consider annual random endometrial biopsies and/or ultrasound beginning at age 30–35 y.*"
- Cowden syndrome management for men and women
  - 1st bullet was modified: "...with particular attention to ~~breast and~~ thyroid exam."
  - 2nd bullet was revised as: "~~Baseline~~ *Annual* thyroid ultrasound *starting* at age 18 y *or 5–10 y before the earliest known thyroid cancer in the family, whichever is earlier.*"
  - 3rd bullet was revised as: "~~Consider~~ Colonoscopy, starting at age 35 y, then every 5-~~10~~ y or more frequently..."
  - 4th bullet was added: "Consider renal ultrasound starting at age 40 y, then every 1–2 y."
  - 5th bullet was changed from "Consider annual dermatologic exam" to "Dermatologic management may be indicated for some patients."
  - 6th bullet was added: "Consider psychomotor assessment in children at diagnosis and brain MRI if there are symptoms."

Note: All recommendations are category 2A unless otherwise indicated.
Clinical Trials: NCCN believes that the best management of any cancer patient is in a clinical trial. Participation in clinical trials is especially encouraged.

NCCN Guidelines Version 2.2014
Breast and/or Ovarian Cancer Genetic Assessment

NCCN Guidelines Index
Genetics Table of Contents
Discussion

CRITERIA FOR FURTHER GENETIC RISK EVALUATION[a]

An affected individual with one or more of the following:

- A known mutation in a breast cancer susceptibility gene within the family
- Early-age-onset breast cancer[b]
- Triple negative (ER-, PR-, HER2-) breast cancer
- Two breast cancer primaries[c] in a single individual
- Breast cancer at any age, and
  - ≥1 close blood relative[d] with breast cancer ≤50 y, or
  - ≥1 close blood relative[d] with epithelial ovarian[e] cancer at any age, or
  - ≥2 close blood relatives[d] with breast cancer and/or pancreatic cancer at any age
  - From a population at increased risk[f]
- ≥1 family member on same side of family with a combination of breast cancer and ≥1 of the following (especially if early onset): pancreatic cancer, prostate cancer (Gleason score ≥7), sarcoma, adrenocortical carcinoma, brain tumors, endometrial cancer, leukemia/lymphoma; thyroid cancer, dermatologic manifestations[g,h] and/or macrocephaly, hamartomatous polyps of GI tract;[h] diffuse gastric cancer[i]
- Ovarian[e] cancer
- Male breast cancer

An unaffected individual with a family history of one or more of the following:[f]

- A known mutation in a breast cancer susceptibility gene within the family
- ≥2 breast primaries in single individual[d]
- ≥2 individuals with breast primaries on the same side of family[d]
- ≥1 ovarian[e] cancer primary from the same side of family
- First- or second-degree relative with breast cancer ≤45 y
- ≥1 family member on same side of family with a combination of breast cancer and ≥1 of the following (especially if early onset): pancreatic cancer, prostate cancer (Gleason score ≥7), sarcoma, adrenocortical carcinoma, brain tumors, endometrial cancer, leukemia/lymphoma; thyroid cancer, dermatologic manifestations[g,h] and/or macrocephaly, hamartomatous polyps of GI tract;[h] diffuse gastric cancer[i]
- Male breast cancer

→ **Referral to cancer genetics professional recommended[j]** → **See Assessment (BR/OV-2)**

[a] The criteria for further risk evaluation and genetic testing are not identical. For the purposes of these guidelines, invasive and ductal carcinoma in situ breast cancers should be included. The maternal and paternal sides of the family should be considered independently for familial patterns of cancer.

[b] Clinically use age ≤50 y because studies define early onset as either ≤40 or ≤50 y.

[c] Two breast primaries includes bilateral (contralateral) disease or two or more clearly separate ipsilateral primary tumors either synchronously or asynchronously.

[d] Close blood relatives include first-, second-, and third-degree relatives. (See BR/OV-3)

[e] For the purposes of these guidelines, fallopian tube and primary peritoneal cancers are included. Ovarian/fallopian tube/primary peritoneal cancers are component tumors of Lynch syndrome/hereditary non-polyposis colorectal cancer; be attentive for clinical evidence of this syndrome. See NCCN Guidelines for Genetic/Familial High-Risk Assessment: Colorectal.

[f] For populations at increased risk, requirements for inclusion may be modified (eg, women of Ashkenazi Jewish descent with breast or ovarian or pancreatic cancer at any age).

[g] For dermatologic manifestations, see COWD-1.

[h] For hamartomatous colon polyps in conjunction with breast cancer and hyperpigmented macules of the lips and oral mucosa, STK11 testing should be considered. See NCCN Guidelines for Genetic/Familial High-Risk Assessment: Colorectal- Peutz-Jeghers syndrome. Melanoma has been reported in some HBOC families.

[i] For lobular breast cancer with a family history of diffuse gastric cancer, *CDH1* gene testing should be considered.

[j] Genetic counseling is highly recommended when genetic testing is offered and after results are disclosed. A genetic counselor, medical geneticist, oncologist, surgeon, oncology nurse, or other health professional with expertise and experience in cancer genetics should be involved early in counseling patients who potentially meet criteria for an inherited syndrome.

Note: All recommendations are category 2A unless otherwise indicated.
Clinical Trials: NCCN believes that the best management of any cancer patient is in a clinical trial. Participation in clinical trials is especially encouraged.

Version 2.2014, 09/23/14 © National Comprehensive Cancer Network, Inc. 2014, All rights reserved. The NCCN Guidelines® and this illustration may not be reproduced in any form without the express written permission of NCCN®.

ASSESSMENT

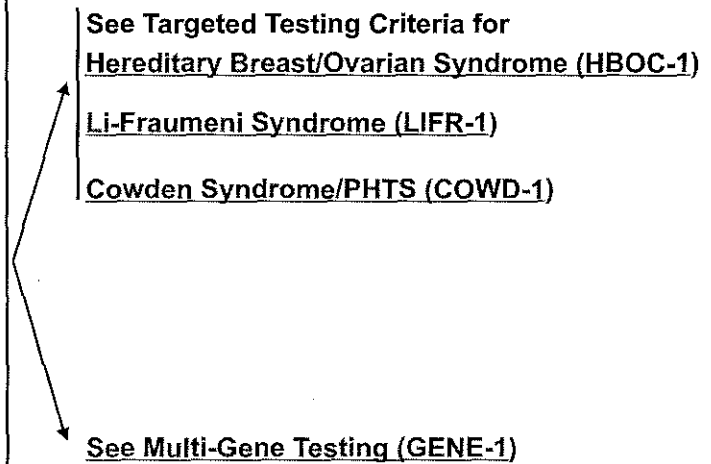
Patient needs and concerns:
- Knowledge of genetic testing for cancer risk, including benefits, risks, and limitations
- Goals for cancer family risk assessment

Detailed family history:
- Expanded pedigree to include first-, second-, and third-degree relatives (parents, siblings, children, grandparents, aunts, uncles, nieces, nephews, grandchildren, half-siblings, great-grandparents, great-aunts, great-uncles, great-grandchildren, and first cousins) (See BR/OV-3)
- Types of cancer, bilaterality, age at diagnosis
- History of chemoprevention and/or risk-reducing surgery
- Medical record documentation as needed, particularly pathology reports of primary cancers

Detailed medical and surgical history:
- Any personal cancer history (eg, age, type, laterality)
- Carcinogen exposure (eg, history of radiation therapy)
- Reproductive history
- Hormone use
- Previous breast biopsies
- History of salpingo-oophorectomy

Focused physical exam (conducted by qualified clinician):
- Breast/ovarian
- Cowden syndrome/PHTS specific:
  - Dermatologic,[k] including oral mucosa
  - Head circumference
  - Thyroid (enlarged or nodular on palpation)

GENE TESTING[l]



[k]For Cowden syndrome dermatologic manifestations, see COWD-1 and for PJS dermatologic manifestations, see NCCN Guidelines for Genetic/Familial High-Risk Assessment: Colorectal.

[l]In some cases, multi-gene testing may be a preferable way to begin testing over the single-gene testing process.

Note: All recommendations are category 2A unless otherwise indicated.
Clinical Trials: NCCN believes that the best management of any cancer patient is in a clinical trial. Participation in clinical trials is especially encouraged.

Version 2.2014, 09/23/14 © National Comprehensive Cancer Network, Inc. 2014, All rights reserved. The NCCN Guidelines® and this illustration may not be reproduced in any form without the express written permission of NCCN®.

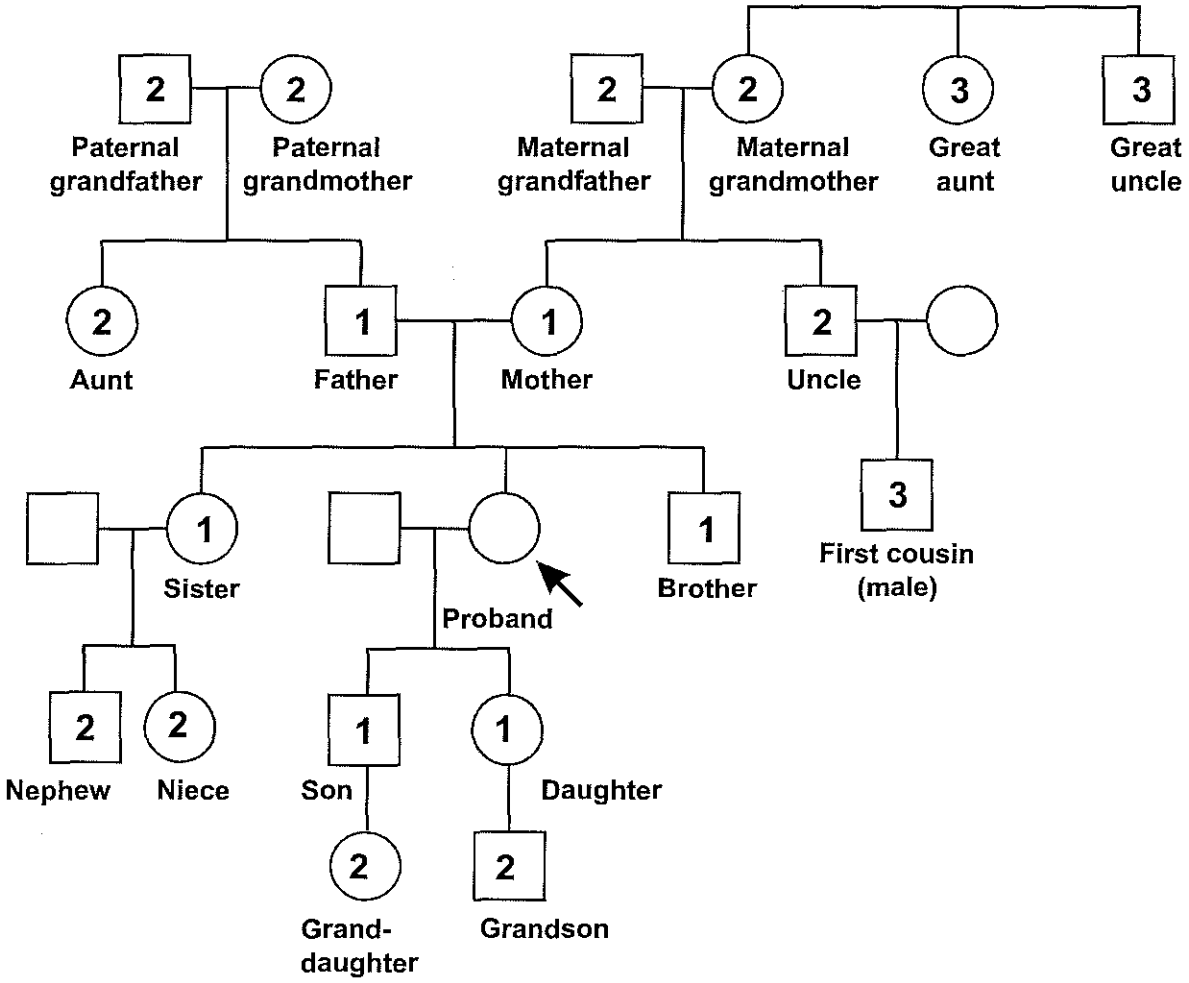
PEDIGREE: FIRST-, SECOND-, AND THIRD-DEGREE RELATIVES OF PROBAND[m]



[m]First-degree relatives: parents, siblings, and children;
second-degree relatives: grandparents, aunts, uncles, nieces, nephews, grandchildren, and half-siblings;
third-degree relatives: great-grandparents, great-aunts, great-uncles, great-grandchildren, and first cousins.

Note: All recommendations are category 2A unless otherwise indicated.
Clinical Trials: NCCN believes that the best management of any cancer patient is in a clinical trial. Participation in clinical trials is especially encouraged.

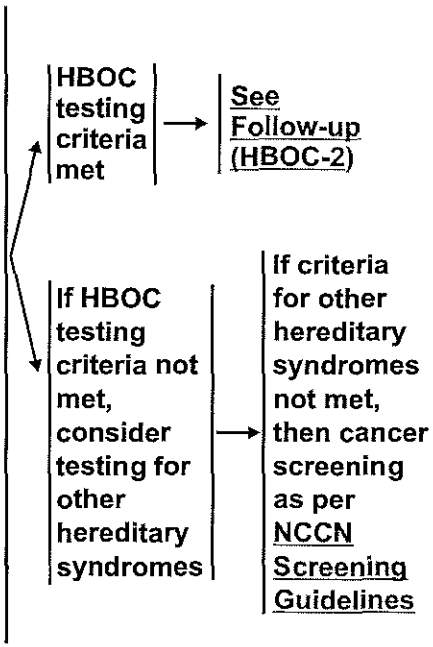
HEREDITARY BREAST AND/OR OVARIAN CANCER SYNDROME TESTING CRITERIA[a,b,c]

- **Individual from a family with a known deleterious *BRCA1/BRCA2* mutation**
- **Personal history of breast cancer[b] + one or more of the following:**
  - Diagnosed ≤45 y
  - Diagnosed ≤50 y with:
    - An additional primary[d]
    - ≥1 close blood relative[e] with breast cancer at any age
    - An unknown or limited family history[a]
  - Diagnosed ≤60 y with a:
    - Triple negative breast cancer
  - Diagnosed at any age with:
    - ≥1 close blood relative[e] with breast cancer diagnosed ≤50 y
    - ≥2 close blood relatives[e] with breast cancer at any age
    - ≥1 close blood relative[e] with epithelial ovarian[f] cancer
    - ≥2 close blood relatives[e] with pancreatic cancer and/or prostate cancer (Gleason score ≥7) at any age
    - A close male blood relative[e] with breast cancer
    - For an individual of ethnicity associated with higher mutation frequency (eg, Ashkenazi Jewish) no additional family history may be required[g]
- **Personal history of epithelial ovarian[f] cancer**
- **Personal history of male breast cancer**
- **Personal history of pancreatic cancer or prostate cancer (Gleason score ≥7) at any age with ≥2 close blood relatives[e] with breast and/or ovarian[f] and/or pancreatic or prostate cancer (Gleason score ≥7) at any age**
  - **For pancreatic cancer, if Ashkenazi Jewish ancestry, only one additional affected relative is needed**
- **Family history only (significant limitations of interpreting test results for an unaffected individual should be discussed):**
  - **First- or second-degree blood relative meeting any of the above criteria**
  - **Third-degree blood relative with breast cancer[b] and/or ovarian[f] cancer with ≥2 close blood relatives[e] with breast cancer (at least one with breast cancer ≤50 y) and/or ovarian[f] cancer**
  - **Clinical judgment should be used to determine if the patient has reasonable likelihood of a mutation, considering the unaffected patient's current age and the age of female unaffected relatives who link the patient with the affected relatives.**
  - **Testing of unaffected individuals should only be considered when an appropriate affected family member is unavailable for testing.**



[a] Meeting one or more of these criteria warrants further personalized risk assessment, genetic counseling, and often genetic testing and management. The probability of mutation detection associated with these criteria will vary based on family structure. Individuals with unknown or limited family history/structure, such as fewer than 2 first- or second-degree female relatives having lived beyond age 45 in either lineage, may have an underestimated probability of familial mutation detection. The likelihood of mutation detection may be very low in families with a large number of unaffected female relatives. Clinical judgment should be used to determine the appropriateness of genetic testing. The maternal and paternal sides should be considered independently.

[b] For the purposes of these guidelines, invasive and ductal carcinoma in situ breast cancers should be included.

[c] Patients who have received an allogeneic bone marrow transplant should not have molecular genetic testing via blood or buccal samples due to unreliable test results from contamination by donor DNA. If available, DNA should be extracted from a fibroblast culture. If this source of DNA is not possible, buccal samples can be considered, subject to the risk of donor DNA contamination.

[d] Two breast primaries includes bilateral (contralateral) disease or two or more clearly separate ipsilateral primary tumors either synchronously or asynchronously.

[e] Close blood relatives include first-, second-, and third-degree relatives on same side of family. (See BR/OV-3)

[f] For the purposes of these guidelines, fallopian tube and primary peritoneal cancers are included. Ovarian/fallopian tube/primary peritoneal cancers are component tumors of Lynch syndrome/hereditary non-polyposis colorectal cancer; be attentive for clinical evidence of this syndrome. See NCCN Guidelines for Genetic/Familial High-Risk Assessment: Colorectal.

[g] Testing for Ashkenazi Jewish founder-specific mutation(s) should be performed first. Full sequencing may be considered if ancestry also includes non-Ashkenazi Jewish relatives or if other HBOC criteria are met. Founder mutations exist in other populations.

Note: All recommendations are category 2A unless otherwise indicated.
Clinical Trials: NCCN believes that the best management of any cancer patient is in a clinical trial. Participation in clinical trials is especially encouraged.

[h] Genetic counseling is highly recommended when genetic testing is offered and after results are disclosed. A genetic counselor, medical geneticist, oncologist, surgeon, oncology nurse, or other health professional with expertise and experience in cancer genetics should be involved early in counseling patients who potentially meet criteria for an inherited syndrome.

[i] Comprehensive genetic testing includes full sequencing of *BRCA1/BRCA2* and testing for large genomic rearrangements.

[j] Genetic testing for familial *BRCA1/2* in children <18 y is generally not recommended.

[k] If of Ashkenazi Jewish descent, in addition to the specific familial mutation, test for all three founder mutations.

[l] Testing of unaffected family members when no affected member is available should be considered. Significant limitations of interpreting test results should be discussed.

[m] If more than one family member affected, first consider: youngest age at diagnosis, bilateral disease, multiple primaries, ovarian cancer, and most closely related to the proband/patient. If no living family member with breast or ovarian cancer, consider testing first- or second-degree family members affected with cancers thought to be related to *BRCA1/BRCA2* (eg, prostate, pancreas, melanoma).

[n] For both affected and unaffected individuals of Ashkenazi Jewish descent with no known familial mutation, first test for the three common mutations. Then, if negative for the three mutations and ancestry also includes non-Ashkenazi Jewish relatives or other HBOC criteria are met, consider comprehensive genetic testing. For both affected and unaffected individuals who are non-Ashkenazi Jewish and who have no known familial mutation, comprehensive genetic testing is the approach, if done.

[o] If no mutation found, consider other hereditary breast/ovarian cancer syndromes such as Li-Fraumeni (LIFR-1) and/or Cowden syndrome (COWD-1) or multi-gene testing (GENE-1). For additional information on other genetic mutations associated with breast/ovarian cancer risk for which genetic testing is clinically available, see ADDIT-1.

[p] Testing family members for a variant of unknown significance should not be used for clinical purposes. Consider referral to research studies that aim to define functional impact of variant.

Note: All recommendations are category 2A unless otherwise indicated.
Clinical Trials: NCCN believes that the best management of any cancer patient is in a clinical trial. Participation in clinical trials is especially encouraged.

HBOC SYNDROME MANAGEMENT (1 of 2)

WOMEN

- **Breast awareness[1] starting at age 18 y.**
- **Clinical breast exam, every 6–12 mo,[2] starting at age 25 y.**
- **Breast screening[3]**
  - **Age 25–29 y, annual breast MRI[4] screening (preferred) or mammogram if MRI is unavailable or individualized based on earliest age of onset in family.**
  - **Age ≥30–75 y, annual mammogram and breast MRI[4] screening.**
  - **Age >75 y, management should be considered on an individual basis.**
- **Discuss risk-reducing mastectomy**
  - **Counseling may include a discussion regarding degree of protection, reconstruction options, and risks.**
- **Recommend risk-reducing salpingo-oophorectomy,[5] ideally between 35 and 40 y, and upon completion of child bearing, or individualized based on earliest age of onset of ovarian cancer in the family.**
  - **Counseling includes a discussion of reproductive desires, extent of cancer risk, degree of protection for breast and ovarian cancer, management of menopausal symptoms, possible short-term hormone replacement therapy to a recommended maximum age of natural menopause, and related medical issues.**
- **Address psychosocial, social, and quality-of-life aspects of undergoing risk-reducing mastectomy and/or salpingo-oophorectomy.**
- **For those patients who have not elected risk-reducing salpingo-oophorectomy, consider concurrent transvaginal ultrasound (preferably day 1–10 of menstrual cycle in premenopausal women) + CA-125 (preferably after day 5 of menstrual cycle in premenopausal women)[6] every 6 mo starting at age 30 y or 5–10 y before the earliest age of first diagnosis of ovarian cancer in the family.**
- **Consider chemoprevention options for breast and ovarian cancer, including discussing risks and benefits[7] (See NCCN Guidelines for Breast Cancer Risk Reduction).**
- **Consider investigational imaging and screening studies, when available (eg, novel imaging technologies, more frequent screening intervals) in the context of a clinical trial.**

Continued on next page

[1] Women should be familiar with their breasts and promptly report changes to their health care provider. Periodic, consistent breast self exam (BSE) may facilitate breast self awareness. Premenopausal women may find BSE most informative when performed at the end of menses.

[2] Randomized trials comparing clinical breast exam versus no screening have not been performed. Rationale for recommending clinical breast exam every 6–12 mo is the concern for interval breast cancers.

[3] The appropriateness of imaging modalities and scheduling is still under study. Lowry KP, et al. Annual screening strategies in BRCA1 and BRCA2 gene mutation carriers: a comparative effectiveness analysis. Cancer 2012;118:2021-2030.

[4] High-quality breast MRI limitations include having: a need for a dedicated breast coil, the ability to perform biopsy under MRI guidance, experienced radiologists in breast MRI, and regional availability. Breast MRI is performed preferably days 7–15 of menstrual cycle for premenopausal women.

[5] Given the high rate of occult neoplasms, special attention should be given to sampling and pathologic review of the ovaries and fallopian tubes. (See Discussion for details.) See NCCN Guidelines for Ovarian Cancer for treatment of findings. See the College of American Pathologists, Protocol for the Examination of Specimens from Patients with Carcinoma of the Ovary.

[6] There are data that show that annual transvaginal ultrasound and CA-125 are not effective strategies for screening for ovarian cancer in high-risk women. There are limited data regarding the effectiveness of a six-month screening interval. Thus, until such data are available it is reasonable to consider this approach in high-risk women, especially in the context of a clinical research setting.

[7] Data suggest that oral contraceptives (OCs) reduce ovarian cancer risk in *BRCA* mutation carriers. The risk/benefit ratio is uncertain because of contradictory evidence about OCs increasing breast cancer risk; however, OC use for contraception is acceptable. Other chemoprevention options for breast cancer include tamoxifen and raloxifene; however, only limited data with these agents are available in patients with *BRCA* mutations. (See Discussion for details.)

Note: All recommendations are category 2A unless otherwise indicated.
Clinical Trials: NCCN believes that the best management of any cancer patient is in a clinical trial. Participation in clinical trials is especially encouraged.

HBOC SYNDROME MANAGEMENT (2 of 2)

MEN

- Breast self-exam training and education starting at age 35 y
- Clinical breast exam, every 6–12 mo, starting at age 35 y
- Consider baseline mammogram at age 40 y;[8] annual mammogram if gynecomastia or parenchymal/glandular breast density on baseline study.
- Starting at age 40 y:
  - Recommend prostate cancer screening for *BRCA2* carriers
  - Consider prostate cancer screening for *BRCA1* carriers

MEN AND WOMEN

- Education regarding signs and symptoms of cancer(s), especially those associated with *BRCA* gene mutations.
- No specific guidelines exist for pancreatic cancer and melanoma, but screening may be individualized based on cancers observed in the family.[9]

RISK TO RELATIVES

- Advise about possible inherited cancer risk to relatives, options for risk assessment, and management.
- Recommend genetic counseling and consideration of genetic testing for at-risk relatives.

REPRODUCTIVE OPTIONS

- For patients of reproductive age, advise about options for prenatal diagnosis and assisted reproduction including pre-implantation genetic diagnosis. Discussion should include known risks, limitations, and benefits of these technologies. See Discussion for details.
- For *BRCA2* mutation carriers, risk of a rare (recessive) Fanconi anemia/brain tumor phenotype in offspring should be discussed if both partners carry a *BRCA2* mutation.[10]

[8]There are only limited data to support breast imaging in men.
[9]Consider full-body skin exam for melanoma and investigational protocols for pancreatic cancer.
[10]Offit K, Levran O, Mullaney B, et al. Shared genetic susceptibility to breast cancer, brain tumors, and Fanconi anemia. J Natl Cancer Inst 2003;95:1548-1551.

Note: All recommendations are category 2A unless otherwise indicated.
Clinical Trials: NCCN believes that the best management of any cancer patient is in a clinical trial. Participation in clinical trials is especially encouraged.

LI-FRAUMENI SYNDROME TESTING CRITERIA

- **Individual from a family with a known *TP53* mutation**
- **Classic Li-Fraumeni syndrome (LFS) criteria:[a]**
  - **Combination of an individual diagnosed age <45 y with a sarcoma[b]**
    AND
    A first-degree relative diagnosed age <45 y with cancer
    AND
    An additional first- or second-degree relative in the same lineage with cancer diagnosed age <45 y, or a sarcoma at any age
- **Chompret criteria:[c,d]**
  - **Individual with a tumor from LFS tumor spectrum (eg, soft tissue sarcoma, osteosarcoma, brain tumor, breast cancer, adrenocortical carcinoma, leukemia, lung bronchoalveolar cancer) before 46 years of age, AND at least one first- or second-degree relative with any of the aforementioned cancers (other than breast cancer if the proband has breast cancer) before the age of 56 years or with multiple primaries at any age**
    OR
  - **Individual with multiple tumors (except multiple breast tumors), two of which belong to LFS tumor spectrum with the initial cancer occurring before the age of 46 years**
    OR
  - **Individual with adrenocortical carcinoma or choroid plexus carcinoma[d,e] at any age of onset, regardless of the family history**
- **Early-age-onset breast cancer:**
  - **Individual with breast cancer ≤35 y, *TP53* testing can be ordered concurrently with *BRCA1/2* testing or as a follow-up test after negative *BRCA1/2* testing**

FOLLOW-UP

LFS testing criteria met[f] → **See Follow-up (LIFR-2)**

LFS testing criteria not met → **Individualized recommendations according to personal and family history**

Cancers associated with LFS include but are not limited to:
- **Premenopausal breast cancer**
- **Bone and soft tissue sarcomas**
- **Acute leukemia**
- **Brain tumor**
- **Adrenocortical carcinoma**
- **Choroid plexus carcinoma**
- **Colon cancer**
- **Early onset of other adenocarcinomas or other childhood cancers**

[g]Comprehensive genetic testing includes full sequencing of *TP53* and deletion/duplication analysis.

[h]Youngest age at diagnosis, bilateral disease, multiple primaries, or sarcoma at age <45 y.

[i]Testing of unaffected family members when no affected member is available may be considered. Significant limitations of interpreting test results should be discussed.

[j]If no mutation is found, consider other hereditary breast cancer syndromes such as HBOC (HBOC-1) and/or Cowden syndrome (COWD-1) or multi-gene testing (GENE-1). For additional information on other genetic mutations associated with breast/ovarian cancer risk for which genetic testing is clinically available, see ADDIT-1.

[k]Testing family members for a variant of unknown significance should not be used for clinical purposes. Consider referral to research studies that aim to define functional impact of variant.

Note: All recommendations are category 2A unless otherwise indicated.
Clinical Trials: NCCN believes that the best management of any cancer patient is in a clinical trial. Participation in clinical trials is especially encouraged.

LI-FRAUMENI SYNDROME MANAGEMENT

BREAST CANCER RISK FOR WOMEN

- **Breast awareness[1] starting at age 18 y.**
- **Clinical breast exam, every 6–12 mo, starting at age 20–25 y or 5–10 y before the earliest known breast cancer in the family (whichever comes first).**
- **Breast screening[2]**
  - **Age 20–29 y, annual breast MRI[3] screening (preferred) or mammogram if MRI is unavailable or individualized based on earliest age of onset in family.**
  - **Age >30–75 y, annual mammogram and breast MRI[3] screening**
  - **Age >75 y, management should be considered on an individual basis.**
- **Discuss risk-reducing mastectomy and counsel regarding degree of protection, degree of cancer risk, and reconstruction options.**
- **Address psychosocial, social, and quality-of-life aspects of undergoing risk-reducing mastectomy.**

OTHER CANCER RISKS

- **Address limitations of screening for many cancers associated with LFS. Because of the remarkable risk of additional primary neoplasms, screening may be considered for cancer survivors with LFS and a good prognosis from their prior tumor(s).**
- **Annual comprehensive physical exam with high index of suspicion for rare cancers and second malignancies in cancer survivors: include careful skin and neurologic examinations.**
- **Therapeutic RT for cancer should be avoided when possible.**
- **Consider colonoscopy every 2–5 y starting no later than 25 y.**
- **Pediatricians should be apprised of the risk of childhood cancers in affected families.**
- **Discuss option to participate in novel screening approaches using technologies, such as whole-body MRI, abdominal ultrasound, and brain MRI.[4]**
- **Additional surveillance based on individual family histories.**
- **Education regarding signs and symptoms of cancer.**

NCCN Guidelines Version 2.2014
Cowden Syndrome/PHTS

NCCN Guidelines Index
Genetics Table of Contents
Discussion

COWDEN SYNDROME/PTEN HAMARTOMA TUMOR SYNDROME TESTING CRITERIA[a,b]

- Individual from a family with a known *PTEN* mutation
- Individual meeting clinical diagnostic criteria[c] for CS/PHTS
- Individual with a personal history of:
  - Bannayan-Riley-Ruvalcaba syndrome (BRRS) or
  - Adult Lhermitte-Duclos disease (cerebellar tumors) or
  - Autism spectrum disorder and macrocephaly or
  - Two or more biopsy-proven trichilemmomas or
  - Two or more major criteria (one must be macrocephaly) or
  - Three major criteria, without macrocephaly or
  - One major and ≥3 minor criteria[d] or
  - ≥4 minor criteria
- At-risk individual[e] with a relative with a clinical diagnosis of CS/PHTS or BRRS for whom testing has not been performed
  - The at-risk individual must have the following:
    - Any one major criterion or
    - Two minor criteria

FOLLOW-UP

- CS/PHTS testing criteria met[f] → See Follow-up (COWD-2)
- CS/PHTS testing criteria not met → Individualized recommendations according to personal and family history

Major criteria:
- Breast cancer
- Endometrial cancer
- Follicular thyroid cancer
- Multiple GI hamartomas or ganglioneuromas
- Macrocephaly (megalocephaly) (ie, ≥97%, 58 cm in adult women, 60 cm in adult men)[g]
- Macular pigmentation of glans penis
- Mucocutaneous lesions[h]
  - One biopsy-proven trichilemmoma
  - Multiple palmoplantar keratoses
  - Multifocal or extensive oral mucosal papillomatosis
  - Multiple cutaneous facial papules (often verrucous)

Minor criteria:[i]
- Autism spectrum disorder
- Colon cancer
- ≥3 esophageal glycogenic acanthoses
- Lipomas
- Mental retardation (ie, IQ ≤75)
- Papillary or follicular variant of papillary thyroid cancer
- Thyroid structural lesions (eg, adenoma, nodule(s), goiter)
- Renal cell carcinoma
- Single GI hamartoma or ganglioneuroma
- Testicular lipomatosis
- Vascular anomalies (including multiple intracranial developmental venous anomalies)

[a] These are testing criteria, clinical diagnostic criteria on COWD-3.

[b] If two criteria involve the same structure/organ/tissue, both may be included as criteria.

[c] Pilarski R, Burt R, Kohlmann W, Pho L, Shannon KM, Swisher E. Cowden syndrome and the PTEN Hamartoma Tumor Syndrome: Systematic review and revised diagnostic criteria. J Natl Cancer Inst 2013;105:1607-1616.

[d] If an individual has two or more major criteria, such as breast cancer and non-medullary thyroid cancer, but does not have macrocephaly, one of the major criteria may be included as one of the three minor criteria to meet testing criteria.

[e] An at-risk individual can be defined as a first-degree relative of an affected individual and/or proband. If a first-degree relative is unavailable or unwilling to be tested, more distant relatives should be offered testing.

[f] Patients who have received an allogeneic bone marrow transplant should not have molecular genetic testing via blood or buccal samples due to unreliable test results from contamination by donor DNA. If available, DNA should be extracted from a fibroblast culture. If this source of DNA is not possible, buccal samples can be considered, subject to the risk of donor DNA contamination.

[g] Roche AF, Mukherjee D, Guo SM, Moore WM. Head circumference reference data: Birth to 18 years. Pediatrics 1987;79:706-712.

[h] The literature available on mucocutaneous lesions is not adequate to accurately specify the number or extent of mucocutaneous lesions required to be a major criterion for CS/PHTS. Clinical judgement should be used.

[i] Insufficient evidence exists in the literature to include fibrocystic disease of the breast, fibromas, and uterine fibroids as diagnostic criteria.

Note: All recommendations are category 2A unless otherwise indicated.
Clinical Trials: NCCN believes that the best management of any cancer patient is in a clinical trial. Participation in clinical trials is especially encouraged.

[j]Comprehensive genetic testing should include full sequence analysis, deletion/duplication analyses, and promoter analysis.

[k]Testing of unaffected family members when no affected member is available may be considered. Significant limitations of interpreting test results should be discussed.

[l]If no mutation is found, consider other hereditary breast cancer syndromes such as HBOC (HBOC-1) and/or Li-Fraumeni syndrome (LIFR-1) or multi-gene testing (GENE-1). For additional information on other genetic mutations associated with breast/ovarian cancer risk for which genetic testing is clinically available, see ADDIT-1.

[m]Testing family members for a variant of unknown significance should not be used for clinical purposes. Consider referral to research studies that aim to define functional impact of variant.

Note: All recommendations are category 2A unless otherwise indicated.
Clinical Trials: NCCN believes that the best management of any cancer patient is in a clinical trial. Participation in clinical trials is especially encouraged.

