Southern Oregon Opioid Prescriber Toolkit

Regional CCO Collaborative For Safer Opioid Prescribing
This toolkit has been prepared through the collaborative efforts of all four Coordinated Care Organizations (CCOs) serving Southwestern Oregon.

**Mission statement**

The primary purpose of the Regional CCO Collaborative provider workgroup is to:
1. Implement opioid related benefit changes successfully at CCOs across the region.
2. Change prescribing practices through outreach, education, and resource delivery.
3. Support providers that are treating patients with pain.
ASSESS HARMs OF OPIOID THERAPy

Long-term opioid therapy can cause harms ranging in severity from constipation and nausea to opioid use disorder and overdose death. Certain factors can increase these risks, and it is important to assess and follow-up regularly to reduce potential harms.

1. **ASSESS.** Evaluate for factors that could increase your patient’s risk for harm from opioid therapy such as:
   - Personal or family history of substance use disorder
   - Anxiety or depression
   - Pregnancy
   - Age 65 or older
   - COPD or other underlying respiratory conditions
   - Renal or hepatic insufficiency

2. **CHECK.** Consider urine drug testing for other prescription or illicit drugs and check your state’s prescription drug monitoring program (PDMP) for:
   - Possible drug interactions (such as benzodiazepines)
   - High opioid dosage (≥50 MED/day)
   - Obtaining opioids from multiple providers

3. **DISCUSS.** Ask your patient about concerns and determine any harms they may be experiencing such as:
   - Nausea or constipation
   - Feeling sedated or confused
   - Breathing interruptions during sleep
   - Taking or craving more opioids than prescribed or difficulty controlling use

4. **OBSERVE.** Look for early warning signs for overdose risk such as:
   - Confusion
   - Sedation
   - Slurred speech
   - Abnormal gait

If harms outweigh any experienced benefits, work with your patient to reduce dose, or taper and discontinue opioids and optimize nonopioid approaches to pain management.

How to approach an opioid taper/cessation

* If diverting, then patient isn’t taking opioid, taper not needed

M. Weimer, DO
Key Concepts for Tapering Opioid Medications

Establish a Relationship

- A relationship with your patient is key to patient engagement and buy-in. Anecdotally, patients who reported a positive relationship with their provider and care team were more likely to engage in non-opioid and non-medication therapies for pain management. Please refer to “The Art of Difficult Conversations” document for techniques on developing a relationship with your patient.

- If a patient is new to you, or if you haven’t prescribed their pain medications in the past, it may be appropriate to introduce the idea of tapering at the first visit and begin the actual taper at a follow-up visit.

Set Expectations

- Shared decision-making should occur, when possible. Please refer to “How to Approach an Opioid Taper/Cessation” for more information. Shared decision-making engages the patient, creates accountability for self-care, and allows the provider to determine or influence available choices.

- Discuss the possible symptoms of withdrawal patients may experience. Short term increases in pain are common during the tapering process. This is usually temporary and once a reduced baseline dose is achieved, patients are likely to report an improvement in their experience of pain. Other common withdrawal symptoms are listed below:

<table>
<thead>
<tr>
<th>Symptoms of Opioid Withdrawal</th>
</tr>
</thead>
<tbody>
<tr>
<td>Early Symptoms</td>
</tr>
<tr>
<td>Agitation</td>
</tr>
<tr>
<td>Anxiety</td>
</tr>
<tr>

</tr>
<tr>
<td>Increased tearing</td>
</tr>
<tr>
<td>Insomnia</td>
</tr>
<tr>
<td>Runny nose</td>
</tr>
<tr>
<td>Sweating</td>
</tr>
<tr>
<td>Yawning</td>
</tr>
</tbody>
</table>

- Reframing the tapering scenario offers support, validation and hope to patients while tapering their medication. Some strategies to reframe the experience may be:
  - Ask your patient to keep a journal of their experience. This serves to track the progression of symptoms over time and creates an opportunity to support your patient through their experience. Review together at each visit and note when progress has been made (i.e. when symptoms begin to decline)
  - Normalize the experience of withdrawal symptoms through discussion. Explain “these symptoms are normal because it means your body is readjusting to the new dose, which means we are making progress and moving in the right direction” (share Phases of Withdrawal document)

- Set a goal and identify what is important to your patient. This can help keep patients goal-oriented and engaged in the tapering process. Goal setting can also be used to create a support network outside of the provider team, such as a close friend or family member.

