#### SECTION 1. LITERATURE USED FOR THE EFFECTS REVIEW

#### **Tide Gate Effectiveness Literature Compilation**

Anisfeld, S.C., M.J. Tobin, and G. Benoit. 1999. Sedimentation Rates in Flow-Restricted and Restored Salt Marshes in Long Island Sound. Estuaries 22 (2A): 231-244.				
Keywords: tide gate removal salmon	<b>Type</b> : Peer-reviewed journal article		Publication Date: 1999	
Include: Maybe	<b>Reason</b> : Compares sediment accretion in a restored marsh with that in reference and restricted marshes and compared all to measurements of sea-level rise.		Relevance:	
Location & Species: 6 marshes in Long Island Sound, Connecticut, sediment cores		Ecosystem(s): salt marsh		
Reference Source:				

**Abstract**: Many salt marshes in densely populated areas have been subjected to a reduction in tidal flow. In order to assess the impact of tidal flow restriction on marsh sedimentation processes, sediment cores were collected from flow- restricted salt marshes along the Connecticut coast of Long Island Sound. Cores were also collected from unrestricted reference marshes and from a marsh that had been previously restricted but was restored to fuller tidal flushing in the 1970's. High bulk densities and low C and N concentrations were found at depth in the restricted marsh cores, which we attribute to a period of organic matter oxidation, sediment compaction, and marsh surface subsidence upon installation of flow restrictions (between 100 and 200 years before the present, depending on the marsh). Recent sedimentation rates at the restricted marshes (as determined by t37C.s and 21<sup>~</sup> dating) were positive and averaged 78% (IsTCs) and 50% (zIoPb) of reference marsh sedimentation rates. The accumulation of inorganic sediment was similar at the restricted and reference marshes, perhaps because of the seasonal operation of the tide gates, while organic sediment accretion (and pore space) was significantly lower in the restricted marshes, perhaps because of higher decomposition rates. Sedimentation rates at the restored marsh were significantly higher than at the reference marshes. This marsh has responded to the higher water levels resulting from restoration by a rapid increase in marsh surface elevation.

NOTE: At the "restored" site, "two tidegates were allowed to fall into disrepair; they were removed and a bridge opening was widened in the mid-1970s." (from Table 1, p. 234.)

**Results Summary**: Vertical accretion rates (rate of increase in substrate elevation) in restored marsh was higher than those in reference sites. In both sites accretion rates were more than accomodating for sea level rise. The rates were lower in sites restricted by tide gates. Mass accumulation rates were similar among marshes, although organic material accumulation was slower at restricted sites. Organic and inorganic material input did not differ by marsh type. Marshes with high carbon had high C:N.

**Broad Outcomes**: The restored marsh is similar to the reference site while the restricted sites are dissimilar. The data supports the idea that there is a period of trauma immediately after restriction and then a period of recovery. The authors mention the idea that marshes should not be restored too quickly so as to avoid the area flooding and becoming open water habitat because of subsidence during the period of restriction.

**Detailed Outcomes**: Cs-137 profiles were good, Pb-210 profiles had some subsurface activity that was unexplained. Vertical accretion rates in reference marshes was 0.37 +/- 0.03 cm/yr (mean SE) with Cs dating and 0.36 +/- 0.07 with Pb dating, so they were more than keeping rate with sea level rise. Restricted marshes had vertical accretion rates that were 78% (0.29 +/- 0.03 Cs) to 50% (0.18 +/- 0.01 Pb) of the reference marshes - this was not a statistically significant difference. The restored marsh has much higher (178%) accretion rate than reference marshes (0.66 +/- 0.03 Cs, 0.55 +/- 0.06 Pb); p=0.002 for Cs - able to adjust to higher water levels resulting from restoration. There were no statistical differences in mass accumulation rates between the three marsh types. Inorganic material accumulated at similar rates. Organic material accumulated more slowly at restricted marshes. Pore space was largest single category in every core. It was the higher porosity in the restored marsh that allowed it to add elevation so quickly - input of organic and inorganic material did not differ with depth. Restricted marshes had higher bulk densities that increased with depth (while C decreased with depth). There was a positive correlation between C and C:N - low C marshes had low C:N.

**Effects Modifiers**: The Pb profiles had varying quality and could only be used as 100-yr averages for comparisons.

<b>Intervention</b> : 3 restricted, 2 reference, 1 restored. In the restored marsh two dilapidated tide gates were removed and a bridge pass under was widened in the 1970s		
Conditions:	Duration: 1 month	
<b>Study Design</b> : Sediment cores were removed, taken to the lab, and density (dry weight/volume, g/cm3) was calculated for each 1-2cm Vertical sedimentation rates were calculated using Cs-137 and Pb-Pb and Cs were also calculated by mass (g/m2/y). Subsamples wer Loss on Ignition for C and N.	section and in 10cm aggregations. 210 dating. Sedimentation rates of	
Statistics: Accretion and accumulation rates for restored and restricted marshes were compared to		

reference sites using t-tests or the non-parametric equivalent. Used t-tests to compare bulk densities of 10-cm sections, maximum bulk density, minimum C, and average C:N in each core.

**Comments**: It has good info on sedimentation but is on the Atlantic coast. This paper could be used in support of other studies in the PNW with similar results.

Bass, A.L. 2010. Juvenile coho salmon movement and migration through tide gates. M.S. Thesis, Dep't. of Fisheries and Wildlife, Oregon State University, Corvallis, OR. 124 pp.				
Keywords: tide gate replacement salmon	Type: M.S. ThesisPublication Date: 2010			
Include: Yes	Reason: Data show movement of coho up and down stream through tide gates.Relevance:			
Location & Species: Coos Bay, OR coho salmonEcosystem(s): freshwater and tidally influe streams			freshwater and tidally influenced	
Reference Source: http://www.cooswatershed.org/Publications/BassArthurL2010Thesis.pdf				

**Abstract**: [Excerpts from ABSTRACT:] We studied three streams, one with a top-hinged tide gate, one with a side-hinged gate, and one without any tide gates that acted as our reference site. Our study species was coho salmon...objectives were to: 1) quantify upstream and downstream sh passage occurrence at all three sites, 2) determine whether juvenile coho salmon passage is associated with a specific range of gate conditions, and 3) identify any associations between coho smolt emigration rate and environmental variables that are influenced by tide gates. Coho salmon smolts passed upstream most frequently at the non-gated channel (48% of all smolts detected at the array), next the side-hinged gate (28%), and lastly, the top-hinged gate (3%). Juvenile coho salmon passed more frequently at a specific range of gate angles and tailwater depths at both top hinged and side-hinged tide gates.

Powerpoint on this work:

http://www.dfw.state.or.us/fish/OHRC/docs/2010/Movements%20And%20Survival%20Of%20Juvenile% 20Coho%20Salmon%20At%20Tide%20Gates.pdf

**Results Summary**: There were differences among channel types (top-hinge and side-hinge gates and ungated) in the frequency of upstream passage. For smolts the largest proportion of tagged fish migrated upstream at the ungated stream (47%), the smallest proportion at the top-hinge gate (3%) and a medium proportion at the side-hinge gate (20%). At the top-hinged and side-hinged gates smolts moved downstream more frequently at a subset of available angles and depths. At the top-hinged gate angles >20 deg were used more often. Smolts moved downstream more frequently with greater depths. At the side-hinged gate angles >40 deg and depths >1.6m were used more often. There was no evidence for a specific subset of conditions for upstream movement at either gate. For subyearlings upstream passage dominated at both gates. At the top-hinge gate angles 7-16 were used for upstream passage and at the side-hinge gate the entire open period was utilized.