REVISED PTEN HAMARTOMA TUMOR SYNDROME CLINICAL DIAGNOSTIC CRITERIA[n]

MAJOR CRITERIA:
- Breast cancer
- Endometrial cancer (epithelial)
- Thyroid cancer (follicular)
- Gastrointestinal hamartomas (including ganglioneuromas, but excluding hyperplastic polyps; ≥3)
- Lhermitte-Duclos disease (adult)
- Macrocephaly (≥97 percentile: 58 cm for females, 60 cm for males)
- Macular pigmentation of the glans penis
- Multiple mucocutaneous lesions (any of the following):
  - Multiple trichilemmomas (≥3, at least one biopsy proven)
  - Acral keratoses (≥3 palmoplantar keratotic pits and/or acral hyperkeratotic papules)
  - Mucocutaneous neuromas (≥3)
  - Oral papillomas (particularly on tongue and gingiva), multiple (≥3) OR biopsy proven OR dermatologist diagnosed

MINOR CRITERIA:
- Autism spectrum disorder
- Colon cancer
- Esophageal glycogenic acanthoses (≥3)
- Lipomas (≥3)
- Mental retardation (ie, IQ ≤75)
- Renal cell carcinoma
- Testicular lipomatosis
- Thyroid cancer (papillary or follicular variant of papillary)
- Thyroid structural lesions (eg, adenoma, multinodular goiter)
- Vascular anomalies (including multiple intracranial developmental venous anomalies)

Operational diagnosis in an individual (either of the following):
1. Three or more major criteria, but one must include macrocephaly, Lhermitte-Duclos disease, or gastrointestinal hamartomas; or
2. Two major and three minor criteria.

Operational diagnosis in a family where one individual meets revised PTEN hamartoma tumor syndrome clinical diagnostic criteria or has a PTEN mutation:
1. Any two major criteria with or without minor criteria; or
2. One major and two minor criteria; or
3. Three minor criteria.

COWDEN SYNDROME/PHTS MANAGEMENT

WOMEN

- **Breast awareness[1] starting at age 18 y.**
- **Clinical breast exam, every 6–12 mo, starting at age 25 y or 5–10 y before the earliest known breast cancer in the family.**
- **Annual mammography and breast MRI screening starting at age 30–35 y or individualized based on earliest age of onset in family.[2,3]**
- **For endometrial cancer screening,[4] encourage patient education and prompt response to symptoms. Consider annual random endometrial biopsies and/or ultrasound beginning at age 30–35 y.**
- **Discuss risk-reducing mastectomy and hysterectomy[5] and counsel regarding degree of protection, extent of cancer risk, and reconstruction options.**
- **Address psychosocial, social, and quality-of-life aspects of undergoing risk-reducing mastectomy and/or hysterectomy.**

MEN AND WOMEN

- **Annual comprehensive physical exam starting at age 18 y or 5 y before the youngest age of diagnosis of a component cancer in the family (whichever comes first), with particular attention to thyroid exam.**
- **Annual thyroid ultrasound starting at age 18 y or 5–10 y before the earliest known thyroid cancer in the family, whichever is earlier.**
- **Colonoscopy, starting at age 35 y, then every 5 y or more frequently if patient is symptomatic or polyps found.**
- **Consider renal ultrasound starting at age 40 y, then every 1–2 y**
- **Dermatologic management may be indicated for some patients**
- **Consider psychomotor assessment in children at diagnosis and brain MRI if there are symptoms.**
- **Education regarding the signs and symptoms of cancer.**

RISK TO RELATIVES

- **Advise about possible inherited cancer risk to relatives, options for risk assessment, and management.**
- **Recommend genetic counseling and consideration of genetic testing for at-risk relatives.**

REPRODUCTIVE OPTIONS

- **For women of reproductive age, advise about options for prenatal diagnosis and assisted reproduction including pre-implantation genetic diagnosis. Discussion should include known risks, limitations, and benefits of these technologies. See Discussion for details.**

[1] Women should be familiar with their breasts and promptly report changes to their health care provider. Periodic, consistent breast self exam (BSE) may facilitate breast self awareness. Premenopausal women may find BSE most informative when performed at the end of menses.

[2] The appropriateness of imaging modalities and scheduling is still under study.

[3] High-quality breast MRI limitations include having: a need for a dedicated breast coil, the ability to perform biopsy under MRI guidance by experienced radiologists in breast MRI, and regional availability. Breast MRI is preferably preformed on days 7–15 of a menstrual cycle for premenopausal women.

[4] There are limited data regarding the lifetime risk of endometrial cancer in CS/PHTS. Surveillance screening and surgical intervention should be on an individual basis.

[5] Oophorectomy is not indicted for CS/PHTS alone but may be indicated for other reasons.

Note: All recommendations are category 2A unless otherwise indicated.
Clinical Trials: NCCN believes that the best management of any cancer patient is in a clinical trial. Participation in clinical trials is especially encouraged.

EXAMPLES OF ADDITIONAL GENETIC MUTATIONS ASSOCIATED WITH BREAST/OVARIAN CANCER RISK

- **Hereditary Diffuse Gastric Cancer Syndrome**
  - ***CDH1* gene**
  - **Diffuse gastric cancer – 67%–83% risk**
  - **Lobular cancer of the breast – 39%–52% risk**

- **Peutz-Jeghers Syndrome (See NCCN Guidelines for Genetic/Familial High-Risk Assessment: Colorectal for more information)**
  - ***STK11/LKB1* gene**
  - **Breast cancer – 44%–50% risk**
  - **Ovarian cancer – 18%–21% risk (ovarian sex cord tumors are the most common)**

- **Lynch Syndrome (See NCCN Guidelines for Genetic/Familial High-Risk Assessment: Colorectal for more information)**
  - **Mismatch Repair (MMR) genes – *MLH1, MSH2, MSH6, PMS2***
  - ***EPCAM* gene deletion**
  - **Ovarian cancer – 9% risk**
  - **Breast cancer – conflicting data regarding increased risks**

Note: All recommendations are category 2A unless otherwise indicated.
Clinical Trials: NCCN believes that the best management of any cancer patient is in a clinical trial. Participation in clinical trials is especially encouraged.

MULTI-GENE TESTING

Overview of multi-gene testing

- The recent introduction of multi-gene testing for hereditary forms of cancer has rapidly altered the clinical approach to testing at-risk patients and their families. Based on next-generation sequencing technology, these tests simultaneously analyze a set of genes that are associated with a specific family cancer phenotype or multiple phenotypes. Multi-gene testing includes "intermediate" penetrant genes of unclear actionability, and may reveal missense variants of unknown significance. It is for these and other reasons that they are ideally offered in the context of professional genetic expertise for pre- and post- test counseling.
- The decision to use multi-gene testing for patient care should be no different than the rationale for testing a single gene known to be associated with the development of a specific type of cancer. Testing is focused on identifying a mutation known to be clinically actionable- that is, whether the management of an individual patient is altered based on the presence or absence of a mutation. However, as the genes on the multi-gene tests may differ in penetrance, cancer pathogenicity, and the availability of specific prevention and screening guidelines, testing and post multi-gene testing management will require consultation with genetic professionals experienced in cancer susceptibility. The benefits, limitations, and management recommendations should all be reviewed by the provider and discussed with the patient when considering the use of multi-gene testing for cancer susceptibility.
- The focus of this guideline is on testing for germline (inherited) mutations. However, genetic testing for mutations in tumors is also available. While this tumor testing is aimed at identifying somatic mutations that could direct treatment, it is possible to incidentally identify germline mutations in the patient. Providers need to be aware of this and discuss the implications with the patient before ordering tumor testing, because it may have implications for the patient and his or her family members.[1]

- Examples of clinical situations where multi-gene testing may be helpful and more cost-effective include:
  - A 35-year-old woman diagnosed with breast cancer, thyroid nodules, two lipomas, and a single hemangioma. The patient meets NCCN testing criteria for *BRCA1*, *BRCA2*, *TP53*, and *PTEN*. In addition, consideration would be given to testing other genes such as *ATM* and *PALB2*.
  - A 49-year-old woman diagnosed with both ovarian and colon cancer. The patient meets testing criteria for *BRCA1*, *BRCA2*, and Lynch syndrome (*MLH1*, *MSH2*, *MSH6*, *PMS2*, and *EPCAM*).
  - A 45-year-old woman diagnosed with ovarian cancer and a family history of colon cancer in a maternal uncle. If the patient is negative for mutations in *BRCA1* and *BRCA2*, consideration should be given to testing the Lynch syndrome genes, and, as data accumulate, possibly others as well as ovarian cancer genes such as *RAD51D*, *RAD 51C*, and *BRIP1*.

MULTI-GENE TESTING

Points in favor of multi-gene testing include:

- Using a broad and unbiased testing approach will increase the likelihood of finding mutations in patients who do not meet specific personal and family history criteria because:
  1. Multiple genes may contribute to the breast/ovarian phenotype, and there is often overlap in the cancers associated with mutations in different genes.
  2. Atypical family presentations or limited family structure can make it difficult to use family history alone to determine the most appropriate gene(s) to test.
  3. Patients with a new mutation could have a negative or minimal family history of cancer.
  4. Studies suggest that as high as 17% of *BRCA*-negative, high-risk breast cancer families, and as high as 24% of unselected ovarian cancer cases, will have a mutation identified on multi-gene testing.[2-4] Although the clinical actionability of all mutations is not clearly known, there is the potential to identify mutations in more patients/families with multi-gene testing than by *BRCA1/BRCA2* alone.[4]
- The higher mutation detection rate may reduce the number of high-risk families with uninformative (negative) tests, and may increase the number of patients who can be provided with tailored surveillance, risk reduction options, and testing of at-risk family members.
- Multi-gene testing is generally more cost- and time-effective than sequentially testing more than 2–3 single genes associated with the phenotype. For example, it is recommended that young women diagnosed with breast cancer be tested for mutations in *BRCA1*, *BRCA2*, and *TP53*. Using a multi-gene test could reduce the cost of testing for these genes individually.
- Multi-gene tests may also reveal more than one pathogenic mutation. In some cases this may alter recommendations for proband screening and family member gene testing for both mutations and follow-up risk reduction recommendations.

Limitations in use of multi-gene testing may include:

- Technical:
  - Commercially available tests may differ significantly in the number of genes analyzed, turn-around time, cost, insurance coverage, analysis/annotation of variants of uncertain significance, depth of gene coverage, extent of intron/exon boundary analysis, methodology of large deletion/duplication, and other factors. Thus, choosing the appropriate laboratory and tests should consider these factors:
    1. There is an increased likelihood of finding variants of unknown significance since more genes are being analyzed.[5,6] This possibility should be included in pre-test counseling with the patient.
    2. Clinical laboratories may differ on their determination of whether a particular variant should be classified as benign, likely benign variant, pathogenic, or likely pathogenic variant. As there are no clinically validated algorithms for classification, members of the same family who undergo testing by different laboratories may thus receive differing result interpretations for the same mutation. These complex test results are best addressed by a genetic specialist.
- In some circumstances mutations may be missed using next-generation sequencing, which would be detectable using traditional single-gene analytic methods.
- Clinical:
  - There are limited data regarding the degree of cancer risk associated with some of the genes on the current multi-gene tests.
  - There is a lack of clear guidelines on risk management for carriers of mutations in some of these genes. This could lead to extra surveillance, surgeries, and utilization of resources downstream that may be considered unnecessary once further data exist. In many cases, management will continue to be based on personal and family history rather than mutation status.
  - It is possible that mutations may be identified in more than one gene in the same patient, making management recommendations more difficult to determine.
  - The potential added turnaround time to receipt of test results inherent in most multi-gene testing can make them an unsuitable starting point for patients needing rapid results (ie, for surgical decision-making or other treatment decisions.)

Note: All recommendations are category 2A unless otherwise indicated.
Clinical Trials: NCCN believes that the best management of any cancer patient is in a clinical trial. Participation in clinical trials is especially encouraged.

MULTI-GENE TESTING

Issues to Consider in Assessing a Positive Multi-Gene Test Result for Less Characterized Genes:

- A key consideration in developing a management plan for a patient with a positive result from a multi-gene test is whether the gene mutation(s) is/are clinically actionable. Not all genes included in available multi-gene tests are necessarily clinically actionable given current data.
- The cancer risks and clinical implications of some genes included on multi-gene tests have not been fully determined, and thus consensus management recommendations may not be available. In these cases, management recommendations should be based on careful review of the available literature and the patient's family history. In many cases the information from testing for moderate penetrance genes may not change risk management guidelines compared to that recommended based on patient's family history alone. Specific issues to consider include:
  - The strength of the evidence supporting each reported cancer risk associated with a particular gene.
  - Studies done only on higher-risk families should be carefully assessed because of the inherent selection bias, which could inflate the estimated cancer risks for that gene or mutation.
  - Cancer risk data may vary by age group, and age-specific risks are unknown for many of the genes on the panels.
  - As is the case with high-risk genes, it is possible that the risks associated with moderate-risk genes may not be entirely due to that gene alone, given the possibility of gene/gene or gene/environment interactions. Therefore, there may be difficulty in using a known mutation to assign risk for relatives.
  - The strength of the family history must be taken into consideration with moderate-risk genes, since the presence of higher numbers of cancers related to the mutated gene may indicate the presence of adverse or protective modifying genetic or environmental factors in the family.
  - Patient should be made aware that results interpretation is likely to change over time, as medical science advances.
  - Although mutations in most genes included on currently available multi-gene tests cause autosomal-dominantly inherited diseases, a few are associated with autosomal-recessive inheritance. For these genes consideration should be given to testing the partner for mutations in the same gene if it would inform reproductive decision-making and/or risk assessment and management. This should be included in all documentation for notification of family members.
  - There may be gaps in the available data sets in the published studies, and therefore a conclusion about risk for a particular type of cancer may be unknown. This is currently true, for example, for ovarian cancer risk for some genes in multi-gene tests.
  - Patients with positive or uncertain results on panel testing should be encouraged to participate in family studies and/or research registries when available.

MULTI-GENE TESTING

GENERAL RECOMMENDATIONS

Provider:

1. **Because of their complexity hereditary cancer multigene tests should be ordered in consultation with a cancer genetics professional.[a]**
2. **As in other genetic testing, an affected family member should be tested first, whenever possible.**
3. **Multi-gene testing may be more cost- and time-effective in certain cases than sequentially testing more than 2–3 single genes associated with a phenotype.**
4. **Since genes can be easily added or removed from multi-gene tests over time by a given lab, medical records must document which genes were included in the specific multi-gene test used for each patient, and in which labs they were performed.**
5. **Multi-gene tests vary in technical specifications (eg, depth of gene coverage, extent of intron/exon boundary analysis, methodology of large deletion/duplication analysis). Tests should be chosen that maximize the likelihood of identifying mutations in the genes of interest and that will likely alter patient management.**
6. **Under certain circumstances, technologies used in multi-gene testing may fail to identify mutations that might be identifiable through single-gene testing. If high clinical suspicion remains for a particular syndrome after negative multi-gene test results, consultation with the testing lab and/or additional targeted genetic testing may be warranted.**

Laboratories:

1. **The classification of variants of uncertain significance remains an ongoing issue. The methods and data sources used to classify genetic variants can differ significantly by laboratory. Genetic testing laboratories should be transparent in the manner by which they classify variants.**
2. **Since variant classification is greatly facilitated by public availability of data, laboratories should make their data available.**
3. **Laboratories have differing policies regarding whether or not to notify providers for interpretation changes of a previously identified variant. Because the notification of variant changes is an important aspect of care, there is an urgent need for standardized procedures across laboratories for handling such notifications.**
4. **Other next-generation sequencing methods, such as whole genome sequencing (WGS) and whole exome sequencing (WES), may become useful testing strategies in the future. At present, however, there is no evidence for the general use of these tests for cancer susceptibility testing.**

[a] Genetic counseling is highly recommended when genetic testing is offered and after results are disclosed. A genetic counselor, medical geneticist, oncologist, surgeon, oncology nurse, or other health professional with expertise and experience in cancer genetics should be involved early in counseling patients who potentially meet criteria for an inherited syndrome.

Note: All recommendations are category 2A unless otherwise indicated.

NCCN Guidelines Version 2.2014 Genetic/Familial High-Risk Assessment: Breast and Ovarian

NCCN Guidelines Index
Genetics Table of Contents
Discussion

Overview

All cancers develop as a result of mutations in certain genes, such as those involved in the regulation of cell growth and/or DNA repair,[1,2] although not all of these mutations are inherited from a parent. For example, sporadic mutations can occur in somatic/tumor cells only, and de novo mutations can occur for the first time in a germ cell (i.e., egg or sperm) or in the fertilized egg itself during early embryogenesis. However, family studies have long documented an increased risk of several forms of cancer among first-degree relatives (i.e., parents, siblings, and children) and second-degree relatives (i.e., grandparents, aunts or uncles, grandchildren, and nieces or nephews) of affected individuals. These individuals may have an increased susceptibility to cancer as the result of one or more gene mutations present in parental germline cells; cancers developing in these individuals may be classified as hereditary or familial cancers.

Hereditary cancers are often characterized by mutations associated with a high probability of cancer development (i.e., a high penetrance genotype), vertical transmission through either mother or father, and an association with other types of tumors.[3,4] They often have an early age of onset, and exhibit an autosomal dominant inheritance pattern (i.e., occur when the individual has a mutation in only one copy of a gene). Familial cancers share some but not all features of hereditary cancers. For example, although familial breast cancers occur in a given family more frequently than in the general population, they generally do not exhibit the inheritance patterns or onset age consistent with hereditary cancers. Familial cancers may be associated with chance clustering of sporadic cancer cases within families, genetic variation in lower penetrance genes, a shared environment, or combinations of these factors.[5-8]

Assessment of an individual's risk of familial or hereditary cancer is based on a thorough evaluation of the family history. With respect to hereditary cancers, advances in molecular genetics have identified a number of genes associated with inherited susceptibility to breast and/or ovarian cancers (e.g., *BRCA1, BRCA2, PTEN, TP53, CDH1*) and provided a means of characterizing the specific gene mutation or mutations present in certain individuals and families exhibiting an increased risk of cancer. The field of cancer genetics has implications for all aspects of cancer management of individuals with hereditary or familial cancers, including prevention, screening, and treatment.

The NCCN Clinical Practice Guidelines in Oncology (NCCN Guidelines®) for Genetic/Familial High-Risk Assessment: Breast and Ovarian were developed with an acute awareness of the preliminary nature of much of our knowledge regarding the clinical application of the rapidly emerging field of molecular genetics, and with an appreciation for the need for flexibility when applying these guidelines to individual families. Furthermore, it should be emphasized that these guidelines were not developed as a substitute for professional genetic counseling. Rather, they are intended to serve as a resource for healthcare providers to identify individuals who may benefit from cancer risk assessment and genetic counseling, to provide genetic counselors with an updated tool for the assessment of individual breast cancer and ovarian cancer risk and to guide decisions related to genetic testing, and to facilitate a multidisciplinary approach in the management of individuals at increased risk of hereditary breast and/or ovarian cancer. Although cancers other than breast and ovarian cancers are associated with these hereditary syndromes, the main focus of this NCCN Guidelines is on the management of breast and ovarian cancer risk in these individuals. During the last few years, a number of genetic aberrations that may contribute to increased risks for development of

Version 2.2014, 09/23/14 © National Comprehensive Cancer Network, Inc. 2014, All rights reserved. The NCCN Guidelines® and this illustration may not be reproduced in any form without the express written permission of NCCN®.

breast and/or ovarian cancers have been identified. The current NCCN Guidelines for Genetic/Familial High-Risk Assessment: Breast and Ovarian focus specifically on assessment of mutations in the genes *BRCA1/BRCA2, TP53 and PTEN*, and recommended approaches to genetic testing/counseling and management strategies in individuals with these genetic mutations.

A glossary of genetic terms is included in Table 1 for reference.

Hereditary Breast or Breast/Ovarian Cancer Syndromes

Breast cancer is the most prevalent type of cancer in women in the U.S. and the second leading cause of cancer death in women.[9] In the U.S., approximately 234,580 new cases of breast cancer and 40,030 deaths are estimated in 2013 (estimated figures include both genders).[9] Up to 10% of breast cancers are due to specific mutations in single genes that are passed down in a family.[6,8] Specific patterns of hereditary breast/ovarian cancers are linked to mutations in the *BRCA1* or *BRCA2* genes.[10,11] In addition, two very rare hereditary cancer syndromes exhibiting an increased risk of breast cancer are Li-Fraumeni syndrome and Cowden syndrome, which are related to germline mutations in the *TP53* and *PTEN* genes, respectively.[12,13] Similar to the *BRCA 1/2* genes, the *TP53* and *PTEN* genes encode for proteins involved in processes related to tumor suppression, such as DNA repair and cell cycle regulation. Hereditary diffuse gastric cancer (HDGC) is another rare hereditary syndrome that is also associated with development of lobular breast cancer. This syndrome arises from mutation(s) in the *CDH1* (cadherin 1, type 1, E-cadherin [epithelial]) gene which encodes for a tumor suppressor gene product.[14] In an analysis of 4 predominantly gastric cancer pedigrees from Newfoundland with a specific *CDH1* mutation, the cumulative risk of female lobular breast cancer by the age of 75 was estimated to be as high as 52%.[15,16] Furthermore, germline *CDH1* mutations may be associated with lobular breast cancer in the absence of diffuse gastric cancer.[17]

These hereditary syndromes share several features beyond elevation of breast cancer risk. These syndromes arise from germline gene mutations that are not within sex-linked genes; hence, the mutations can be inherited from either parent. The syndromes are associated with breast cancer onset at an early age and development of other types of cancer, and exhibit an autosomal dominant inheritance pattern (see Table 1). Offspring of an individual with one of these hereditary syndromes have a 50% chance of inheriting the mutation. In addition, individuals with these hereditary syndromes share increased risks of multiple cases of early onset disease as well as bilateral disease. The gene mutations associated with these hereditary syndromes are considered to be highly penetrant, although a subsequent alteration in the second copy of the gene without the hereditary mutation is believed to be necessary for the initiation of cancer development (i.e., 2-hit hypothesis).[18,19] In addition, the manifestations (i.e., expression) of these hereditary syndromes are often variable in individuals within a single family (e.g., age of onset, tumor site, and number of primary tumors). The risk of developing cancer in individuals with one of these hereditary syndromes depends upon numerous variables including the gender and age of the individual.

Hereditary Breast/Ovarian Cancer Syndrome

The overall prevalence of disease-related mutations in *BRCA1* and *BRCA2* genes has been estimated as 1 in 300 and 1 in 800, respectively.[20,21] Currently, hundreds of unique mutations have been identified in both *BRCA1* and *BRCA2* genes. However, a number of founder effects (see Table 1) have been observed in certain populations, wherein the same mutation has been found in multiple,

Printed by Ariel Smits on 10/14/2014 12:23:15 PM. For personal use only. Not approved for distribution. Copyright © 2014 National Comprehensive Cancer Network, Inc., All Rights Reserved.

unrelated families and can be traced back to a common ancestor. Among the Ashkenazi Jewish population, for example, the frequency of 187delAG and 5385insC mutations in *BRCA1* and the 6174delT mutation in *BRCA2* approximates 1 in 40.[6,22] Certain founder mutations have also been identified in other populations.[20,23-28] It has been estimated that over 90% of early onset cancers in families with both breast and ovarian cancers are caused by mutation(s) in the *BRCA1* or *BRCA2* genes.[29] Hence, the degree of clinical suspicion for a *BRCA* mutation in a single individual with both breast and ovarian cancer or someone with a family history of both breast and ovarian cancer should be very high.

Both the *BRCA1* and *BRCA2* genes encode for proteins involved in tumor suppression. The *BRCA1* gene is located on chromosome 17 and is believed to be involved in both DNA repair and in the regulation of cell-cycle checkpoints in response to DNA damage. However, the molecular mechanism through which *BRCA1* functions to preserve genomic stability remains unclear.[30] The *BRCA2* gene, located on chromosome 13, is involved in repair of replication-mediated double-strand DNA breaks.[31,32]

Mutations in the *BRCA1* or *BRCA2* genes can be highly penetrant (for definition, see Table 1) although the probability of cancer development in carriers of *BRCA1* or *BRCA2* mutations is variable, even within families with the same mutation.[33-35] Estimates of penetrance range from 41% to 90% lifetime risk for breast cancer, with an increased risk of contralateral breast cancer.[36-42] In addition, female carriers of these genes have an estimated 8% to 62% lifetime risk for ovarian cancer, depending upon the population studied.[37,54,38-44] In a meta-analysis (2007) of published data that evaluated *BRCA1* and *BRCA2* penetrance, estimates for mean cumulative risks of breast cancer and ovarian cancer by age 70 years for *BRCA1* mutation carriers were 57% and 40%, respectively.[38] The corresponding estimates for *BRCA2* mutation carriers were 49% and 18%, respectively. In a recent prospective analysis of risk estimates from individuals with *BRCA1* and *BRCA2* mutations in the UK (N=1887), estimates for mean cumulative risks of breast cancer and ovarian cancer by age 70 years for *BRCA1* mutation carriers were 60% and 59%, respectively.[41] The corresponding estimates for *BRCA2* mutation carriers were 55% and 16.5%, respectively. Among the patients diagnosed with unilateral breast cancer (n=651), the mean cumulative risks for contralateral breast cancer by age 70 years were estimated to be 83% for *BRCA1* carriers and 62% for *BRCA2* carriers.[41] At present, it is unclear whether penetrance is related to the specific mutation identified in a family or whether additional factors, either genetic or environmental, affect disease expression. It is generally accepted, however, that carriers of mutations in *BRCA1* or *BRCA2* genes have an excessive risk for both breast and ovarian cancer that warrants consideration of more intensive screening and preventive strategies.

Some histopathologic features have been reported to occur more frequently in breast cancers characterized by a *BRCA1/2* mutation. For example, several studies have shown that *BRCA1* breast cancer is more likely to be characterized as ER-,PR-negative, and HER2-negative (i.e., "triple negative").[45-50] Studies have reported *BRCA1* mutations in 9% to 28% of patients with triple-negative breast cancer.[50-56] In addition, it appears that among patients with triple-negative disease, *BRCA* mutation carriers were diagnosed at a younger age compared with non-carriers.[53,57] A recent study in a large cohort of patients with triple-negative breast cancer (N=403) reported a median age of diagnosis of 39 years among carriers of *BRCA1* mutations (n=65).[52] Patients in this population-based study were unselected for family history or age. Among the group of patients with early onset (age

at diagnosis <40 years) triple-negative breast cancer (n=106), the incidence of *BRCA1* mutations was 36%; among those diagnosed before age 50 years (n=208), the incidence was 27%. For patients with triple-negative breast cancer with a family history of breast and/or ovarian cancer (n=105), *BRCA1* mutations were found in 48%.[52] An increased incidence of *BRCA* mutations was reported in triple-negative breast cancer cases from at-risk populations. Among Ashkenazi Jewish women with breast cancer unselected for family history (N=451), triple-negative disease was observed in 14% and *BRCA* founder mutations were found in 11% of patients.[58] Among the subgroup with triple-negative breast cancer (n=65), the incidence of *BRCA* mutations was 39% (*BRCA1* mutation in 30%; *BRCA2* mutation in 9%).[58] Although many of the mutation studies in triple-negative breast cancer have reported on the association with *BRCA1* mutations, several reports have also suggested the role of *BRCA2* mutations in triple-negative breast cancer. The incidence of *BRCA2* mutations range from 4% to 17% in studies of triple-negative breast cancer cases unselected for age or family history.[51,58,59]

An increased frequency of other malignancies has been reported in families with mutations in the *BRCA1* or *BRCA2* gene.[39,60,61] Germline *BRCA1* and *BRCA2* mutations have been associated with an increased risk of prostate cancer in numerous reports.[39,60-67] In particular, *BRCA2* mutations have been associated with 2- to 6-fold increase in risk of prostate cancer,[62-64,67,68] while increased risks were not observed for *BRCA1* mutation carriers in some studies.[62-64,68] Prostate cancer with germline *BRCA* mutations appear to have a more aggressive phenotype (e.g., more frequently associated with Gleason score ≥8) than tumors from non-carrier patients.[69,70] A recent study in a large cohort of patients with prostate cancer from Spain (N=2019) showed that the group of patients with *BRCA* mutations had significantly higher rates of aggressive prostate cancer (Gleason score ≥8), nodal involvement and distant metastasis compared with non-carriers.[69] Moreover, cause-specific survival outcome was significantly poorer in *BRCA* mutation carriers compared with non-carriers (median survival 8.6 years vs. 15.7 years; P=0.015). Subgroup analysis by mutation type showed poor outcomes in patients with *BRCA2* mutations (n=61); the role of *BRCA1* mutations was not well defined, possibly due to the small patient size (n=18) and limited follow-up in this subgroup.[69] Prostate cancer in patients with *BRCA2* mutations has also been associated with a higher histologic grade in other studies.[62,63] In addition, analyses of data obtained from cancer registries and treatment center databases showed that *BRCA2* mutation carriers with prostate cancer had more aggressive or rapidly progressive disease, and significantly decreased survival compared with patients who were *BRCA1* mutation carriers or non-carriers.[71-73] In a study of patients with prostate cancer from a population-based cancer registry in Iceland (N=596), patients with *BRCA2* mutations had significantly decreased median survival compared with non-carriers (having wild type *BRCA2*) patients (2 years vs. 12 years; P<0.001).[73] Moreover, in a study of patients with prostate cancer using data obtained from cancer center databases (N=301), patients with *BRCA2* mutations had significantly decreased median survival compared with patients with *BRCA1* mutations (4 years vs. 8 years; P<0.01).[71] *BRCA2* mutation carriers have also been reported to have a higher risk of pancreatic cancer and melanoma.[60,61,67,74,75] Both *BRCA1* and *BRCA2* mutations have been associated with increased propensity for developing pancreatic cancer.[67,75-78] In an analysis of samples taken from patients with familial pancreatic cancer (kindreds in which ≥3 family members had pancreatic cancer, at least 2 of which were first-degree relatives), *BRCA2* mutations were detected in 17% of patient samples.[78] Among the Ashkenazi Jewish population, *BRCA2*

Printed by Ariel Smits on 10/14/2014 12:23:15 PM. For personal use only. Not approved for distribution. Copyright © 2014 National Comprehensive Cancer Network, Inc., All Rights Reserved.

mutations have been identified in about 4% of patients with pancreatic cancer.[74,79]

Some data related to the risk of cancers in this population at some sites other than the breast/ovary are contradictory.[80] For example, it has been suggested that the increased risk of endometrial cancer observed in some *BRCA1* or *BRCA2* mutation carriers is mainly due to the use of tamoxifen therapy by these women rather than the presence of a gene mutation.[81]

Germline mutations in *BRCA1* and *BRCA2* are responsible for 5% to 10% of epithelial ovarian cancers (i.e., ovarian cancer developing on the surface of the ovary).[82] Increased risks of cancers of the fallopian tube and primary peritoneal cancer are also observed in this population. In the setting of an invasive ovarian cancer diagnosis, as many as 15% of unselected individuals will have a germline *BRCA1* or *BRCA2* mutation.[42,83] However, it has been reported that about half of families showing a genetic predisposition to ovarian cancer do not have identifiable mutations in *BRCA1/2* genes.[84] Hence, other gene mutations predisposing to ovarian cancer are likely to exist.[85] Of note, ovarian cancer is a component tumor of Lynch syndrome which is associated with germline mutations in mismatch repair genes.[86] Interestingly, results from a prospective study suggest that women from families at increased risk of hereditary breast cancer without site-specific *BRCA* mutations are not at increased risk for ovarian cancer, although these results may have been confounded by the ethnic characteristics and size of the study population.[87]

It is interesting to note that several recent studies have reported more favorable survival outcomes among *BRCA1/2* mutation carrier patients with ovarian cancer compared with non-carrier patients.[88-93] In a case-control study of patients with epithelial ovarian cancer (N=66), patients with *BRCA1/2* mutations had improved outcomes compared with patients with non-hereditary ovarian cancer, including significantly longer median survival from time of diagnosis (101 months vs. 35 months; $P<0.002$).[92] In a large case-control study of Jewish patients with epithelial invasive ovarian cancer (N=779), patients with *BRCA1/2* mutations had significantly longer median survival compared with non-carrier patients (54 months vs. 38 months; $P=0.002$).[91] Results from a recent pooled analysis from 26 observational studies that included invasive epithelial ovarian cancer cases from *BRCA1/2* mutation carriers (n=1213) and non-carriers (n=2666) showed favorable survival outcomes for patients with *BRCA1/2* mutations.[89] The 5-year survival rate for non-carriers, *BRCA1* carriers and *BRCA2* carriers was 36%, 44%, and 52%, respectively. The survival advantage compared with non-carriers was significant for both the *BRCA1* carriers (hazard ratio=0.78; 95% CI, 0.68-0.89; $P<0.001$) and *BRCA2* mutation carriers (hazard ratio=0.61; 95% CI, 0.50-0.76; $P<0.001$).[89] In a recent population-based case-control study of women with invasive epithelial (nonmucinous) ovarian cancer (N=1001) from the Australian Ovarian Cancer Study Group, *BRCA1/2* mutation carriers had improved survival outcomes compared with non-carriers in terms of median progression-free survival (20 months vs. 16 months; not statistically significant) and median survival (62 months vs. 55.5 months; $P=0.031$).[88] Moreover, *BRCA* mutation carriers appeared to be more responsive to cytotoxic chemotherapy (regardless of class of agent) compared with non-carrier patients. Outcomes appeared to be most favorable for *BRCA2* mutation carriers; in the subgroup of patients with *BRCA2* mutations (n=53), the median survival was 70 months.[88] In an observational study of patients with high-grade serous ovarian cancer (N=316), patients with *BRCA2* mutations had significantly favorable survival outcomes (hazard ratio=0.33; 95% CI, 0.16–0.69; $P=0.003$; 5-year rate: 61% vs. 25%) and progression-free survival (hazard ratio=0.40; 95% CI, 0.22–0.74;

P=0.004; 3-year rate: 44% vs. 16%) compared with non-carrier patients (having wild type *BRCA*).[93] Additionally, *BRCA2* mutations were associated with significantly higher response rates (compared with non-carriers or with *BRCA1* mutation carriers) to primary chemotherapy. In contrast, *BRCA1* mutations were not associated with prognosis or improved chemotherapy response.[93]

The histology of ovarian cancers in carriers of a *BRCA1* or *BRCA2* mutation is more likely to be characterized as serous adenocarcinoma and high grade compared with ovarian cancers in non-mutation carriers, although endometrioid and clear cell ovarian cancers have also been reported in the former population.[82,94-97] In studies of women with *BRCA1/2* mutations who underwent risk reduction salpingo-oophorectomy (RRSO), occult gynecological carcinomas were identified in 4.5%-9% of cases based on rigorous pathological examinations of the ovaries and fallopian tubes.[98-100] Tubal intraepithelial carcinoma (TIC) is thought to represent an early precursor lesion for serous ovarian cancers, and TIC (with or without other lesions) was detected in 5% to 8% of cases from patients with *BRCA1/2* mutations who underwent RRSO.[98,101,102] The fimbriae or distal tube was reported to be the predominant site of origin for these early malignancies found in patients with *BRCA1/2* mutations.[98,102,103] Although TIC appeared to present more frequently among *BRCA1/2* mutation carriers compared with non-carriers undergoing RRSO,[102,103] TIC has also been documented among patients with serous carcinomas unselected for family history or *BRCA* mutation status.[104] Because TIC was identified in individuals who underwent surgery for risk reduction (for *BRCA1/2* mutation carriers) or other gynecological indications, the incidence and significance of these early lesions within the general population is unclear. Hence, at the present time, there is no justifiable role for *BRCA* testing for cases based solely on the finding of TIC during pathology evaluation for gynecological indications.