- Maintain current prescribing best practices and processes throughout tapering process, including risk management strategies. This should include, but is not limited to, PDMP check and UDS screens.

Key Concepts for Tapering Opioid Medications

Challenges Experienced When Tapering

- The slower the taper, the less short-term discomfort for the patient. Offering choices to the patient for tapering speed can help the patient manage their experience and engage in working towards the common goal: reducing risk while maintaining or improving function.

- With increased pain during taper there may be a temporary reduced level of functioning. However, patients should improve in their function and experience of pain as the taper progresses and their body adjusts.

- If patients are experiencing many adverse effects during the taper process, it is important to re-evaluate the increment of dose reduction and frequency of reduction. It may be appropriate to make smaller incremental changes or make changes less often (i.e. move every two week adjustments to every four weeks).

- Opioid Use Disorder (OUD) may become apparent during the tapering process. It is important for primary care clinicians to be able to offer or successfully connect patients to evidence-based treatment for this chronic condition. Please contact your local CCO for more information on community providers.

- It may be appropriate to “pause” a taper; however, doses should not be increased once a taper has begun. Increasing the dose after a patient has begun tapering is counterproductive to the goal of reducing risk and prolongs the patient’s tapering experience.

- Withdrawal symptoms are common during tapering; however, duration and severity will likely vary from patient to patient depending on a host of factors. There are several non-controlled adjuvant medications that may be prescribed to attenuate these symptoms and support patients through their taper. The list below includes medications used to manage common withdrawal symptoms. Duration and dosing should be tailored to each patient.

### Opioid Withdrawal Attenuation Cocktail

**Acute Withdrawal**
- Clonidine 0.1mg QID x anticipated length of withdrawal. *(Check BP and watch for hypotension.)*
- Diarrhea: Loperamide 4mg then 2mg QID. May have opioid effects at high doses. Alternatively, consider Hycosamine 0.125mg q 4-6 hrs PRN
- Myalgia: ibuprofen 400mg po QID or Acetaminophen 325mg po Q8hrs
- Anxiety: Hydroxyzine 25mg po TID
- Insomnia: Trazodone 50-100mg po OHS
- Nausea: Ondansetron 8mg po BID x anticipated length of withdrawal. *(Check QTc)*

**Anticipated Withdrawal as a Part of a Planned Taper**
- Anxiety: Gabapentin Escalating Dose to 1200mg/day. Start loading one month prior to planned taper.
- Clonidine 0.1mg QID x anticipated length of withdrawal. *(Check BP and watch for hypotension.)*
- Diarrhea: Loperamide 4mg then 2mg QID
- Myalgia: ibuprofen 400mg po QID or Acetaminophen 325mg po Q8hrs
- Anxiety: Hydroxyzine 25mg po TID
- Insomnia: Trazodone 50-100mg po OHS
- Nausea: Ondansetron 8mg po BID x anticipated length of withdrawal. *(Check EKG for QTc interval)*

THE ART OF DIFFICULT CONVERSATIONS

It is common for the provider/healthcare team to experience challenging conversations with patients as safety guidelines in the area of chronic pain and prescription opioids are implemented. Some topics that may elicit fear in patients and therefore potential discord may include:

- Discussing controlled substance client/clinic agreements.
- Discussing community, state, and national guidelines for safe-prescribing practices.
- Informing new patients that opioids or other controlled substances will not be prescribed and/or increased.
- Informing patients that opioids will be discontinued and/or tapered.
- Discussing the dangers and side effects of the medication.