**Broad Outcomes**: Ch 2. 796 (top-hinged), 215 (side-hinged), 129 (ungated) unique coho smolts were detected. Top-hinged: 50% passed downstream, 3% upstream. Side-hinged: 36% downstream, 20% upstream. Ungated: 92% downstream, 47% upstream. The highest counts of upstream movement by an individual were at the ungated stream (median=2, average=4.4, maximum=27. At tide gates smolts rarely passed upstream more than once. Rejected 1st hypothesis of no difference between channel types in how frequently fish passed upstream. At the top-hinged gate 78% of subyearlings passed

upstream and 8% downstream. Of the subyearlings detected at the side-hinged gate 31% passed downstream and 38% upstream. At the top-hinged and side-hinged gates smolts moved downstream more frequently with a distribution of angles and depths that differ significantly from the distribution of available angles and depths. At the top-hinged gate angles >20 deg were used more often. Smolts moved downstream more frequently with greater depths. At the side-hinged gate angles > 40 deg and depths >1.6m were used more often. No evidence for a specific subset of conditions for upstream movement at either gate. Rejected 2nd hypothesis. Subyearlings passed upstream at angles of 7-16 deg at the top-hinged gate. At the side-hinged gate subyearlings did not utilize any subset of conditions for upstream passage -they could utilize the entire open period. Downstream they used angles of 10-17 deg.

**Detailed Outcomes**: Ch 3. Salinity above the leaky top-hinged gate tracked estuary salinity, ~4-5ppt lower, but much higher than the other two creeks. T in gated creeks was higher than the bay Jul-Oct 2009, but lower during peak migration time Apr 18 - Jun 17 2009. ~50% of fish approaching tide gates emigrated in < 1min, 24% at the non-gated array. Emigration likelihood at the top-hinged gate was explained by the full model (T, FL, precipitation, tag date, salinity). At Larson the best model included only precipitation At Winchester Creek the best model included T and FL. Larger FL led to higher likelihood of passage at top-hinge and ungated. Increase in salinity = lower passage likelihood at top-hinge gate. Higher rainfall = higher passage likelihood at side-hinge gate. Higher T = increased passage likelihood. Smolts used the reservoir most. Emigration likelihood. Logistic regression showed that gate angle, tag reach, salinity best explained passage on first approach. Larger gate angle, tagging in reservoir, and lower salinity increased likelihood of passage on first approach.

# **Effects Modifiers**:

Intervention:				
<b>Conditions</b> : Larsen Cr has 2 steel side-hinged doors Palouse Cr has 2 wood top-hinged doors	Duration: 22 months			
<b>Study Design</b> : Ch 2. Fish were collected in screw traps and seines. Fish >60 mm were PIT tagged with 12mm tags, fish 48-60 mm with 8mm tags. PIT arrays were built and installed above and below the tide gates and at the mouth of the ungated creek. Independent passage events were recorded. Logged gate opening angle, tailwater depth, velocity. Ch 3. Salinity and T were logged and averaged daily. Recorded precipitation, FL at tagging, tag date.				
Statistics: Ch 2. Compared distributions of used and available angles and tailwaters with KolmogorovSmirnov and Kuiper's test.Ch 3. Determined how explanatory variables influenced				

Smirnov and Kuiper's test.Ch 3. Determined how explanatory variables influencedfish travel times in Palouse Creek reaches with Cox proportional hazard regression. Logistic regressiondetermined which variables influenced downstream movement through the tide gate.

**Comments**: This study was done on 3 streams: ungated, top-hinge gated, side-hinge gated. The sampling methods allow the author to determine which conditions are best for movement through the tide gates and to show that movement occurs in both up- and down-stream directions, and to quantify those movements.

Beamer, E., R. Henderson, and K. Wolf. 2013. Juvenile salmon, estuarine, and freshwater fish utilization of habitat associated with the Fisher Slough Restoration Project in 2012. Skagit River System Cooperative, La Conner, WA. 101 pp.				
Keywords: tide gate replacement salmonType: 2012 Project ReportPublication Date: 2013				
Include: Yes	Reason: Post tide gate replacement and dike setback.Relevance: High			
Location & Species: South Fork Skagit River, WA.Ecosystem(s): tidal wetlandChinook salmonChinook salmon				
<b>Reference Source</b> : https://salishsearestoration.org/images/5/54/ Beamer_et_al_2013_fisher_slough_fish_monitoring_2012.pdf				

**Abstract**: Excerpted from The Fisher Slough Restoration Project in the south fork Skagit River tidal delta is intended to help recover 6 populations of wild Chinook in the Skagit River and its estuary. Project Element 1 was to improve fish passage and tidal inundation to areas upstream of the floodgate and to protect adjacent farmland from flooding by replacing an existing floodgate with a new floodgate within Fisher Slough. Element 2 resolved a drainage conflict preventing implementation of Element 3- a dike setback to allow more of the agricultural area to be inundated by tidal and freshwater hydrology, increasing fish carrying capacity. Tidal habitat area increased from 9.8 acres to 55.7 acres. All three phases were completed before monitoring in 2012. Monitoring results related to Elements 1 and 3 are presented in this report. Our limited statistical tests and graphical trends over four years of monitoring support two tentative conclusions: (1) The new floodgate alone did not influence juvenile wild Chinook salmon as hypothesized (i.e., juvenile wild Chinook salmon abundance would increase upstream of the floodgate after its replacement) in 2010 and 2011, and (2) juvenile Chinook salmon responded as hypothesized to dike setback restoration (along with the new floodgate) in 2012.

NOTES: Full abstract too lengthy to include here. This report contains pre- and post-restoration data, and is a companion to the report below which contains pre-treatment, baseline data.

**Results Summary**: In 2012 sites upstream and downstream of the tide gate were 38.9% and 20.9% juvneile salmon. Chinook density was related to date, habitat strata, and their interaction up- and downstream in 2012. Before restoration there were no differences in density, after tide gate replacement density was higher downstream, and after dike setback density was higher upstream. Chinook size increased more upstream than downstream. For Coho, yearlings were mainly caught upstream, subyearlings were caught up- and downstream. Chum were collected upstream in all months sampled and downstream in May. Pinks were mainly caught downstream. Cutthroat were caught upstream in most sample months and downstream in two months. Steelhead and hatchery Chinook were present at low numbers. Water quality: Salinity was less than 0.1ppt. T was higher upstream but did not go above 15C at most sites. Dissolved oxygen was higher upstream and stayed above the stress threshhold most of the time. Water depth was >0.2m for all samples.

