How do I lower radon levels in my home?

Reducing radon levels in your home requires technical knowledge and skill, and typically involves hiring a radon mitigation contractor. The most common approach to mitigating a radon problem is referred to as sub-slab depressurization or sub-slab suction. This technique draws radon-filled air from beneath the foundation through a pipe using a fan, and vents the radon outside. Sealing cracks and holes in the foundation makes this technique more effective.

Typical Radon mitigation system

For a list of mitigation contractors visit our website at www.healthoregon.org/radon.

Did you know?

RADON is the second-leading cause of lung cancer, second only to cigarette smoking.

RADON levels in your home can vary significantly from your neighbor’s.

RADON can be found in homes with all types of construction, including slab-on-grade foundations, crawlspaces and basements.

HAVE YOU TESTED YOUR HOME FOR RADON?
How does radon enter a home?

- The major source of radon in a home is the ground beneath it. Radon moves up through soil and enters through cracks and holes in the foundation.
- Radon gas can become trapped inside a home and build to unhealthy levels.
- Any home can have a radon problem: new or old, well-insulated or drafty, with or without a basement.
- Radon can also enter through a home’s water supply. Some wells have elevated levels of radon, and radon can be released into the air during household uses like showers.
- The only way to know if you have high levels of radon in your home is to test for it.

What is radon?

- Radon is a naturally occurring radioactive gas that you can’t see, smell or taste.
- It is produced by the natural breakdown of uranium in soil, rock and water.
- Radon can enter your home through your water supply.
- Radon can be released into the air when water is used in the home.

Why is radon harmful?

- Radon breaks down into solid particles known as radon decay products.
- These particles can become trapped in the lungs when inhaled and damage lung tissue by emitting radiation.
- Over time, exposure to elevated levels of radon increases a person’s risk of developing lung cancer.
- This risk is greatly increased for smokers.

How can I get my home tested?

- You can hire a radon measurement company to test your home or perform the test yourself.
- Visit our website at www.healthoregon.org/radon for contact information and a list of measurement companies that provide services in Oregon.
- The EPA recommends taking a short-term test first. Short-term tests take from two to 90 days to analyze and provide a “snapshot” of radon concentrations. If your short-term test results come back over 8 pCi/L, perform another test to confirm your results.
- If your long-term test results are below 4 pCi/L, you can purchase a radon mitigation system if you choose.

Which test should I use?

- The EPA recommends taking a short-term test first. Short-term tests take from two to 90 days and allow for quick results that offer the best estimate of the radon levels in your home.
- If your short-term test results come back between 4 and 8 pCi/L, follow up with a long-term test to confirm your results.
- If the results from your initial short-term test come back over 8 pCi/L, perform another short-term test to confirm the results and average the short-term test results together.
- If your home has high levels of radon, you should fix your home if the average of your short-term tests or result of your long-term test are 4 pCi/L or higher.

The number of deaths caused by radon compared to other causes:

<table>
<thead>
<tr>
<th>Cause</th>
<th>Deaths per Year</th>
</tr>