It is understandable and predictable for patients to express strong feelings when they are presented with information such as the need to reduce or eliminate opioids. Pain medications can become a patient’s primary coping strategy for dealing with physical, emotional, psychological and post-traumatic pain. Delivering a message about reducing or stopping such medications can be triggering and even terrifying for a patient and the patient’s family. In such situations, patient’s emotions are commonly first expressed in the form of anger directed toward the prescribing provider and healthcare team. When facing a highly emotional patient, it is helpful to consider what may be underlying the strong emotional expression. Often underneath the heightened emotional response such as anger, there is fear, grief, panic, sadness, and/or a belief that living without prescription opioids is impossible. Being curious and understanding about what may be beneath a highly emotional expression does not mean one should not take action in the service of safety; however, treading lightly and following the recommendations below will make for a more positive outcome.

Value Identification

Prior to engaging in potentially challenging conversations, it is advisable to spend time reflecting on the core values and principles that you are upholding in the difficult conversation. For example, it may be in the service of practicing safe medicine, being in alignment with your colleagues, the medical board and/or community, state, and national safe opioid prescribing guidelines. When you are in alignment with your values and the healthcare team believes that the change is in the patient’s best interest, the difficult conversations are often more manageable and rewarding.
Realistic Expectations

When asking a patient to do something they may be afraid to do or that they do not want to do, they may leave the appointment highly distressed, very angry, and/or insconsolably sad. It is common for providers and the healthcare team to feel that if a patient leaves in such a highly agitated way, this indicates that the outcome of the appointment was a failure. Reconsider this belief. When a provider or healthcare team member asks a patient to make a change that is guided by core principles and values and a belief that it is in the patient’s best interest to make the change, then the state the patient is leaving in can be considered a natural part of the patient’s therapeutic process, and a positive step toward the individual’s overall health and well-being.

Willingness to Feel Uncomfortable

Difficult conversations often bring about discomfort for patients, their families, providers, and healthcare team members. When we model our willingness to be uncomfortable to our patients, it helps the process. Consider saying to yourself before engaging in such a conversation, “I am willing to be uncomfortable having this conversation because it is in the service of my value of safety and best-practice medicine.” It can be helpful to notice your own sympathetic nervous system activation (e.g., rapid, shallow breathing; clenching fists or jaw), and then engage in an activity to activate your parasympathetic nervous system (e.g., slowing down your exhale and softening your hands or jaw). Just as these situations can be highly triggering for our patients, they can be highly triggering for providers and the healthcare team, as well. These conversations go much more smoothly when providers or healthcare team members can identify which types of patients and situations trigger them the most and develop an intervention strategy to notice the trigger and proceed calmly and effectively with delivering effective patient care.

Relationship as a Resource

It is important not to underestimate the relationship between the patient and the provider or healthcare team as a resource. Most patients genuinely care for their providers and/or healthcare team and want to work collaboratively with them. Often, genuinely communicating with patients that you will stick by their side through the changes can be one of the most powerful tools. Patients often fear their providers or healthcare team will abandon them, ask them to make changes too quickly, not listen to their fears, and or “fire” them from their practice. Proactively quasuing such fears and acknowledging that the fear is real to them will go a long way toward reducing those fears.

Belief and Confidence

Expressing the belief in the patient’s ability to make the change is one of the most valuable tools for creating positive clinical outcomes such as removing or reducing opioids. You may think the patient knows this; however, it is highly advisable to overtly tell the patient, even over multiple appointments, and even if it feels redundant or if you don’t completely believe that your patient will be able to make such changes. Believing the patient can change is critical to the success of the process. Over time, as you see your patient making such changes and actually increasing functioning and quality of life, you will be more confident in your patient’s abilities and it will be easier to relay your belief in them.

Difficult Conversations: Real life examples, Helpful Hints, and Tools - [www.oregonpaignuidance.org/clinical-tools](http://www.oregonpaignuidance.org/clinical-tools)
Motivational Interviewing Resources - [www.motivationalinterviewing.org](http://www.motivationalinterviewing.org)
Consider opioid taper for patients with opioid MED> 90 mg/d or methadone> 30 mg/d, aberrant behaviors, significant behavioral/physical risks, lack of improvement in pain and function.

1. Frame the conversation around tapering as a safety issue.
2. Determine rate of taper based on degree of risk.
3. If multiple drugs involved, taper one at a time (e.g., start with opioids, follow with BZPs).
4. Set a date to begin and set a reasonable date for completion. Provide information to the patient and establish behavioral supports prior to instituting the taper. See OPG guidelines.