Male carriers of a *BRCA* gene mutation also have a greater risk for cancer susceptibility.[61] In one study of 26 high-risk families with at least one case of male breast cancer, 77% demonstrated a *BRCA2* mutation.[29] Among male patients with breast cancer who were not selected on the basis of family history, 4% to 14% tested positive for a germline *BRCA2* mutation.[105-108] In a recent series of male breast cancer cases (N=115; primarily from cancer registry data), *BRCA2* mutations were detected in 16% of cases; the incidence of *BRCA2* mutations was 40% among patients selected for family history of breast cancer and 13% among those unselected for family history.[107] For males with a *BRCA2* mutation, the cumulative lifetime risk of breast cancer has been estimated at 7% to 8%.[109,110] In contrast, for men without such a mutation, the lifetime risk of breast cancer has been estimated at approximately 0.1% (1 in 1,000).[107,111]

The NCCN panel recommends that individuals from a family with a known deleterious *BRCA1* or *BRCA2* mutation be considered for testing (see Guidelines section on HBOC Syndrome Testing Criteria).

In individuals from a family without a known deleterious *BRCA* mutation, testing should be considered for those individuals who meet the testing criteria discussed below. In evaluating risks based on family history factors, the maternal and paternal sides should be considered independently. For the testing criteria mentioned below, "close relatives" pertain to first-, second- or third-degree blood relatives on the same side (either maternal or paternal side) of the family. Individuals with a limited family history (e.g., having fewer than 2 first- or second-degree relatives or female relatives surviving beyond 45 years of age on either the maternal or paternal side) may have an underestimated probability

Printed by Ariel Smits on 10/14/2014 12:23:15 PM. For personal use only. Not approved for distribution. Copyright © 2014 National Comprehensive Cancer Network, Inc., All Rights Reserved.

of a familial gene mutation. The panel recommends that patients with a personal history of breast cancer *in addition to* one or more of the following criteria be considered for *BRCA1/BRCA2* testing:

- Diagnosed at age 45 years or younger;
- Having 2 breast primaries (bilateral tumors or 2 or more clearly separate ipsilateral tumors, occurring synchronously or asynchronously) with the first breast cancer diagnosed at age 50 years or younger;
- Diagnosed at 50 years or younger with 1 or more close relative with breast cancer at any age (or with a limited family history);
- Diagnosed with triple-negative breast cancer at age 60 years or younger;
- Diagnosed at any age with 1 or more close relative with breast cancer diagnosed at age 50 years or younger;
- Diagnosed at any age with 2 or more close relatives with breast cancer at any age; diagnosed at any age with 1 or more close relative with epithelial ovarian cancer diagnosed at any age;
- Diagnosed at any age with 2 or more close relatives with pancreatic cancer or aggressive prostate cancer (Gleason score ≥7) at any age; or
- Having a close male relative with breast cancer at any age.

In patients with a personal history of breast cancer and with an ethnic background associated with higher mutation frequency (e.g., Ashkenazi Jewish heritage), no additional family history may be needed to meet testing criteria. In addition, the NCCN panel recommends testing for patients with a personal history of the following:

- Epithelial ovarian cancer diagnosed at any age;
- Male breast cancer diagnosed at any age; or
- Pancreatic cancer or aggressive prostate cancer (Gleason score ≥7) diagnosed at any age, with 2 or more close relatives with breast cancer and/or ovarian cancer and/or pancreatic or aggressive prostate cancer diagnosed at any age.

In unaffected individuals with a family history only (i.e., no personal history of breast or ovarian cancer), significant limitations of interpreting test results should be discussed prior to any testing. Moreover, testing of unaffected individuals should only be considered when an appropriate affected family member is unavailable for testing. Clinical judgement should be used to evaluate each unaffected individual for his/her likelihood of carrying the mutation based on factors such as the unaffected individual's current age and the age of unaffected female relatives who link the individual with an affected close relative.

Individuals not meeting testing criteria, including those with an increased risk of familial breast cancer, should be followed according to the recommendations in the NCCN Guidelines for Breast Cancer Screening and Diagnosis.

Li-Fraumeni Syndrome

Li-Fraumeni syndrome (LFS) is a rare hereditary cancer syndrome associated with germline *TP53* gene mutations.[13] It has been estimated to be involved in only about 1% of hereditary breast cancer cases,[112] although results from a recent study suggest that germline *TP53* gene mutations may be more common than previously believed.[113] The tumor suppressor gene, *TP53*, is located on chromosome 17,[114,115] and the protein product of the *TP53* gene (i.e., p53) is located in the cell nucleus and binds directly to DNA. It has been called the "guardian of the genome" and plays important roles in controlling the cell cycle and apoptosis.[114-116] Germline mutations in the *TP53* gene have been observed in over 50% (and in over 70% in some studies) of families

DISCUSSION
Updates in progress

meeting the classic definition of LFS (see Guidelines section on Li-Fraumeni Syndrome Testing Criteria).[13,113,117] Additional studies are needed to investigate the possibility of other gene mutations in families meeting these criteria not carrying germline *TP53* mutations.[118]

LFS, a highly penetrant cancer syndrome associated with a high lifetime risk of cancer, is characterized by a wide spectrum of neoplasms occurring at a young age. It is associated with soft-tissue sarcomas, osteosarcomas (although Ewing's sarcoma is less likely to be associated with LFS), premenopausal breast cancer, acute leukemia, and cancer of the colon, adrenal cortex, and brain tumors.[13,113,116,119-124] Sarcoma, breast cancer, adrenocortical tumors and certain brain tumors have been referred to as the "core" cancers of LFS since they account for the majority of cancers observed in individuals with germline mutations in the *TP53* gene, and in one study, at least one of these cancers was found in one or more members of all families with a germline *TP53* gene mutation.[113] Interestingly, recent retrospective studies have reported a very high frequency of HER2-positive breast tumors (67%–83% of evaluated breast tumors) among patients with germline *TP53* mutations, which suggest that amplification of HER2 may arise in conjunction with *TP53* mutations.[125,126] This association between HER2-positive breast cancer and germline *TP53* mutations warrants further investigation, as such patients may potentially benefit from chemoprevention therapies that incorporate HER2-targeted agents.

Individuals with LFS often present with certain cancers (e.g., soft-tissue sarcomas, brain tumors, and adrenocortical carcinomas) in early childhood,[121] and have an increased risk of developing multiple primary cancers during their lifetimes.[127] Results of a segregation analysis of data collected on the family histories of 159 patients with childhood soft tissue sarcoma showed carriers of germline *TP53* mutations to have estimated cancer risks of approximately 60% and 95% by age 45 and 70 years, respectively.[128] Although similar cancer risks are observed in men and women with LFS when gender-specific cancers are not considered, female breast cancer is commonly associated with the syndrome.[113] It is important to mention that estimations of cancer risks associated with LFS are limited to at least some degree by selection bias since dramatically affected kindreds are more likely to be identified and become the subject of further study.

A number of different sets of criteria have been used to help identify individuals with LFS. For the purposes of the NCCN Guidelines, 2 sets of these criteria are used to facilitate the identification of individuals who are candidates for *TP53* gene mutation testing.

Classic LFS criteria, based on a study by Li and Fraumeni involving 24 LFS kindreds, include the following: member of a kindred with a known *TP53* mutation; combination of an individual diagnosed at age 45 years or younger with a sarcoma, and a first-degree relative diagnosed with cancer at age 45 years or younger, and an additional first- or second-degree relative in the same lineage with cancer diagnosed at age younger than 45 years or a sarcoma at any age (see Guidelines section on Li-Fraumeni Syndrome Testing Criteria). Classic LFS criteria have been estimated to have a high positive predictive value (estimated at 56%) as well as a high specificity, although the sensitivity is relatively low (estimated at 40%).[113] Thus, it is not uncommon for individuals with patterns of cancer outside of these criteria to be carriers of germline *TP53* mutations.[124,129] Classic LFS criteria make up one set of criteria included in the Guidelines to guide selection of individuals for *TP53* gene mutation testing (see Guidelines section on Li-Fraumeni Syndrome Testing Criteria).

Printed by Ariel Smits on 10/14/2014 12:23:15 PM. For personal use only. Not approved for distribution. Copyright © 2014 National Comprehensive Cancer Network, Inc., All Rights Reserved.

Other groups have broadened the classic LFS criteria to facilitate identification of individuals with LFS,[119,130-132] One set of these less strict criteria proposed by Birch and colleagues shares many of the features of classic LFS criteria, although a larger range of cancers are included.[113,119] Uncommonly, individuals with de novo germline *TP53* mutations (no mutation in either biological parent) have been identified.[113,120,133] These cases would not be identified as *TP53* testing candidates based upon classic LFS criteria due to requirement of a family history. This issue is circumvented, in part, by the criteria for *TP53* testing proposed by Chompret and colleagues, which recommends testing for patients with multiple primary tumors of at least 2 "core' tumor types (i.e., sarcoma, breast cancer, adrenocortical carcinoma, brain tumors) diagnosed at age <36 years or patients with adrenocortical carcinoma diagnosed at any age, regardless of family history (see Guidelines section on Li-Fraumeni Syndrome Testing Criteria).[131] The Chompret criteria have an estimated positive predictive value of 20% to 35%,[113,131] and when incorporated as part of *TP53* testing criteria in conjunction with classic LFS criteria, have been shown to improve the sensitivity to 95% (i.e., the Chompret criteria added to classic LFS criteria detected 95% of patients with *TP53* mutations).[113] The Chompret criteria are the second set of criteria included in the NCCN Guidelines. Although not part of the original published criteria set forth by Chompret et al., the panel recommends adding lung bronchoalveolar cancer and leukemia as one of the core tumor types (for inclusion in criterion 1 and 2 of the Chompret criteria) and also recommends testing individuals with choroid plexus carcinoma diagnosed at any age and regardless of family history (for inclusion in criterion 3), based upon reports of high incidence of *TP53* mutations found in patients with this rare form of brain tumor.[113,120,134,135] The above inclusion of lung bronchoalveolar cancer and leukemia as one of the core tumors and recommendation for testing for individuals with choroid plexus carcinoma (i.e., updated Chompret criteria) was recently proposed by Tinat et al,[135] and is supported by the NCCN Guidelines panel. The panel also supports the broader age cut-offs proposed by Tinat et al, based upon a study in a large number of families, which detected germline *TP53* mutations in affected individuals with later tumor onsets.[134,135]

Women with early-onset breast cancer (age of diagnosis ≤35 years), with or without family history of core tumor types, are another group for whom *TP53* gene mutation testing may be considered. Several recent studies have investigated the likelihood of a germline *TP53* mutation in this population.[113,134,136-139] In a study of *TP53* mutations evaluated at a single reference laboratory, Gonzalez et al. found that all women younger than 30 years of age with breast cancer who had a first- or second-degree relative with at least one of the core cancer types (n=5), had germline *TP53* mutations.[113] In a recent analysis of data of patients with early-onset breast cancer (age of diagnosis <30 years) tested for *TP53* mutation at a single institution (N=28), 6 patients (33%) were found to have *TP53* mutations.[140] Among the patients who were tested, a *TP53* mutation was found in approximately 8% who did not meet traditional LFS criteria for testing. In another recent study in patients with *BRCA1/BRCA2* mutation-negative early-onset breast cancer (age of diagnosis ≤35 years) tested for *TP53* mutation at a single institution (N=83), approximately 5% were found to have *TP53* mutations.[138] Deleterious *TP53* mutations were identified in 3 of 4 patients (75%) with a family history of at least 2 LFS-associated tumors (breast cancer, bone or soft tissue sarcoma, brain tumors or adrenocortical cancer) and in 1 of 17 patients (6%) with a family history of breast cancer only.[138] Among women <30 years of age with breast cancer and without a family history, the incidence of *TP53* mutations has been reported at 3% to 8%.[113,137,139,140] Other studies have found an even lower incidence of

Printed by Ariel Smits on 10/14/2014 12:23:15 PM. For personal use only. Not approved for distribution. Copyright © 2014 National Comprehensive Cancer Network, Inc., All Rights Reserved.

germline *TP53* gene mutations in this population. For example, Bougeard et al reported that only 0.7% of unselected women with breast cancer before age 33 were carriers of a germline *TP53* mutation.[134] Furthermore, Ginsburg and colleagues found no germline *TP53* mutations in 95 unselected women with early-onset breast cancer who previously tested negative for *BRCA* mutations.[136]

Finally, a member of a family with a known *TP53* mutation is considered to be at sufficient risk to warrant gene mutation testing, even in the absence of any other risk factors. Individuals not meeting testing criteria should be followed according to recommendations tailored to his/her personal cancer history and family history.

Cowden Syndrome

Cowden syndrome, a rare hereditary cancer syndrome, was first described in 1963 and named after the Cowden family, the first family documented with signs of the disease.[141] The incidence of Cowden syndrome has been reported to be 1 in 200,000, although it is likely to be underestimated due to difficulties associated with making a clinical diagnosis of the disease.[142,143] Cowden syndrome is an autosomal dominant disorder associated with germline mutations in the *PTEN* ("*phosphatase* and *ten*sin homologue deleted on chromosome 10"[144]) tumor suppressor gene located on chromosome 10q23; the gene is thought to be involved in cell cycle arrest and apoptosis, and other cell survival pathways.[12] It is considered to be part of the spectrum of PTEN hamartoma tumor syndromes (PHTS), which also includes Bannayan-Riley-Ruvalcaba syndrome (BRRS), Proteus syndrome, and Proteus-like syndrome.[12,145,146] Additional clinical syndromes related to germline mutations in *PTEN* include Lhermitte-Duclos disease and autism spectrum disorders with macrocephaly, both of which have been associated with Cowden syndrome.[12,146,147] The estimated penetrance of *PTEN* mutation is high, at approximately 80%.[148] Hamartomas, a common manifestation of these syndromes, are benign tumors resulting from an overgrowth of normal tissue.

Cowden syndrome is associated with multiple hamartomatous and/or cancerous lesions in various organs and tissues, including the skin, mucous membranes, breast, thyroid, endometrium and brain.[12,149] This syndrome is the only PHTS disorder associated with a documented predisposition to malignancies; hence, it is included in these Guidelines. However, it has been suggested that patients with other PTHS diagnoses associated with *PTEN* mutations should be assumed to have Cowden-associated cancer risks. In a study of patients meeting diagnostic criteria for Cowden syndrome (N=211; identified from published literature and records from a single institution), the cumulative lifetime risk of any cancer was 89%.[150] *PTEN* mutations had been identified in 97 of 105 patients (92%) who underwent testing. The cumulative lifetime cancer risks for all evaluable patients (n=210) were 81% for female breast cancer, 21% for thyroid cancer, 19% for endometrial cancer, 15% for renal cancer, and 16% for colorectal cancer.[150] In a recent prospective study that evaluated genotype-phenotype associations between *PTEN* mutations and cancer risks, a large number of patients meeting modified (relaxed) International Cowden Consortium criteria (N=3399) were enrolled and tested for *PTEN* mutations.[151] Deleterious germline mutations in *PTEN* were identified in 368 patients (11%). Calculation of age-adjusted standardized incidence ratios (SIRs) using cancer incidence data from the SEER database showed elevated SIRs among individuals with *PTEN* mutations for breast cancer (25), thyroid cancer (51), endometrial cancer (43), colorectal cancer (10), renal cancer (31), and melanoma (8.5). The estimated cumulative lifetime cancer risks were 85% for breast, 35% for thyroid, 28% for endometrial, 9% for colorectal, 34% for

Discussion Updates in Progress

renal and 6% for melanoma.[151] In another recent study in individuals with PHTS found to have deleterious germline *PTEN* mutations (N=154; detailed information available in n=146), age- and gender-adjusted SIRs were elevated for female breast cancer (39), endometrial cancer (49), female thyroid cancer (43), male thyroid cancer (199.5), female melanoma (28), and male melanoma (39).[152] The cumulative lifetime risks in these individuals were 77% for female breast cancer and 38% for thyroid cancer. The cumulative lifetimes risk for any cancer was 85% overall, and women with PHTS were found to have a 2-fold greater cancer risk compared with men with PHTS.[152]

Women diagnosed with Cowden syndrome have a high risk of benign fibrocystic breast disease and their lifetime risk of breast cancer has been estimated at 25% to 50% with an average age of 38 to 46 years at diagnosis.[12,149,153] Recent studies (as discussed above) have reported a higher cumulative lifetime risk of breast cancer (77–85%) in individuals with Cowden syndrome or *PTEN* mutations.[150-152] There have been only 2 cases of breast cancer reported in men with Cowden syndrome.[12] Thyroid disease, including benign multinodular goiter, adenomatous nodules, and follicular adenomas have been reported to occur in up to approximately 70% of individuals with Cowden syndrome[154] and the lifetime risk of thyroid cancer (follicular or papillary) has been estimated at 3% to 10%.[12,155] A higher cumulative lifetime risk of thyroid cancer (21–38%) was reported in several recent studies in individuals with Cowden syndrome or *PTEN* mutations (as discussed earlier).[150-152] As in many other hereditary cancer syndromes, affected individuals are more likely to develop bilateral and multifocal cancer in paired organs.[148] Although not well defined, women with Cowden syndrome may have a 5% to 10% risk of endometrial cancer,[12,156] and an increased risk of uterine fibroids. Recent studies showed a higher lifetime risk of endometrial cancer (19–28%) in women with Cowden syndrome or *PTEN* mutations.[150,151] As discussed earlier, increased lifetime risks for colorectal cancer (9–16%), renal cancer (15–34%) and melanoma (6%) were also reported recently in individuals with Cowden syndrome or *PTEN* mutations.[150,151] In addition, brain tumors and vascular malformations affecting any organ are occasionally seen in individuals with Cowden syndrome, although the risks for developing these conditions are not well defined.[12] It is important to note, however, that most of the data on the frequencies of the clinical features of Cowden syndrome are from compilations of case reports of relatively young individuals who may have subsequently developed additional signs of the disease (i.e., new cancerous lesions), and these data are also likely to be confounded by selection bias.[12] Furthermore, a considerable number of these studies were published prior to the establishment in 1996 of the International Cowden Consortium operational diagnostic criteria for the syndrome which were based on published data and the expert opinion of individuals representing a group of centers mainly in North America and Europe.[12,157]

Classic features of Cowden syndrome include mucocutaneous papillomatous papules, palmoplantar keratoses, and trichilemmomas (i.e., benign tumors derived from the outer root sheath epithelium of a hair follicle).[12,158] Most individuals with Cowden syndrome exhibit characteristic mucocutaneous lesions by their twenties, and such lesions have been reported to occur in 99% of individuals with Cowden syndrome, a syndrome showing nearly complete penetrance.[82,145] The presence of 2 or more trichilemmomas has been reported to be pathognomonic for Cowden syndrome.[159,160] However, since most of this evidence is from the older literature, it is possible that the association between these 2 entities is somewhat overestimated.[12] There are reports of individuals with a solitary trichilemmoma who do not have Cowden syndrome.[159,160] Nevertheless, due to the strong association

Printed by Ariel Smits on 10/14/2014 12:23:15 PM. For personal use only. Not approved for distribution. Copyright © 2014 National Comprehensive Cancer Network, Inc., All Rights Reserved.

between these lesions and Cowden syndrome and the difficulty in clinically distinguishing between a trichilemmoma and another mucocutaneous lesion, it is important that a diagnosis of trichilemmoma is histologically confirmed.

It has historically been reported that about 40% individuals with Cowden syndrome have gastrointestinal polyps (often colonic), although more recent data suggest that this risk may be 80% or higher. Indeed, a recent analysis of *PTEN* mutation carriers reported gastrointestinal polyps in 93% of patients.[161] Most of the polyps are hamartomatous, although ganglioneuromas (i.e., rare, benign peripheral nervous system tumors) have also been reported to occur.[12,162] However, early-onset (age <50 years) colorectal cancer has been reported in 13% of patients with *PTEN* mutation-associated Cowden syndrome, suggesting that routine colonoscopy may be warranted in this population.[161]

Adult Lhermitte-Duclos disease (LDD) and autism spectrum disorder characterized by macrocephaly are strongly associated with Cowden syndrome.[145,148,150,163] A rare, slow growing, benign hamartomatous lesion of the brain, LDD is a dysplastic gangliocytoma of the cerebellum.[12,150] In a study of individuals meeting the diagnostic criteria for Cowden syndrome, the cumulative lifetime risk of LDD was reported to be 32%.[150] The preponderance of evidence supports a strong association between adult-onset LDD and the presence of a *PTEN* gene mutation,[148] although exceptions have been reported.[164] In addition, there is a relatively large body of evidence to support that 10% to 20% of individuals with autism spectrum disorder and macrocephaly carry germline *PTEN* mutations.[147,165-168] Macrocephaly (defined as head circumference greater than the 97th percentile)[169] is a common finding in patients with Cowden syndrome. It has been estimated that approximately 80% of individuals with this syndrome will exhibit this clinical finding.[12]

The BRRS variant of PHTS has been characterized by the presence of multiple lipomas, gastrointestinal hamartomatous polyps, macrocephaly, hemangiomas, developmental delay, and in males, pigmented macules on the glans penis,[170] although formal diagnostic criteria have not been established for this syndrome. *PTEN* gene mutations testing in individuals characterized with BRRS have been reported in approximately 60% of these patients.[171] Further, in another study, 10% of patients with BRRS for whom a *PTEN* gene mutation test was negative were shown to be carriers of large *PTEN* gene deletions.[163]

The *PTEN* mutation frequency in individuals meeting International Cowden Consortium criteria for Cowden syndrome has been estimated at about 80%.[12,171] However, a recent evaluation of data based on samples analyzed at a single academic pathology laboratory (N=802 evaluable) reported a much lower frequency (34%) of *PTEN* mutations among individuals meeting diagnostic criteria[143] for Cowden syndrome.[145] The authors concluded that the current Consortium diagnostic criteria are not as sensitive in identifying individuals with *PTEN* mutations as previously estimated. The International Cowden Consortium criteria have been updated several times since 1996[12,143,145,172,173] and they have largely served as the basis for the list of *PTEN* mutation testing criteria included in the NCCN Guidelines. On the basis of literature reports and expert consensus, the panel has recently revised both the list of criteria associated with this genetic syndrome as well as the combinations of criteria that establish which individuals are candidates for *PTEN* gene mutation testing (see Guidelines section on Cowden Syndrome Testing Criteria). Similar to earlier versions, criteria are grouped into 3 general categories. A patient is considered for *PTEN* gene mutation testing based on whether he/she meets certain criteria or combinations of criteria from these 3 categories. The first criteria category includes individuals meeting diagnostic criteria for Cowden

Printed by Ariel Smits on 10/14/2014 12:23:15 PM. For personal use only. Not approved for distribution. Copyright © 2014 National Comprehensive Cancer Network, Inc., All Rights Reserved.

syndrome[172]; or a personal history of BRRS, adult LDD, autism spectrum disorder with macrocephaly, or 2 or more biopsy proven trichilemmomas. Any individual presenting with one or more of these diagnoses warrants *PTEN* testing. Previously, some of the criteria from this group have sometimes been referred to as "pathognomonic" although it is unlikely that any of these conditions can stand alone as a definitive diagnostic criterion of Cowden syndrome. Another criterion which can be considered to be sufficient to warrant *PTEN* gene mutation testing is a family history which includes the presence of a known deleterious *PTEN* mutation.

The next category of criterion represents "major" features associated with Cowden syndrome.[143,146,172,174] The major criteria include the presence of breast cancer, macrocephaly (i.e., megalocephaly),[169] endometrial cancer, follicular thyroid cancer, multiple gastrointestinal hamartomas or ganglioneuromas, macular pigmentation of glans penis, and certain mucocutaneous lesions that are often observed in patients with Cowden syndrome (i.e., one biopsy proven trichilemmoma, multiple palmoplantar keratoses, multiple or extensive oral mucosal papillomatosis, multiple cutaneous facial papules). With respect to decisions related to the presence of mucocutaneous lesions, the panel did not consider the available literature to be adequate to accurately specify the number or extent of these lesions required for the condition to be defined as a major criterion for Cowden syndrome, and clinical judgment is needed when evaluating such lesions. An individual exhibiting 2 or more major criteria where one of these is macrocephaly meets the testing threshold. An individual with 3 or more major criteria (without macrocephaly) are also considered to meet the threshold for testing. In addition, individuals exhibiting 1 major criterion with 3 or more minor criteria (discussed below) also meet the testing threshold; if an individual exhibits 2 or more major criteria (e.g., breast cancer and follicular thyroid cancer) but does not have macrocephaly, then one of the major criteria may be included as one of the 3 minor criteria to meet the testing threshold.

The final category of criteria represents features with a "minor" association with Cowden syndrome.[143,146,172,174] These include autism spectrum disorder (without macrocephaly), colon cancer, esophageal glycogenic acanthosis (3 or more), lipomas, mental retardation, papillary or follicular variant of papillary thyroid cancer, thyroid structural lesions other than follicular thyroid cancer (e.g., adenoma, nodules, goiter), renal cell carcinoma, a single gastrointestinal hamartoma or ganglioneuroma, testicular lipomatosis, or vascular anomalies (including multiple intracranial developmental venous anomalies). The panel felt that evidence from the literature was insufficient to include fibrocystic breast disease, fibromas or uterine fibroids as part of the testing criteria. An individual would need to exhibit 4 or more minor criteria or as discussed above, 3 or more minor and one major criterion to meet testing criteria (see Guidelines section on Cowden Syndrome Testing Criteria and the Discussion section below on Risk Assessment, Counseling, and Management: Cowden Syndrome).

Lastly, an at-risk individual (first-degree relative of an affected individual) with one or more major criterion or 2 or more minor criteria, along with a relative diagnosed with Cowden syndrome or BBRS (for whom testing has not been performed), would also meet the threshold for *PTEN* testing. Individuals not meeting testing criteria should be followed according to recommendations tailored to his/her personal cancer history and family history.

Other Genetic Lesions Associated with Breast/Ovarian Cancer

Although the highly penetrant *BRCA1* and *BRCA2* gene mutations (together with genomic rearrangements in *BRCA* and other high-

Printed by Ariel Smits on 10/14/2014 12:23:15 PM. For personal use only. Not approved for distribution. Copyright © 2014 National Comprehensive Cancer Network, Inc., All Rights Reserved.

penetrance mutations such as *TP53* or *PTEN* mutations discussed above) are thought to account for a large proportion of familial breast cancers, other breast and/or ovarian cancer susceptibility genes have been identified. For instance, germline mutations in *CDH1* are associated with hereditary diffuse gastric cancer and lobular breast cancer, and studies have reported a cumulative lifetime risk of breast cancer of 39% to 52% among women who carry *CDH1* mutations.[15,175] Germline mutations in *STK11* is associated with Peutz-Jeghers syndrome, an autosomal dominant disorder characterized by gastrointestinal polyps, mucocutaneous pigmentation, and elevated risk of gastrointestinal cancers as well as breast or ovarian cancers. Further information on Peutz-Jeghers syndrome can be found in the NCCN Guidelines for Genetic/Familial High-Risk Assessment: Colorectal. Other breast and/or ovarian cancer susceptibility genes with lower or moderate penetrance have been identified in recent years, and include mutations in *CHEK2, PALB2, BRIP1, RAD51C*, among others.[176-179] In a study of breast cancer patients in the U.S. with strong family history of breast or ovarian cancer but who tested negative for *BRCA1* or *BRCA2* mutations, 12% were found to have large genomic rearrangements (deletion or duplication) in *BRCA*, and 5% had *CHEK2* mutations.[178] Deleterious *CHEK2* mutations have been reported to occur with a higher frequency in Northern and Eastern European countries compared with North America.[176,177,180,181] The cumulative lifetime risk of breast cancer in women with *CHEK2* mutations and familial breast cancer has been estimated to range from approximately 28% to 37%.[182,183] In the NCCN Guidelines for Genetic/Familial High-Risk Assessment: Breast and Ovarian, the panel specifically focuses on assessment of known high-penetrance mutations (i.e., *BRCA1, BRCA2, TP53 and PTEN*) and recommendations for genetic testing, counseling and management strategies in individuals with these mutations. A comprehensive review of other lower or moderate-penetrance susceptibility genes is beyond the scope of the Guidelines, but has been reviewed in a recent publication.[176]

With recent advances in genomic sequencing technologies, it is now possible to test for multiple breast and/or ovarian cancer susceptibility genes in parallel using multigene or multiplex panels.[176,179,184] Although multigene sequencing approaches may be resource efficient in terms of time and costs, several issues must be addressed before multiplex testing panels can be incorporated as part of standard clinical practice. At the present time, no consensus exists on recommendations for optimal management or surveillance approaches for carriers of lower or moderate penetrance genes, and no data are available to address cancer risk assessments in individuals who are found to carry multiple gene mutations with moderate penetrance.[184] Importantly, additional genetic counseling approaches must be vetted and developed in order to adequately address the limitations and implications associated with interpretation of multiplex testing results.

Initial Risk Assessment

For a patient concerned about or suspected of having a hereditary propensity to breast and/or ovarian cancer, an initial risk evaluation should be performed in order to determine if a formal risk assessment should be undertaken (see Guidelines section on Criteria for Further Genetic Risk Evaluation). The first step in this preliminary assessment is a broad and flexible evaluation of the personal and family history of the individual with respect to breast and/or ovarian cancer.[185,186] The magnitude of the risk increases with the number of affected relatives in the family, the closeness of the relationship, and is affected by the age at which the affected relative was diagnosed.[187,188] The younger the age at diagnosis, the more likely it is that a genetic component is present. When assessing a family history for a hereditary pattern, the equal

likelihood of paternal or maternal transmission of a gene that predisposes to breast cancer must also be kept in mind.

If an individual or a close family member of that individual meets any one of the criteria presented in the NCCN Guidelines (see Guidelines section on Criteria for Further Genetic Risk Evaluation), that individual may be at increased risk for breast and/or ovarian cancer, and a referral for genetic assessment is recommended. The maternal and paternal sides of the family should be considered independently for familial patterns of cancer.

For individuals potentially meeting established criteria for one or more of the hereditary cancer syndromes, genetic testing should be considered along with appropriate pre-test counseling. A genetic counselor and/or a medical geneticist should be involved in this process. Those not meeting criteria for testing who are still considered at increased risk of familial breast cancer are also likely to benefit from appropriate risk-reduction strategies (e.g., a change in the frequency of, or modalities used for, breast cancer screening).[5] The panel recommends that these individuals follow recommendations in the NCCN Guidelines for Breast Cancer Screening and Diagnosis.

Formal Risk Assessment and Genetic Counseling

Risk Assessment

Cancer genetic risk assessment and genetic counseling is a multi-step process of identifying and counseling individuals at risk for familial or hereditary cancer.

Cancer genetic risk assessment involves use of pedigree analysis with available risk assessment models to determine whether a family history is suggestive of sporadic, familial, or hereditary cancer. Risk assessment includes both an evaluation of an individual's absolute risk of breast and/or ovarian cancer as well as an estimation of the likelihood that the individual has a heritable genetic mutation in his/her family. Genetic risk assessment is a dynamic process and can change if additional relatives are diagnosed with cancer.

Statistical models based on personal and family history characteristics have been developed to estimate a person's interval and lifetime risks of developing breast cancer. For example, the Claus tables may be useful in providing breast cancer risk estimates for white women without a known cancer-associated gene mutation who have one or two first- or second-degree female relatives with breast cancer.[189] In addition, decision models developed to estimate the likelihood that a *BRCA1/2* mutation is present include BRCAPRO[190,191] and the Breast and Ovarian Analysis of Disease Incidence and Carrier Estimation Algorithm (BOADICEA)[190]; A lifetime risk of breast cancer of 20% to 25% or greater as assessed by models based largely on family history has been used in some guidelines to identify a woman as being at high risk of breast cancer. For example, this risk threshold was used in updates to the American Cancer Society (ACS) guidelines on breast screening which incorporates magnetic resonance imaging (MRI).[192,193]

First-degree relatives of individuals with a known deleterious gene mutation in *BRCA1/2*, *TP53* or *PTEN* genes are considered to have a 50% risk of carrying that mutation.

Evaluation of Patient's Needs and Concerns

The first step in evaluating a individual's risk for hereditary breast cancer is to assess her/his concerns and reasons for seeking counseling and to guarantee that her/his personal needs and priorities will be addressed in the counseling process. Several studies have documented a highly exaggerated perception of risk among women with a family history of breast cancer who seek cancer risk counseling.[194]

This is a situation that can interfere with the adoption of appropriate health behaviors. In addition, the patient's knowledge about the benefits, risks, and limitations of genetic testing should be assessed as well as the patient's goals. A positive, supportive interaction with the counseling team is an important determinant of ultimate satisfaction with the counseling process and of adherence to recommended health behaviors.

Detailed Family History

A detailed family history is the cornerstone of effective genetic counseling. An examination of family history involves development of an expanded pedigree collected beginning with the health of the proband (index case) and proceeding outward to include first-, second-, and third-degree relatives on both the maternal and paternal sides. Standardized pedigree nomenclature should be used.[195,196] Unaffected family members, both living and deceased, are also included, as their histories also provide information about the magnitude of genetic risk.

Information collected includes cancer diagnoses by primary site, age at diagnosis, bilaterality (when appropriate), and current age or age at death. Whenever possible, cancer diagnoses in the family are verified by obtaining medical records, pathology reports, or death certificates. This is particularly important in the case of a report of an "abdominal" cancer in a female relative—a situation in which cancers of the cervix, uterus, ovary, and/or colon is often confused. It is also important to know the ancestry/ethnicity of the individual.

Other medical conditions that may be associated with or predispose an individual to breast and/or ovarian cancer should also be noted. Family history data are then graphically represented on a pedigree that follows standard nomenclature to illustrate family relationships and disease information. Factors that limit the informativeness of the pedigree are small family size, a small number of individuals of the susceptible gender for sex-limited cancers, reduced penetrance, early deaths in family members (which precludes the possibility that they will develop adult diseases), prophylactic surgeries that remove an organ from subsequent risk of cancer (e.g., hysterectomy for uterine fibroids in which the ovaries are also removed), adoptions, and inaccurate or incomplete information on family members.[5,197]

A recent prospective registry study of 306 women diagnosed with breast cancer at < 50 years of age, who had no first- or second-degree relatives with breast or ovarian cancer, showed that those individuals with a limited family history (defined as fewer than 2 first- or second-degree female relatives or fewer than 2 female relatives surviving beyond age 45 years in either lineage) may have an underestimated probability of a *BRCA1/2* gene mutation based on models dependent on family history.[198]

Medical and Surgical History

The collection of a detailed medical and surgical history from the proband allows the counselor to estimate the contribution of other risk factors that may interact with or modify family history to determine the risk of breast cancer. A history of previous breast biopsies, especially those in which the pathology revealed atypical hyperplasia or lobular carcinoma in situ (LCIS), is associated with an increased risk of breast cancer.[199,200] Pathologic verification of these diagnoses is encouraged. History of salpingo-oophorectomy and potential exposure to carcinogens (e.g., radiation therapy) should also be included in the patient's assessment. When taking the medical history, the clinician should also be alert to the physical manifestations of Cowden syndrome, especially skin conditions (see below under Focused Physical Examination).