**Broad Outcomes**: Upstream sampling produced 13, 802 fish (19 spp) - 39.8% juv salmon. Salmon catch: 27.4% Chin, 66.9% coho, 0.8% cutthroat. All other spp minor. Remaining catch: 57% three-spine stickleback, 2.2% peamouth, 0.1% prickly sculpin, 0.4% pumkinseed, 0.1% starry flounder, 0.56% large scale sucker, 0.04% red-sided shiner. Downstream sampling collected 1,028 fish (14 spp) - 20.9% juv. salmon. Salmon catch: 74.9% sub Chin, 2.8% sub coho, 12.1% pink fry. Remainder were minor. Other catch: 56.7% three-spine stickleback, 17.7% peamouth, 3.7% prickly sculpin, 0.68% starry flounder, 0.1% pumpkinseed, 0.1% large scale sucker, 0.1% Pacific staghorn sculpin. Chinook density was related to date, habitat strata, and their interaction up- and downstream in 2012. Before rest (09) no diffs, 1 and 2 yr post (10 -sig and 11 -NS) higher downstream, 3 yr post tidegate & 1yr post dike setback (12 -NS) higher upstream. Connectivity explains 38-74% of variation in Chin density. Density compared to long term monitoring sites: Before - generally fall in with long term sites, 1yr and 2 yr post tide gate downstream sites similar to long term sites while upstream sites are lower, 3yr post tidegate/1yr post dike setback - downstream and upstream densities similar to long-term monitoring sites. Chin size increased more upstream than downstream. Yearling coho: more coho collected upstream, mostly in a blind channel but found at all up- sites in May. Collected at one down- site only in May. Subyearling coho: upstream density increased Apr-Jun (large catch in a blind channel after a freshet), downstream collected Apr-end - peak in June. Chum were collected up (all months) and downstream (mainly in Apr). Pink were more abundant downstream, mostly in Apr. Only found up- in blind channel 2 in Apr. Cutthroat were caught up- every month but Mar, down- Mar & Jun. Densities higher upstream. Hatchery Chinook caught upstream (8) 6CWTs, all from Marblemount on the Skagit R. Steelhead were present - 3 capture in upstream sites. Other species: Rough skinned newts and freshwater mussels were collected upstream. Numbers lower than previous years - large numbers collected at sites not utilized in 2012.

Detailed Outcomes: Water Quality and Substrate: Salinity was below 0.1ppt - essentially freshwater. T was related to site, strata and season. T increased with date, was higher above tide gates than below, and was higher in blind channel lobes than main channels (p< 0.001). T did not go above 15C threshhold at most sites and then only late in the season. Dissolved oxygen (DO) differed by date, site, and strata (p< 0.001). DO was higher above the tide gates and the difference increased with date. DO decreased with date above and below. Blind channel DO lower than main channel DO. DO below 6.5 mg/L threshhold 4.9% of the time upstream and 8.7% of the time downstream of tidegates.DO seemed to follow day/night and tidal cycles somewhat. Water depth surpassed min 0.2m at all sampling periods. Water shallowed gradually upstream. Velocity exceeded preference and presence were exceeded 10% of the sample dates (1 day) upstream and 9.7% for presence and 22.5% for preference downstream. Substrate upstream (except s5) and 2 sites downstream were mixed fines. s5 and Tom Moore were sand. Vegetation upstream moved from unvegetated to aquatic (mostly pondweed), downstream unvegetated all season. Fish: Three-spine stickleback were most abundant, Chinook subyearlings were 2nd most abundant at all sites except Fisher S1 Blind (Chinook most abundant) and Blind Ch2 (coho, stickleback, Chinook). Additional salmonids: coho, chum, pink, steelhead and hatchery Chinook subyearlings and yearlings, cutthroat, unID'd trout, and whitefish. Other spp: peamouth chub, large scale sucker, prickly sculpin, Pacific staghorn sculpin, starry flounder, redside shiner, unID'd bass, bluegill, pumpkinseed, unID'd juv sunfish, unID'd chub, lamprey, roughskin newt, freshwater mussel.

**Effects Modifiers**: There is more vegetation upstream but no way to determine if that was related to differences in up- and downstream catches. Tidegate operation may influence upstream densities of

Chin but this cannot be tested because operation varied around construction projects in 2010 and 2011 and dike setback was completed prior to 2012 sampling.

**Intervention**: Dike setback completed, increasing tidal habitat from 9.8 ac to 55.7ac 2 years prior: 3 paired side hinge wooden doors replaced with 3 aluminum one-piece side hinge doors. Two lower flapgates are below the middle and south doors. One opens with flow, one with adjustable arm.

Conditions: big ditch siphon culvert was relocated so that dike	Duration: 4 years but this report
could be set back	focuses on 2012

**Study Design**: Fish collected in fyke trap and beach seine above and below the tide gate; once in Feb and then twice a month throughout season. Sites used were consistent among years - although 3 new channels created during dike setback. Fish were ID'd, measured (n=20 per species), and CWTs collected. Water T, salinity, dissolved oxygen, velocity, vegetation, substrate, water depth, water surface elevation measured.

**Statistics**: Strata, site, or date differences in salinity, T, velocity, depth, dissolved oxygen were compared graphically or with ANOVA with Sheffe pair-wise testing. Calculated density and compared by strata, treatment, sampling type with ANOVA with Sheffe pair-wise testing. Calculated average abundance, determined fish days and divided by average residence time to calculate population of Chinook using each habitat type in 2012.

**Comments**: This data is interesting because there was a time lag between replacing the tide gates and dike setback. There may be the opportunity to determine relative benefit derived from each action. The data included are different than covered in later reports, which is why both are included in the review.

<b>Location &amp; Species</b> : South Fork Skagit River tidal delta. Chinook salmon, water quality (temp, dissolved oxygen)		Ecosystem(s):		
<b>Reference Source</b> : http://skagitcoop.org/wp-content/uploads/2013_FisherSl_Fish_Final_061014.pdf				

**Abstract**: From ABSRACT: The Fisher Slough Restoration Project, located in the S. Fork Skagit River tidal delta near the town of Conway, is intended to help recover the six populations of wild Chinook salmon present within the Skagit River and its natal estuary. The restoration project was phased in three parts. Project Element 1, completed in 2009 was to improve fish passage and tidal inundation to areas upstream of the floodgate and to protect adjacent farmland from flooding by replacing an existing floodgate with a new floodgate within Fisher Slough at the Pioneer Highway crossing. Element 2 resolved a drainage conflict preventing implementation of Element 3- completed in 2011- a dike setback to allow more of the agricultural area to be inundated by tidal and freshwater hydrology, increasing fish carrying capacity. Juvenile Chinook salmon monitoring results related to Project Elements 1 and 3 are presented in this report for all years of monitoring: 2009–2013. With five years of monitoring data and all restoration elements complete, we answer five key questions:

1. Did tidal habitat area increase following dike setback restoration at Fisher Slough? (Chapter 3)

2. Does restoration at Fisher Slough influence water temperature and dissolved oxygen? (Chapter 4)

3. Is juvenile Chinook salmon presence within Fisher Slough influenced by variable local environmental conditions, such as water temperature, dissolved oxygen, depth, and velocity? (Chapter 5)

4. How did floodgate operation vary over the juvenile Chinook salmon monitoring period for all years? (Chapter 6)

5. Did the dike setback restoration and floodgate operation influence juvenile Chinook salmon abundance, density, and size? (Chapter 7)

**Results Summary**: Restoration increased available habitat by 45.9 acres in Fisher Slough and increased the carrying capacity by 21,823 juvenile salmonids (mainly focused on Chinook subyearlings). Operating the tide gate in conjunction with tidal cycles has increased habitat connectivity and has had a positive benefit to Chinook smolts rearing in the estuary. Non-ebb passage opportunity was highest in 2012 and 2013 and lowest in 2009 and 2010. Chinook presence was not associated with water depth, velocity,

surface temperature, surface dissolved oxygen, minimun or maximum dissolved oxygen, or maximum temperature.

**Broad Outcomes**: Restoration increased available habitat by 45.9 acres in Fisher Slough and increased the carrying capacity by 21,823 juvenile salmonids (mainly focused on Chinook subyearlings). Operating the tide gate in conjunction with tidal cycles has increased habitat connectivity and has had a positive benefit to Chinook smolts rearing in the estuary.