**OPIOID TAPER**

**Opioids**

Basic principle: For longer-acting drugs and a more stable patient, use slower taper. For shorter-acting drugs, less stable patient, use faster taper.

1. Use an MED calculator to help plan your tapering strategy. Methadone MED calculations increase exponentially as the dose increases, so methadone tapering is generally a slower process.
2. Long-acting opioid: Decrease total daily dose by 5-10% of initial dose per week.
   - **Short-acting opioids:** Decrease total daily dose by 5-15% per week.
3. See patient frequently during process and stress behavioral supports. Consider UDS, pill counts, and POMP to help determine adherence.
4. After % to Y2 of the dose has been reached, with a cooperative patient, you can slow the process down.
5. Consider adjuvant medications: antidepressants, gabapentin, NSAIDs, clonidine, anti-nausea, anti-diarrhea agents.

**Opiate Withdrawal**

These are the 3 phases of withdrawal most people experience while detoxing from opiates.

### Phase 1

**Symptoms**
- Depression
- Insomnia
- Nausea
- Vomiting
- Diarrhea
- Abdominal Cramps

**Acute Withdrawal**

Phase 1 symptoms begin about 12 hours after your last opiate use (or within 30 hours of the last methadone dose), peak around the 3 day mark, and last about 5 days total.

### Phase 2

**Symptoms**
- Chills
- Dilated Pupils
- Leg Cramps

**Rebalance**

Phase 2 of opiate withdrawal lasts about 2 weeks. As the body works to get all substances out, it also works to rebalance endorphin levels that were depleted during opioid use.

### Phase 3

**Symptoms**
- Anxiety
- Restlessness
- Insomnia

**Longest Phase**

Phase 3 of detox from opiates is the longest phase; lasting anywhere from 1 week to 2 months, but it is the least severe.

---

**What to expect when detoxing from opiates**

**Phase One**

This is the phase right after you reduce your dose or stop taking the medications, about 12 to 30 hours after your last use. You can experience any of the following symptoms: depression, nausea, cramps, diarrhea, and insomnia. At this point, your body is reacting to the immediate absence of the drug it has become used to. It is the physical phase where you will go through most of the physical pain. This phase could last 5 days to a week. You should start to feel better as you move into phase two.

**Phase Two**

At this point, your body is going to start working out most of the toxins that you have built up over the time period of using the medication. The less time you have been on the drug and the less you have used, the easier this stage may be. Phase two can last about two weeks. As your body works to get rid of all the toxins, it also works to balance the natural substances in your body (endorphins) that were reduced while you used opiates. Symptoms that might be experienced at this phase include chills, sweating, goose bumps, dilated pupils, leg cramps, and restless leg syndrome.

**Phase Three**

This phase can be the most difficult for some people. Phase three is generally the longest, but people who have successfully tapered off of opiates say it is often the least severe phase. The symptoms here can be more psychological than physical but there will still be some physical pain and discomfort. Symptoms here might include anxiety, restlessness, and insomnia.

NONOPIOID TREATMENTS FOR CHRONIC PAIN

PRINCIPLES OF CHRONIC PAIN TREATMENT

Patients with pain should receive treatment that provides the greatest benefit. Opioids are not the first-line therapy for chronic pain outside of active cancer treatment, palliative care, and end-of-life care. Evidence suggests that nonopioid treatments, including nonopioid medications and nonpharmacological therapies can provide relief to those suffering from chronic pain, and are safer. Effective approaches to chronic pain should:

- Use nonopioid therapies to the extent possible
- Identify and address co-existing mental health conditions (e.g., depression, anxiety, PTSD)
- Focus on functional goals and improvement, engaging patients actively in their pain management
- Use disease-specific treatments when available (e.g., triptans for migraines, gabapentin/pregabalin/duloxetine for neuropathic pain)

Use first-line medication options preferentially

- Consider interventional therapies (e.g., corticosteroid injections) in patients who fail standard non-invasive therapies
- Use multimodal approaches, including interdisciplinary rehabilitation for patients who have failed standard treatments, have severe functional deficits, or psychosocial risk factors