Reproductive variables are important determinants of risk for both breast and ovarian cancer, suggesting a significant contribution of hormones to the etiology of these cancers. This possible link is supported by the increased breast cancer risk seen among women who have had prolonged exposure to exogenous estrogens and progestins and the reduction in risk for ovarian cancer observed among women who report using oral contraceptives.[201-204]

Focused Physical Examination

A physical examination performed by a physician or nurse should be part of the risk assessment. Particular attention should be paid to organs/areas of the body known to be affected in individuals with specific hereditary breast and/or ovarian syndromes. For example, certain patterns of mucocutaneous manifestations are associated with Cowden syndrome, as discussed earlier; a focused physical examination for Cowden syndrome should include a comprehensive dermatologic examination (including oral mucosa), evaluation of head circumference (to determine presence of macrocephaly) and palpation of the thyroid (see section above on Cowden Syndrome).

Genetic Counseling

Genetic counseling is a critical component of the cancer risk assessment process. Counseling for hereditary breast and/or ovarian cancer uses a broad approach to place genetic risk in the context of other related risk factors, thereby customizing counseling to the experiences of the individual. The purpose of cancer genetic counseling is to educate individuals about the genetic, biological, and environmental factors related to the individual's cancer diagnosis and/or risk of disease to help them derive personal meaning from cancer genetic information, to and empower them to make educated, informed decisions about genetic testing, cancer screening, and cancer prevention. Individuals need to understand the relevant genetic, medical, and psychosocial information and be able to integrate this information before they can make an informed decision. The presentation of information is most effective when tailored to the age and education of the person undergoing counseling, and that individual's personal exposure to the disease, level of risk, and social environment.[7]

Pre-test counseling is an essential element of the genetic counseling process in the event that genetic testing for a gene mutation associated with a hereditary cancer syndrome is under consideration.[7] The foundation of pre-test genetic counseling is based on the principle of informed consent. Pre-test counseling should include a discussion of why the test is being offered and how test results may impact medical management, cancer risks associated with the gene mutation in question, the significance of possible test results (see section on Genetic Testing, below), the likelihood of a positive result, technical aspects and accuracy of the test, economic considerations, risks of genetic discrimination, psychosocial aspects, confidentiality issues, as well as other topics.[7] A discussion of confidentiality issues should include an explanation of the federal Genetic Information Nondiscrimination Act (GINA) enacted in 2008 which prohibits health insurers and employers from discrimination on the basis of genetic test results.[205]

Post-test counseling must also be performed and includes disclosure of results, a discussion of the significance of the results, an assessment of the impact of the results on the emotional state of the individual, a discussion of the impact of the results on the medical management of the individual, and how and where the patient will be followed. In addition, identification of a gene mutation associated with a hereditary predisposition to breast and/or ovarian cancer in an individual necessitates a discussion of possible inherited cancer risk to relatives

Printed by Ariel Smits on 10/14/2014 12:23:15 PM. For personal use only. Not approved for distribution. Copyright © 2014 National Comprehensive Cancer Network, Inc., All Rights Reserved.

and the importance of informing family members about test results.[7] It may also be appropriate to offer genetic testing to both parents of an individual who tests positive for one of these gene mutations (i.e., *BRCA1/2*, *PTEN*, *TP53*) when the lineage is in question.

Genetic Testing

The selection of appropriate candidates for genetic testing is based on the personal and familial characteristics that determine the individual's prior probability of being a mutation carrier, and on the psychosocial degree of readiness of the person to receive genetic test results. The potential benefits, limitations, and risks of genetic testing are also important considerations in the decision-making process. Many women feel that they are already doing everything they can to minimize their risk of developing breast cancer, and others fear the emotional toll of finding out that they are a mutation carrier, especially if they have children who would be at risk of inheriting the mutation. For those who choose not to proceed with testing, the counseling team tailors recommendations for primary and secondary prevention based on the individual's personal and family history.

In the statement on Genetic Testing for Cancer Susceptibility from the American Society of Clinical Oncology (ASCO) updated in 2003, genetic testing is recommended when there is: (i) a personal or family history suggesting genetic cancer susceptibility (ii) the test can be adequately interpreted and (iii) the results will aid in the diagnosis or influence the medical or surgical management of the patient or family members at hereditary risk of cancer.[206] These recommendations were reiterated in the latest 2010 ASCO update on Genetic and Genomic Testing for Cancer Susceptibility with respect to testing individuals for gene mutations known to cause hereditary breast and/or ovarian cancer(s).[207]

As part of pre-test counseling, the counselor reviews the distinctions between true-positive, true-negative, indeterminate (or uninformative), and inconclusive (or variants of unknown significance) test results (see Table 2), as well as the technical limitations of the testing process. A clear distinction is made between the probability of being a mutation carrier and the probability of developing cancer. The probabilistic nature of genetic test results and the potential implications for other family members must also be discussed. Individuals who have received allogeneic hematopoietic stem cell transplantation (HSCT) should not have molecular genetic testing performed on blood samples, as these blood cells would represent donor-derived DNA. In such cases, DNA of the individual being tested should be extracted from a fibroblast culture, if available. If this is not possible, buccal cells may be considered as an alternative source for DNA; however, a study has reported that over time, buccal epithelial cells are replaced by donor-derived cells in allogeneic HSCT recipients.[208,209] Therefore, genetic testing using buccal swab samples may be limited given this known risk of donor DNA contamination.

The genetic testing strategy is greatly facilitated when a deleterious mutation has already been identified in another family member. In that case, the genetic testing laboratory can limit the search for mutations in additional family members to the same location in the gene. In most cases, an individual testing negative for a known familial gene mutation predisposing to breast cancer can be followed with routine breast screening. Individuals who meet testing criteria but do not undergo gene testing should be followed as if a gene mutation (i.e., *BRCA*, *PTEN*, or *TP53* gene mutation) is present, if they have a close family member who is a known carrier of the deleterious mutation.

For the majority of families in whom mutation status is unknown, it is best to consider testing an affected family member first, especially a

Printed by Ariel Smits on 10/14/2014 12:23:15 PM. For personal use only. Not approved for distribution. Copyright © 2014 National Comprehensive Cancer Network, Inc., All Rights Reserved.

family member with early-onset disease, bilateral disease, or multiple primaries, because that individual has the highest likelihood for a positive test result. Unless the affected individual is a member of an ethnic group for which particular founder gene mutations are known, comprehensive genetic testing (i.e., full sequencing of the genes and detection of large gene rearrangements) should be performed.

For individuals with family histories consistent with a pattern of hereditary breast and/or ovarian cancer on both the maternal and paternal sides, the possibility of a second deleterious mutation in the family should be considered, and full sequencing may be indicated.

In the situation of an unaffected individual with a family history only, the testing of the unaffected individual (or of unaffected family members) should only be considered when no affected family member is available for testing. In such cases, the unaffected individual or unaffected close relative with the highest likelihood of testing positive for the mutation should be tested. A negative test result in such cases, however, is considered indeterminate (see Table 2) and does not provide the same level of information as when there is a known deleterious mutation in the family. Thus, one should be mindful that when testing unaffected individuals (in the absence of having tested affected family members), significant limitations may exist in interpreting the test results.

In the case of hereditary breast/ovarian cancer (i.e., *BRCA* mutation), if no family member with breast or ovarian cancer is living, consideration can be given to testing first- or second-degree family members affected with cancers thought to be related to the deleterious mutation in question (e.g., prostate or pancreatic cancer).

Another counseling dilemma is posed by the finding of a variant or mutation of unknown significance (see Table 2), a mutation that may actually represent a benign polymorphism unrelated to an increased breast cancer risk or may indicate an increased breast cancer risk. The individual must be counseled in such a situation, because additional information about that specific mutation will be needed before its significance can be understood. These patients should be considered for referral to research studies that aim to define the functional impact of the gene variant.

Finally, it is important to mention that certain large genomic rearrangements are not detectable by a primary sequencing assay, thereby necessitating supplementary testing, in some cases.[210-213] For example, there are tests that detect rare, large cancer-associated rearrangements of DNA in the *BRCA1* and *BRCA2* genes that are otherwise not detected by direct sequencing of the *BRCA1/2* genes. Therefore, the NCCN Guidelines panel emphasizes the need for comprehensive testing, which encompasses full *BRCA1/2* sequencing and detection of large gene rearrangements.

Risk Assessment, Counseling, and Management: Hereditary Breast/Ovarian Cancer Syndrome

Detailed in the NCCN Guidelines is a set of specific risk assessment criteria which form part of the decision-making process in evaluating whether an individual suspected of being carriers of a *BRCA1/2* mutation should be considered for genetic testing (see Guidelines section on Hereditary Breast and/or Ovarian Cancer Syndrome Testing Criteria). Following risk assessment and counseling, genetic testing should be considered for individuals for whom hereditary breast/ovarian cancer syndrome testing criteria are met. Testing is generally not recommended in children under the age of 18 years.

Individuals from a family with a known deleterious *BRCA1* or *BRCA2* mutation should be tested for the specific familial mutation. For

Printed by Ariel Smits on 10/14/2014 12:23:15 PM. For personal use only. Not approved for distribution. Copyright © 2014 National Comprehensive Cancer Network, Inc., All Rights Reserved.

individuals from a family without a known *BRCA1* or *BRCA2* mutation (and who meet testing criteria), genetic testing should be comprehensive, including full sequencing of *BRCA1* and *BRCA2*, and testing for large genomic rearrangements. Individuals from a family with a known deleterious *BRCA1/BRCA2* mutation who test positive for the familial mutation, or for whom *BRCA1/BRCA2* mutation testing is not performed, should follow the screening recommendations outlined under the Guidelines section on HBOC Syndrome Management (and discussed below).

Individuals of Ashkenazi Jewish descent with no known familial *BRCA1/BRCA2* mutations should first be tested for the three known founder mutations; if the tests are negative for founder mutations, and if the individual's ancestry also included non-Ashkenazi ethnicity (or if other *BRCA1/BRCA2* testing criteria are met), comprehensive genetic testing should be considered. Comprehensive genetic testing (i.e., full sequence of *BRCA1/2* and testing for large gene rearrangements) is also recommended for individuals from other ethnic groups who meet testing criteria. In cases where testing of unaffected individuals are being considered, an affected family member with the highest likelihood of carrying the *BRCA1/BRCA2* mutation should be tested first. If more than one family member is affected, members with the following factors should be considered for testing first: youngest age at diagnosis; having bilateral disease or multiple primaries; or having ovarian cancer. If no living family member with breast or ovarian cancer exists, consider testing first- or second-degree family members affected with cancer thought to be related to deleterious *BRCA1/BRCA2* mutations (e.g., prostate cancer, pancreatic cancer, melanoma). As previously discussed, testing of unaffected individuals should only be considered when an appropriate affected family member is not available for testing; importantly, the significant limitations of interpreting testing results for an unaffected individual should be discussed prior to testing. Individuals from a family with no known deleterious *BRCA1/BRCA2* mutation who test positive for a mutation should follow the screening recommendations outlined under the Guidelines section on HBOC Syndrome Management (and discussed below). Those who test negative for *BRCA1/BRCA2* mutations can be considered for risk assessment/genetic testing for other hereditary breast/ovarian cancer syndromes such as Li-Fraumeni syndrome or Cowden syndrome, if testing criteria for these syndromes are met. For individuals who have not been tested or for those in whom variants of unknown significance are found (uninformative testing results), participation in a research program or individualized recommendations based on personal history and family history should be offered.

Counseling issues specific for both female and male carriers of a *BRCA1/2* mutation include the increased incidence of pancreatic cancer and melanoma. In addition, the risks to family members of individuals with a known *BRCA1/2* gene mutation (see Discussion sections on Risk Assessment and Genetic Testing) should also be discussed as well as the importance of genetic counseling for these individuals. Counseling issues pertaining specifically to male breast cancer have also been described, and include an increased risk of prostate cancer in male carriers of a *BRCA1/2* mutation.[214-216]

Recommendations for the medical management of hereditary breast/ovarian cancer syndrome are based on an appreciation of the early onset of disease, the increased risk of ovarian cancer, and the risk for male breast cancer in *BRCA1/2* carriers. An individual with a known deleterious *BRCA1/2* mutation in a close family member who does not undergo gene testing should be followed according to the same screening/management guidelines as a carrier of a *BRCA1/2* mutation. An individual from a family with a known deleterious *BRCA1/2* mutation

who tests negative for the familial mutation should be followed according to the recommendations in the NCCN Guidelines for Breast Cancer Screening and Diagnosis. In situations where an individual (or family member) from a family with no known familial *BRCA1/2* mutations undergoes genetic testing, and no mutation is found, testing for other hereditary breast syndromes should be considered if testing criteria are met (see sections on Li-Fraumeni Syndrome Testing Criteria and Cowden Syndrome Testing Criteria).

Screening Recommendations

The emphasis on initiating screening considerably earlier than standard recommendations is a reflection of the early age of onset seen in hereditary breast/ovarian cancer.[217] For a woman who is a carrier of a *BRCA1/2* mutation, training in breast awareness with regular monthly practice should begin at age 18 years, and semiannual clinical breast examinations should begin at age 25 years. The woman should have annual mammograms and breast MRI screening (to be performed on day 7-15 of menstrual cycle for premenopausal women) beginning at age 25 years or on an individualized timetable based on the earliest age of cancer onset in family members.[192,217-220]

Mammography has served as the standard screening modality for detection of breast cancer during the last few decades. False-negative mammography results have been correlated with factors such as presence of *BRCA1/2* mutation and high breast tissue density,[221-224] both of which may occur more frequently among younger women. Rapidly growing or aggressive breast tumors—also more common among younger women—have also been associated with decreased sensitivity of mammographic screening methods.[221,225] Prospective studies on comparative surveillance modalities in women at high risk for familial breast cancer (i.e., confirmed *BRCA1/BRCA2* mutation or suspected mutation based on family history) have consistently reported higher sensitivity of MRI screening (77–94%) compared with mammography (33–59%) in detecting breast cancers; false-positive rates were higher with MRI in some reports, resulting in a slightly lower or similar specificity with MRI screening (81–98%) compared with mammography (92–100%).[217-219,226-228] The sensitivity with ultrasound screening (33–65%) appeared similar to that of mammography in this high-risk population.[217,226-228] In a recent prospective screening trial (conducted from 1997–2009) that evaluated the performance of annual MRI and mammography in women (age 25–65 years; N=496) with confirmed *BRCA1/BRCA2* mutation, sensitivity with MRI was significantly higher compared with mammography during the entire study period (86% vs. 19%; $P<0.0001$).[229] Sensitivity with MRI was higher during the early years (1997–2002; 74% vs. 35%) as well as the later years of the study (2003–2009; 94% vs. 9%). Factors such as age, mutation type or invasiveness of the tumor did not significantly influence the relative sensitivity of the 2 screening modalities. Importantly, the large majority (97%) of cancers detected by MRI screening were early stage tumors.[229] Among previously unaffected women diagnosed with invasive breast cancer during the study (n=28), 1 patient had died due to the cancer and 3 additional patients died due to other causes; the annual breast cancer-specific mortality rate was 0.5%. At a median follow up of 8 years from diagnosis, none of the surviving patients (n=24) has developed distant recurrence.[229] All of the studies discussed above evaluated a screening strategy that was conducted on an annual basis, and many of the studies included individuals without confirmed *BRCA1/BRCA2* mutation status. A recent retrospective study evaluated a different screening interval, using alternating mammography and MRI screening every 6 months in women with confirmed *BRCA1/BRCA2* mutation (N=73).[230] After a median follow up of 2 years, 13 breast cancers were detected among 11 women; 12 of the tumors were

Printed by Ariel Smits on 10/14/2014 12:23:15 PM. For personal use only. Not approved for distribution. Copyright © 2014 National Comprehensive Cancer Network, Inc., All Rights Reserved.

detected by MRI screening but not by mammography obtained 6 months earlier. The sensitivity and specificity with MRI screening was 92% and 87%, respectively.[230]

The optimal surveillance approach in women at high risk for familial breast cancer remains uncertain, especially for women between the ages of 25 and 30 years. Although earlier studies have reported an unlikely association between radiation exposure from mammography and increased risk of breast cancer in carriers of *BRCA1/BRCA2* mutation,[231,232], a recent report from a large cohort study suggested an increased risk in women exposed to radiation at a young age.[233] A retrospective cohort study (from the GENE-RAD-RISK study) showed that exposure to diagnostic radiation (including mammography) prior to age 30 years was associated with increased risk of breast cancer in women with *BRCA1/BRCA2* mutation (N=1993).[233] Thus, one of the potential benefits of incorporating MRI modalities into surveillance strategies may include minimizing the radiation risks associated with mammography, in addition to the higher sensitivity of MRI screening in detecting tumors. The use of MRI, however, may potentially be associated with higher false-positive results and higher costs relative to mammography. The appropriate imaging modalities and surveillance intervals are still under investigation. In a recent report based on a computer simulation model that evaluated different annual screening strategies in *BRCA1/BRCA2* mutation carriers, a screening approach that included annual MRI starting at age 25 years combined with alternating digital mammography/MRI starting at age 30 years was shown to be the most effective strategy when radiation risks, life expectancy and false-positive rates were considered.[234] Future prospective trials are needed to evaluate the different surveillance strategies in individuals at high risk for familial breast cancer. Annual MRI as an adjunct to screening mammogram and clinical breast examination for women aged 25 years or older with a genetic predisposition for breast cancer is supported by guidelines from the ACS.[192]

Post-test counseling in women with confirmed *BRCA1/BRCA2* mutation (or highly suspected of having the mutation based on presence of known deleterious mutation in the family) includes discussion of risk-reducing mastectomy and/or salpingo-oophorectomy. Counseling for these risk-reducing surgeries may include discussion of extent of cancer risk reduction/protection, risks associated with surgeries, reconstructive options, management of menopausal symptoms, and discussion of reproductive desires. It is important to address the psychosocial and quality-of-life aspects of undergoing risk-reducing surgical procedures.

For women who have not elected ovarian cancer risk-reducing surgery, concurrent transvaginal ultrasound and CA-125 determination should be considered every 6 months, starting at age 30 years or 5 to 10 years earlier than the earliest age of first diagnosis of ovarian cancer in the family, for the early detection of ovarian cancer (see Guidelines section on HBOC Syndrome Management). Although there are retrospective data indicating that annual ovarian screening using transvaginal ultrasound and measurement of serum CA-125 levels is neither an effective strategy for the early detection of ovarian tumors nor a reasonable substitute for a bilateral risk-reduction salpingo-oophorectomy,[235,236] the data are limited regarding the effectiveness of these screening interventions when used every 6 months. Investigational imaging and screening studies may be considered for this population.

Men testing positive for a *BRCA1/2* mutation should have a semiannual clinical breast examination, and undergo training in breast self-examination with regular monthly practice starting at age 35 years.

Printed by Ariel Smits on 10/14/2014 12:23:15 PM. For personal use only. Not approved for distribution. Copyright © 2014 National Comprehensive Cancer Network, Inc., All Rights Reserved.

Baseline mammography should be considered at age 40 years, followed by annual screening with mammography for those men with gynecomastia or parenchymal/glandular breast density on baseline study. In addition, screening for prostate cancer starting at age 40 years should be considered. Involvement in population screening guidelines for prostate cancer is recommended. For both men and women testing positive for a *BRCA1/2* mutation, a full body skin exam for melanoma screening and investigational protocols for pancreatic cancer screening should be considered. Although no specific screening guidelines exist for these tumor types, individualized screening approaches may be provided according to personal or family history of cancer.

Risk Reduction Surgery

Bilateral Total Mastectomy

Retrospective analyses with median follow-up periods of 13-14 years have indicated that bilateral risk reduction mastectomy (RRM) decreased the risk of developing breast cancer by at least 90% in moderate- and high-risk women and in known *BRCA1/2* mutation carriers.[237,238] Results from smaller prospective studies with shorter follow-up periods have provided support for concluding that RRM provides a high degree of protection against breast cancer in women with a *BRCA1/2* mutation.[239,240]

The NCCN Guidelines panel supports discussion of the option of RRM for women on a case-by-case basis. Counseling regarding the degree of protection offered by such surgery and the degree of cancer risk should be provided.

It is important that the potential psychosocial effects of RRM are addressed, although these effects have not been well studied.[241] Multidisciplinary consultations are recommended prior to surgery and should include the discussions of the risks and benefits of surgery, and surgical breast reconstruction options. Immediate breast reconstruction is an option for many women following RRM, and early consultation with a reconstructive surgeon is recommended for those considering either immediate or delayed breast reconstruction.[242]

Bilateral Salpingo-oophorectomy

Women with a *BRCA1/2* mutation are at increased risk for both breast and ovarian cancers (including fallopian tube cancer and primary peritoneal cancer).[243,244] Although the risk of ovarian cancer is generally considered to be lower than the risk of breast cancer in a *BRCA1/2* mutation carrier,[36,37,245] the absence of reliable methods of early detection and the poor prognosis associated with advanced ovarian cancer have lent support for the performance of bilateral risk reduction salpingo-oophorectomy (RRSO) after completion of childbearing in these women. In the studies of Rebbeck et al, the mean age at diagnosis of ovarian cancer was 50.8 years for *BRCA1/2* carriers.[246]

The effectiveness of RRSO in reducing the risk of ovarian cancer in carriers of a *BRCA1/2* mutation has been demonstrated in a number of studies. For example, results of a meta-analysis involving 10 studies of *BRCA1/2* mutation carriers showed an approximately 80% reduction in the risk of ovarian or fallopian cancer following RRSO.[247] In a large prospective study of women who carried deleterious *BRCA1* or *BRCA2* mutations (N=1079), RRSO significantly reduced the risk of *BRCA1*-associated gynecological tumors (including ovarian, fallopian tube or primary peritoneal cancers) by 85% compared with observation, during a 3-year follow-up period (hazard ratio=0.15; 95% CI, 0.04-0.56; *P*=0.005).[248] However, a 1%-4.3% residual risk of a primary peritoneal carcinoma has been reported in some studies.[99,246,247,249-251]

RRSO is also reported to reduce the risk of breast cancer in carriers of a *BRCA1/2* mutation by approximately 50%.[246,247,251,252] In the case-

Printed by Ariel Smits on 10/14/2014 12:23:15 PM. For personal use only. Not approved for distribution. Copyright © 2014 National Comprehensive Cancer Network, Inc., All Rights Reserved.

control international study by Eisen et al., a 56% (odds ratio=0.44; 95% CI, 0.29-0.66; *P*<0.001) and a 43% (odds ratio=0.57; 95% CI, 0.28-1.15; *P*=0.11) breast cancer risk reduction (adjusted for oral contraceptive use and parity) was reported following RRSO in carriers of a *BRCA1* and a *BRCA2* mutation, respectively.[252] Hazard ratios of 0.47 (95% CI, 0.29-0.77)[246] and 0.30 (95% CI, 0.11-0.84; *P*=0.022)[250] were reported in two other studies comparing breast cancer risk in women with a *BRCA1/2* mutation who had undergone RRSO with carriers of these mutations who opted for surveillance only. These studies are further supported by a recent meta-analysis which found similar reductions in breast cancer risk of approximately 50% for *BRCA1* and *BRCA2* mutation carriers following RRSO,[247] although results of a prospective cohort study suggest that RRSO may be associated with a greater reduction in breast cancer risk for *BRCA2* mutation carriers compared with *BRCA1* mutation carriers.[248]

Reductions in breast cancer risk for carriers of a *BRCA1/2* mutation undergoing RRSO may be associated with decreased hormonal exposure following surgical removal of the ovaries. Greater reductions in breast cancer risk were observed in women with a *BRCA1* mutation who had a RRSO at age 40 years or younger (odds ratio=0.36, 95% CI, 0.20-0.64) relative to *BRCA1* carriers aged 41-50 years who had this procedure (odds ratio=0.50, 95% CI, 0.27-0.92).[252] A nonsignificant reduction in breast cancer risk was found for women aged 51 or older although only a small number of women were included in this group.[252] However, results from Rebbeck et al also suggest that RRSO after age 50 is not associated with a substantial decrease in breast cancer risk.[251] Due to the limited data, an optimal age for RRSO is difficult to specify.

The NCCN Guidelines panel recommends RRSO for women with a known *BRCA1/2* mutation, ideally between ages 35 and 40 years and upon completion of child bearing or at an individualized age based on earliest age of ovarian cancer diagnosed in the family. Peritoneal washings should be performed at surgery, and pathologic assessment should include fine sectioning of the ovaries and fallopian tubes.[100,101] The protocol published by the College of American Pathologists (2009) can be consulted for details on specimen evaluation.[253]

Other topics which should be addressed with respect to RRSO include the increased risk of osteoporosis and cardiovascular disease associated with premature menopause, as well as the potential effects of possible cognitive changes, accelerated bone loss, and vasomotor symptoms on quality of life.

It has been reported that short-term hormone replacement therapy (HRT) in women undergoing RRSO does not negate the reduction in breast cancer risk associated with the surgery.[254] In addition, results of a recent case-control study of *BRCA1* mutation carriers showed no association between use of HRT and increased breast cancer risk in postmenopausal *BRCA1* mutation carriers.[255] However, caution should be used when considering use of HRT in mutation carriers following RRSO, given the limitations inherent in nonrandomized studies.[256,257]

Chemoprevention

The use of selective estrogen receptor modulators (i.e., tamoxifen, raloxifene) has been proven to reduce the risk of invasive breast cancer in postmenopausal women considered at high risk for developing breast cancer.[258-263] However, only limited data are available on the specific use of these agents in patients with *BRCA* mutations. As previously discussed, patients with *BRCA* mutations who are diagnosed with breast cancer have elevated risks for developing contralateral breast tumors. In one of the largest prospective series of *BRCA* mutation carriers evaluated, the mean cumulative lifetime risks for contralateral breast cancer were estimated to be 83% for *BRCA1* carriers and 62%

Printed by Ariel Smits on 10/14/2014 12:23:15 PM. For personal use only. Not approved for distribution. Copyright © 2014 National Comprehensive Cancer Network, Inc., All Rights Reserved.

for *BRCA2* carriers.[41] Patients with *BRCA* mutations who have intact contralateral breast tissue (and who do not undergo oophorectomy or receive chemoprevention) have an estimated 40% risk of contralateral breast cancer at 10 years.[264] Case control studies from the Hereditary Breast Cancer Clinical Study Group reported that the use of tamoxifen protected against contralateral breast cancer with an odds ratio of 0.38 (95% CI, 0.19–0.74) to 0.50 (95% CI, 0.30–0.85) among *BRCA1* mutation carriers and 0.42 (95% CI, 0.17–1.02) to 0.63 (95% CI, 0.20–1.50) among *BRCA2* carriers.[265,266] This translates to an approximately 45% to 60% reduction in risk of contralateral tumors among *BRCA* mutation carriers with breast cancer. The data were not consistent with regards to the protective effects of tamoxifen in the subset of *BRCA* mutation carriers who also underwent oophorectomy. In addition, no data were available on the estrogen receptor status of the tumors. An evaluation of the subset of healthy individuals with a *BRCA1/2* mutation in the Breast Cancer Prevent Trial revealed that breast cancer risk was reduced by 62% in those with a *BRCA2* mutation receiving tamoxifen relative to placebo (risk ratio=0.38; 95% CI, 0.06–1.56).[267] However, tamoxifen use was not associated with a reduction in breast cancer risk in those with a *BRCA1* mutation.[267] These findings may be related to the greater likelihood for development of estrogen receptor-negative tumors in *BRCA1* mutation carriers relative to *BRCA2* mutation carriers. However, this analysis was limited by the very small number of individuals with a *BRCA1/2* mutation (n=19; 7% of study population). Recently, common single-nucleotide polymorphisms were identified in genes (*ZNF423* and *CTSO* genes) that are involved in estrogen-dependent regulation of *BRCA1* expression.[268] These gene variants were associated with alterations in breast cancer risk during treatment with selective estrogen receptor modulators, and may eventually pave the way for predicting the likelihood of benefit with these chemopreventive approaches in individual patients.

With respect to the evidence regarding the effect of oral contraceptives on cancer risks in women with known *BRCA1/2* gene mutations, case-control studies have demonstrated that oral contraceptives reduced the risk of ovarian cancer by 45%-50% in *BRCA1* mutation carriers and by 60% in *BRCA2* mutation carriers[269,270]; moreover, risks appeared to decrease with longer duration of oral contraceptive use.[270] In a recent meta-analysis conducted in a large number of *BRCA1/2* mutation carriers with (n=1503) and without (n=6315) ovarian cancer, use of oral contraceptives significantly reduced the risk of ovarian cancer by approximately 50% for both the *BRCA1* mutation carriers (summary relative risk [SRR]=0.51; 95% CI, 0.40–0.65) and *BRCA2* mutation carriers (SRR=0.52; 95% CI, 0.31–0.87).[271]

Studies on the effect of oral contraceptive use on breast cancer risk among *BRCA1/2* mutation carriers have reported conflicting data. In one case-control study, use of oral contraceptives was associated with a modest but statistically significant increase in breast cancer risk among *BRCA1* mutation carriers (odds ratio=1.20; 95% CI, 1.02-1.40), but not among *BRCA2* mutation carriers.[272] Among *BRCA1* mutation carriers, breast cancer risks with oral contraceptives were significantly associated with ≥5 years of oral contraceptive use (odds ratio=1.33; 95% CI,1.11–1.60), breast cancer diagnosed before age 40 (odds ratio=1.38; 95% CI,1.11–1.72), and use of oral contraceptives before 1975 (odds ratio=1.42; 95% CI, 1.17–1.75).[272] In another case-control study, oral contraceptive used for at least 1 year was not significantly associated with breast cancer risks in either *BRCA1* or *BRCA2* mutation carriers.[273] However, among *BRCA2* mutation carriers, use of oral contraceptives for at least 5 years was associated with a significantly increased risk for breast cancer (odds ratio=2.06; 95% CI, 1.08-3.94); results were similar when only the cases with oral contraceptives use on or after 1975 were considered.[273] Other case-control studies have

Printed by Ariel Smits on 10/14/2014 12:23:15 PM. For personal use only. Not approved for distribution. Copyright © 2014 National Comprehensive Cancer Network, Inc., All Rights Reserved.

reported no significant associations with oral contraceptives use (especially with the use of low-dose formulations after 1975) and risks for breast cancer in *BRCA1/2* mutation carriers.[274,275] In fact, in one study, the use of low-dose oral contraceptives for at least 1 year was associated with significantly decreased risks for breast cancer among *BRCA1* mutation carriers (odds ratio=0.22; 95% CI, 0.10–0.49; $P<0.001$), though not for *BRCA2* mutation carriers.[275] Differences in the study design employed by these case-control studies make it difficult to compare outcomes between studies, and likely accounts for the conflicting results. The study design might have differed with regards to factors such as the criteria for defining the 'control' population for the study (e.g., non-*BRCA1/2* mutation carriers vs. mutation carriers without a cancer diagnosis), consideration of family history of breast or ovarian cancer, baseline demographics of the population studied (e.g., nationality, ethnicity, geographic region, age groups), age of onset of breast cancer, and formulations or duration of oral contraceptives used. In a meta-analysis conducted in a large number of *BRCA1/2* mutation carriers with (n=2855) and without (n=2954) breast cancer, use of oral contraceptives was not found to be significantly associated with breast cancer risks in either the *BRCA1* mutation carriers (SRR=1.09; 95% CI, 0.77–1.54) or the *BRCA2* mutation carriers (SRR=1.15; 95% CI, 0.61–2.18).[271]

Reproductive Options

The outcomes of genetic testing can have profound impact on family planning decisions for individuals of reproductive age who are found to be carriers of *BRCA1/2* mutations. For example, in cases where both partners carry a *BRCA2* mutation, there may be a high risk for the offspring to develop a rare Fanconi anemia/brain tumor phenotype (recessive disorder).[215] Counseling for reproductive options such as prenatal diagnosis, preimplantation genetic diagnosis (PGD) and assisted reproduction may therefore be warranted for couples expressing concern over the *BRCA* mutation carrier status of their future offspring. Such counseling should include a comprehensive discussion of the potential risks, benefits, and limitations of reproductive options.

Prenatal diagnosis involves postimplantation genetic analysis of an early embryo, utilizing chorionic villi or amniotic fluid cell samples; genetic testing is typically conducted between week 12 and week 16 of gestation, and testing results may potentially lead to a couple's decision to terminate pregnancy.[216,276] During the past 2 decades, PGD has emerged as an alternative method of genetic testing in early embryos. PGD involves the testing of 1 or 2 cells from embryos in very early stages of development (i.e., 6 to 8 cells) after in vitro fertilization (IVF). This procedure allows for the selection of unaffected embryos to be transferred to the uterus,[216,276] and may, therefore, offer the advantage of avoiding potential termination of pregnancy. However, procedures such as PGD are not without limitations as it may still require a confirmatory prenatal diagnosis depending upon a couple's medical needs or requests. Moreover, the PGD process requires the use of IVF regardless of the fertility status of the couple (i.e., also applies to couples without infertility issues), and IVF may not always lead to a successful pregnancy. Lastly, the technology or expertise may not be readily available in a couple's geographical location. Various factors, both medical and personal, must be weighed in the decision to utilize prenatal diagnosis or PGD. Medical considerations may include factors such as the age of onset of the hereditary cancer, penetrance, severity or associated morbidity and mortality of the cancer, and availability of effective cancer risk reduction methods or effective treatments.[216,276] Although the use of prenatal diagnosis or PGD is relatively well established for severe hereditary disorders with very high penetrance,

Printed by Ariel Smits on 10/14/2014 12:23:15 PM. For personal use only. Not approved for distribution. Copyright © 2014 National Comprehensive Cancer Network, Inc., All Rights Reserved.

their use in conditions associated with lower penetrance (e.g., hereditary breast or ovarian cancer syndrome) remains somewhat controversial from both an ethical and regulatory standpoint. Personal considerations for the decision to utilize prenatal diagnosis or PGD may include individual ethical beliefs, value systems, cultural and religious beliefs, as well as social and economic factors. Based on results from surveys administered to women at high risk for hereditary breast or ovarian cancer, 50% to 75% of respondents felt that PGD was an acceptable option for high-risk individuals,[277,278] yet only about 14% to 33% would consider undergoing PGD themselves.[277,279] A survey in high-risk men (N=228; carriers of *BRCA* mutation; or having a partner or first-degree relative with *BRCA* mutation) showed that 80% of these men were unaware of PGD; after being informed of the definition of PGD, 34% indicated that they would consider the option of using PGD.[280] Importantly, these surveys suggested that the majority of high-risk women and men have little or no knowledge of PGD,[278,280,281] highlighting the need for better awareness and education regarding potential reproductive options. Successful births have been reported with the use of PGD and IVF in *BRCA1/2* mutation carriers,[282,283] but data in the published literature are still very limited. In addition, data pertaining to long-term safety or outcomes of PDG and assisted reproduction in *BRCA* mutation carriers are not yet available.

Risk Assessment, Counseling, and Management: Li-Fraumeni Syndrome

The approach to families with other hereditary breast cancer syndromes, such as LFS, reflects that of hereditary breast/ovarian cancer in many ways. However, there are some syndrome-specific differences with regard to assessment and management. In the case of LFS, there are multiple associated cancers, both pediatric and adult, that should be reflected in the expanded pedigree (see Guidelines section on Li-Fraumeni Syndrome Testing Criteria). Cancers associated with LFS include but are not limited to premenopausal breast cancer, bone and soft tissue sarcomas, acute leukemia, brain tumor, adrenocortical carcinoma, unusually early onset of other adenocarcinomas, or other childhood cancers.[113,127] Verification of these sometimes very rare cancers is particularly important.