**Detailed Outcomes**: Water temperature: Longer floodgate closure times and warmer river T led to warmer T in Fisher Slough. Dike setback was associated with warmer surface temps upstream of the tidegate. Average logger T decreased after setback upstream but not downstream. Dissolved oxygen: longer tidegate opening times are associated with higher dissolved oxygen in Fisher Slough. Higher tributary flow and lower tributary dissolved oxygen lead to lower dissolved oxygen in Fisher Slough. Surface dissolved oxygen was higher after dike setback and was higher before Aug. Average dissolved oxygen was not influenced by any of the factors tested. Minimum dissolved oxygen was lower after dike setback and was influenced by tidegate open times (longer opening means higher dissolved oxygen) and tributary inflow and tributary dissolved oxygen in the same way as surface dissolved oxygen. Chinook presence was not associated with water depth, velocity, or surface T (except maybe in Aug), surface dissolved oxygen, minimum dissolved oxygen, and maximum dissolved oxygen, or maximum T. Non-ebb fish passage opportunity was higher in 2009 than 2010-2013. Tidegate door opening as %channel width was lower in 2011 than 2012 or 2013, which were not different. 2012 & 2013 had highest ebb passage opportunity , while 2009 & 2010 had the lowest (at <0.89 ft/s and <1.1 ft/s).

**Effects Modifiers**: The spot measures alone did not capture the overall decrease in average T because they were never taken at night.

**Intervention**: 3 wooden paired tide gates were replaced with aluminum gates in 2009. New floodgates are managed by season: fall/winter flood control, spring: salmon migration, summer: irrigation. In 2011 dike setback increased marsh area from 9.8 to 55.7 acres. Additionally, Big and Little Fisher creeks were rerouted and tidal channels were excavated.

Conditions:	Duration: 5 years	
<b>Study Design</b> : Fish were collected up and downstream of the tide gates in main channel and blind slough habitats using beach seines and fyke traps. ID'd and counted all fish, measured up to 20 of each species. Measured water elevation, T, and/or dissolved oxygen, velocity.		
<b>Statistics</b> : Calculated fish densities for beach seine and fyke net catch width tide gates are open when velocity is less than 0.89 ft/s (critical (maximum recommended velocity for upstream migration of salmon fish sampling. Used ANOVA to test for mixed effects on environment testing was used to test between group comparison. Used generalize juvenile Chinook abundance and density.	fatigue swim speed) and 1.1 ft/s < 60 mm) for the week prior to al variables. Scheffe pairwise

<b>Location &amp; Species</b> : Wiley Slough, Skagit Bay, WA. Chinook salmon, other salmonids		Ecosystem(s): t	idal sloughs		
Reference Source: http://skagitcoop.org/wp-content/uploads/Wiley-Slough-2012-2013-Final.pdf					

Abstract: Restoration of Skagit River delta habitat was identified as a priority to help recover Skagit Chinook salmon listed as Threatened under the ESA. The Wiley Slough Restoration Project was completed in 2009. Fish monitoring was conducted within restored habitat area of the Wiley Slough Restoration Project in 2012 and 2013. The monitoring design primarily consisted of a post-treatment (i.e., after restoration) stratified random design using beach seines to capture fish. The monitoring effort caught over 22,000 fish representing at least 23 fish species, including 7 species of salmon. Unmarked juvenile Chinook salmon dominated the catch of salmon. Unmarked juvenile Chinook salmon density varied within the Wiley Slough Restoration Project by lobe, year, and season, but not habitat type. The Wiley Slough lobe had higher densities of juvenile Chinook salmon than the Teal Slough lobe; higher densities of juvenile Chinook salmon were found in 2013 than in 2012; seasonal use of restored areas by juvenile Chinook salmon began in February, peaked from April through June, then declined afterward. Juvenile Chinook salmon density did not vary by channel and impoundment. In general, juvenile Chinook salmon are using the restored areas of both Wiley and Teal Slough lobes at seasonal density levels consistent with other long term monitoring sites in the Skagit River estuary. An estimated 88,206 (37,326-139,086, 95% CI) and 247,692 (128,973-366,412, 95% CI) unmarked juvenile Chinook salmon used restored habitat of the Wiley Slough Restoration Project in 2012 and 2013, respectively. Based on two years of monitoring the number of juvenile Chinook salmon that used the restored areas of the Wiley Slough Restoration Project: 1) exceeded the updated carrying capacity estimate based on actual restored channel habitat, and 2) exceeded the Skagit Chinook Recovery Plan's estimated benefit to juvenile Chinook salmon. However, the number of juvenile Chinook salmon that used the restored areas were somewhat less than predicted by the carrying capacity estimate that included all wetted areas (29 hectares of channel and impoundment combined). Sustainable channel conditions are reached after natural hydrologic and sedimentation processes achieve a balance at the site. Sustainable channel area is estimated at 2.03 hectares (0.50-8.25, 95% CI) suggesting total habitat area will be less than the 29 hectares currently present. Thus, actual juvenile Chinook salmon carrying capacity could change within the Wiley Slough Restoration Project based on how channel/impounded areas evolve over time. The issue of restored habitat conditions within recently restored areas using dike setback design and the long term sustainability of that habitat may be an emerging theme for estuary restoration adaptive management. This issue is of particular importance when restoration projects are intended to achieve specific goals, such as recovery of listed Chinook salmon populations. If as-built restoration conditions

are not in a sustainable state, then a false sense of restored benefits might be accepted without sufficient monitoring and adaptive management of projects.

**Results Summary**: Depth, velocity, temperature, salinity, and dissolved oxygen differed between the two lobes of the slough. Temperature increased with month and dissolved oxygen decreased with month in both lobes. The Wiley lobe was more tidally influenced and the Teal lobe was more influenced by the river. In the two sampling years >22,000 fish were collected including 7 species of salmonids which were mainly Chinook, chum, and pink (even years). Chinook salmon density was higher in Wiley slough, but it did not appear to be influenced by depth, velocity, or dissolved oxygen. Temperature and salinity were significant factors. The juvenile Chinook population both years was higher than estimated from tidal channel length, but lower than estimated by total wetted area.

**Broad Outcomes**: Depth was less in the Wiley lobe than the Teal lobe, and was lower in 2013 than 2012 but did not change with month. Velocity was lower in Wiley and did not differ with month or year. T was greater in Wiley than Teal and increased with month in both lobes and both years. Salinity was greater in Wiley and in 2013. Dissolved oxygen was less in Wiley and decreased with month. Wiley shows more tidal influence and Teal more river influence. Depth, velocity, salinity, and dissolved oxygen were not likely influencing Chinook rearing between sites but T might be. Collected >22,000 fish (7 species of salmonids, mostly juvenile Chinook, chum, and even year pink). Stickleback, starry flounder, and peamouth were the most abundant non-salmonids. Chin density was greater in Wiley, and did not vary by habitat or between channel and impoundment but did vary by year and week. Density was highest Mar-Jun. Significant factors were T (positive) and salinity (negative). Landscape connectivity explained 53-85% of Chinook density at Skagit Bay longterm monitoring sites. Wiley ('12, '13) and Teal ('13) values plotted in the long term site scatter. In both years the juvenile Chinook population was higher than the estimated carrying capacity based on tidal channel, but lower than the estimate based on wetted area.

# **Detailed Outcomes:**

Effects Modifiers: Sustainability of impoundements as natural processes occur need to be considered.