NONOPIOID MEDICATIONS

<table>
<thead>
<tr>
<th>MEDICATION</th>
<th>MAGNITUDE OF BENEFITS</th>

RECOMMENDED TREATMENTS FOR COMMON CHRONIC PAIN CONDITIONS

Low back pain

**Self-care and education in all patients;** advise patients to remain active and limit bedrest

**Nonpharmacological treatments:** Exercise, cognitive behavioral therapy, interdisciplinary rehabilitation

**Medications**
- First-line: acetaminophen, non-steroidal anti-inflammatory drugs (NSAIDs)
- Second-line: Serotonin and norepinephrine reuptake inhibitors (SNRIs)/tricyclic antidepressants (TCAs)

Migraine

**Preventive treatments**
- Beta-blockers
- TCAs
- Antiseizure medications
- Calcium channel blockers
- Non-pharmacological treatments (Cognitive behavioral therapy, relaxation, biofeedback, exercise therapy)
- Avoid migraine triggers

**Acute treatments**
- Aspirin, acetaminophen, NSAIDs (may be combined with caffeine)
- Antinausea medication
- Triptans-migraine-specific

Neuropathic pain

**Medications:** TCAs, SNRIs, gabapentin/pregabalin, topical lidocaine

Osteoarthritis

**Nonpharmacological treatments:** Exercise, weight loss, patient education

**Medications**
- First-line: Acetaminophen, oral NSAIDs, topical NSAIDs
- Second-line: Intra-articular hyaluronic acid, capsaicin (limited number of intra-articular glucocorticoid injections if acetaminophen and NSAIDs insufficient)

Fibromyalgia

**Patient education:** Address diagnosis, treatment, and the patient’s role in treatment

**Nonpharmacological treatments:** Low-impact aerobic exercise (e.g., brisk walking, swimming, water aerobics, or bicycling), cognitive behavioral therapy, biofeedback, interdisciplinary rehabilitation

**Medications**
- FDA-approved: Pregabalin, duloxetine, milnacipran
- Other options: TCAs, gabapentin

General opioid taper guidelines (adapted from resources below):

- Gradual tapers can often be completed anywhere in the range of 2 weeks to 6 months. Slower tapers may be necessary for patients who have been on high-dose opioids for longer periods.
- Do not reverse the taper; it must be unidirectional. The rate may be slowed or paused while monitoring for and managing withdrawal symptoms.
- The decision to first taper long or short acting opioids should be based on the type of pain the patient has (intermittent vs constant), their total daily dose of opioids, and patient preference.
- Start with a taper of ≤10% of the original dose per week and assess the patient’s functional and pain status at each visit.
- During opioid tapers, we suggest that you see the patient every 2-4 weeks.
- Patients on fentanyl patches should be transitioned to a different long-acting opioid, then tapered according to the long-acting guideline. IMPORTANT: reduce dose to account for cross-tolerance.
- Multiple non-opioid medications are available to treat withdrawal symptoms (ie clonidine, anti-emetics).
- Tapering plan may be reassessed if pain/function deteriorate or withdrawal symptoms persist- if the dosing schedule needs to be adjusted, you will need to submit a taper plan modification.
- Do not treat withdrawal symptoms with benzodiazepines or additional opioids.

Opioid Alternative Pain Management Options

These are suggested alternatives and this is not an all-inclusive list. There may be specific authorization requirements or restrictions for alternative treatments. If you have questions regarding specific opioid pain alternatives, please contact the CCO directly.

- **Alternative medications:** NSAIDs, gabapentin, amitriptyline, nortriptyline, acetaminophen, topical agents.
- **Counseling:** Available to all patients for mental health, pain management, and alcohol and drug abuse.
- **Massage therapy:** Subject to authorization requirements
- **Physical/Occupational therapy:** Subject to authorization requirements
- **Chiropractic manipulation:** Where available, Subject to authorization requirements
- **Acupuncture:** Where available, Subject to authorization requirements

CCO variances may exist. Please refer to CCO information or contact the representative for more information.