Following risk assessment and counseling, genetic testing should be considered in individuals for whom testing criteria are met. This recommendation is category 2A for adults and 2B for children. The NCCN Guidelines panel also suggests consideration of *TP53* mutation testing in those with early onset breast cancer (≤35 years of age) for whom *BRCA1/2* testing result is negative, especially if there is a family history of LFS related cancers. The NCCN Guidelines panel recommends comprehensive testing, which should include full sequencing and analysis of gene deletion/duplication. In the absence of additional family history, early breast cancer alone is associated with a low likelihood of mutation identification. Individuals who have tested positive for a *TP53* mutation may have greater distress than anticipated, so provisions for supportive interventions should be provided. An individual with a known deleterious *TP53* mutation in a close family member who does not undergo testing should be followed according to the same recommendations as a carrier of a *TP53* mutation (see Guidelines section on Li-Fraumeni Syndrome Management). In situations where an individual (or family member) from a family with no known familial *TP53* mutation undergoes genetic testing, and no mutation is found, testing for other hereditary breast syndromes should be considered if testing criteria are met (see sections on Hereditary Breast and/or Ovarian Cancer Syndrome Testing Criteria and Cowden Syndrome Testing Criteria). As previously discussed in the *BRCA1/BRCA2* testing section above, testing of unaffected individuals

Printed by Ariel Smits on 10/14/2014 12:23:15 PM. For personal use only. Not approved for distribution. Copyright © 2014 National Comprehensive Cancer Network, Inc., All Rights Reserved.

should only be considered when an appropriate affected family member is not available for testing; importantly, the significant limitations of interpreting testing results for an unaffected individual should be discussed prior to testing.

Management of LFS should address the limitations of screening for the many cancers associated with this syndrome. For those at risk for breast cancer, training and education in breast self-examination should start at age 18 years, with the patient performing regular self-examination on a monthly basis. For members of families with LFS, it is recommended that breast cancer surveillance by clinical breast examination, every 6 to 12 months, begin between the ages of 20 and 25 years (or 5 to 10 years before the earliest known breast cancer in the family, whichever is earlier) because of the very early age of breast cancer onset seen in these families. Annual mammograms and breast MRI screening should begin at ages 20 to 25 years or be individualized, based on earliest age of onset in the family. For relatively young patients (age 20 to 30 years), only an annual breast MRI screening may be considered (given the theoretical risks of radiation exposure with mammography in these patients) based on the physician's discretion. Although there are no data regarding risk reduction surgery in women with LFS, options for risk reducing mastectomy should be discussed on a case-by-case basis (see Discussion section on Bilateral Total Mastectomy for HBOC). Counseling for risk-reducing surgeries may include discussion of extent of cancer risk reduction/protection, risks associated with surgeries, and reconstructive options. It is also important to address the psychosocial and quality-of-life aspects of undergoing risk-reducing surgical procedures.

Many of the other cancers associated with germline mutations in *TP53* do not lend themselves to early detection. Thus, additional recommendations are general and include annual comprehensive physical examinations starting at age 20 to 25 years among family members who have survived one cancer when there is a high index of suspicion for second malignancies (Guidelines section on Li-Fraumeni Syndrome Management). Clinicians should address screening limitations for other cancers associated with LFS. The option to participate in clinical trials evaluating novel screening approaches using technologies such as whole-body MRI, abdominal ultrasound and brain MRI should also be discussed if such trials are available. Colonoscopy should be considered every 2 to 5 years, starting at no later than 25 years. Education regarding signs and symptoms of cancer is important. Patients should be advised about the risk to relatives, and genetic counseling for relatives is recommended. Annual physical examination is recommended for cancer survivors with a high index of suspicion for rare cancers and second malignancies. Pediatricians should be made aware of the risk of childhood cancers in affected families. For couples expressing the desire that their offspring not carry a familial *TP53* mutation, options for prenatal diagnosis should be discussed (for discussion on known risks, limitations, and benefits of such technologies, see section above on Reproductive Options under Risk Assessment, Counseling, and Management: Hereditary Breast and/or Ovarian Cancer Syndrome).

A recent prospective observational study incorporated a clinical surveillance protocol for asymptomatic *TP53* mutation carriers from eight families affected by LFS.[284] In this study, 18 of the 33 asymptomatic mutation carriers agreed to undergo surveillance while the remainder of the carriers did not. The surveillance protocol included both biochemical methods and imaging techniques, such as annual brain MRI for brain tumor surveillance (both children and adults); annual rapid total-body MRI (both children and adults) and ultrasound of abdomen and pelvis every 6 months (for adults only) for soft

tissue/bone sarcoma surveillance; colonoscopy every 2 years beginning at age 40 years (or 10 years before earliest known colon cancer in the family); ultrasound of abdomen and pelvis every 3-4 months, complete urinalysis every 3-4 months, blood test every 4 months for adrenocortical carcinoma surveillance (children only); and complete blood counts and blood tests every4 months for leukemia/lymphoma surveillance (both children and adults); for surveillance of breast cancers, the protocol was similar to the NCCN Guidelines for LFS management.[284] Using this surveillance protocol, asymptomatic tumors were detected in 7 of the patients; after a median follow-up time of 24 months, all 7 of these carriers were alive. Ten individuals in the non-surveillance group developed high-grade, advanced stage tumors; only 2 of these individuals were alive at the end of follow up. The 3-year overall survival rate was significantly higher for the surveillance group compared with the non-surveillance group (100% vs. 21%; P=0.016).[284] Although this was a small study in a limited number of patients, the clinical surveillance protocol employed was feasible and detected asymptomatic tumors in about 40% of individuals with *TP53* mutations. The protocol may represent an emerging option for surveillance/management of at-risk individuals from families with LFS; further evaluation of this protocol is warranted.

Only very limited data exists on the use of prenatal diagnostics/genetic testing for *TP53* mutations in families with LFS.[285,286] Counseling for reproductive options such as prenatal diagnosis, preimplantation genetic diagnosis (PGD) and assisted reproduction may be warranted for couples expressing concern over the mutation carrier status of their future offspring. Such counseling should include a comprehensive discussion of the potential risks, benefits, and limitations of reproductive options. For general discussions on the topic of reproductive options and counseling considerations, see the Discussion section above on Reproductive Options under Risk Assessment, Counseling, and Management: Hereditary Breast/Ovarian Cancer Syndrome.

Risk Assessment, Counseling, and Management: Cowden Syndrome

The assessment of individuals suspected of having Cowden syndrome incorporates both a history of the benign and malignant conditions associated with the syndrome and a targeted physical examination, including the skin and oral mucosa, breast, and thyroid gland (see Guidelines section on Cowden Syndrome Testing Criteria). The NCCN Guidelines panel has recently revised both the list of criteria associated with this genetic syndrome as well as the combinations of criteria that establish which individuals are candidates for *PTEN* gene mutation testing (see Guidelines section on Cowden Syndrome Testing Criteria and Discussion section on Cowden Syndrome). These criteria are recommended to assess the need for further risk assessment and genetic testing, but are not intended to serve as clinical diagnostic criteria. Following risk assessment and counseling, genetic testing should be considered in individuals for whom testing criteria are met. The NCCN Guidelines panel recommends comprehensive testing, which should include full sequencing, gene deletion/duplication analysis, and promoter analysis. Unlike the "pathognomonic" criteria, none of the individual major or minor criteria are considered by the NCCN Guidelines panel to be sufficient to warrant genetic testing in the absence of other clinical evidence of Cowden syndrome. However, the panel recommends genetic testing in an individual exhibiting 2 or more major criteria where one is macrocephaly, 3 or more major criteria when one is not macrocephaly, one major criterion along with 3 or more minor criteria, or in someone meeting specifications for 4 minor criteria. Furthermore, any of the major criteria can be classified as a minor criterion for the purpose of meeting the threshold required for genetic

Printed by Ariel Smits on 10/14/2014 12:23:15 PM. For personal use only. Not approved for distribution. Copyright © 2014 National Comprehensive Cancer Network, Inc., All Rights Reserved.

testing if 2 or more major criteria are present in a single individual but the individual does not have macrocephaly. The testing threshold is lower for an individual considered to be "at risk" (e.g., a first-degree relative of an individual and/or proband with a clinical diagnosis of Cowden syndrome or BRRS for whom genetic testing has not been performed). In this case, any one major criterion or 2 minor criteria are considered to be sufficient for genetic testing to be recommended. Recommendations for individuals not meeting these testing criteria should be individualized according to personal and family history.

An individual with a known deleterious *PTEN* mutation in a close family member who does not undergo gene testing should be followed according to the same guideline as a carrier of a *PTEN* mutation (see Guidelines section on Cowden Syndrome Management). In situations where an individual (or family member) from a family with no known familial *PTEN* mutation undergoes genetic testing, and no mutation is found, testing for other hereditary breast syndromes should be considered if testing criteria are met (see sections on Hereditary Breast and/or Ovarian Cancer Syndrome Testing Criteria and Li-Fraumeni Syndrome Testing Criteria).

Current medical management recommendations for individuals with Cowden syndrome focus on primary and secondary prevention options for breast cancer and on annual physical examinations, starting at age 18 years (or 5 years before the youngest age of diagnosis of a component cancer in the family) to detect skin changes and to monitor the thyroid gland for abnormalities. A baseline thyroid ultrasound should be performed at age 18 years and considered annually thereafter for both men and women with Cowden syndrome. Annual dermatological examination should also be considered. In addition, colonoscopy should be considered starting at age 35 years, performed every 5 to 10 years or more frequently in cases where the patient is symptomatic or polyps are found. Education regarding the signs and symptoms of cancer is important; patients should also be advised about the risk to relatives, and genetic counseling is recommended for at-risk relatives.

Women should begin regular monthly breast self-examinations at age 18 years and have a semiannual clinical breast examination, beginning at age 25 years or 5-10 years earlier than the earliest known breast cancer in the family. Women should also have an annual mammogram and breast MRI screening starting at ages 30-35 years, or 5 to 10 years earlier than the earliest known breast cancer in the family. Although there are no data regarding risk reduction surgery in women with Cowden syndrome, the option of risk-reduction mastectomy and hysterectomy should be discussed on a case-by-case basis (see Discussion section on Bilateral Total Mastectomy). Oophorectomy is not indicated for Cowden syndrome alone, but may be indicated for other reasons. Counseling for risk-reducing surgeries may include discussion of extent of cancer risk reduction/protection, risks associated with surgeries, reconstructive options and reproductive desires. It is also important to address the psychosocial and quality-of-life aspects of undergoing risk-reducing surgical procedures. The panel recommends patient education regarding the symptoms of endometrial cancer including the necessity of a prompt response to such symptoms. Women diagnosed with Cowden syndrome should consider participation in a clinical trial to determine the effectiveness and necessity of endometrial cancer screening. No published data exists on the use of prenatal diagnostics/genetic testing for *PTEN* mutations in families with Cowden syndrome. However, for couples expressing the desire that their offspring not carry a familial *PTEN* mutation, options for prenatal diagnosis, preimplantation genetic diagnosis (PGD) and assisted reproduction can be discussed. Such counseling should include a comprehensive discussion of the potential risks, benefits, and

limitations of reproductive options. For general discussions on the topic of reproductive options and counseling considerations, see the Discussion section above on Reproductive Options, under Risk Assessment, Counseling, and Management: Hereditary Breast/Ovarian Cancer Syndrome.

Table 1. Glossary of relevant genetic terms (from the National Cancer Institute [NCI])

Autosomal dominant
Autosomal dominant inheritance refers to genetic conditions that occur when a mutation is present in one copy of a given gene (i.e., the person is heterozygous).

Autosomal recessive
Autosomal recessive inheritance refers to genetic conditions that occur only when mutations are present in both copies of a given gene (i.e., the person is homozygous for a mutation, or carries two different mutations of the same gene, a state referred to as compound heterozygosity).

de novo mutation
An alteration in a gene that is present for the first time in one family member as a result of a mutation in a germ cell (egg or sperm) of one of the parents, or a mutation that arises in the fertilized egg itself during early embryogenesis. Also called new mutation.

Familial: A phenotype or trait that occurs with greater frequency in a given family than in the general population; familial traits may have a genetic and/or nongenetic etiology.

Family history
The genetic relationships within a family combined with the medical history of individual family members. When represented in diagram form using standardized symbols and terminology, it is usually referred to as a pedigree or family tree.

Founder effect
A gene mutation observed with high frequency in a population founded by a small ancestral group that was once geographically or culturally isolated, in which one or more of the founders was a carrier of the mutant gene.

Germline
The cells from which eggs or sperm (i.e., gametes) are derived.

Kindred
An extended family.

Pedigree
A graphic illustration of family history.

Penetrance
A characteristic of a genotype; it refers to the likelihood that a clinical condition will occur when a particular genotype is present.

Proband
The individual through whom a family with a genetic disorder is ascertained. In males this is called a propositus, and in females it is called a proposita.

Sporadic cancer
This term has two meanings. It is sometimes used to differentiate cancers occurring in people who do not have a germline mutation that confers increased susceptibility to cancer from cancers occurring in people who are known to carry a mutation. Cancer developing in people who do not carry a high-risk mutation is referred to as sporadic cancer. The distinction is not absolute, because genetic background may influence the likelihood of cancer even in the absence of a specific predisposing mutation. Alternatively, sporadic is also sometimes used to describe cancer occurring in individuals without a family history of cancer.

Table 2. Genetic test results to determine the presence of a cancer-predisposing gene

Result	*Description*
True-positive	The person is a carrier of an alteration in a known cancer-predisposing gene.
True-negative	The person is not a carrier of a known cancer-predisposing gene that has been positively identified in another family member.
Indeterminate (Uninformative)	The person is not a carrier of a known cancer-predisposing gene, and the carrier status of other family members is either also negative or unknown.
Inconclusive (Variants of unknown significance)	The person is a carrier of an alteration in a gene that currently has no known significance.

Breast Cancer Risk Reduction

NCCN Breast Cancer Risk Reduction Panel Members
Summary of the Guidelines Updates

Familial Risk Assessment (BRISK-1)
Elements of Risk, Risk Management (BRISK-3)
Risk-Reduction Therapy Not Desired: Risk Assessment and Screening/Follow-up (BRISK-4)
Risk-Reduction Therapy Desired: Baseline Assessment, Intervention, and Follow-up (BRISK-5)
Clinical Symptoms and Management While on Tamoxifen or Raloxifene Therapy (BRISK-7)
Components of Risk/Benefit Assessment and Counseling (BRISK-A)
Breast Cancer Risk-Reduction Agents (BRISK-B)

Clinical Trials: NCCN believes that the best management for any cancer patient is in a clinical trial. Participation in clinical trials is especially encouraged.

To find clinical trials online at NCCN Member Institutions, click here: nccn.org/clinical_trials/physician.html.

NCCN Categories of Evidence and Consensus: All recommendations are category 2A unless otherwise specified.

See NCCN Categories of Evidence and Consensus.

The NCCN Guidelines® are a statement of evidence and consensus of the authors regarding their views of currently accepted approaches to treatment. Any clinician seeking to apply or consult the NCCN Guidelines is expected to use independent medical judgment in the context of individual clinical circumstances to determine any patient's care or treatment. The National Comprehensive Cancer Network® (NCCN®) makes no representations or warranties of any kind regarding their content, use or application and disclaims any responsibility for their application or use in any way. The NCCN Guidelines are copyrighted by National Comprehensive Cancer Network®. All rights reserved. The NCCN Guidelines and the illustrations herein may not be reproduced in any form without the express written permission of NCCN. ©2014.

Guidelines Version 1.2014 Updates
Breast Cancer Risk Reduction

NCCN Guidelines Index
Breast Cancer Risk Reduction TOC
Discussion

Updates in the 1.2014 version of the NCCN Guidelines for Breast Cancer Risk Reduction from the 1.2013 version include:

BRISK-1
- Under Familial/genetic factors:
- Known genetic predisposition for breast cancer (BRCA1/2, p53, PTEN, or other gene mutation) is new to the page,
  - Footnote "~~b~~" ~~See BRISK-1 for women with a known genetic predisposition for breast cancer (BRCA1/2, p53, PTEN, or other gene mutation)~~ has been deleted.
- Modified Criteria for further genetic risk evaluation to include, "for women who do not have a personal history of invasive breast cancer or DCIS"
- Under Family history:
  - 2nd sub sub-bullet was reorganized and modified:
    - ≥2 primary~~ies~~ breast *cancers* in a single individual
  - 3rd sub sub-bullet was reorganized and modified:
    - ≥2 individuals with breast ~~primaries~~ *cancers* on the same side of family (maternal or paternal)
  - 4th sub sub-bullet was reorganized and modified:
    - ≥1 ovarian/*fallopian tube/primary peritoneal* cancer from the same side of family (maternal or paternal)
  - 7th sub sub-bullet was modified:
    - From a population at increased risk for *genetic predisposition*
- Corresponding footnote "g" was modified: For populations at increased risk, requirements for inclusion may be modified (eg, women of Ashkenazi Jewish descent with *a personal history of* breast, ovarian, or pancreatic cancer at any age).
- 2nd sub-bullet under Family history has been modified: *Personal history of* ovarian/fallopian tube/primary peritoneal cancer
- The branch off the 2nd column–
  - Yes: *"Referral to cancer genetics professional recommended"* is new to the page as is corresponding footnote "h"
  - No: reader is directed to ***BRISK-2***

BRISK-2
- ~~Woman meets one or more of the familial risk criteria~~ has been deleted.
- ~~Referral to cancer genetics professional recommended~~ has been deleted.
- *Known genetic predisposition* is new to the page
- *Woman meets one or more of the familial risk criteria (See BRISK-1)* is a new footnote corresponding to "Pedigree suggestive of genetic predisposition." (Also for BRISK-4)
- Footnote "k" has been modified to include: *"See life expectancy calculator (www.eprognosis.com)."* (Also for BRISK-3, 4, and 5)

BRISK-3
- Under Elements of Risk:
- ~~Demographics~~ has been replaced with *Elements that increase risk*
- 1st bullet "Increasing age," is new to the page
  - ~~Utility of risk reduction agents for breast cancer risk reduction in women <35 years of age is unknown~~ has been deleted.
- 2nd bullet, "Ethnicity/race" has a new corresponding footnote: *"For example, there is an increased incidence of specific BRCA1/2 mutations in women of Ashkenazi Jewish decent."*
- 3rd bullet, "Lifestyle factors" is new to the page.
  - Increased body mass index (BMI)
  - Alcohol consumption
  - Current or prior estrogen and progesterone hormone therapy
    - ~~Risk factor in caucasian women~~ has been deleted.
    - ~~BMI and breast cancer risk in African American women is complex~~
    - ~~Obesity is a risk factor in postmenopausal women~~ has been deleted.
- 4th bullet, 2nd sub-bullet, *"Nulliparity"* is new to the page.
- New to the page: *Elements that decrease risk*, and includes the following:
  - Prior oophorectomy
  - Prior risk-reduction therapy
  - Exercise

BRISK-5
- 6th column, bottom branch, changed Exemestane to *Aromatase inhibitors* with a corresponding footnote, *"Exemestane and anastrozole are not currently FDA approved for breast cancer risk reduction. There are currently no data comparing the benefits and risks of exemestane and anastrozole to those of tamoxifen or raloxifene."* (Also for BRISK-A and BRISK-B)

BRISK-6 Footnotes:
- *"s" has been modified: Risk-reduction mastectomy should generally be considered only in women with a genetic mutation conferring a high risk for breast cancer (BRCA1/2, PTEN, TP53, CDH1, STK11), compelling family history, or possibly with LCIS or prior thoracic radiation therapy at <30 yrs of age. The value of risk-reducing mastectomy in women with deleterious mutations in other genes associated with a 2-fold or greater risk for breast cancer (based on large epidemiologic studies) in the absence of a compelling family history of breast cancer is unknown.* ~~Risk-reduction mastectomy should generally be considered only in women with BRCA1/2, or other strongly predisposing gene mutation, compelling~~

Version 1.2014, 06/09/14 © National Comprehensive Cancer Network, Inc. 2014, All rights reserved. The NCCN Guidelines® and this illustration may not be reproduced in any form without the express written permission of NCCN®.

Guidelines Version 1.2014 Updates
Breast Cancer Risk Reduction

NCCN Guidelines Index
Breast Cancer Risk Reduction TOC
Discussion

BRISK-6 Footnotes (continued)

~~family history, or possibly with LCIS or prior thoracic radiation therapy at <30 y of age. Women considering risk reduction masteetomy should receive multidisciplinary counseling including consultation with genetics if not already done. Psychological consultation may also be of value.~~

- ~~"aa" Other aromatase inhibitors have shown prevention of contralateral breast cancer and there are ongoing clinical trials.~~ has been deleted.
- "y" Axillary node assessment *has limited indication at the time of* ~~is not part of the~~ risk reduction ~~procedure~~ *surgery.*

BRISK-7

- Footnote "ff": "Some selective serotonin reuptake inhibitors (SSRIs) decrease the formation of endoxifen, the active metabolite of tamoxifen. However, citalopram and venlafaxine appear to have minimal impact on tamoxifen metabolism. The clinical impact of these observations is not known." The footnote was deleted from this page and moved to BRISK-B, corresponding to Tamoxifen.

BRISK-A

- ~~Exemestane~~ has been replaced with *aromatase inibitors.*
- Under Surgery, 3rd sub-bullet, *Consider nipple-sparing mastectomy for risk reduction* is new to the page.
- Under Healthy lifestyle
  - 1st sub-bullet modified: Consider breast cancer risks associated with ~~hormone~~ *combined estrogen/progesterone* therapy
  - The reference that corresponds to "Limit alcohol consumption to less than 1 drink per day" has been deleted. ~~Mahoney MG, Bevers T, Linos E, Willett WC. Opportunities and strategies for breast cancer prevention through risk reduction. CA Cancer J Clin 2008;58(6):347-71.~~

BRISK-B

- Under Tamoxifen
  - 3rd sub-bullet modified: ~~Limited data are currently available regarding~~ The efficacy of tamoxifen risk reduction in women who are carriers of BRCA1/2 mutations or who have had prior thoracic radiation *is less well studied than in other risk groups. Available data suggest a benefit.*
- 3rd column: ~~Exemestane~~ has been changed to *Aromatase inhibitors (Exemestane and Anastrozole)*

BRISK-B (continued)

- The following is new to the guidelines: 2nd sub-bullet, Data regarding anastrozole are from a single large randomized study limited to postmenopausal women 40-70 years of age with the following risk compared with the general population:
  - Aged 40-44 years - 4 times higher
  - Aged 45-60 years - ≥2 times higher
  - Aged 60-70 years - ≥1.5 times higher

  Women who did not meet these criteria but had a Tyrer-Cuzick model 10-year breast cancer risk >5% were also included.

- Exemestane: 25 mg per day was found to reduce the relative incidence of invasive breast cancer by 65 % from 0.55% to 0.19% with a median follow-up of 3 years. ~~There are ongoing trials evaluating prolonged aromatase inibitor therapy in postmenopausal healthy women at risk for breast cancer.~~

- Anastrozole: 1 mg per day was found to reduce the relative incidence of breast cancer by 53% with a median follow-up of 5 years.

- There are no data regarding the use of ~~exemestane~~ *aromatase inhibitors* in women who are carriers of BRCA1/2 mutations or who have had prior thoracic radiation.

- For high-risk postmenopausal women, data regarding the risk/benefit ratio for ~~exemestane~~ *aromatase inhibitor* therapy are influenced by age and comorbid conditions such as osteoporosis (category 1). There are insufficient data on ethnicity and race.

- Use of ~~exemestane~~ *aromatase inhibitors* for breast cancer risk reduction in premenopausal women is inappropriate unless part of a clinical trial.

- Reference 3 has been deleted: ~~Fisher B, et al. Tamoxifen for prevention of breast cancer: report of the National Surgical Adjuvant Breast and Bowel Project P-1 Study. J Natl Cancer Inst 1998;90(18):1371-88.~~

MS-1

- The Discussion section has been updated to reflect the changes to the algorithm.

NCCN Guidelines Version 1.2014
Breast Cancer Risk Reduction

NCCN Guidelines Index
Breast Cancer Risk Reduction TOC
Discussion

FAMILIAL RISK ASSESSMENT[a]

Familial/genetic factors

- **Known genetic predisposition for breast cancer (BRCA1/2, p53, PTEN, or other gene mutation)** → See BRISK-2

- **Criteria for further genetic risk evaluation for women who do not have a personal history of invasive breast cancer or ductal carcinoma in situ (DCIS):[b]**
  - **Family history**
    - **Member of a family with a known mutation in a breast cancer susceptibility gene**
    - **≥2 primary breast cancers[c] in a single individual**
    - **≥2 individuals with breast cancers on the same side of family (maternal or paternal)**
    - **≥1 ovarian/fallopian tube/primary peritoneal cancer from the same side of family (maternal or paternal)**
    - **First- or second-degree relative with breast cancer ≤45 y**
    - **≥1 family member on same side of family with a combination of breast cancer and ≥1 of the following (especially if early onset): pancreatic cancer, aggressive prostate cancer (Gleason score ≥7), sarcoma, adrenocortical carcinoma, brain tumors, endometrial cancer, leukemia/lymphoma, thyroid cancer, dermatologic manifestations,[d] and/or macrocephaly, hamartomatous polyps of GI tract,[e] or diffuse gastric cancer[f]**
    - **From a population at increased risk for genetic predisposition[g]**
    - **Male breast cancer**
  - **Personal history of ovarian/fallopian tube/primary peritoneal cancer**

→ **Woman meets one or more of the familial/genetic risk criteria**
- **Yes** → **Referral to cancer genetics professional recommended[h]** See BRISK-2
- **No** → See BRISK-2

[a] See NCCN Guidelines for Genetic/Familial High-Risk Assessment.

[b] The criteria for further genetic risk assessment and genetic testing are not identical. For the purposes of these guidelines, invasive and ductal carcinoma in situ breast cancers should be included. The maternal and paternal sides of the family should be considered independently for familial patterns of cancer.

[c] Two breast primaries including bilateral disease or cases where there are two or more clearly separate ipsilateral primary tumors.

[d] For dermatologic manifestations, see NCCN Guidelines for Genetic/Familial High-Risk Assessment - Cowden Syndrome (See COWD-1).

[e] For hamartomatous colon polyps in conjunction with breast cancer and hyperpigmented macules of the lips and oral mucosa, STK11 testing should be considered. See NCCN Guidelines for Colorectal Cancer Screening: Peutz-Jeghers Syndrome.

[f] For lobular breast cancer with a family history of diffuse gastric cancer, *CDH1* gene testing should be considered.

[g] For populations at increased risk, requirements for inclusion may be modified (eg, women of Ashkenazi Jewish descent with a personal history of breast, ovarian, or pancreatic cancer at any age).

[h] A genetic counselor, medical geneticist, oncologist, surgeon, oncology nurse, or other health professional with expertise and experience in cancer genetics should be involved early in counseling patients who potentially meet criteria for an inherited syndrome. Genetic counseling is highly recommended when genetic testing is offered and after results are disclosed.

Note: All recommendations are category 2A unless otherwise indicated.
Clinical Trials: NCCN believes that the best management of any cancer patient is in a clinical trial. Participation in clinical trials is especially encouraged.

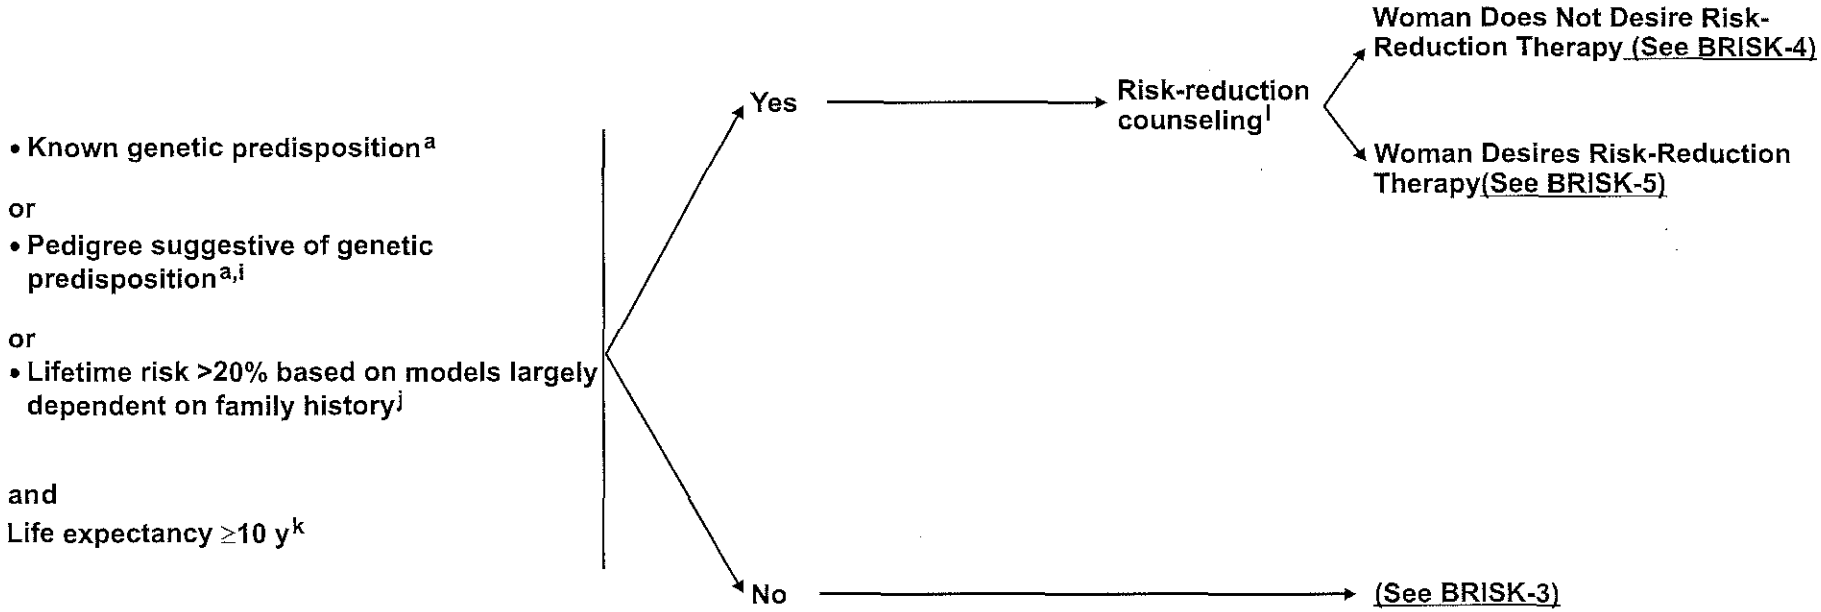
ADDITIONAL RISK ASSESSMENT



[a] See NCCN Guidelines for Genetic/Familial High-Risk Assessment.
[i] Woman meets one or more of the familial risk criteria (See BRISK-1).
[j] Risk models that are largely dependent on family history (eg, Claus, BRCAPRO, BOADICEA, Tyrer-Cuzick).
[k] See life expectancy calculator (www.eprognosis.com). For a reference point, the life expectancy of the average 78-y-old woman in the United States is 10.2 years. (See NCCN Guidelines for Senior Adult Oncology).
[l] See Components of Risk/Benefit Assessment and Counseling (BRISK-A).

Note: All recommendations are category 2A unless otherwise indicated.
Clinical Trials: NCCN believes that the best management of any cancer patient is in a clinical trial. Participation in clinical trials is especially encouraged.

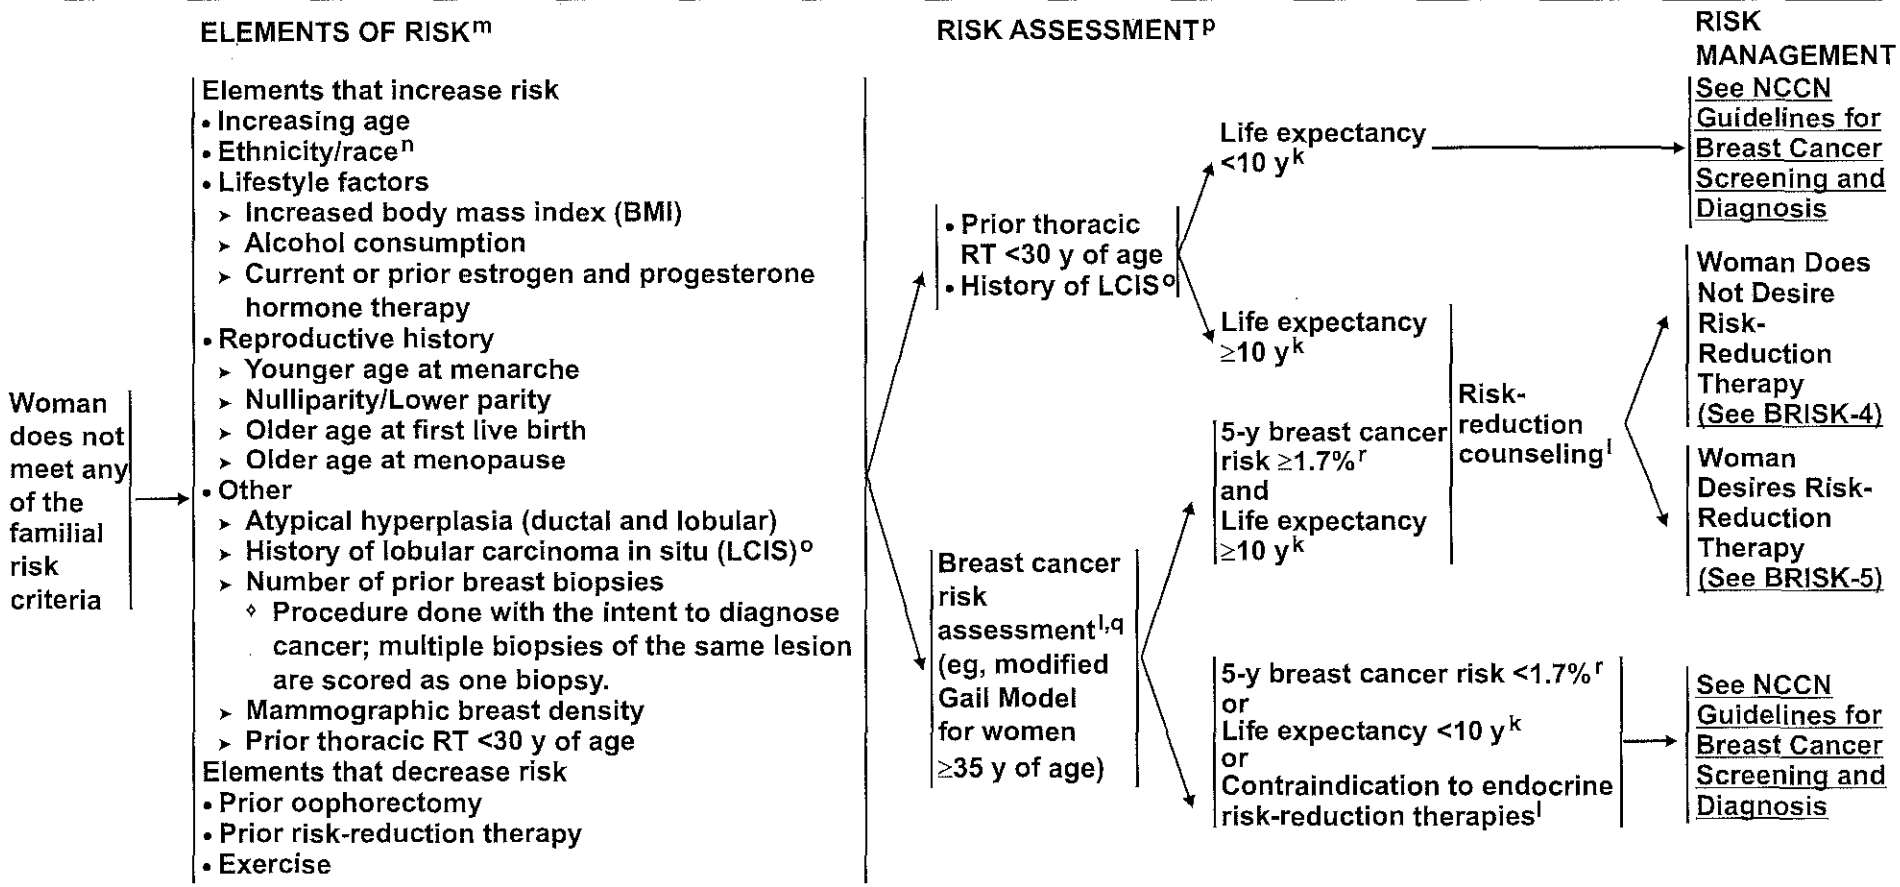
NCCN Guidelines Version 1.2014
Breast Cancer Risk Reduction

NCCN Guidelines Index
Breast Cancer Risk Reduction TOC
Discussion



[k] See life expectancy calculator (www.eprognosis.com). For a reference point,the life expectancy of the average 78-y-old woman in the United States is 10.2 years. (See NCCN Guidelines for Senior Adult Oncology).