<b>Intervention</b> : Dike setback with tide gate removal. New tide gate installed in the new smaller perimeter dike. Borrow ditches filled. Native plantings.			
Conditions:	Duration: 2 yrs		
<b>Study Design</b> : seined fish, measured salinity, T, dissolved oxygen, velocity, depth, and classed substrate and vegetation. Results were compared to estimated expected values and to long-term monitoring sites that were used as references.			
<b>Statistics</b> : ANOVA: lobe, year (factors), month (covariate) for environmental variables. ANOVA: year, lobe, season, habitat type (factors) for juvenile Chinook density. T and salinity or dissolved oxygen (correlate) were covariates. Calculated cumulative Chinook density and landscape connectivity - compared to long term Skagit monitoring sites. Calculated estimated juvenile abundance and usage of each lobe each year and calculated the available habitat. Determined carrying capacity and whether it was met.			

Comments: The restoration was completed in 2009 and monitoring was carried out in 2012 and 2013.

Beamer, E., B. Brown, K. Wolf, R. Henderson, and C. Ruff. 2016. Juvenile Chinook salmon and nearshore fish use in habitat associated with Crescent Harbor Salt Marsh, 2011-2015. Skagit River System Cooperative Research Program. Prepared for: U. S. <b>Reference Source</b> : http://skagitcoop.org/wp-content/uploads/Crescent-Harbor-Fish-Report- Final_2016-05-09.pdf				

**Abstract**: [From Eric's 1/26/17 email] "This report is about fish and environmental (water quality) response to tidegate removal. Multiple years of data/analysis. Post treatment study design."

[From "Study Area and Purpose of Report", p. 4] Restoration actions mainly consisted of: a) increasing tidal connectivity within the historic marsh area, and b) replacing the system's outlet channel tide gate with a Mabey-Johnson bridge [a portable pre-fabricated truss bridge, designed for use by military engineering units] thus restoring tidal flooding and fish access to more than 200 acres of Crescent Harbor Salt Marsh...In response to the completed restoration at Crescent Harbor Salt Marsh, we monitored fish use of the restored areas and its adjacent nearshore beaches from 2011 through 2015 over the juvenile Chinook salmon rearing period for pocket estuaries (January through June). The fish monitoring design for the Crescent Harbor Salt Marsh Restoration Project is a post-treatment (i.e., after restoration) stratified (lobes within the restored area) design.

**Results Summary**: Prior to restoration only stickleback were caught in Crescent Marsh. After restoration 10-16 species were caught including subyearling Chinook (wild and hatchery), subyearling and yearling coho, pink, chum, yearling sockeye, cutthroat, and native char (Salvelinus sp). Pink salmon fry timing did not differ inside and outside the marsh. Chum fry abundance peaked inside the marsh earlier than the adjacent beaches but densities were similar inside and outside. Wild Chinook were collected mainly in the main marsh and adjacent beaches, but were also collected in the creek. Fish size was negatively correlated with outmigrant abundance. Density was higher in the marsh than at adjacent beaches, which follows a pattern seen at natural pocket marshes in Puget Sound but the difference was smaller.

**Broad Outcomes**: Prior to restoration only stickleback were caught in Crescent Marsh. Salmonid Results: Caught Chinook subyearlings (wild and hatchery), coho subyearlings and yearlings, pink, chum, sockeye yearlings, cutthroat, native char (Salvelinus sp). Pink salmon fry timing did not differ inside and outside the marsh. Chum fry abundance peaked inside the marsh earlier than the adjacent beaches. Densities were similar inside and outside. Chinook wild were collected mainly in the adjacent beaches (highest 4 yrs, peak Mar and May) and main marsh (highest 2 yrs, peak Apr), but were also collected in the creek (peak Apr). Chinook juvenile length varied with month and by year,  $R^2 = 0.70$ . Fish size is negatively correlated with outmigrant population size. Density was higher in the marsh than at adjacent beaches, this follows a pattern seen at natural pocket marshes in Puget Sound but the difference is smaller.

**Detailed Outcomes**: T was influenced by area and year and varied with month (+) R<sup>2</sup> = 0.89. T never exceeded 24.8C lethal limit but did surpass 15C stress level in May or Jun each year. The only T diff by areas was between adjacent beach and mid-marsh. Salinity differed among years but did not have any sig covariates. DO differed among areas but not years, R<sup>2</sup> = 0.877 with no sig covariates. DO was higher at the adjacent beach than any area in the marsh. 10% of total DO measurements were below 7.0 mg/L threshhold for juvenile salmon. Low DO mainly occurred in May and Jun. Fish Assemblage: 2011 18,959 fish (13 species), 2012 8,690 fish (10 species), 2013 5,842 fish (13 species), 2014 4,637 fish (15 species), 2015 4,928 (16 species). Aside from juvenile salmon, the 3 most abundant species were stickleback (27,410), shiner perch (5,830), and Pacific staghorn sculpin (2.752). Other species include prickly sculpin, padded sculpin, sharpnose sculpin, surf smelt, Pacific sandlance, starry flounder, English sole, and 2 non-natives: American shad, and bluegill.

# Effects Modifiers:

**Intervention**: Removed a tide gate and replaced it with a bridge. Increased connectivity within the marsh. Completed 2009.

Conditions:

Duration: 5 yrs post-restoration

**Study Design**: Sampled every two weeks Feb to May. Beach seining was completed in 3 distinct areas of the marsh and in adjacent nearshore waters. Electrofishing was used to sample Crescent Creek. All fish were ID'd and counted. Measured T, salinity, dissolved oxygen, velocity, set depth, vegetation, substrate type.

**Statistics**: Used ANOVA to determine factor (marsh area and year) and covariate (month, T, salinity, dissolved oxygen if not autocorrelated with the test variable) influences on T, salinity, dissolved oxygen - each analyzed seperately.

**Comments**: At this site the fish used the beaches, the marsh, and a tributary creek that had also been restored.

Beamer, E., R. Henderson, and C. Ruff. 2016. Juvenile Chinook response to Fisher Slough restoration and floodgate operation: An update including 2015 results. Skagit River System Cooperative, La Conner, WA. 21 pp.

	restoration year.		
Location & Species: Fisher Slough	, South Fork	Ecosystem(s):	
Skagit River, WA Chinook salmo	n		

**Reference Source**: http://skagitcoop.org/wp-content/uploads/2009-2015-Fisher-Slough-Chinook-Analysis-Update-Final.pdf

**Abstract**: [From Eric's 1/26/17 email] "This report is about fish and environmental (water quality, area) response to tidegate (TNC insisted the structure be called a floodgates) replacement and dike setback restoration. Multiple years of data/analysis. Before/after control impact study design. This report teased out the fish and environmental effect of tidegate operation from dike setback restoration. Both were important. We also presented a conceptual model on how to think about (and statistically test) upstream chinook fry migration into tidal habitat influenced by tidegates."

**Results Summary**: After tide gate replacement and before dike setback the Fisher Slough sites did not follow the pattern of higher abundance with increased connectivity seen at long term monitoring sites in the Skagit River delta. However, after dike set back the Fisher Slough sites demonstrated this positive relationship. Water temperature influenced Chinook abundance only in 2015. When fish abundance was expressed as a percent of carrying capacity the 2015 data was consistent with other monitored years and all years fell close to the 1:1 line between Fisher Slough and Skagit River delta with outmigrant population as a percent carrying capacity.

**Broad Outcomes**: Post tide gate replacement and dike setback the sites at Fisher Slough followed the pattern of positive relationship between fish density and landscape connectivity found at the long term monitoring sites in the Skagit delta. Post tide gate replacement but pre dike set back the Fisher slough upstream sites did not follow the expected pattern. Water T influenced Chinook presence in 2015 but no other year.

