Groundwater Under the Direct Influence (GWUDI)

The federal Surface Water Treatment Rule requires that all public water systems that use surface water, or use groundwater under the direct influence of surface water, meet performance standards of filtration and disinfection to deactivate pathogenic organisms within the water. This requirement is addressed in Oregon in Administrative Rule 333-061-0032.

What is groundwater under the direct influence (GWUDI)?

Groundwater under the direct influence (GWUDI) of surface water occurs when, because of its proximity to surface water and the character of the aquifer, pathogenic organisms can move from the surface water source to the well or infiltration gallery.

What are the public health concerns associated with GWUDI?

Pathogens, such as Giardia and Cryptosporidium, are often found in surface water, and can cause gastrointestinal illness and other health risks. In many cases, this water needs to be filtered and disinfected through the use of additives such as chlorine to inactivate (or kill) microbial pathogens.

Cryptosporidium is a significant concern in drinking water due to the fact it is resistant to chlorine and other disinfectants; it responsible for waterborne disease outbreaks that have caused severe illness. It may be especially harmful to people with weakened immune systems (e.g., infants and the elderly) and potentially fatal in people with severely compromised immune systems (e.g., cancer and AIDS patients).

In the photomicrograph on the top right of this page, Giardia and Cryptosporidium are shown as seen through a microscope. These organisms are very small. The white bar in the diagram is approximately 10 microns (0.0004 inches) in length.

Because of their small size, Giardia and Cryptosporidium can readily move through the open spaces in the aquifer, i.e., through the openings between sand and gravel size particles or in fractures in bedrock. However, the farther they travel the more likely it is that they will be filtered out of the water by natural processes. Through previous studies, we believe that the risk related to these organisms is substantially reduced after travel of 200 feet in sand and gravel, and after 500 feet in fractured bedrock or layered volcanic rocks.

What's involved in determining GWUDI?

Analysis of water for Giardia or Cryptosporidium is complex and costly. The EPA has indicated that monitoring source water for coliform bacteria may serve as a useful surrogate for the other pathogens. Consequently, we will require monthly coliform testing at the wellhead of the source for a period of up to 12 months. If at any time, the system fails to monitor, or experiences a confirmed positive E. Coli test, the water system would be required to have two microscopic particulate analyses performed on the water.