[l] See Components of Risk/Benefit Assessment and Counseling (BRISK-A).

[m] The management for women with DCIS is available in the NCCN Guidelines for Breast Cancer.

[n] For example, there is an increased incidence of specific BRCA1/2 mutations in women of Ashkenazi Jewish decent.

[o] The management for women with LCIS is also available in the NCCN Guidelines for Breast Cancer.

[p] The clinical utility and role of random periareolar fine needle aspiration, nipple aspiration, or ductal lavage are still being evaluated and should only be used in the context of a clinical trial.

[q] The modified Gail Model (NCI Breast Cancer Risk Assessment Tool) is a computer-based version and may be obtained through the NCI website (http://www.cancer.gov/bcrisktool/Default.aspx). There are circumstances in which the Gail Model underestimates risk for development of breast cancer, for instance, BRCA1/2 carriers and those with a strong family history of breast cancer or family history of ovarian cancer in the maternal or paternal family lineage or non-white women. The Claus, BRCAPRO, Tyrer-Cuzick, and BOADICEA models may be particularly helpful in determining risk for breast cancer in women with a strong family history of breast, ovarian, or other cancers. See Discussion, MS-2.

[r] The definition of risk as defined by the National Surgical Adjuvant Breast and Bowel Project Breast Cancer Prevention Trial (NSABP BCPT).

Note: All recommendations are category 2A unless otherwise indicated.
Clinical Trials: NCCN believes that the best management of any cancer patient is in a clinical trial. Participation in clinical trials is especially encouraged.

FOOTNOTES FOR RISK-REDUCTION THERAPY

[k] See life expectancy calculator (www.eprognosis.com). For a reference point, the life expectancy of the average 78-y-old woman in the United States is 10.2 years. (See NCCN Guidelines for Senior Adult Oncology).

[s] Risk-reduction mastectomy should generally be considered only in women with a genetic mutation conferring a high risk for breast cancer (ie, BRCA1/2, PTEN, TP53, CDH1, STK11), compelling family history, or possibly with LCIS or prior thoracic radiation therapy at <30 yrs of age. The value of risk-reducing mastectomy in women with deleterious mutations in other genes associated with a 2-fold or greater risk for breast cancer (based on large epidemiologic studies) in the absence of a compelling family history of breast cancer is unknown.

[t] The additional benefit of concurrent hysterectomy is not clear at this time.

[u] There are no data regarding the use of risk-reduction agents in women with prior thoracic radiation therapy.

[v] CYP2D6 genotype testing is not recommended in women considering tamoxifen.

[w] See Breast Cancer Risk-Reduction Agents (BRISK-B).

[x] Discuss risks and benefits of nipple-areolar sparing surgery.

[y] Axillary node assessment has limited indication at the time of risk-reduction surgery.

[z] Clinical trials in breast cancer have utilized a variety of definitions of menopause. Menopause is generally the permanent cessation of menses, and as the term is utilized in breast cancer management includes a profound and permanent decrease in ovarian estrogen synthesis. Reasonable criteria for determining menopause include any of the following: Prior bilateral oophorectomy; age ≥60 y; age <60 y; and amenorrhea for 12 or more months in the absence of chemotherapy, tamoxifen, toremifene, or ovarian suppression and follicle-stimulating hormone (FSH) and estradiol in the postmenopausal range. If taking tamoxifen or toremifene and age <60 y, FSH and plasma estradiol level in postmenopausal ranges.

[aa] Bone density may play a role in choice of therapy.

[bb] Women in clinical trial should have baseline exam, follow-up, and monitoring as per protocol.

[cc] Utility of tamoxifen or raloxifene for breast cancer risk reduction in women <35 years of age is unknown. Raloxifene is only for post-menopausal women >35 y. While raloxifene in long-term follow-up appears to be less efficacious in risk reduction than tamoxifen, consideration of toxicity may still lead to the choice of raloxifene over tamoxifen in women with an intact uterus.

[dd] When counseling postmenopausal women regarding the risk/benefit of tamoxifen and raloxifene, refer to tables in Freedman AN, et al. Benefit/risk assessment for breast cancer chemoprevention with raloxifene or tamoxifen for women age 50 years or older. J Clin Oncol 2011;29(17):2327-2333.

[ee] Exemestane and anastrozole are not currently FDA approved for breast cancer risk reduction. There are currently no data comparing the benefits and risks of exemestane and anastrozole to those of tamoxifen or raloxifene.

[ff] Routine endometrial ultrasound and biopsy are not recommended for women in the absence of other symptoms.

Note: All recommendations are category 2A unless otherwise indicated.
Clinical Trials: NCCN believes that the best management of any cancer patient is in a clinical trial. Participation in clinical trials is especially encouraged.

COMPONENTS OF RISK/BENEFIT ASSESSMENT AND COUNSELING

Options for risk reduction should be discussed in a shared decision-making environment. For breast cancer risk reduction, elements of this discussion include:

- **If a woman is at high risk secondary to a strong family history or very early onset of breast or ovarian cancer, genetic counseling should be offered. See NCCN Guidelines for Genetic/Familial High-Risk Assessment.**

- **Risk-reduction agents - See the Discussion section.**
  - **Discussion of relative and absolute risk reduction with tamoxifen, raloxifene, or aromatase inhibitors[1].**
  - **Contraindications to tamoxifen or raloxifene: history of deep vein thrombosis, pulmonary embolus, thrombotic stroke, transient ischemic attack, or known inherited clotting trait.**
  - **Contraindications to tamoxifen, raloxifene, and aromatase inhibitors[1]: current pregnancy or pregnancy potential without effective nonhormonal method of contraception.**
  - **Common and serious adverse effects of tamoxifen, raloxifene, or aromatase inhibitors[1] with emphasis on age-dependent risks.**

- **Surgery**
  - **Discussion of risk-reduction mastectomy in high-risk women. Risk-reduction mastectomy should generally be considered only in women with BRCA1/2, or other strongly predisposing gene mutation, compelling family history, or possibly women with LCIS or prior thoracic RT <30 y of age. Evaluation should include consultation with surgery and reconstructive surgery. Psychological consultation may also be considered.**
  - **Discussion regarding the risk for breast or ovarian cancer and the option of risk-reduction bilateral salpingo-oophorectomy.**
  - **Consider nipple-sparing mastectomy for risk reduction.**

- **Option of participation in clinical research for screening, risk assessment, or other risk-reduction intervention.**

- **Healthy lifestyle**
  - **Consider breast cancer risks associated with combined estrogen/progesterone therapy**
  - **Limit alcohol consumption to less than 1 drink per day**
  - **Exercise[2]**
  - **Weight control**

[1] Exemestane and anastrozole are not currently FDA approved for breast cancer risk reduction. There are currently no data comparing the benefits and risks of exemestane and anastrozole to those of tamoxifen or raloxifene.

[2] See American Cancer Society Guidelines.

Note: All recommendations are category 2A unless otherwise indicated.
Clinical Trials: NCCN believes that the best management of any cancer patient is in a clinical trial. Participation in clinical trials is especially encouraged.

BREAST CANCER RISK-REDUCTION AGENTS

- Tamoxifen[1,2,3]
  - Data regarding tamoxifen risk reduction are limited to pre- and postmenopausal women 35 y of age or older with a Gail Model 5-year breast cancer risk of ≥1.7% or a history of LCIS.
  - Tamoxifen: 20 mg per day for 5 years was shown to reduce risk of breast cancer by 49%. Among women with a history of atypical hyperplasia, this dose and duration of tamoxifen was associated with an 86% reduction in breast cancer risk.
  - The efficacy of tamoxifen risk reduction in women who are carriers of BRCA1/2 mutations or who have had prior thoracic radiation is less well studied than in other risk groups. Available data suggest a benefit.
  - For high-risk premenopausal women, data regarding the risk/benefit ratio for tamoxifen appear relatively favorable (category 1).
  - For high-risk postmenopausal women, data regarding the risk/benefit ratio for tamoxifen are influenced by age, presence of uterus, or comorbid conditions (category 1). There are insufficient data on ethnicity and race.

- Raloxifene[1,2]
  - Data regarding raloxifene risk reduction are limited to postmenopausal women 35 y of age or older with a Gail model 5-year breast cancer risk ≥1.7% or a history of LCIS.
  - Raloxifene: 60 mg per day was found to be equivalent to tamoxifen for breast cancer risk reduction in the initial comparison. While raloxifene in long-term follow-up appears to be less efficacious in risk reduction than tamoxifen, consideration of toxicity may still lead to the choice of raloxifene over tamoxifen in women with an intact uterus.
  - There are no data regarding the use of raloxifene in women who are carriers of BRCA1/2 mutations or who have had prior thoracic radiation.
  - For high-risk postmenopausal women, data regarding the risk/benefit ratio for raloxifene are influenced by age or comorbid conditions (category 1). There are insufficient data on ethnicity and race.
  - Use of raloxifene for breast cancer risk reduction in premenopausal women is inappropriate unless part of a clinical trial.

- Aromatase inhibitors (Exemestane and Anastrozole)[4]
  - Data regarding exemestane are from a single large randomized study limited to postmenopausal women 35 years of age or older with a Gail model 5-year breast cancer risk ≥1.7% or a history of LCIS.
  - Data regarding anastrozole are from a single large randomized study limited to postmenopausal women 40-70 years of age with the following risk compared with the general population:
    - Aged 40-44 years - 4 times higher
    - Aged 45-60 years - ≥2 times higher
    - Aged 60-70 years - ≥1.5 times higher

    Women who did not meet these criteria but had a Tyrer-Cuzick model 10-year breast cancer risk >5% were also included.
  - Exemestane: 25 mg per day was found to reduce the relative incidence of invasive breast cancer by 65% from 0.55% to 0.19% with a median follow-up of 3 years.
  - Anastrozole: 1 mg per day was found to reduce the relative incidence of breast cancer by 53% with a median follow-up of 5 years.
- There are no data regarding the use of aromatase inhibitors in women who are carriers of BRCA1/2 mutations or who have had prior thoracic radiation.
- For high-risk postmenopausal women, data regarding the risk/benefit ratio for aromatase inhibitor therapy are influenced by age and comorbid conditions such as osteoporosis (category 1). There are insufficient data on ethnicity and race.
- Use of aromatase inhibitors for breast cancer risk reduction in premenopausal women is inappropriate unless part of a clinical trial.

[1]There are limited data regarding >5 years of tamoxifen or raloxifene use in breast cancer prevention. Moreover, there may be safety concerns related to use of tamoxifen for greater than 5 years. Based on the recent update of the STAR trial data, continuing raloxifene beyond 5 years (there are no high-level experience or clinical trial data evaluating these agents for risk reduction beyond 5 years) may be an approach to maintain the risk-reduction activity of the agent.

[2]When counseling postmenopausal women regarding the risk/benefit of tamoxifen and raloxifene, refer to tables in Freedman AN, et al. Benefit/risk assessment for breast cancer chemoprevention with raloxifene or tamoxifen for women age 50 years or older. J Clin Oncol 2011;29(17):2327-2333.

[3]Some selective serotonin reuptake inhibitors (SSRIs) decrease the formation of endoxifen, the active metabolite of tamoxifen. However, citalopram and venlafaxine appear to have minimal impact on tamoxifen metabolism. The clinical impact of these observations is not known.

[4]Exemestane and anastrozole are not currently FDA approved for breast cancer risk reduction. There are currently no data comparing the benefits and risks of exemestane and anastrozole to those of tamoxifen or raloxifene.

Note: All recommendations are category 2A unless otherwise indicated.
Clinical Trials: NCCN believes that the best management of any cancer patient is in a clinical trial. Participation in clinical trials is especially encouraged.

Discussion

NCCN Categories of Evidence and Consensus

Category 1: Based upon high-level evidence, there is uniform NCCN consensus that the intervention is appropriate.

Category 2A: Based upon lower-level evidence, there is uniform NCCN consensus that the intervention is appropriate.

Category 2B: Based upon lower-level evidence, there is NCCN consensus that the intervention is appropriate.

Category 3: Based upon any level of evidence, there is major NCCN disagreement that the intervention is appropriate.

All recommendations are category 2A unless otherwise noted.

Overview

Breast cancer is the most commonly diagnosed cancer in American women, with an estimated 235,030 cases of invasive breast cancer and an estimated death of 40,430 women with breast cancer in 2014.[1] This highlights the need for effective breast cancer screening and risk-reduction strategies.

For a woman who does not have a personal history of breast cancer, the risk factors for the development of breast cancer can be grouped into categories including familial/genetic factors; factors related to demographics; reproductive history lifestyle factors; and other factors such as number of breast biopsies, atypical hyperplasia or lobular carcinoma in situ [LCIS], breast density, or prior thoracic irradiation before age 30 [eg, to treat Hodgkin's disease).

Estimating breast cancer risk for the individual woman is difficult, and most breast cancers are not attributable to risk factors other than female gender and increased age. The development of effective strategies for the reduction of breast cancer incidence has also been difficult, because few of the existing risk factors are modifiable and some of the potentially modifiable risk factors have social implications extending beyond concerns for breast cancer (eg, age at first live birth). Nevertheless, effective breast cancer risk-reduction strategies such as use of risk-reduction agents, and risk-reduction surgery, have been identified. However, women and their physicians who are considering interventions to reduce risk for breast cancer must balance the demonstrated benefits with the potential morbidities of the interventions. Surgical risk-reduction strategies (eg, risk-reduction bilateral mastectomy) may have psychosocial and/or physical consequences for the woman, and risk-reduction agents, used for non-surgical risk reduction, are associated with certain adverse effects.[2-4] To assist women who are at increased risk of developing breast cancer and their physicians in the application of individualized strategies to reduce breast cancer risk, NCCN has developed these guidelines for breast cancer risk reduction.

Risk Assessment

Estimation of breast cancer risk for an individual woman who does not have a personal history of invasive breast cancer or ductal carcinoma in situ (DCIS) begins with an initial assessment of familial/genetic factors associated with increased breast cancer risk for the purpose of determining whether more extensive genetic risk assessment and counseling should be undertaken.

Familial/Genetic Factors

The first step in this primary assessment is a broad and flexible evaluation of the personal and family history of the individual, primarily with respect to breast and/or ovarian cancer.[5,6]

Genetic predispositions conferring a high risk for breast cancer include Hereditary Breast and Ovarian Cancer (*BRCA1/2*),[7,8] Li-Fraumeni syndrome (*TP53*),[9] Peutz-Jeghers syndrome (*STK11*),[10] Cowden syndrome (*PTEN*),[11,12] and Hereditary Diffuse Gastric Cancer (*CDH1*).[13]

If the individual has a known genetic predisposition for breast cancer such as mutations in *BRCA1/2, TP53, PTEN*, or other gene mutation associated with breast cancer risk, that individual must be counselled for risk reduction.

If the familial/genetic factors are not known, a thorough evaluation must be performed. The magnitude of the risk increases with the number of affected relatives in the family, the closeness of the relationship, and

age at which the affected relative was diagnosed.[14-16] The younger the age at diagnosis of the first- or second-degree relative, the more likely it is that a genetic component is present. The maternal *and* paternal sides of the family should be considered independently for familial patterns of cancer (see NCCN Guidelines for Genetic/Familial Risk Assessment: Breast and Ovarian).

Hereditary cancers are often characterized by gene mutations associated with a high probability of cancer development (ie, a high penetrance genotype), vertical transmission through either mother or father, and an association with other types of tumors.[17,18] They often have an early age of onset and exhibit an autosomal-dominant inheritance pattern (ie, they occur when the individual has a germline mutation in only one copy of a gene).

Familial cancers share some but not all features of hereditary cancers. For example, although familial breast cancers occur in a given family more frequently than in the general population, they generally do not exhibit the inheritance patterns or onset age consistent with hereditary cancers. Familial cancers may be associated with chance clustering of sporadic cancer cases within families, genetic variation in lower penetrance genes, a shared environment, or combinations of these factors.[19-22]

If an individual or a close family member of that individual meets one or more of the criteria listed in the NCCN Guidelines for Breast Cancer Risk Reduction under "Familial Risk Assessment" (and also NCCN Guidelines for Genetic/Familial Risk Assessment: Breast and Ovarian), that individual may be at increased risk for familial/hereditary breast cancer, and referral for formal genetic assessment/counseling is recommended.

A cancer genetic professional should be involved in determining whether the individual has a lifetime risk for breast cancer greater than 20% based on models dependent on family history (eg, Claus,[23] Tyrer-Cuzick,[24] and others[25-27]). BRCAPRO[28] and Breast and Ovarian Analysis of Disease Incidence and Carrier Estimation Algorithm (BOADICEA)[29] are more commonly used to estimate the risk based on *BRCA* mutations. Strong genetic association between breast and ovarian cancer has been demonstrated in some families by linkage analyses. The Claus tables may be useful in providing breast cancer risk estimates for white women without a known cancer-associated gene mutation who have one or two first- or second-degree female relatives with breast cancer[23] and ovarian cancer.[30] Based on this risk assessment, women with a *BRCA1/2*, *TP53*, or *PTEN* gene mutation, or a pedigree strongly suggestive of genetic predisposition to breast cancer, may be identified. The NCCN Guidelines for Genetic/Familial Risk Assessment: Breast and Ovarian also describe management strategies for women with a known or suspected *BRCA1/2, TP53, or PTEN* mutation or a pedigree strongly suggestive of genetic predisposition to breast cancer.

Other Elements of Risk

For women not considered to be at risk for familial/hereditary breast cancer, an evaluation of other elements of risk that contribute to increased breast cancer risk is recommended. These include ethnicity/race. There is an increased incidence of BRCA1/2 mutation reported in women of Ashkenazi Jewish decent.[31] It also includes increasing age and reproductive history. Strong risk factors linked to reproductive history include nulliparity, current use of menopausal hormone therapy (HT), and prolonged interval between menarche and age at first birth.[32-36]

Body mass index (BMI) is an independent risk factor for breast cancer, especially in Caucasian women. Several studies have established the association between high BMI and adult weight gain to increased risk for breast cancer in postmenopausal women. This increase in risk has been attributed to increase in circulating endogenous estrogen levels from fat tissue.[37-39] In addition, the association between BMI and risk for postmenopausal breast cancer is stronger for hormone-positive tumors.[40-43]

Lifestyle factors such as current or prior HT,[36] alcohol consumption,[44,45] and smoking[46] also contribute to the risk of developing breast cancer. Other factors to consider are number of breast biopsies, prior thoracic irradiation before age 30 (eg, to treat Hodgkin's disease), atypical hyperplasia or LCIS, and changes in breast density.[47] Breast density is not included in any of the commonly used risk assessment models/tools.[26] However, dense breast tissue as measured by mammography is increasingly recognized as an important risk factor for breast cancer.[48,49] For example, a report of a large case-cohort study of women 35 years and older with no history of breast cancer who underwent mammographic screening, first at baseline and then at an average of 6 years later, suggested that longitudinal changes in breast density are associated with changes in breast cancer risk.[49]

Women ≥35 years of age *without* a *BRCA1/2*, *TP53*, or *PTEN* mutation; a strong family history of breast cancer; a history of thoracic radiation before age 30; or a history of LCIS should have their risk for breast cancer estimated according to the modified Gail model.[50-52] The modified Gail model is a computer-based, multivariate, logistic regression model that uses age, race, age at menarche, age at first live birth or nulliparity, number of first-degree relatives with breast cancer, number of previous breast biopsies, and histology of the breast biopsies to produce actuarial estimates of future breast cancer risk.[50,51,53,54] The criteria used to determine risk by the modified Gail model are described in Table 1. The Gail model, as modified by the National Surgical Adjuvant Breast and Bowel Project (NSABP) investigators, is available on the National Cancer Institute website (http://www.cancer.gov/bcrisktool/Default.aspx).

The risk threshold required for a woman to consider the use of risk-reduction strategies must depend on an evaluation of the efficacy, morbidity, and expense of the proposed intervention. As a reasonable discriminating threshold, the NCCN Breast Cancer Risk Reduction Panel has adopted the 1.7% or greater 5-year actuarial breast cancer risk as defined by the modified Gail model, which was used to identify women eligible for the NSABP, Breast Cancer Prevention Trial (BCPT),[55,56] and the Study of Tamoxifen and Raloxifene (STAR) trial.[57,58]

The Gail model was updated using combined data from the Women's Contraceptive and Reproductive Experiences (CARE) study and the SEER database, as well as causes of death from the National Center of Health Statistics, to provide a more accurate determination of risk for African-American women.[59] The model was updated using data from the Asian American Breast Cancer Study (AABCS) and the SEER database to provide a more accurate risk assessment for Asian and Pacific Islander women in the United States.[60] Application of the Gail model to recent immigrants from Japan or China may overestimate the risk for breast cancer.[60]

As previously mentioned, the Gail model is not an appropriate breast cancer risk assessment tool for women who received prior thoracic radiation to treat Hodgkin's disease (eg, mantle radiation) or those with LCIS. In the Late Effects Study Group trial, the overall risk for breast cancer associated with prior thoracic irradiation at a young age was

Printed by Ariel Smits on 10/22/2014 1:57:36 PM. For personal use only. Not approved for distribution. Copyright © 2014 National Comprehensive Cancer Network, Inc., All Rights Reserved.

found to be 56.7–fold (55.5-fold for female patients) greater than the risk for breast cancer in the general population.[61] In that study, the relative risk according to follow-up interval was: 0 at 5 to 9 years; 71.3 at 10 to 14 years; 90.8 at 15 to 19 years; 50.9 at 20 to 24 years; 41.2 at 25 to 29 years; and 24.5 at >29 years.[61] Results from a case-control study of women treated at a young age (30 years or younger) for Hodgkin lymphoma with thoracic radiation indicated that the estimated, cumulative, absolute risk for breast cancer at 55 years of age was 29.0% (95% confidence interval [CI], 20.2%–40.1%) for a woman treated at 25 years of age with 40 Gy of radiation and no alkylating agents.[62] Women with a history of treatment with thoracic radiation for Hodgkin's disease are at a high risk for breast cancer on the basis of radiation exposure alone.[61-66] Women with a history of LCIS are also at substantially increased risk for invasive breast cancer in both the affected and contralateral breast.[67,68]

Women with a life expectancy ≥10 years and no diagnosis/history of breast cancer who are considered to be at increased risk for breast cancer based on any of the above-mentioned assessments should receive counseling, that is tailored to the individual, to decrease breast cancer risk (eg, risk-reduction surgery in *BRCA1/2* mutation carriers; therapy with risk-reduction agents in those without a contraindication to these agents) (see section below on *Components of Risk-Reduction Counseling*, page MS-20), and should undergo breast screening as detailed in the NCCN Guidelines for Breast Cancer Screening and Diagnosis.

If life expectancy is <10 years, there is probably minimal if any benefit to risk-reduction therapy or screening (see NCCN Guidelines for Breast Cancer Screening and Diagnosis and NCCN Guidelines for Breast Cancer).

Women with a diagnosis of DCIS should be managed according to recommendations outlined in the NCCN Guidelines for Breast Cancer.

Risk-Reduction Interventions

Lifestyle Modifications

Evidence from immigration studies indicate that in addition to family history and genetics, environmental factors play a significant role. Life style modifications such as diet, body weight, exercise, and alcohol consumption are some of the modifiable components of breast cancer risk. While there is no clear evidence that specific dietary components can effectively reduce breast cancer risk, weight gain and obesity in adulthood are risk factors for the development of postmenopausal breast cancer.[39,69,70] Alcohol consumption, even at moderate levels, increases breast cancer risk.[45,70-73] Patients should be encouraged to maintain a healthy lifestyle and to remain up-to-date with recommendations for screening and surveillance (see section on *Counseling regarding lifestyle modifications* on MS-24).

Risk-Reduction Surgery

Bilateral Total Mastectomy

The lifetime risk for breast cancer in *BRCA1/2* mutation carriers has been estimated to be 56% to 84%.[74-76] Retrospective analyses with median follow-up periods of 13 to 14 years have indicated that bilateral risk–reducing mastectomy (RRM) decreased the risk of developing breast cancer by at least 90% in moderate- and high-risk women and in known *BRCA1/2* mutation carriers.[77,78] An analysis of results from the study by Hartmann et al,[77] determined that to prevent one case of breast cancer in women with high risk, the number of needed to be treated with RRM was equal to 6.[79] Results from smaller prospective studies with shorter follow-up periods have provided support for concluding that RRM provides a high degree of protection against

Printed by Ariel Smits on 10/22/2014 1:57:36 PM. For personal use only. Not approved for distribution. Copyright © 2014 National Comprehensive Cancer Network, Inc., All Rights Reserved.

breast cancer in women with a *BRCA1/2* mutation.[80,81] The NCCN Breast Cancer Risk Reduction Panel supports the use of RRM for carefully selected women at high risk for breast cancer who desire this intervention (eg, women with a *BRCA1/2*, *TP53*, *PTEN*, *CDH1*, or *STK11* mutation or, possibly, women with a history of LCIS). Although the consensus of the NCCN Breast Cancer Risk Reduction Panel is that consideration of RRM is an option for a woman with LCIS without additional risk factors, it is not a recommended approach for most of these women. There are no data regarding RRM in women with prior mantle radiation exposure. The value of RRM in women with deleterious mutations in other genes associated with a high risk for breast cancer (based on large epidemiologic studies) in the absence of a compelling family history of breast cancer is unknown.

Women considering RRM should first have appropriate multidisciplinary consultations and a clinical breast examination and bilateral mammogram if not performed within the past 6 months. If results are normal, women who choose RRM may undergo the procedure with or without immediate breast reconstruction. Bilateral mastectomy performed for risk reduction should involve removal of all breast tissue (ie, a total mastectomy). Axillary node assessment has limited utility at the time of RRM. Women undergoing RRM do not require an axillary lymph node dissection unless breast cancer is identified on pathologic evaluation of the mastectomy specimen.[82]

Some patients may be at risk for an occult primary tumor, such as patients with abnormal imaging findings on either mammogram or breast MRI, who do not undergo biopsy, and patients with familial history who have not had a breast MRI prior to surgery. In such patients, a sentinel lymph node biopsy may be performed to stage the axilla for an occult cancer during the RRM, and a secondary axillary lymph node dissection could be avoided if an occult invasive cancer is discovered. This procedure has not been found to increase the risk for lymphedema.[83]

Following RRM, women who carry a *BRCA1/2* mutation should be monitored according to the NCCN Guidelines for Genetic/Familial Risk Assessment: Breast and Ovarian. Women found to have invasive breast cancer or DCIS at the time of RRM should be treated according to the NCCN Guidelines for Breast Cancer. All other women should be followed up with routine health maintenance following RRM. Most health maintenance recommendations are not related to the breast. For monitoring breast health, women should continue with annual exams of the chest/reconstructed breast as there is still a small risk of developing breast cancer. Mammograms are not recommended in this situation.

Bilateral Salpingo-oophorectomy

Women with a *BRCA1/2* mutation are at increased risk for both breast and ovarian cancers (including fallopian tube cancer). Although the risk for ovarian cancer is lower than the risk for breast cancer in a *BRCA1/2* mutation carrier (eg, estimated lifetime risks of 36%–46% and 10%–27% in *BRCA1* and *BRCA2* mutation carriers, respectively[75,84-87]), the absence of reliable methods of early detection and the poor prognosis associated with advanced ovarian cancer have lent support for the performance of bilateral risk-reducing salpingo-oophorectomy (RRSO) after completion of childbearing in these women. In the studies of Rebbeck et al, the mean age at diagnosis of ovarian cancer was 50.8 years for *BRCA1/2* carriers.[88]

The effectiveness of RRSO in reducing the risk for ovarian cancer in carriers of a *BRCA1/2* mutation has been demonstrated in a number of studies. For example, results of a meta-analysis involving 10 studies of *BRCA1/2* mutation carriers showed an approximately 80% reduction in

Printed by Ariel Smits on 10/22/2014 1:57:36 PM. For personal use only. Not approved for distribution. Copyright © 2014 National Comprehensive Cancer Network, Inc., All Rights Reserved.

the risk for ovarian or fallopian cancer following RRSO.[89] However, a 1% to 4.3% residual risk for a primary peritoneal carcinoma has been reported in some studies.[88-93]

RRSO is also reported to reduce the risk for breast cancer in carriers of a *BRCA1/2* mutation by approximately 50%.[88,89,93,94] In the case-control international study, a 56% (odds ratio = 0.44; 95% CI, 0.29–0.66) and a 46% (odds ratio = 0.57; 95% CI, 0.28–1.15) breast cancer risk reduction was reported following RRSO in carriers of a *BRCA1/2* mutation, respectively.[94] Hazard ratios of 0.47 (95% CI, 0.29–0.77)[88] and 0.30 (95% CI, 0.11–0.84)[92] were reported in two other studies comparing breast cancer risk in women with a *BRCA1/2* mutation who had undergone RRSO with carriers of these mutations who opted for surveillance only. These studies are further supported by a meta-analysis that found similar reductions in breast cancer risk of approximately 50% for *BRCA1/2* mutation carriers following RRSO.[89] The results of a prospective cohort study suggest that RRSO may be associated with a greater reduction in breast cancer risk for *BRCA1* mutation carriers compared with *BRCA2* mutation carriers.[95]

Reductions in breast cancer risk for carriers of a *BRCA1/2* mutation after RRSO may be associated with decreased hormonal exposure following surgical removal of the ovaries. Greater reductions in breast cancer risk were observed in women with a *BRCA1* mutation who had an RRSO at age 40 years or younger (odds ratio = 0.36, 95% CI, 0.20–0.64) relative to *BRCA1* carriers aged 41–50 years who had this procedure (odds ratio = 0.50, 95% CI, 0.27–0.92).[94] Nonsignificant risk reduction of developing breast cancer was found for women aged 51 years or older, although only a small number of women were included in this group.[94] However, results from Rebbeck et al also suggest that RRSO after age 50 is not associated with a substantial decrease in breast cancer risk.[93]

Although data are limited regarding an optimal age for RRSO, the Monte Carlo simulation model provides estimates of the survival impact of breast and ovarian risk-reduction strategies (eg, mammographic/MRI breast screening; risk-reduction surgery) in women who are carriers of *BRCA1/2* mutations according to the type of *BRCA* mutation present, the specific risk-reduction intervention(s), and the age of the women at the time of the intervention(s).[96] Survival estimates generated from this model can facilitate shared decision-making regarding choice of a risk-reduction approach (see Table 2).

A prospective multicenter study reported the benefit of risk-reducing procedures for women with strong genetic predispositions for breast cancer.[97] The study involved 2482 women diagnosed with *BRCA1/2* gene mutations, almost half of whom chose either RRSO or RRM. During the 3 years of follow up, no cases of breast cancer occurred in the women who opted for RRM. In the same time period, 7% of the women who adopted other approaches received a breast cancer diagnosis. In *BRCA2*-mutation carriers, no cases of ovarian cancer occurred after salpingo-oophorectomy over a 6-year follow-up period, whereas 3% of those who did not undergo the same surgery were diagnosed with ovarian cancer. None of the women who underwent RRM developed breast cancer. RRSO was associated with a reduction in overall mortality (hazard ratio [HR] = 0.40), breast cancer–specific mortality (HR = 0.44), and ovarian cancer–specific mortality (HR = 0.21). Among women who underwent RRSO, only 1.1% developed ovarian cancer.

The NCCN Breast Cancer Risk Reduction Panel recommends limiting RRSO to women with a known or strongly suspected *BRCA1/2* mutation. Peritoneal washings should be performed at surgery, and pathologic assessment should include fine sectioning of the ovaries and fallopian tubes.[98] The additional benefit of concurrent hysterectomy is

Printed by Ariel Smits on 10/22/2014 1:57:36 PM. For personal use only. Not approved for distribution. Copyright © 2014 National Comprehensive Cancer Network, Inc., All Rights Reserved.

not clear at this time. Women who undergo RRSO should continue with routine health maintenance and breast screening as per the NCCN Guidelines for Breast Cancer unless a woman has had RRM.

Risk-Reduction Agents

Risk-reduction agents (ie, tamoxifen, raloxifene, anastrozole, exemestane) are recommended for women ≥35 years of age only, as the utility of these agents in women younger than 35 years is unknown.