**Detailed Outcomes**: The population estimate for wild subyearling Chinook in the Skagit River during the 6 years of the Fisher Slough study ranged from 1.13 to 5.64 million. Non-ebb upstream opportunity varied among years but was <50% of the week except in 2015 when the tide gate was chained open. A model using month, tide gate %open, and pre-vs post dike setback did not make a good prediction of juvenile abundance in Fisher Slough in 2015 - a year with low outmigrant population and higher water T. New analyses presented in the appendices showed that 2015 was warmer with lower dissolved oxygen and that both significantly influence presence of juvenile Chinook. T had a greater effect than dissolved oxygen. Chinook density was influenced by year and strata (up- or down-stream of tide gate) and the

year\*strata interaction. Chinook density was only significantly different between strata in 2010. After dike setback the growth rate of juvenile Chinook was higher in the slough during spring and summer; FL was higher in Apr, May, Jun after dike setback than before dike setback. When fish abundance is expressed as a percent of carrying capacity the 2015 data is consistent with other monitored years and all fall close to the 1:1 line between 'Fisher Slough abundance as % project carrying capacity' vs 'Skagit River outmigrant population as % of Skagit delta carrying capacity'.

**Effects Modifiers**: Top candidate model did not accurately predict the 2015 abundance in Fisher Slough. Possible explanations: Tide gate was chained open - value outside of values used to build the model. The model does not include any measure of Skagit outmigrant population size or any local environmental data.

**Intervention**: 3 wooden paired tide gates were replaced with aluminum gates in 2009. New floodgates are managed by season: fall/winter flood control, spring salmon migration, summer irrigation. In 2011 dike setback increased marsh area from 9.8 to 55.7 acres. Additionally, Big and Little Fisher creeks were rerouted and tidal channels were excavated.

Conditions:

Duration: 6 years

**Study Design**: Fish were collected up- and downstream of the tide gates in main channel and blind slough habitats using beach seines and fyke traps. ID'd and counted all fish, measured up to 20 of each species. Measured water elevation, T, and/or dissolved oxygen, velocity.

**Statistics**: Calculated fish densities for beach seine and fyke net catches. Calculated the time and width tide gates were open when velocity was less than 0.89 ft/s (critical fatigue swim speed) and 1.1 ft/s (maximum recommended velocity for upstream migration of salmon < 60 mm) for the week prior to fish sampling. Used ANOVA to test for mixed effects on environmental variables. Scheffe pairwise testing was used for between group comparison. Used generalized linear models to analyze juvenile Chinook abundance and density.

**Comments**: Intervention, study design, and statistics information was taken from Beamer et al. 2014, the Fisher Slough project report for 2009-2013. This report should be included as an extension and update of that report as that is the way it is intended. These two reports focus on juvenile Chinook response to restoration while Henderson et al. 2016 focuses on the hydrologic changes after restoration at Fisher Slough.

Bocker, E.J. 2015. Restoring connectivity for migratory native fish: investigating the efficacy of Fish Friendly Gates. M.Sc. Thesis, Massey University, Palmerston North, NZ. 89 pp.				
Keywords: flood gate replacement salmon	Type: M.S. ThesisPublication Date: 2015			
Include: Yes	<b>Reason</b> : Directly relevant to the question of modifying tide gates.		Relevance:	
Location & Species: Bay of Plenty Region, New Zealand		Ecosystem(s):		
Reference Source: http://mro.massey.ac.nz/handle/10179/7544				

Abstract: Stream connectivity and habitat diversity are key components of healthy river ecosystems. Human modification of natural flow regimes disrupts natural connectivity, and results in physical, chemical, and biological changes that impair natural river function. Such changes can be detrimental to freshwater species, particularly those which have evolved to be reliant on a variety of different habitats throughout their life cycles. Consequently, restoring connectivity has become a major restoration goal in freshwater ecology. Tide gates, a man-made coastal structure designed to protect low-land infrastructure from flooding, can negatively impact freshwater ecosystems. Through disrupting connectivity, tide gates impede the movement of aquatic biota and degrade upstream habitats. It is thought that the vast majority of tide gates in New Zealand and worldwide could be modified to enhance connectivity and fauna passage through the installation of Fish Friendly Gates (FFG's). This study is the first to investigate these claims. FFG's increased both the duration and distance that tide gates were held open over a tide cycle. These operational changes reintroduced some tidal fluctuation to upstream habitats but water levels remained within safe levels for infrastructure. FFG influence enabled upstream passage for giant bully and adult inanga, for which tide gates were otherwise impassable. Furthermore, upstream passage of whitebait (migratory galaxiid juveniles) and common bully were significantly increased when aided by FFG's. Although rapid and sustained increases in migratory species richness of resident populations were observed following FFG installation, due to small sample sizes these changes could not be regarded as statistically significant. Additionally, evidence of rehabilitation of degraded sites was limited and suggests care should be taken when restoring connectivity to poor quality habitat. Overall, this study demonstrated that FFG's can enhance upstream fish passage at tide gates while maintaining adequate flood protection. Whether FFG's can provide ecological benefits to degraded habitats requires supplementary research. Provided the limitations of FFG's are recognised and they are only installed where tide gate removal is not feasible, FFG's are an effective tool for facilitating fish passage through tide gates in New Zealand and worldwide.

**Results Summary**: After 'fish-friendly' modification (installing a large lever that delayed closing time) tidal fluctuation, and opening distance and duration increased. When levers were engaged the total number of species collected upstream of gates was higher. Weak-swimming species were caught only when the levers were engaged. Separately, three gated systems were retrofit with fish-friendly levers and three paired gated systems were unmodified. Prior to retrofit, species richness was significantly lower above the tide gates. One month post retrofit, differences in species richness up- and

downstream were no longer significant and more diadromous species were collected upstream of gates. One year post retrofit all test sites had equal species richness up- and downstream. Although more diadromous species were found upstream of gates at test sites relative to controls, there were no significant differences in fish abundance between control and test sites for any species or group. After fish-friendly modification conductivity was higher, salt intrusion was greater, dissolved oxygen was higher at two sites and lower at one, and water T did not differ.

**Broad Outcomes**: Impacts of tide gates as barriers are not equal between types. FFGs increase connectivity at tide gates. FFGs facilitate upstream fish passage, especially of weak swimmers. Upstream habitat passive rehabilitation is limited.

Detailed Outcomes: Ch 3 FFG reinstated some tidal fluctuation upstream but depth increases were small. Opening duration and opening distance increased at all retrofitted gates although the increase ranged from an hour to 8 hours. Ch 4 When the FFG was engaged at least 7 species were caught: common bully (473), giant bully, shrimp (292), grey mullet, eels (long- and short- fin), whitebait species (171). The number of individuals in all species not enumerated above is <20 combined. Common bully and whitebait had significant differences in catch associated with tidal cycle. Whitebait: high on flood tides, no differences among other tide cycle parts. Common bully: fewer migrated on the low tide, no differences between flood, ebb, high. No differences for shrimp. During part tide sampling all full tide species were caught plus flounder, and goldfish. Common bully (880), whitebait (498), shrimp (354), were the 3 most abundant species again, 94% of total. Giant bully, adult inanga, grey mullet, and flounder only caught when FFG engaged. More common bully (sig), whitebait (sig), and shrimp (NS) were caught upstream when FFG was engaged. Total number of species increased, addition of weakswimming species, with FFG. Ch 5 A total of 13 species from 10 families were collected. Species richness varied upstream of tidegates. Richness was lower upstream (sig) and pest species were abundant upstream. Estuarine species were absent at the Kaituna River sites. One month post FFG, differences in species richness up- and downstream were no longer significant. Diamdromous species increased upstream at all test sites (NS). No difference in fish abundance between control and test sites for any species. When all sites were combined, goldfish abundance decreased post FGG. Diadromous fish and species both increased at test sites relative to paired controls (NS). One year post FFG, all test sites showed equal species richness up- and downstream. Inanga abundance increased at test sites and control sites. Common bully increased at control 2 and test 2. Shortfin eel increased at all sites post FFG. No species groups showed difference in abundance after FFG retrofit, although the increase in diadromous fish at test sites relative to controls was close to significance. Water quality: T was high at all sites and were similar after a year, except test 1 which was hotter. Dissolved oxygen was low at all sites prior to FGG. Test sites 2 and 3 had higher (sig) dissolved oxygen after a year, test 1 had lower (sig) dissolved oxygen and control sites had no change. Conductivity was higher one year post FFG (sig) and salt intrusion was greater.

**Effects Modifiers**: Ch 3 Did not measure water velocity during opening periods to more fully estimate fish passage increase Ch 4 Sampling was only done at one site and Ch 3 showed that there could be large differences between sites.

**Intervention**: Ch 3 Retrofitted 5 of 6 tide gates with a fish friendly gate (FFG - a large lever that delays the gate closing time - they are adjustable and can be fit onto existing gates.) Maketu - light cast alloy

circular, Otumakoro - cast iron circular, Bell Road - square wooden on culverts (2), Awatapu Lagoon - circular cast iron on culverts (2)). Ch 4 two tide gates on culverts were FFG retrofitted. Ch 5 6 gated sites were studied, 3 FFG retrofit, 3 unmodified. FFG and control sites were paired.

# Conditions:Duration:Study Design: Ch 3 Measured water depth, gate opening width and time open before and after FFG<br/>retrofit. Ch 4 Compared fish passage through unmodified gates and with FFG retrofit. Sock nets were<br/>installed over upstream end of culverts to collect migrating fish over 5 full tide cycles and 12<br/>flood/ebb only samples collected with the FFG engaged and 12 flood/ebb only samples with FFG<br/>disengaged. Fish were ID'd and measured. Ch 5 Pre-installation: Fish collected with fyke and minnow<br/>traps upstream (6 sites) and downstream (4 sites). Each site sampled 3 dates. Fish ID'd, measured.<br/>Vegetation (in-stream and bank), water clarity, water levels, weather were noted. Salinity, dissolved<br/>oxygen, T measured. Post-installation: Trapping was done 1 month and 1 year after FFG retrofit.<br/>Conductivity and dissolved oxygen measured on each sampling date.

**Statistics**: Ch 4 Non-parametric Kruskal-Wallis rank sum tests and pair-wise differences with Tukey and Kramer tests. Wilcoxon rank sum tests were used for potential bias between nets and on part-tide samples to examine tide, FFG, and diurnal effects on the 3 most abundant species. Ch 5 Friedman's Rank Sum was used to test whether species abundance differed between sampling periods (before, 1 month, 1 year).The number of species groups (pest, marine, diadromous fish, diadromous species) were considered. Calculated daily mean environmental variables and used ANOVA to explore change in T and conductivity, and Kruskal-Wallis rank sums for dissolved oxygen.

**Comments**: Although this is not in our region, this study directly links tide gate modification to the passage of weak-swimming fishes. The authors also found that simply increasing opening angle and duration did not improve all habitat metrics.

Abstract: We examined variations in the juvenile life history of fall-spawning Chinook salmon, Oncorhynchus tshawytscha, for evidence of change in estuarine residency and migration patterns following the removal of dikes from 145 ha of former salt-marsh habitat in the Salmon River estuary (Oregon). Mark-recapture studies and abundance patterns in the estuary during 2000-2002 describe the following life-history types among Chinook salmon: (1) fry disperse throughout the estuary, and many move into restored tidal-marsh habitats in the early spring soon after emergence; (2) juveniles reside in freshwater for several months, enter the estuary in June or July, and remain for (a) a few weeks or (b) several months before entering the ocean; and (3) juveniles enter the ocean later in the fall after an extended period of rearing upriver and/or in the estuary. The absence of fry migrants in the estuary during spring and early summer in 1975-1977 - a period that precedes restoration of any of the diked marshes - and the extensive use of marsh habitats by fry and fingerlings April-July, 2000-2002 indicate that wetland restoration has increased estuarine rearing opportunities for juvenile Chinook salmon. Year-to-year patterns of estuarine rearing and abundance by juvenile salmon may be influenced by flood and drought conditions that affected adult spawner distribution and over-winter survival of salmon eggs. However, persistent changes in spawner distribution since 1975-1977, including the concentration of hatchery strays in the lower river, may account for the large proportion of fry that now disperse into the estuary soon after emergence in the spring. Although few of these earliest migrants survived to the river mouth, many fry and fingerlings from mid- and upper-basin spawning areas distributed throughout a greater portion of the estuary during the spring and summer and migrated to the ocean over a broader range of sizes and time periods than thirty years ago. The results suggest that wetland recovery has expanded life history variation in the Salmon River population by allowing greater expression of estuarine-resident behaviors.

NOTE: Tide gates were probably removed from study area, but this is not clear: "In the early 1960s, construction of a network of earthen dikes and tide gates converted more than 250 ha (approximately 65%) of the original salt-marsh habitat to pasture land, confining most of the estuary to a narrow ribbon of main-river channel. Subsequently, a cumulative total 145 ha of shallow wetland habitat was returned to the estuary after three successive dike-removal projects were completed in 1978, 1987, and 1996." [p.80]

**Results Summary**: Flow level variability and pattern were similar in the before and after periods. Juvenile salmon used the estuary and salt marsh areas earlier in the year and for a longer period after dike breaching. The increased use of the estuary after dike removal, especially by fry/fingerlings increased life history variation. Migration timing and ocean entry variation was higher post-restoration. Hatchery juveniles and adults were present after dike and tide gate removal. The contemporary spawning period was truncated relative to the historic period.

**Broad Outcomes**: Increased use of estuary after dike removal, especially fry/fingerlings, increased life history variation. Migration timing and ocean entry variation higher.

**Detailed Outcomes**: Flow level variability and pattern were similar in the before and after periods. Contemporary: Juveniles used marshes Apr - Aug, and main channel hab Apr-Oct.Mid-estuary May-Oct and lower-Estuary Jun - Nov or later. Historical: Abundance increased later and for a shorter time. Fish were not often caught in mid- or lower-estuary habs before July. Contemporary: median estuary residence time is 5 wks Spawning Contemporary: % hatchery decreases as move upstream, most spawn late Oct-Nov. Historical: no hatchery, spawn mid-Oct - mid-Jan.

**Effects Modifiers**: Hatchery spawners and juveniles that were not present prior to dike and tide gate implementation.

<b>Intervention</b> : Three salt marsh areas of 22, 63, and 60 ha were restored by removal of dikes and associated tide gates in 1978, 1987, and 1996.			
<b>Conditions</b> : The dike removal is focused on, but the tide gates were also removed.	<b>Duration</b> : Juveniles: 2000-2002 Adults: 1999-2001, 1975-1977		
<b>Study Design</b> : Monitor adult spawning and juvenile outmigration and estuary usage in 2000, 2001, and 2002 juvenile outmigration years. Monitored both restored and previously undiked areas. Three restoration events complete 4, 13, and 22 years prior to the project outset. These data were compared with data from 1975-1977, a decade or more after dikes and tide gates were constructed, but before hatchery fish first returned to spawn in the system.			
Statistics: All statistics are descriptive.			