Tamoxifen for Risk Reduction

The benefits of tamoxifen, a selective estrogen receptor (ER) modulator (SERM), in the treatment of breast cancer in the adjuvant and metastatic settings are well documented. Retrospective analysis of randomized, controlled, clinical trials comparing tamoxifen to no tamoxifen in the adjuvant treatment of women with breast cancer has shown a reduction in the incidence of contralateral second primary breast cancer.[99-102] The meta analyses by Early Breast Cancer Trialists' Collaborative Group confirmed that the risk for contralateral primary breast cancer is substantially reduced (ie, a statistically significant annual recurrence rate ratio = 0.59) by 5 years of tamoxifen therapy in women with first breast cancers that are ER-positive or have an unknown ER status.[103]

NSABP Breast Cancer Prevention Trial

The effectiveness of tamoxifen in the setting of breast cancer treatment gave rise to the NSABP BCPT study, also known as the P-1 study. It was a randomized clinical trial of healthy women aged 60 years or older, aged 35 to 59 years with a 1.7% or greater cumulative 5-year risk for developing breast cancer, or with a history of LCIS.[55] Both premenopausal and postmenopausal women were enrolled in the trial and randomized in a double-blinded fashion to treatment with tamoxifen, 20 mg daily for 5 years, or placebo. Invasive breast cancer incidence was the primary study endpoint; high-priority secondary endpoints included the occurrence of thromboembolic disease, cardiovascular disease, bone fracture, endometrial cancer, noninvasive breast cancer, and breast cancer mortality. The trial was unblinded and initial findings were reported in 1998. A subsequent report on this trial has been published, which takes into account 7 years of follow-up data subsequent to the point where the study was unblinded. However, nearly one-third of the placebo participants began taking a SERM when the study was unblinded, which decreased the proportion of women in the placebo group relative to the tamoxifen group, potentially confounding the long-term results.[56]

The results of the P-1 study showed that treatment with tamoxifen decreased the short-term risk for breast cancer by 49% in healthy women aged 35 years or older who had an increased risk for the disease.[55] Risk-reduction benefits were demonstrated across all age groups, in pre-menopausal and post-menopausal women. The difference in average annual rates for invasive breast cancer was 3.30 cases per 1,000 women (ie, 6.76 cases per 1,000 women in the placebo group and 3.43 cases per 1,000 women in the group taking tamoxifen). The absolute risk reduction was 21.4 cases per 1,000 women over 5 years.[55] In terms of numbers needed to treat, this corresponds to treatment of 47 women with tamoxifen to prevent 1 case of invasive breast cancer. Updated results indicate that breast cancer risk was reduced by 43% in this population after 7 years of follow-up.[56] The reduction in invasive breast cancer risk in participants with atypical hyperplasia was particularly striking (risk ratio [RR], 0.14; 95% CI, 0.03–0.47) in the initial study analysis, and a RR of 0.25 (95% CI, 0.10–0.52) was found after 7 years of follow-up. An additional benefit of tamoxifen was a decrease in bone fractures (RR, 0.81; 95% CI, 0.63–1.05). However, as was anticipated from the experience in studies of

Printed by Ariel Smits on 10/22/2014 1:57:36 PM. For personal use only. Not approved for distribution. Copyright © 2014 National Comprehensive Cancer Network, Inc., All Rights Reserved.

women taking tamoxifen following a breast cancer diagnosis, major toxicities included hot flashes, invasive endometrial cancer in postmenopausal women, and cataracts. A significant increase in the incidence of pulmonary embolism was also observed in women ≥50 years of age taking tamoxifen. The average annual rates of pulmonary embolism per 1000 women were 1.00 versus 0.31 (RR= 3.19; 95% CI, 1.12–11.15).[55]

No differences were observed in overall rates of mortality by treatment group with a follow-up period of up to 7 years. The initial study analysis revealed that average annual mortality from all causes in the tamoxifen group was 2.17 per 1,000 women compared with 2.71 per 1,000 women treated with placebo, for a RR of 0.81 (95% CI, 0.56–1.16).[55]Annual mortality after 7 years of follow-up was 2.80 per 1,000 women compared with 3.08 per 1,000 women in the tamoxifen and placebo groups, respectively, for a RR of 1.10 (95% CI, 0.85–1.43).[56]

An evaluation of the subset of patients with a *BRCA1/2* mutation in the P-1 study revealed that breast cancer risk was reduced by 62% in study patients with a *BRCA2* mutation receiving tamoxifen relative to placebo (RR = 0.38; 95% CI, 0.06–1.56). However, tamoxifen use was not associated with a reduction in breast cancer risk in patients with a *BRCA1* mutation.[104] These findings may be related to the greater likelihood for development of ER-positive tumors in *BRCA2* mutation carriers relative to *BRCA1* mutation carriers. However, this analysis was limited by the very small number of patients with a *BRCA1/2* mutation.

Based on the BCPT [P-1] study results, in October 1998 the U.S. Food and Drug Administration (FDA) approved tamoxifen for breast cancer risk reduction for women at increased risk for breast cancer.

European Studies of Tamoxifen

Three European studies comparing tamoxifen with placebo for breast cancer risk reduction have also been reported. The Royal Marsden Hospital study was a pilot trial of tamoxifen versus placebo in women ages 30 to 70 years who were at increased breast cancer risk based largely on their family history.[105,106] Women in the trial were allowed to continue or to initiate postmenopausal HT. With 2471 participants available for interim analysis, no difference in the frequency of breast cancer was observed between the 2 study groups. Moreover, the toxicity experienced by the 2 groups did not show statistically significant differences.[106] An analysis of updated findings from the Royal Marsden Hospital study did demonstrate a nonsignificant breast cancer risk-reduction benefit with tamoxifen use (ie, 62 cases of breast cancer in 1238 women receiving tamoxifen vs. 75 cases of breast cancer in 1233 women in the placebo arm).[105]

Most recently, an analysis of blinded results from the Royal Marsden Hospital trial at 20-year follow-up showed no difference in breast cancer incidence between the groups randomly assigned to tamoxifen or placebo (HR = 0.78; 95% CI, 0.58– 1.04; P = .10).[107] However, the incidence of ER-positive breast cancer was significantly lower in the tamoxifen arm vs. placebo arm of the trial (HR = 0.61; 95% CI, 0.43–0.86; P = .005). Importantly, the difference between the 2 arms became significant only in the posttreatment period (ie, after 8 years of treatment).

The Italian Tamoxifen Prevention Study randomized 5408 women ages 35 to 70 years without breast cancer, who had undergone a previous hysterectomy, to receive tamoxifen or placebo for 5 years.[108] Women in the trial were allowed to receive HT. No significant difference in breast cancer occurrence in the overall study population was identified at median follow-up periods of 46, 81.2, and 109.2 months.[108-110]

Printed by Ariel Smits on 10/22/2014 1:57:36 PM. For personal use only. Not approved for distribution. Copyright © 2014 National Comprehensive Cancer Network, Inc., All Rights Reserved.

Thromboembolic events, predominantly superficial thrombophlebitis, were increased in women treated with tamoxifen. A subset of women in the Italian Tamoxifen Prevention Study who had used HT and were classified as at increased breast cancer risk based on reproductive and hormonal characteristics were found to have a significantly reduced risk for breast cancer with tamoxifen therapy.[110,111] However, only approximately 13% of the patients in the trial were at high risk for breast cancer.

It is unclear why no overall breast cancer risk reduction was observed in the Italian Tamoxifen Prevention Study. Possible reasons include concurrent use of HT, and different study populations (ie, populations at lower risk for breast cancer).[112]

The first International Breast Cancer Intervention Study (IBIS-I) randomized 7152 women aged 35 to 70 years at increased risk for breast cancer to receive either tamoxifen or placebo for 5 years.[113] Tamoxifen provided a breast cancer (invasive or ductal carcinoma in situ) risk reduction of 32% (95% CI, 8–50; $P = .013$). Thromboembolic events increased with tamoxifen (odds ratio = 2.5; 95% CI, 1.5–4.4; $P = .001$), and endometrial cancer showed a nonsignificant increase ($P = .20$). An excess of deaths from all causes was seen in the tamoxifen-treated women ($P = .028$).

In an updated analysis of the blinded IBIS-I trial at a median follow-up of 96 months, the relative risk for breast cancer for the tamoxifen arm compared with placebo was 0.73 (95% CI, 0.58–0.91; $P = .004$).[114] Although no difference in the risk for ER-negative–invasive tumors was observed between the 2 groups, those in the tamoxifen arm were found to have a 34% lower risk for ER-positive invasive breast cancer. Slightly higher risk reduction with tamoxifen was observed for premenopausal patients. Importantly, the increased risk for venous thromboembolism (VTE) observed with tamoxifen during the treatment period was no longer significant in the posttreatment period. Gynecologic and vasomotor side effects associated with active tamoxifen treatment were not observed during the posttreatment follow-up. These results provide randomized evidence that the benefits of tamoxifen continue following cessation of treatment while many of the side effects diminish or disappear.

The use of tamoxifen as a breast cancer risk-reduction agent has most recently been evaluated in the STAR Trial[57,58] (see section on *The STAR Trial* below, MS-11).

Raloxifene for Risk Reduction

Raloxifene is a second-generation SERM that is chemically different from tamoxifen and appears to have similar anti-estrogenic effects with considerably less endometrial stimulation. The efficacy of raloxifene as a breast cancer risk-reduction agent has been evaluated in several clinical studies. In 2007, the FDA expanded the indications for raloxifene to include reduction in risk for invasive breast cancer in postmenopausal women with osteoporosis, and reduction in risk for invasive breast cancer in postmenopausal women at high risk for invasive breast cancer.

The MORE Trial

The Multiple Outcomes of Raloxifene Evaluation (MORE) trial was designed to determine whether 3 years of raloxifene treatment reduced the risk of fracture in postmenopausal women with osteoporosis.[115] A total of 7705 postmenopausal women 31 to 80 years of age were randomized to receive placebo, 60 mg/day of raloxifene, or 120 mg/day of raloxifene for 3 years. At study entry, participants were required to have osteoporosis (defined as a bone density at least 2.5 standard deviations below the mean for young women) or a history of

Printed by Ariel Smits on 10/22/2014 1:57:36 PM. For personal use only. Not approved for distribution. Copyright © 2014 National Comprehensive Cancer Network, Inc., All Rights Reserved.

osteoporotic fracture. The study showed a reduction in the vertebral fracture risk and an increase in bone mineral density (BMD) in the femoral neck and spine for the women treated with raloxifene, compared with those who received placebo.

After a median follow-up of 40 months in the MORE trial, breast cancer was reported in 40 patients: 27 cases in 2576 women receiving placebo and 13 cases in 5129 women receiving raloxifene.[116] The relative risk of developing invasive breast cancer on raloxifene, compared with placebo, was 0.24 (95% CI, 0.13–0.44). Raloxifene markedly decreased the risk for ER-positive cancers (relative risk = 0.10; 95% CI, 0.04–0.24) but did not appear to influence the risk of developing an ER-negative cancer (relative risk = 0.88; 95% CI, 0.26–3.0). Although breast cancer incidence was a secondary endpoint in the MORE trial, it is important to note that breast cancer risk was not a prospectively determined characteristic for the women enrolled and stratified into treatment arms in this study.[112] Furthermore, the patients enrolled in the MORE trial were, on average, at lower risk for breast cancer and older than the patients enrolled in the NSABP BCPT [P-1] study.

Side effects associated with the raloxifene use included hot flashes, influenza-like syndromes, endometrial cavity fluid, peripheral edema, and leg cramps. In addition, there was an increased incidence of deep venous thromboses (DVT) (0.7% for women receiving 60 mg/day raloxifene vs. 0.2% for placebo) and pulmonary emboli (0.3% for women receiving 120 mg/day raloxifene vs. 0.1% for placebo) associated with raloxifene treatment. However, there was no increase in the risk for endometrial cancer associated with raloxifene.

The CORE Trial

The early findings related to breast cancer risk in the MORE trial led to the continuation of this trial under the name Continuing Outcomes Relevant to Evista (CORE) trial. Because breast cancer incidence was a secondary endpoint in the MORE trial, CORE was designed to assess the effect of 4 additional years of raloxifene on the incidence of invasive breast cancer in postmenopausal women with osteoporosis. A secondary endpoint was the incidence of invasive ER-positive breast cancer. Data from the CORE trial were reported in 2004.[117]

During the CORE trial, the 4-year incidence of invasive breast cancer was reduced by 59% (HR = 0.41; 95% CI, 0.24–0.71) in the raloxifene group compared with the placebo group. Raloxifene, compared to placebo, reduced the incidence of invasive ER-positive breast cancer by 66% (HR = 0.34; 95% CI, 0.18–0.66) but had no effect on invasive ER-negative breast cancers.[117] Over the 8 years of both trials (MORE + CORE), the incidence of invasive breast cancer was reduced by 66% (HR = 0.34; 95% CI, 0.22–0.50) in the raloxifene group compared with the placebo group. Compared to placebo, 8 years of raloxifene reduced the incidence of invasive ER-positive breast cancer by 76% (HR = 0.24; 95% CI, 0.15–0.40). Interestingly, the incidence of noninvasive breast cancer was not significantly different for patients in the raloxifene and placebo arms (HR = 1.78; 95% CI, 0.37–8.61).[117]

The adverse events in the CORE trial were similar to those seen in the MORE trial. There was a nonsignificant increase in the risk for thromboembolism (relative risk = 2.17; 95% CI, 0.83–5.70) in the raloxifene group of the CORE trial compared to the placebo group. There was no statistically significant difference in endometrial events (bleeding, hyperplasia, and cancer) between the raloxifene and placebo groups during the 4 years of CORE or the 8 years of MORE and CORE. During the 8 years of the MORE and CORE trials, raloxifene increased the risk for hot flushes and leg cramps compared with placebo; these risks were observed during the MORE trial but not during the additional 4 years of therapy in CORE. While it is possible

Printed by Ariel Smits on 10/22/2014 1:57:36 PM. For personal use only. Not approved for distribution. Copyright © 2014 National Comprehensive Cancer Network, Inc., All Rights Reserved.

that hot flushes and leg cramps are early events that do not persist with continued therapy, it is also possible that an increased risk of these adverse events was not observed in the CORE trial as a result of selection bias (ie, women who experienced these symptoms in the MORE trial may have chosen not to continue in the CORE trial).

The results from the CORE trial are not entirely straightforward because of the complex design of the trial. Of the 7705 patients randomized in the MORE trial, only 4011 chose to continue, blinded to therapy, in CORE; this drop off likely introduces bias in favor of the treatment group. In the CORE trial, the researchers did not randomize the patients again (1286 in the placebo arm, 2725 in the raloxifene arm), maintaining the double blinding of the original trial.

The RUTH Trial

In the Raloxifene Use for The Heart (RUTH) trial, postmenopausal women with an increased risk for coronary heart disease were randomly assigned to raloxifene or placebo arms.[118,119] Invasive breast cancer incidence was another primary endpoint of the trial, although only approximately 40% of the study participants had an increased risk for breast cancer according to the Gail model. Median exposure to study drug was 5.1 years and median duration of follow-up was 5.6 years.[119] Raloxifene did not reduce risk of cardiovascular events, but there was a 44% decrease in the incidence of invasive breast cancer in the raloxifene arm (HR=0.56; 95% CI, 0.38–0.83], with a 55% lower incidence of ER-positive breast cancer (HR=0.45; 95% CI, 0.28–0.72). No reduction in the risk for noninvasive breast cancer was found for patients receiving raloxifene, in agreement with the initial results of the STAR trial, although only 7% of breast cancers in the RUTH trial were noninvasive.

The STAR Trial

Despite issues of trial design, the results from the CORE trial and the previous MORE study provided support for concluding that raloxifene may be an effective breast cancer risk-reduction agent. However, neither of these studies was designed to directly evaluate the efficacy of raloxifene versus tamoxifen in this regard. This issue was addressed in the NSABP STAR trial (P-2), which was initiated in 1999; initial results became available in 2006.[57]

In the STAR trial, 19,747 postmenopausal women 35 years or older at increased risk for invasive breast cancer as determined by the modified Gail model or with a personal history of LCIS were enrolled into one of two treatment arms (no placebo arm). The primary study endpoint was invasive breast cancer; secondary endpoints included quality of life, and incidences of noninvasive breast cancer, DVT, pulmonary embolism, endometrial cancer, stroke, cataracts, and death. At an average follow-up of approximately 4 years, no statistically significant differences between patients receiving 20 mg/day of tamoxifen or 60 mg/day of raloxifene were observed with respect to invasive breast cancer risk reduction (RR = 1 .02;95% CI, 0.82–1.28). Because there was no placebo arm, it was not possible to determine a raloxifene-versus-placebo RR for invasive breast cancer; however, tamoxifen was shown in the BCPT [P-1] study to reduce breast cancer risk by nearly 50%. In addition, raloxifene was shown to be as effective as tamoxifen in reducing the risk for invasive cancer in the subset of patients with a history of LCIS or atypical hyperplasia. However, raloxifene was not as effective as tamoxifen in reducing the risk for noninvasive breast cancer, although the observed difference was not statistically significant (RR = 1.40; 95% CI, 0.98–2.00).[55]

At a median follow-up of nearly 8 years (81 months) involving 19,490 women, raloxifene was shown to be about 76% as effective as

Printed by Ariel Smits on 10/22/2014 1:57:36 PM. For personal use only. Not approved for distribution. Copyright © 2014 National Comprehensive Cancer Network, Inc., All Rights Reserved.

tamoxifen in reducing the risk for invasive breast cancer (RR = 1.24; 95% CI, 1.05–1.47), suggesting that tamoxifen has greater long-term benefit with respect to lowering invasive breast cancer risk.[58] Raloxifene remained as effective as tamoxifen in reducing the risk for invasive cancer in women with LCIS (RR, 1.13; 95% CI, 0.76–1.69), but was less effective than tamoxifen for those with a history of atypical hyperplasia (RR, 1.48; 95% CI = 1.06–2.09). Interestingly, at long-term follow-up, the risk for noninvasive cancer in the raloxifene arm grew closer to that observed for the group receiving tamoxifen (RR = 1.22; 95% CI, 0.95–1.50). No significant differences in mortality were observed between the 2 groups. In the initial analysis of the STAR trial data, invasive endometrial cancer occurred less frequently in the group receiving raloxifene compared with the tamoxifen group, although the difference did not reach statistical significance. It is important to note, however, that the incidence of endometrial hyperplasia and hysterectomy were significantly lower in the raloxifene group compared to the tamoxifen group. However, at long-term follow-up, the risk for endometrial cancer was significantly lower in the raloxifene arm (RR, 0.55; 95% CI, 0.36–0.83).

The lower incidences of thromboembolic events (RR, 0.75; 95% CI, 0.60–0.93) and cataract development (RR, 0.80; 95% CI, 0.72–0.89) observed in the raloxifene group compared to the tamoxifen group when the STAR trial results were initially analyzed were maintained at long-term follow-up.[58] The incidences of stroke, ischemic heart disease, and bone fracture were similar in the two groups. In the initial report, overall quality of life was reported to be similar for patients in both groups, although patients receiving tamoxifen reported better sexual function.[120]

Aromatase Inhibitors for Risk Reduction

A number of clinical trials testing the use of aromatase inhibitors (AIs) in the adjuvant therapy of postmenopausal women with invasive breast cancer have been reported. The first of these studies, the Arimidex, Tamoxifen, Alone or in Combination trial (ATAC trial), randomized postmenopausal women with invasive breast cancer to anastrozole versus tamoxifen versus anastrozole plus tamoxifen in a double-blinded fashion.[121] The occurrence of contralateral second primary breast cancers was a study endpoint. At 47 months median follow-up, a nonsignificant reduction in contralateral breast cancers was observed in women treated with anastrozole alone compared with tamoxifen (odds ratio = 0.62; 95% CI, 0.38–1.02; P = .062) and a significant reduction in contralateral breast cancers was seen in the subset of women with hormone receptor-positive first cancers (odds ratio= 0.56; 95% CI, 0.32–0.98; P = .04).[122] Similar reductions in the risk for contralateral breast cancer have been observed with sequential tamoxifen followed by exemestane compared with tamoxifen alone and with sequential tamoxifen followed by letrozole compared with tamoxifen followed by placebo.[123,124]

In the Breast International Group (BIG) 1-98 trial postmenopausal women with early-stage breast cancer were randomized to receive 5 years of treatment with one of the following therapeutic regimens: letrozole; sequential letrozole followed by tamoxifen; tamoxifen; or sequential tamoxifen followed by letrozole. Risk for breast cancer recurrence was lower in women in the letrozole arm relative to the tamoxifen arm.[125]

The results of the MAP.3 trial show promising use of exemestane in the breast cancer prevention setting. MAP.3 is a randomized, double-blind, placebo-controlled, multicenter, multinational trial in which 4560 women were randomly assigned to either exemestane (2285 patients) or

Printed by Ariel Smits on 10/22/2014 1:57:36 PM. For personal use only. Not approved for distribution. Copyright © 2014 National Comprehensive Cancer Network, Inc., All Rights Reserved.

placebo (2275 patients).[3] The study authors reported that about 5% of patients in each group had discontinued the protocol treatment. The major reasons for early discontinuation of the protocol treatments were toxic effects (15.4% in the exemestane group vs. 10.8% in the placebo group, $P < .001$) and patient refusal (6.9% vs. 6.0%, $P = .22$). After a median follow-up of 3 years, compared to the placebo exemestane was found to reduce the relative incidence of invasive breast cancers by 65%, from 0.55% to 0.19% (HR, 0.35 with exemestane; 95% CI, 0.18–0.70).[3]

The IBIS-II study included 3864 postmenopausal women at high risk for breast cancer, defined by family history of breast cancer or prior diagnosis of DCIS, LCIS, or atypical ductal hyperplasia.[4] (HR, 0.47; 95% CI, 0.32–0.68). The advantage of anastrozole was greater prevention of high-grade tumors (HR, 0.35; 95% CI, 0.16–0.74) compared with intermediate- or low-grade tumors. The follow-up period in this trial was longer than that for the MAP.3 trial. The cumulative incidence after 7 years was predicted to rise 2.8% in the anastrozole group compared with 5.6% in the placebo group.[4]

NCCN Breast Cancer Risk Reduction Panel Recommendations for Risk-Reduction Agents

Based on data from the BCPT[55] and STAR[57] trials, Freedman et al have developed tables of benefit/risk indices for women aged 50 years and older to compare raloxifene versus no treatment (placebo) and tamoxifen versus no treatment.[2] The risk and benefit of treatment with either tamoxifen or raloxifene depends on age, race, breast cancer risk, and history of hysterectomy. There are separate tables in the report listing the level of 5-year invasive breast cancer risk by age group for non-Hispanic white women with and without a uterus, black women with and without a uterus, and Hispanic women with and without a uterus. The NCCN Breast Cancer Risk Reduction Panel recommends using these tables [2] while counseling postmenopausal women regarding use of raloxifene and tamoxifen for breast cancer risk reduction.

Tamoxifen Recommendations

The NCCN Breast Cancer Risk Reduction Panel recommends tamoxifen (20 mg/day) as an option to reduce breast cancer risk in healthy pre- and postmenopausal women ≥35 years of age, whose life expectancy is ≥10 years, and who have a ≥1.7% 5-year risk for breast cancer as determined by the modified Gail model, or who have had LCIS (category 1). The consensus of the NCCN Breast Cancer Risk Reduction Panel is that the risk/benefit ratio for tamoxifen use in premenopausal women at increased risk for breast cancer is relatively favorable (category 1), and that the risk/benefit ratio for tamoxifen use in postmenopausal women is influenced by age, presence of uterus, or other comorbid conditions (category 1). Early studies suggest that lower doses of tamoxifen over shorter treatment periods may reduce breast cancer risk in postmenopausal women, but these findings need to be validated in phase III clinical trials.[126] Only limited data are currently available regarding the efficacy of tamoxifen risk reduction in *BRCA1/2* mutation carriers and women who have received prior thoracic radiation. The efficacy of tamoxifen risk reduction in women with *BRCA1/2* mutations is less well studied than in other risk groups. However, available data suggest a benefit.[104]

The utility of tamoxifen as a breast cancer risk-reduction agent in women <35 years of age is not known. There are insufficient data on the influence of ethnicity and race on the efficacy and safety of tamoxifen as a risk-reduction agent.

There is evidence that certain drugs (eg, serotonin reuptake inhibitors [SSRIs]) interfere with the enzymatic conversion of tamoxifen to endoxifen by inhibiting a particular isoform of cytochrome P-450 2D6

Printed by Ariel Smits on 10/22/2014 1:57:36 PM. For personal use only. Not approved for distribution. Copyright © 2014 National Comprehensive Cancer Network, Inc., All Rights Reserved.

enzyme (CYP2D6) involved in the metabolism of tamoxifen.[127] The consensus of the NCCN Breast Cancer Risk Reduction Panel is that alternative medications that have minimal or no impact on plasma levels of endoxifen should be substituted when possible.[127] Citalopram and venlafaxine do not disrupt tamoxifen metabolism.

It has also been reported that certain CYP2D6 genotypes are markers of poor tamoxifen metabolism.[128,129] Nevertheless, the consensus of the NCCN Breast Cancer Risk Reduction Panel is that further validation of this biomarker is needed before it can be used to select patients for tamoxifen therapy.

Raloxifene Recommendations

The NCCN experts serving on the Breast Cancer Risk Reduction Panel feel strongly that tamoxifen is a superior choice of risk-reduction agent for most postmenopausal women desiring non-surgical risk-reduction therapy. This is based on the updated STAR trial results that showed diminished benefits of raloxifene compared to tamoxifen after cessation of therapy.[58] However, consideration of toxicity may still lead to the choice of raloxifene over tamoxifen in some women.

If raloxifene is chosen, the NCCN Breast Cancer Risk Reduction Panel recommends use of 60 mg/day. Data regarding use of raloxifene to reduce breast cancer risk is limited to healthy postmenopausal women ≥35 years who have a ≥1.7% 5-year risk for breast cancer as determined by the modified Gail model, or who have a history of LCIS. The consensus of the NCCN Breast Cancer Risk Reduction Panel is that the risk/benefit ratio for raloxifene use in postmenopausal women at increased risk for breast cancer is influenced by age and comorbid conditions (category 1). Since there are no currently available data regarding the efficacy of raloxifene risk reduction in *BRCA1/2* mutation carriers and women who have received prior thoracic radiation, use of raloxifene in these populations is designated as a category 2A recommendation by the NCCN Breast Cancer Risk Reduction Panel. Use of raloxifene to reduce breast cancer risk in premenopausal women is inappropriate unless part of a clinical trial. The utility of raloxifene as a breast cancer risk-reduction agent in women <35 years of age is not known. There are insufficient data on the influence of ethnicity and race on the efficacy and safety of raloxifene as a risk-reduction agent.

AI Recommendations (Anastrozole and Exemestane)

The NCCN experts serving on the Breast Cancer Risk Reduction Panel have included exemestane and anastrozole as choices of risk-reduction agent for most postmenopausal women desiring non-surgical risk-reduction therapy (category 1). This is based on the results of the MAP.3 trial[3] and the IBIS-II trial.[4] The NCCN Breast Cancer Risk Reduction Panel recommends use of 25 mg/day of exemestane or 1 mg per day of anastrozole. Data regarding use of AI (exemestane and anastrozole) to reduce breast cancer risk are limited to postmenopausal women 35 years of age or older with a Gail model 5-year risk score >1.66% or a history of LCIS. The consensus of the NCCN Breast Cancer Risk Reduction Panel is that the risk/benefit ratio for use of an AI in postmenopausal women at increased risk for breast cancer is influenced by age, bone density, and comorbid conditions. Use of an AI to reduce breast cancer risk in premenopausal women is inappropriate unless part of a clinical trial. The utility of an AI as a breast cancer risk-reduction agent in women <35 years of age is not known. There are insufficient data on the influence of ethnicity and race on the efficacy and safety of raloxifene as a risk-reduction agent.

Exemestane and anastrazole are not currently FDA approved for breast cancer risk reduction. Currently, there are no data comparing the benefits and risks of AI to those of tamoxifen or raloxifene.

Monitoring Patients on Risk Reduction Agents

Follow-up of women treated with risk-reduction agents for breast cancer risk reduction should focus on the early detection of breast cancer and the management of adverse symptoms or complications. Appropriate monitoring for breast cancer and the evaluation of breast abnormalities should be performed according to the guidelines described for high-risk women in the NCCN Guidelines for Breast Cancer Screening and Diagnosis. The population of women eligible for risk-reduction therapy with tamoxifen, raloxifene, anastrozole, or exemestane is at sufficiently increased risk for breast cancer to warrant, at a minimum, yearly bilateral mammography, a clinical breast examination every 6–12 months, and encouragement of breast awareness.

Endometrial Cancer

Results from the BCPT [P-1] study indicated that women ≥50 years of age treated with tamoxifen have an increased risk of developing invasive endometrial cancer. For women ≥50 years the risk of developing endometrial cancer while on tamoxifen compared to placebo was high (RR, 4.01, 95% CI 1.70–10.90).[55,56] An increased risk for endometrial cancer was *not* observed in women ≤49 years of age treated with tamoxifen in this study (RR, 1.21, 95% CI, 0.41–3.60).[55,56] Although the only death from endometrial cancer in the NSABP BCPT [P-1] occurred in a placebo-treated subject,[55,56] analyses of the NSABP data have revealed a small number of uterine sarcomas among the number of patients with an intact uterus taking tamoxifen. Uterine sarcoma is a rare form of uterine malignancy reported to occur in 2% to 4% of all patients with uterine cancer.[130] Compared with other uterine cancers, uterine sarcomas present at a more advanced stage and thus may carry a worse prognosis in terms of disease-free and overall survival.[131,132]

Updated results from the NSABP studies have indicated that incidence of both endometrial adenocarcinoma and uterine sarcoma is increased in women taking tamoxifen when compared to the placebo arm.[133] Several other studies have also supported an association between tamoxifen therapy and an increased risk of developing uterine sarcoma.[131,132,134,135] A "black box" FDA warning has been included on the package insert of tamoxifen to highlight the endometrial cancer risk (both epithelial endometrial cancer and uterine sarcoma) of tamoxifen.[136]

Use of raloxifene has not been associated with an increased incidence of endometrial cancer in the MORE trial.[116] Long-term results from the STAR trial showed the incidence of invasive endometrial cancer to be significantly lower in the group receiving raloxifene compared with the tamoxifen group (RR, 0.55, 09% CI 0.36–0.83).[58] For women with an intact uterus, a baseline gynecologic assessment is recommended prior to administration of the risk-reduction agent, and follow-up gynecologic assessments should be performed at each visit.[137] The vast majority of women with tamoxifen-associated endometrial cancer present with vaginal spotting as an early symptom of cancer. Therefore, prompt evaluation of vaginal spotting in the postmenopausal woman is essential.

At present, there is insufficient evidence to recommend the performance of uterine ultrasonography or endometrial biopsy for routine screening in asymptomatic women.[138-140] In women diagnosed with endometrial cancer while taking a risk-reduction agent, the drug should be discontinued until the endometrial cancer has been fully treated. The NCCN Breast Cancer Risk Reduction Panel believes that it is safe and reasonable to resume therapy with a risk-reduction agent after completion of treatment for early-stage endometrial cancer.

Retinopathy and Cataract Formation

There have been reports of tamoxifen being associated with the occurrence of retinopathy, although most of this information has come from case studies.[141,142] Furthermore, these reports have not been confirmed in the randomized controlled trials of tamoxifen. A 1.14 relative risk of cataract formation (95% CI, 1.01–1.29), compared with placebo, has been reported in the BCPT [P-1] study, and individuals developing cataracts while on tamoxifen have a relative risk for cataract surgery of 1.57 (95% CI, 1.16–2.14), compared with placebo.[55] After 7 years of follow-up in the BCPT [P-1] study, relative risks of cataract formation and cataract surgery were similar to those initially reported.[56] In the MORE trial, raloxifene use was not associated with an increase in the incidence of cataracts compared with placebo (relative risk = 0.9; 95% CI, 0.8–1.1).[143] In the STAR trial, the incidence of cataract development and occurrence of cataract surgery was significantly higher in the group receiving tamoxifen compared with the group receiving raloxifene.[58,143] The rate of cataract development (RR = 0.80; 95% CI, 0.72– 0.89) and the rate of cataract surgery (RR = 0.79; 95% CI, 0.70–0.90) were about 20% less in the raloxifene group than in the tamoxifen group.[58,143] Thus, patients experiencing visual symptoms while undergoing treatment with tamoxifen should seek ophthalmologic evaluation.

Bone Mineral Density

Bone is an estrogen-responsive tissue, and tamoxifen can act as either an estrogen agonist or estrogen antagonist with respect to bone, depending on the menstrual status of a woman.[106,144-146] In premenopausal women, tamoxifen may oppose the more potent effects of estrogen on the bone and potentially increase the risk for osteoporosis, whereas tamoxifen in the presence of typically lower estrogen levels in postmenopausal women is associated with an increase in BMD.[55,56] However, the NCCN Breast Cancer Risk Reduction Panel does not recommend monitoring BMD in premenopausal patients on tamoxifen, since development of osteopenia/osteoporosis in this population is considered unlikely. Changes in BMD are of concern in women on AI therapy. Therefore, a baseline BMD scan is recommended before initiating therapy with an AI such as anastrozole or exemestane.

Raloxifene has been shown to increase BMD and to reduce incidence of vertebral bone fracture in postmenopausal women when compared with placebo.[115,118] Results from the STAR trial did not reveal any difference in the incidence of bone fracture in the groups of postmenopausal women on either raloxifene or tamoxifen.[57,58]

Thromboembolic Disease and Strokes

Tamoxifen and raloxifene have been associated with an increased risk of thromboembolic events (ie, DVT, pulmonary embolism) and stroke.[55,56-58,116,147] Increased incidences of VTE were observed in the tamoxifen arms of all the placebo-controlled, randomized, risk-reduction trials. Although not statistically significant, all of these trials with the exception of the Royal Marsden trial (which enrolled only younger women) also showed an increase in risk for stroke for women receiving tamoxifen. This risk was found to be significantly elevated in 2 meta analyses of randomized controlled trials evaluating tamoxifen for breast cancer risk reduction or treatment.[148,149] Comparison of the raloxifene and tamoxifen arms of the STAR trial did not show a difference with respect to incidence of stroke,[57,58] and the risk of fatal stroke was significantly higher for women in the RUTH trial with underlying heart disease receiving raloxifene.[119] However, evidence has shown that women with a Factor V Leiden or prothrombin G20210 → A mutation receiving tamoxifen therapy in the BCPT [P-1] study were not at increased risk of developing VTE compared to women without these mutations.[150] Although prospective screening of women for Factor V Leiden or

Printed by Ariel Smits on 10/22/2014 1:57:36 PM. For personal use only. Not approved for distribution. Copyright © 2014 National Comprehensive Cancer Network, Inc., All Rights Reserved.

prothrombin mutations or intermittent screening of women for thromboembolic disease is unlikely to be of value, women taking tamoxifen or raloxifene should be educated regarding the symptoms associated with DVT and pulmonary emboli. They should also be informed that prolonged immobilization may increase risk of VTE, and should be instructed to contact their physicians immediately if they develop symptoms of DVT or pulmonary emboli. Women with documented thromboembolic disease should receive appropriate treatment for the thromboembolic condition and should permanently discontinue tamoxifen or raloxifene therapy.

Managing Side Effects of Risk-Reduction Agents

Hot flashes are a common menopausal complaint. In the BCPT [P-1] study, hot flashes occurred in approximately 81% of women treated with tamoxifen and 69% of women treated with placebo.[55] In the STAR trial, women receiving tamoxifen reported a significantly increased incidence of vasomotor symptoms relative to women receiving raloxifene,[120] although raloxifene use has also been associated with an increase in hot flash severity and/or frequency when compared with placebo.[116] In women whose quality of life is diminished by hot flashes, an intervention to eliminate or minimize hot flashes should be undertaken. Estrogens and/or progestins have the potential to interact with SERMs and are not recommended by the NCCN Breast Cancer Risk Reduction Panel for the treatment of hot flashes for women on a risk-reduction agent outside of a clinical trial.

Gabapentin, a gamma-aminobutyric acid (GABA) analog used primarily for seizure control and management of neuropathic pain, has been reported to moderate both the severity and duration of hot flashes.[151-154] It has been hypothesized that the mode of action of gabapentin is via central temperature regulatory centers.[151,152] Results from a randomized, double-blind, placebo-controlled study involving the use of gabapentin to treat hot flashes in 420 women with breast cancer have been reported. The three treatment arms of the trial were as follows: 300 mg/day gabapentin; 900 mg/day gabapentin; and placebo. Study duration was 8 weeks, and most of the women in the study (68%–75% depending on treatment arm) were taking tamoxifen as adjuvant therapy. Women in the placebo group experienced reductions in severity of hot flashes of 21% and 15% at 4 and 8 weeks, respectively, whereas those in the treatment arms reported reductions of 33% and 31% with lower-dose gabapentin, and 49% and 46% with higher-dose gabapentin at 4 and 8 weeks, respectively. Only women receiving the higher dose of gabapentin had significantly fewer and less severe hot flashes. Side effects of somnolence or fatigue were reported in a small percentage of women taking gabapentin.[154]

Venlafaxine, a serotonin and norepinephrine inhibitor anti-depressant, has been shown to be effective in the management of hot flash symptoms in a group of breast cancer survivors, 70% of whom were taking tamoxifen. Significant declines were observed for both hot flash frequency and severity scores for all doses of venlafaxine (37.5 mg, 75 mg, and 150 mg) compared to placebo; incremental improvement was seen at 75 mg versus 37.5 mg (P = .03).[155] Participants receiving venlafaxine reported mouth dryness, reduced appetite, nausea, and constipation with increased prevalence at increased dosages. Based on these findings the authors suggested a starting dose of 37.5 mg with an increase, as necessary after one week, to 75 mg if a greater degree of symptom control is desired. However, this study followed subjects for only 4 weeks.

Another antidepressant, paroxetine, an SSRI, has also been studied for the relief of hot flash symptoms. A double-blind, placebo-controlled trial recruited 165 menopausal women who were randomized into 3 arms

Printed by Ariel Smits on 10/22/2014 1:57:36 PM. For personal use only. Not approved for distribution. Copyright © 2014 National Comprehensive Cancer Network, Inc., All Rights Reserved.

(placebo, paroxetine 12.5 mg daily, or paroxetine 25 mg daily). After 6 weeks, significant reductions in composite hot flash scores were noted for both dosages of paroxetine (12.5 mg, 62% reduction and 25 mg, 65% reduction); there were no significant differences between dose levels.[156] Adverse events, reported by 54% of subjects receiving placebo and 58% receiving paroxetine, generally included nausea, dizziness, and insomnia.

In a stratified, randomized, double-blind, cross-over, placebo-controlled study, 151 women reporting a history of hot flashes were randomized to one of 4 treatment arms (10 mg or 20 mg of paroxetine for 4 weeks followed by 4 weeks of placebo or 4 weeks of placebo followed by 4 weeks of 10 mg or 20 mg of paroxetine).[157] Hot flash frequency and composite score were reduced by 40.6% and 45.6%, respectively, for patients receiving 10 mg paroxetine compared to reductions of 13.7% and 13.7% in the placebo group. Likewise, reductions of 51.7% and 56.1% in hot flash frequency and score were found in women receiving 20 mg paroxetine compared with values of 26.6% and 28.8% in the placebo group. No significant differences in efficacy were observed with the lower and higher paroxetine doses. Rates of the most commonly reported side effects did not differ among the 4 arms, although nausea was significantly increased in women receiving 20 mg paroxetine relative to the other arms, and a greater percentage of patients receiving the higher dose of paroxetine discontinued treatment.

While these reports appear promising, further randomized studies of the use of these agents in women experiencing hot flash symptoms, especially those also taking tamoxifen, are needed to assess the long-term effectiveness and safety of these agents. In this context it should be noted that recent evidence has suggested that concomitant use of tamoxifen with certain SSRIs (eg, paroxetine and fluoxetine) may decrease plasma levels of endoxifen and 4-OH tamoxifen, active metabolites of tamoxifen, and may impact its efficacy.[127,158] These SSRIs may interfere with the enzymatic conversion of tamoxifen to its active metabolites by inhibiting a particular isoform of cytochrome P-450 enzyme (CYP2D6) involved in the metabolism of tamoxifen. Caution is advised about co-administration of these drugs with tamoxifen. Citalopram and venlafaxine appear to have only minimal effects on tamoxifen metabolism.

Of interest in this context are results of a retrospective evaluation of data from the Women's Healthy Eating and Living randomized trial, which suggest an inverse association between hot flashes and breast cancer recurrence for women with a history of breast cancer receiving tamoxifen. These results suggest that hot flashes in women receiving tamoxifen may be an indicator of the biologic availability and, thus, effectiveness of the drug. However, additional studies are needed to further elucidate whether hot flashes are predictive of benefit from tamoxifen.[159]

A recent report of 2 nonrandomized, parallel study cohorts of women with DCIS or those at high risk for breast cancer (eg, those with LCIS, atypical hyperplasia, or ≥1.7% 5-year breast cancer risk by the Gail model) comparing women receiving tamoxifen alone with women receiving tamoxifen concomitantly with HT (mean duration of HT at start of study approximately 10 years) did not show a difference in the rate of tamoxifen-induced hot flashes.[160] The NCCN Breast Cancer Risk Reduction Panel recommends against the use of HT for women taking tamoxifen or raloxifene outside of a clinical trial.

A variety of other substances for the control of hot flashes have been described.[161] Both the oral and transdermal formulations of clonidine reduce hot flashes in a dose-dependent manner.[162-164] Toxicities associated with clonidine include dry mouth, constipation, and

Printed by Ariel Smits on 10/22/2014 1:57:36 PM. For personal use only. Not approved for distribution. Copyright © 2014 National Comprehensive Cancer Network, Inc., All Rights Reserved.

drowsiness. Anecdotal evidence suggests that the use of a number of different herbal or food supplements may alleviate hot flashes. Vitamin E may decrease the frequency and severity of hot flashes, but results from a randomized clinical trial demonstrated that only a very modest improvement in hot flashes was associated with this agent compared with placebo.[165] Results from a double-blind, randomized, placebo-controlled, crossover trial of the use of black cohosh to treat hot flashes did not show significant differences between groups with respect to improvement in hot flash symptoms.[166] Some herbal or food supplements contain active estrogenic compounds, the activity and safety of which are unknown. Other strategies such as relaxation training, acupuncture, avoidance of caffeine and alcohol, and exercise for the management of hot flashes, while potentially beneficial, remain unsupported.[167]

It should be noted that the observed placebo effect in the treatment of hot flashes is considerable, typically falling in the range 25% or more,[151,153-157] suggesting that a considerable proportion of patients might be helped through a trial of therapy of limited duration. However, not all women who experience hot flashes require medical intervention, and the decision to intervene requires consideration of the efficacy and toxicity of the intervention. In addition, a study of women receiving tamoxifen for early-stage breast cancer showed a decrease in hot flashes over time.[168]

Components of Risk Reduction Counseling

Women should be monitored according to the NCCN Guidelines for Breast Cancer Screening and Diagnosis. Women with known or suspected *BRCA 1/2, TP53, PTEN*, or other gene mutations associated with breast cancer risk or those with close relatives with breast and/or ovarian cancer should also be followed according to the NCCN Guidelines for Genetic/Familial Risk Assessment: Breast and Ovarian whether or not they choose to undergo risk-reduction therapy. Women who have abnormal results from their clinical breast examination or bilateral mammogram should be managed according to the NCCN Guidelines for Breast Cancer Screening and Diagnosis or, if results indicate malignancy, the women should be treated according to the NCCN Guidelines for Breast Cancer. Although the NCCN Breast Cancer Risk Reduction Panel recommends that women with LCIS be managed according to the NCCN Breast Cancer Risk Reduction Guidelines, risk-reduction strategies for patients with LCIS are also described in the NCCN Guidelines for Breast Cancer.

All women who are appropriate candidates for breast cancer risk-reduction intervention should undergo counseling that provides a description of the available strategies, including a healthy lifestyle, to decrease breast cancer risk.[169] Options for breast cancer risk reduction should be discussed in a shared decision-making environment. The counseling should include a discussion and consideration of: 1) the individual's overall health status, including menopausal status, medical history, and medication history (eg, hysterectomy status, prior history of VTE, current use of hormones or SSRI, previous use of a SERM); 2) absolute and relative breast cancer risk reduction achieved with the risk-reduction intervention; 3) risks of risk-reduction therapy with an emphasis on age-dependent risks; 4) the contraindications to therapy with tamoxifen and raloxifene (eg, history of VTE, history of thrombotic stroke, history of transient ischemic attack, pregnancy or pregnancy potential without an effective nonhormonal method of contraception); and 5) the common and serious side effects of tamoxifen and raloxifene.

The 2009 ASCO Guidelines comparing the effectiveness of breast cancer risk-reduction agents provide some estimates of either the

Printed by Ariel Smits on 10/22/2014 1:57:36 PM. For personal use only. Not approved for distribution. Copyright © 2014 National Comprehensive Cancer Network, Inc., All Rights Reserved.

number needed to treat (NNT) to prevent breast cancer or the number needed to harm (NNH) by causing a specific side effect in a single patient receiving a specific risk-reduction agent.[170] Both NNT and NNH can be useful aids in communicating risks and benefits of tamoxifen and raloxifene in this setting (eg, using long-term data from the IBIS-1 trial, NNH with respect to VTE was determined to be 73 with tamoxifen, whereas this value was 150 for patients receiving raloxifene using data from the RUTH study).

Counseling Prior to Therapy with Risk Reduction Agents

Counseling sessions with women who are considering non-surgical breast cancer risk reduction should incorporate an explanation of data from the BCPT [P-1], STAR, MAP.3, and/or IBIS-II trial as appropriate.

Germline mutations in *PTEN* occur in 85% of patients with Cowden syndrome, an inherited condition associated with increased endometrial carcinoma risk. Therefore, increased risk for endometrial cancer in women with *PTEN* mutations should be discussed while considering a risk-reducing agent.

Counseling on Use of a SERM for Breast Cancer Risk Reduction

The BCPT [P-1] study showed that the toxicity profile of tamoxifen is much more favorable in younger women, and the benefits in relative risk reduction are similar across all age groups and risk groups.[55] The tamoxifen treatment risk/benefit ratio is especially favorable in women between the ages of 35 and 50 years. Unfortunately, individualized data regarding the risk/benefit ratio for tamoxifen are not generally available except for the broad age categories of ages 50 years and younger versus older than 50 years of age. Tamoxifen, unlike raloxifene, is a risk-reduction agent that can be used by premenopausal women. In addition, tamoxifen may be more effective than raloxifene in reducing the incidence of noninvasive breast cancer, although the difference is not statistically significant at long-term follow-up.[57,58] Further, tamoxifen was reported by patients in the STAR trial to be associated with better sexual function than raloxifene.[120] However, tamoxifen has been associated with an increased incidence of invasive endometrial cancer relative to placebo in women ≥50 years of age,[55,56] and an increased incidence of endometrial hyperplasia and invasive endometrial cancer relative to raloxifene,[57,58] possibly making it a less attractive choice in women with a uterus. Use of raloxifene to reduce breast cancer risk may be preferred by postmenopausal women with a uterus or those at risk for developing cataracts. All women receiving a breast cancer risk-reduction agent should be counseled with respect to signs and symptoms of possible side effects associated with use of these agents, and the recommended schedules for monitoring for the presence of certain adverse events. Contraindications to tamoxifen or raloxifene include history of VTE, thrombotic stroke, transient ischemic attack, current pregnancy or pregnancy potential without effective method of contraception, or known inherited clotting trait.

The optimal duration of SERM therapy for breast cancer risk reduction is not known. The BCPT [P-1] and STAR trials studied 5 years of risk-reduction therapy with either tamoxifen or raloxifene.[55,57] However, based on the updated STAR results, which showed that the benefits of raloxifene diminished after cessation of therapy,[58] continuing raloxifene beyond 5 years might be an approach to maintain the risk-reduction activity of the agent.

The use of tamoxifen for periods longer than 5 years has been evaluated in the *adjuvant treatment* setting. Results of two randomized trials on extended adjuvant tamoxifen treatment[171,172] have demonstrated that tamoxifen for up to 10 years is more effective than shorter durations at preventing cancer *recurrence* and improving breast cancer survival. The option of 10 years of adjuvant tamoxifen therapy is

Printed by Ariel Smits on 10/22/2014 1:57:36 PM. For personal use only. Not approved for distribution. Copyright © 2014 National Comprehensive Cancer Network, Inc., All Rights Reserved.

now recommended for both premenopausal women and postmenopausal women for preventing cancer recurrence in the NCCN Guidelines for Breast Cancer and the recently updated ASCO Guidelines.[173] There are limited data on tamoxifen use for more than 5 years in the risk-reduction setting. Until further information is available, a period of 5 years appears to be appropriate for tamoxifen therapy when the agent is used to reduce breast cancer risk.

After completing 5 years of tamoxifen therapy, women should continue to be monitored according to the NCCN Guidelines for Breast Cancer Screening and Diagnosis and should continue to undergo monitoring for late toxicity, especially for endometrial cancer and cataracts.

The prolonged effectiveness of tamoxifen as an agent to reduce breast cancer risk, particularly with respect to the development of ER-positive disease, is supported by results of several placebo-controlled, randomized trials at long-term follow-up.[56,107,114] The recent results from the STAR trial suggest that although a 5-year course of raloxifene retains considerable benefit with respect to the prevention of invasive breast cancer at a median follow-up of 81 months, the breast cancer preventive benefit of tamoxifen therapy for 5 years appears to be sustained for a longer period of time.[58]

The NCCN Breast Cancer Risk Reduction Panel recommends using the tables from the Freedman et al publication[2] while counseling postmenopausal women regarding use of raloxifene and tamoxifen for breast cancer risk reduction.

Counseling on Use of an AI for Breast Cancer Risk Reduction

Currently, there are no data comparing the benefits and risks of AIs (exemestane or anastrozole) to those of tamoxifen or raloxifene. Data regarding exemestane are from the single, large, randomized MAP.3 trial[3] limited to postmenopausal women 35 years of age or older with a Gail model 5-year breast cancer risk of 1.7% or a history of LCIS, which may be used while counseling patients. The data show that exemestane has a completely different toxicity profile than the SERMs. Compared to the placebo group in the MAP.3 trial, exemestane had no increased risk of serious side effects. The incidence of osteoporosis, cardiac events, and bone fractures were identical for women in the MAP.3 trial taking exemestane and for those taking the placebo. Women taking exemestane had a small, but not statistically significant increase in menopausal symptoms, such as hot flashes (18.3% vs. 11.9%) and arthritis (6.5% vs. 4.0%).[3]

Data regarding anastrozole are from a single, large, randomized trial, IBIS-II.[4] The trial included postmenopausal women 40 to 70 years of age with a higher risk of developing cancer compared with the general population. Women who did not meet these criteria but had a Tyrer-Cuzick model 10-year breast cancer risk >5% were also included.[4] Musculoskeletal and vasomotor events were reported in both arms of the trial and were found to be significantly higher in the anastrazole arm (P = .0001); fracture rates were similar in both arms.[4] The optimal duration of AI therapy is currently unknown. Changes in BMD are of concern in women receiving AI therapy. Therefore, a baseline BMD scan is recommended before initiating exemestane therapy. The role of calcium, vitamin D, and maintaining a healthy lifestyle in maintaining bone health must be emphasized in healthy postmenopausal women who are receiving exemestane.

Counseling Prior to Risk Reduction Surgery

For women at very high risk for breast cancer who are considering RRM, it is important that the potential psychosocial effects of RRM are addressed, although these effects have not been well studied.[174-176] Such surgery has the potential to negatively impact perceptions of body image, ease of forming new relationships, and the quality of existing

Printed by Ariel Smits on 10/22/2014 1:57:36 PM. For personal use only. Not approved for distribution. Copyright © 2014 National Comprehensive Cancer Network, Inc., All Rights Reserved.

relationships. Moreover, the procedure also eliminates the breast as a sexual organ. Multidisciplinary consultations are recommended prior to surgery, and should include a surgeon familiar with the natural history and therapy of benign and malignant breast disease[177] to enable the woman to become well informed regarding treatment alternatives, the risks and benefits of surgery, nipple-sparing mastectomy, and surgical breast reconstruction options. Immediate breast reconstruction is an option for many women following RRM, and early consultation with a reconstructive surgeon is recommended for those considering either immediate or delayed breast reconstruction.[178] Psychological consultations may also be considered.

Discussions regarding the risk for ovarian cancer and the option of RRSO for breast and ovarian cancer risk reduction should also be undertaken with women who are known carriers of a *BRCA1/2* mutation. Other topics that should be addressed with respect to RRSO include the increased risk for osteoporosis and cardiovascular disease associated with premature menopause, as well as the potential effects of possible cognitive changes, accelerated bone loss, and vasomotor symptoms on quality of life. Furthermore, the surgery itself may have some associated complications.

It has been reported that short-term HT in women undergoing RRSO did not negate the reduction in breast cancer risk associated with the surgery.[179] In addition, results of a recent case-control study of *BRCA1* mutation carriers showed no association between use of HT and increased breast cancer risk in postmenopausal *BRCA1* mutation carriers.[179] However, the consensus of the NCCN Breast Cancer Risk Reduction Panel is that caution should be used when considering HT use in mutation carriers following RRSO, given the limitations inherent in nonrandomized studies (see also section below on *Breast Cancer Risks Associated with Hormone Therapy*).[180,181] It is unlikely that a prospective randomized study on the use of RRSO for breast cancer risk reduction will be performed. Whether the resulting reduction in the risk for breast cancer from this procedure is preferable to a RRM is likely to remain a personal decision.[182] Table 2 provides estimates based on a Monte Carlo simulation model of the survival impact of breast and ovarian risk-reduction strategies. These data can be used as a tool to facilitate shared decision-making regarding choice of a risk-reduction approach, particularly with respect to issues related to risk-reduction surgery (see Table 2).

Counseling Regarding Lifestyle Modifications

There is evidence to indicate that certain lifestyle characteristics, such as obesity, increased alcohol consumption, and use of certain types of HT, are factors or markers for an elevated risk for breast cancer.[70] However, the association between a lifestyle modification and a change in breast cancer risk is not as clear. Nevertheless, a discussion of lifestyle characteristics associated with increased risk for breast cancer also provides "a teachable moment" for the promotion of overall health, and an opportunity to encourage women to make choices and changes compatible with a healthy lifestyle.

Breast Cancer Risks Associated with Hormone Therapy

The Women's Health Initiative (WHI) enrolled 161,809 postmenopausal women 50 to 79 years of age into a set of clinical trials from 1993 through 1998. Two of these trials were randomized controlled studies involving the use of HT (estrogen with/without progestin) in primary disease prevention: a trial involving 16,608 women with intact uteri at baseline randomized to receive estrogen plus progestin or placebo,[183] and a trial of 10,739 women with prior hysterectomy randomized to receive estrogen alone or placebo.[184] The former trial was terminated early due to evidence for breast cancer harm, along with a global index associated with overall harm. In that study, a 26% increased incidence

of breast cancer was observed in the treatment group (HR =1.26; 95% CI, 1.00–1.59). An increased incidence of abnormal mammograms was also observed for women in the WHI who received estrogen plus progestin, and was attributed to an increase in breast density.[185] Of greater concern is that HT was associated with significant increase in rates of both breast cancer incidence and breast cancer–related mortality,[186] although the increased risk for breast cancer rapidly declined following cessation of HT.[187]

However, an increased risk for breast cancer was not observed in the trial of women who had undergone hysterectomies and were receiving unopposed estrogen. In fact, the rate of breast cancer was lower in the group receiving estrogen relative to the placebo group, although this difference was not considered to be statistically significant.[184] The lower incidence of breast cancer seen among women randomized to estrogen alone during the intervention period became statistically significant with extended follow-up for a mean of 10.7 years.[188] However, an increased incidence of abnormal mammograms was observed in the group of women receiving estrogen,[189] as well as a doubling of the risk for benign proliferative breast disease.[190] Analysis of the data from this randomized controlled WHI trial showed use of estrogen alone to significantly increase mammographic breast density compared with women receiving placebo; this effect was observed for at least a 2-year period.[191] Contrary to the results from the WHI randomized controlled trials, results from several prospective, population-based, observational studies have shown use of estrogen-only HT to be associated with increased risks for breast cancer. These studies include the Black Women's Health Study where use of estrogen alone for a duration of 10 years or longer was associated with a nonsignificant increase in risk for invasive breast cancer (relative risk = 1.41; 95% CI, 0.95–2.10);[192] the Million Women Study of women 50 to 64 years of age, which showed an association between current use of estrogen-only HT and increased risk for breast cancer (relative risk = 1.30; 95% CI, 1.21–1.40; $P <$ .0001);[193] and the Nurses' Health Study, which demonstrated a significantly increased breast cancer risk after long-term use (20 years or longer) of estrogen alone (relative risk = 1.42; 95% CI, 1.13–1.77).[194]

It has been noted that there are important differences in the populations enrolled in the WHI randomized clinical trials relative to the women followed in the observational studies with respect to duration of exposure to HT and age at initiation of HT.[195] For example, many of the women in the WHI clinical trials did not start receiving HT until years after menopause, whereas those in the population-based studies were more likely to initiate HT at menopause and to have been exposed to such treatment for longer periods of time. One hypothesis put forward to explain the apparent contradictions in the summary of studies of HT described above is that short-term use of estrogen following a period of estrogen deprivation may decrease breast cancer risk by inducing apoptosis of occult breast cancer tumors, whereas long-term use of estrogen may initiate and promote the growth of new tumors, thereby increasing breast cancer risk.[196] However, further studies are needed to evaluate this hypothesis. Another possible explanation for the decrease in breast cancer risk observed in the first 2 years of the WHI randomized controlled trial of postmenopausal women receiving estrogen plus progestin may be related to HT effects on breast tissue and subsequent interference with the ability of mammography to detect new breast cancer tumors.[195]

The use of estrogen/progestin therapy and estrogen therapy alone has also been associated with increased risk for cardiovascular disease (eg, stroke) and decreased risk for bone fractures.[183,184] However, a more recent secondary analysis from the WHI randomized controlled trials showed a trend for more effective reduction in the risk for

Printed by Ariel Smits on 10/22/2014 1:57:36 PM. For personal use only. Not approved for distribution. Copyright © 2014 National Comprehensive Cancer Network, Inc., All Rights Reserved.

cardiovascular disease with initiation of HT closer to menopause compared with administration of HT to women who experienced a greater time gap between menopause and the start of such therapy.[197] Nevertheless, recent results from a large French cohort control study show a significantly increased risk for breast cancer in women receiving short-term (ie, 2 years or less) estrogen and progesterone shortly after menopause when compared with nonusers.[198]

The NCCN Breast Cancer Risk Reduction Panel recommends against the use of HT for women taking tamoxifen, raloxifene, anastrozole, or exemestane outside of a clinical trial.

Alcohol Consumption

Numerous studies have demonstrated that the intake of moderate amounts of alcohol (one to two drinks per day) is associated with an increased risk for breast cancer. [70,71,72] A 10% increase in breast cancer risk for every 10 grams of alcohol consumed each day was seen in analyses of two cohort studies.[45,73] A population-based study of 51,847 postmenopausal women provided evidence to support an association between increased alcohol consumption and an increased likelihood of development of ER-positive breast cancer.[199] However, the effect of a reduction in alcohol consumption on the incidence of breast cancer has not been well studied. Even one drink per day modestly elevates breast cancer risk.[70] The consensus of the NCCN Breast Cancer Risk Reduction Panel is that alcohol consumption should be limited to <1 drink per day.

Exercise

Increased levels of physical activity have been associated with a decreased risk for breast cancer.[70,200-203] For example, the effect of exercise on breast cancer risk was evaluated in a population-based study of 90,509 women between the ages of 40 and 65 years.[203] A relative risk of 0.62 (95% CI, 0.49–0.78) was observed for women who reported more than five hours of vigorous exercise per week compared to women who did not participate in recreational activities. These results are supported by another population-based, case-control study of 4538 case patients with newly diagnosed invasive breast cancer and control patients grouped according to race (eg, 1605 black and 2933 white patients). Both black and white women with annual lifetime exercise activity levels exceeding the median activity level for active control subjects were found to have a 20% lower risk for breast cancer when compared to inactive women (odds ratio = 0.82; 95% CI, 0.71–0.93).[200] In addition, a prospective assessment evaluating the association of physical activity among 45,631 women showed the greatest reduction in breast cancer risk for women who reported walking/hiking for ≥10 hours per week (relative risk = 0.57; 95% CI, 0.34–0.95).[201] A study of 320 postmenopausal sedentary women randomly assigned to 1 year of aerobic exercise or a control group showed modest but significant changes in serum levels of estradiol and sex hormone-binding globulin from baseline (ie, a decrease and an increase in these levels, respectively).[204] However, it has been suggested that other, as yet unidentified, mechanisms are more likely to be responsible for the association between increased activity level and decreased risk for breast cancer.[205]

Diet

Results from the WHI controlled intervention trial of 48,835 postmenopausal women designed to test the effect of a low-fat diet (eg, fat intake limited to 20% of total caloric intake per day, and increased consumption of fruits, vegetables, and grains) on risk for breast cancer did not show a statistically significant reduction in the incidence of invasive breast cancer in women who followed a low-fat diet over an average of 8.1 years (HR = 0.91, 95% CI, 0.83–1.01).[206] Limitations of

this type of study include inherent difficulties in assuring compliance with dietary interventions, recall biases, the relatively short duration of the follow-up period, and the likelihood of insufficient differences between the 2 arms with respect to fat intake.[207] Furthermore, it is possible that the impact of certain diets on breast cancer risk may be dependent on the age of the study population.[207,208] For example, results of a number of population-based studies have suggested that the effect of diet composition on breast cancer risk may be much greater during adolescence and early adulthood.[208,209] Nevertheless, diets in which the main sources of dietary fat are non-hydrogenated and unsaturated have been shown to have cardiovascular benefits.[208,210]

Epidemiologic studies suggest that vitamin D (from dietary sources and the sun) may play a protective role with respect to decreasing risk of breast cancer development.[208,211] Furthermore, there is some evidence to suggest that such protection is greatest for women who had more prolonged skin exposure to sunlight and higher dietary intake of sources of vitamin D during adolescence.[212,213] Current studies are ongoing to evaluate the role of vitamin D on breast cancer risk.

Weight/BMI

There is a substantial amount of evidence indicating that overweight or obese women have a higher risk for postmenopausal breast cancer.[39,69,70]

Recent results from the Nurses' Health Study evaluating the effect of weight change on the incidence of invasive breast cancer in 87,143 postmenopausal women suggested that women experiencing a weight gain of 25.0 kg or more since age 18 have an increased risk for breast cancer when compared with women who have maintained their weight (relative risk = 1.45; 95% CI, 1.27–1.66).[39] Furthermore, women who had never used postmenopausal HT and lost 10.0 kg or more since menopause and kept the weight off had a significantly lower risk for breast cancer than women who had maintained their weight (relative risk = 0.43; 95% CI, 0.21–0.86). Interestingly, there is evidence that the risk for breast cancer is lower in premenopausal women who are overweight compared with women who are not overweight.[70]

Results from a case-control study of 1073 pairs of women with *BRCA1/2* mutations indicated that a weight loss of 10 or more pounds in women with the *BRCA1* mutation between the ages of 18 and 30 was associated with a decreased risk of developing breast cancer between the ages of 30 and 40 years. (odds ratio = 0.35; 95% CI, 0.18–0.67).[214]

Clinical Trials

Risk-reduction counseling should include a discussion of breast cancer risk-reduction interventions available in clinical trials.

Summary

Breast cancer risk assessment provides a means of identifying healthy women without a history of personal breast cancer, who are at increased risk for future development of this disease. All women should be counseled regarding healthy lifestyle recommendations to decrease breast cancer risk and to avoid lifestyles that would adversely impact their chance of developing the disease. However, many of the risk factors for breast cancer are not modifiable. The demonstration that use of tamoxifen, raloxifene, anastrozole, or exemestane substantially decreases the future risk for breast cancer provides an opportunity for a risk-reduction intervention. However, the risks and benefits associated with use of risk-reduction agents for an individual woman should be evaluated and discussed with the woman as part of a shared decision-making process. Women taking a risk-reduction agent must be closely monitored for potential side effects associated with use of these

agents. In special circumstances, such as in women who are carriers of a *BRCA1/2* mutation, where the risk for breast cancer is very high, the performance of a bilateral mastectomy or bilateral salpingo-oophorectomy may be considered for breast cancer risk reduction. Women considering either surgery should undergo multidisciplinary consultations prior to surgery so as to become well informed about all treatment alternatives, the risks and benefits of risk-reduction surgery, and, in the case of bilateral mastectomy, the various reconstruction options available. The NCCN Guidelines for Breast Cancer Risk Reduction Panel strongly encourage women and health care providers to participate in clinical trials to test new strategies for decreasing the risk for breast cancer. Only through the accumulated experience gained from prospective and well-designed clinical trials will additional advances in breast cancer risk reduction be realized.

Table 2

Survival Probability According to Breast/Ovarian Cancer Risk-Reduction Strategy at Age 70* for 25-Year-Old *BRCA1/2* Mutation Carrier

Variable	Survival probability (%) in *BRCA1* mutation carriers	Survival probability (%) in *BRCA2* mutation carriers
No intervention	53% [BCD=41%;OCD=36%]	71% [BCD=36%;OCD=20%]
RRSO only at age 40	68% [BCD=45%;OCD=12%]	77% [BCD=30%;OCD=4%]
RRSO only at age 50	61% [BCD=51%;OCD=20%]	75% [BCD=42%;OCD=6%]
RRM only at age 25	66% [BCD=5%;OCD=58%]	79% [BCD=4%;OCD=30%]
RRM only at age 40	64% [BCD=13%;OCD=53%]	78% [BCD=9%;OCD=28%]
Breast Screening only from ages 25-69	59% [BCD=26%;OCD=46%]	75% [BCD=21%;OCD=25%]
RRSO at age 40 and RRM at age 25	79% [BCD=6%;OCD=21%]	83% [BCD=3%;OCD=6%]
RRSO at age 40 and breast screening from ages 25-69	74% [BCD=30%;OCD=15%]	80% [BCD=18%;OCD=5%]
RRSO at age 40, RRM at age 40; and breast screening from ages 25-39	77% [BCD=18%;OCD=18%]	82% [BCD=9%;OCD=6%]

*Survival probability for 70-year-old woman from general population = 84%

[Probability of death as a result of breast cancer (BCD) or ovarian cancer (OCD); RRSO – risk-reducing bilateral salpingo-oophorectomy; RRM – risk-reducing bilateral mastectomy; Breast screening – annual mammography and MRI]

CDT Code	Code description	Proposed Placement	Comments
D0171	re-evaluation – post-operative office visit	**Excluded**	Service should be bundled into the original treatment code
D0351	3D PHOTOGRAPHIC IMAGE-This procedure is for dental or maxillofacial diagnostic purposes. Not applicable for a CAD-CAM procedure	**Excluded**	Experimental
D1353	SEALANT REPAIR-PER TOOTH	**57** PREVENTIVE DENTAL SERVICES	D1351 Sealant is on line 57. Rule limits sealants to every 5 yrs unless they fail, then sealant can be redone. Monitor use to ensure not abused.
D6110	implant /abutment supported removable denture for edentulous arch – maxillary	**627** DENTAL CONDITIONS (EG. MISSING TEETH) Treatment: IMPLANTS	
D6111	implant /abutment supported removable denture for edentulous arch – mandibular	**627** DENTAL CONDITIONS (EG. MISSING TEETH) Treatment: IMPLANTS	
D6112	implant /abutment supported removable denture for partially edentulous arch – maxillary	**627** DENTAL CONDITIONS (EG. MISSING TEETH) Treatment: IMPLANTS	
D6113	implant /abutment supported removable denture for partially edentulous arch – mandibular	**627** DENTAL CONDITIONS (EG. MISSING TEETH) Treatment: IMPLANTS	
D6114	implant /abutment supported fixed denture for edentulous arch – maxillary	**627** DENTAL CONDITIONS (EG. MISSING TEETH) Treatment: IMPLANTS	
D6115	implant /abutment supported fixed denture for edentulous arch – mandibular	**627** DENTAL CONDITIONS (EG. MISSING TEETH) Treatment: IMPLANTS	
D6116	implant /abutment supported fixed denture for partially edentulous arch – maxillary	**627** DENTAL CONDITIONS (EG. MISSING TEETH) Treatment: IMPLANTS	
D6117	implant /abutment supported fixed denture for partially edentulous arch – mandibular	**627** DENTAL CONDITIONS (EG. MISSING TEETH) Treatment: IMPLANTS	
D6549	RESIN RETAINER--FOR RESIN BONDED FIXED PROSTHESIS	**609** DENTAL CONDITIONS (EG. MISSING TEETH) Treatment: COMPLEX PROSTHODONTICS	
D9931	Cleaning and inspection of a removable appliance. This procedure does not include any required adjustments	**457** DENTAL CONDITIONS (EG. MISSING TEETH, PROSTHESIS FAILURE) Treatment: REMOVABLE PROSTHODONTICS	Includes ultrasonic cleaning of dentures. DMAP to create rule to limit frequency to once per year and can not be billed with a prophylactic cleaning.
D9936	missed appointment	**Excluded**	Specifically excluded in OAR from being billed
D9987	Cancelled appointment	**Excluded**	Specifically excluded in OAR from being billed
D9219	evaluation for deep sedation or general anesthesia	**Exempt**	Anesthesia codes are all Exempt

Dentures Guideline and Rule Conflict

Question: What should be done about a conflict between the removable prosthodontics guideline and rule?

Question source: Katie Noah, Willamette Dental; DMAP

Issue:
Katie Noah noticed a discrepancy between DMAP rules and Guideline Note 62. Under the Dental Services Program Rulebook, 410-123-1260, the rule shows that under 21 is 4 missing posterior teeth but over 21 is 6 missing posterior teeth for the benefit.
http://www.dhs.state.or.us/policy/healthplan/guides/dental/123rb010112.pdf

However, Guideline note 62 states that **4** or more posterior missing teeth per arch are required, not **6**.

On 1/1/2012, DMAP changed the coverage rules so adults age 21+ could only receive coverage of a partial dentures if they are missing 6 or more posterior or one or more anterior teeth. This was a benefit reduction and made coverage different for adults versus children. The guideline did not change at the same time. The rationale for this was:
"Limits on some dental services for adult clients (age 21 and older) due to reduced payments to managed Dental Care Organizations (DCOs) to comply with budget limitations required by the 2011 Legislative Assembly in SB 5529. This will help assure access to services through sufficient provider networks will be maintained following this approximate 11% reduction in capitation rates."

Prioritized List Status:

Line:	**477**
Condition:	DENTAL CONDITIONS (EG. MISSING TEETH, PROSTHESIS FAILURE) (See Guideline Note 62)
Treatment:	REMOVABLE PROSTHODONTICS (E.G. FULL AND PARTIAL DENTURES, RELINES)
HCPCS:	D5110-D5212,D5520-D5761,D5820,D5821

GUIDELINE NOTE 62, REMOVEABLE PROSTHODONTICS
Line 477
Must have one or more anterior teeth missing or four or more posterior teeth missing per arch with resulting space equivalent to that loss demonstrating inability to masticate; third molars are not a consideration when counting missing teeth (D5211, D5212).

Expert input:
OHAP reviewed this guideline and felt that deletion of the guideline would provide the most clarity to the dental community.

Dentures, Issue #719

Dentures Guideline and Rule Conflict

HERC staff recommendation:

1) Delete guideline note 62 REMOVEABLE PROSTHODONTICS

Dentures, Issue #719