**Comments**: This paper is an early study of salmon responses to estuary restoration. It is useful to include. However, it should be noted that dikes around the marshes were removed along with the tide gates. Therefore, the results cannot be entirely attributed to tide gate removal.

Abstract: [Excerpted from Exec Summary] Our studies in the lower 100-km of the Columbia River estuary quantified historical habitat changes and provided new information about contemporary abundance patterns, life histories, and habitat associations of Chinook salmon. In Part I, we detail our reconstruction of historical habitat opportunities and changes in the estuary as influenced by the tide, river flows, and temperature. In Part II, we depict contemporary habitat opportunities based on presentday patterns of salmon distribution and abundance and upon various physical factors that influence fish access to shallow-water rearing areas. In Part III, we compare the capacity of different wetland and nearshore habitats in supporting juvenile Chinook salmon as indicated by variations in prey availability, salmon diet, and rates of consumption. Finally, in Part IV, we examine the effects of upriver population structure and life histories on estuary rearing behavior and performance, including the genetic sources of individual Chinook salmon found within particular habitats and stock-specific patterns of residency and growth. These surveys provided new information about the present estuarine habitat associations of juvenile salmon. They also provided data for estimates of historical change in habitat conditions, estimates of historical change in salmon life histories, and analyses of food webs. Conclusions: 1) Extensive wetland loss has substantially decreased the quantity and quality of wetland habitats that support salmonid food webs and provide off-channel rearing areas for subyearling migrants with estuary-resident life histories. 2) Together, the loss of rearing opportunities and the decline of historical populations upriver have reduced life history diversity and late-season abundance of Chinook salmon in the estuary. 3) Salmon habitat use and residence times vary with fish size, but all wetland habitat types in the lower estuary are utilized by the smallest subyearling size classes, which tend to remain in the estuary for the longest periods. 4) Naturally produced subyearling salmon dominate in shallow wetland channels and may benefit most directly from restoration of wetland habitats. 5) Large releases from hatcheries have replaced diverse, naturally spawning populations with fewer hatchery stocks; these stocks are reared primarily as freshwater phenotypes with short estuary residence times. In the Columbia River estuary, contemporary patterns of abundance, stock composition, habitat use, and residency are largely driven by artificial propagation programs. 6) The response of the estuarine ecosystem to large subsidies of hatchery fish and estuary interactions between hatchery and naturally

produced salmon remain poorly understood. Such interactions may ultimately determine whether estuary restoration is an effective tool for salmon recovery. 7) Wetland-derived food webs support juvenile salmon throughout the estuary, including larger individuals that do not typically occupy wetland channels. 8) Different genetic stock groups of Chinook salmon exhibit characteristic patterns of temporal and spatial distribution in the lower estuary. 9) Most Chinook salmon Evolutionarily Significant Units (ESUs) are capable of expressing subyearling life histories. Both lower and upper Columbia River stock groups can produce subyearlings that reside in the estuary for several months. 10) The lower Columbia River estuary supports foraging and growth of juvenile migrants and contributes to the life history diversity of Chinook salmon populations.

**Results Summary**: Tidal amplitude has increased since 1925 in the lower Columbia River estuary; this and other factors have resulted in 75% of the shallow water habitat being lost. 273, 180 individuals of 50 species were collected. One-fifth of the total species were non-native. Chinook and chum were among the top ten most abundant species. Species presence was primarily driven by salinity. Chinook in all zones were actively foraging; mean stomach fullness was >60%. Rations were highest in the marine zone and lowest in the mixing zone. Stickleback were 86, 68, 24% of total fish in freshwater, estuarine mixing, marine sites, respectively.Stickleback diet overlapped Chinook diet in early spring but only caused lower growth in April at the highest fish densities. The daily rations were the same or higher than those reported for in-river foraging. Stock diversity increased with salinity. Otolith chemistry showed that 30-55% of the fish remained in the estuary a month or more. Size at estuary entrance increased with time and was negatively correlated with estuary residence time. Fish entering the estuary during summer had higher growth rates than those entering during winter. Estuary residence time was positively correlated with increase in fork length and rate of growth.

Broad Outcomes: Part I Tidal amplitude has increased at Astoria 0.3m since 1925. rkm 83-120 (Eagle Cliff to Kalama) 75% shallow water habitat lost during freshet and 74% during non-freshet. Water T is now 1.8-2.9 C higher from May-Dec than historic T. Reservoir manipulation (storage, withdrawal) account for >50% of the change. Feb-Mar T lower because of manipulation, but still higher than historic. Climate change caused 0.6-1 C Jun-Oct. Part II Collected 273,180 individuals of 50 species - 17 species comprised 99% of total. 20% of total species (10) non-native, including banded killifish and American shad. Chinook and chum were among the top 10 most abund. species. Others were stickleback, surf smelt, shiner perch, English sole, starry flounder, Pacific staghorn sculpin, American shad, peamouth. Species presence was primarily driven by salinity. Stickleback were 86, 68, 24% of total fish in Freshwater, estuarine mixing, marine sites, respectively. Caught 13,059 Chinook (mostly subyearlings), 2,983 chum, 250 coho, 33 steelhead, 24 cutthroat 3 sockeye. Chinook size increased with time and was 20-50 mm higher in lower estuary zones. chum size increased with time in all zones, but more quickly at marine sites. In wetland sampling collected 876,480 individuals of 22 taxa (7 confirmed non-natives). Stickleback were 91-99% at all sites between rkm 35 and 53, upstream 47 and 49%. In spring and summer Chinook were 2nd or 3rd most abundant species at all site types and rkms. 2.8% of Chinook in wetland channels were hatchery origin. Wetland channel availability should have been 60% in all survey months. Part III In all years prey were mostly Chironomid midges(39%), collembolans(28%), other dipterans(22%) and increased Mar-Jul. Annual mean densities were 551-4,365/m<sup>2</sup>. Benthic macroinvertebrates were annelids(14%), gammarid amphipods and other crustaceans(30%), insects(42%). Chironomid emergence peaked in mid-Jun and emergent Dolichopodiae were abund in Jul&Aug. Chin in all zones were actively foraging and ~25% of stomach contents were identifiable. Mean fullness was >60%. Rations were highest in marine zone and lowest in mixing. Adult dipterans and a benthic amphipod were most important in most zones and months (except Aug when cladocerans important). In the mixing zone Mysids were also important Jan-Mar. In wetland habitats emergent chironomids dominated except for 80-90mm individuals in scrub-shrub habitat, which ate gammarid amphipods. Stickleback diet overlaps Chinook in early spring but only caused lower growth in Apr at highest densities - competition may happen before terrestrial prey is available. Feeding peaked in early morning and before dark. Diet composition did not vary with time. Daily rations same or higher than those reported for in-river foraging.

**Detailed Outcomes**: Part IV Genetics Samples were made up of all stocks except Mid-UpCRSp. Spring Cr (SpCr) and West Cascades Fall (WCF) groups were highest proportions. Along salinity gradient stock diversity increased with salinity. WCF was more abundant in tidal fresh, Spring Cr Fall in the marine habitats. Other stocks had different distributions in space and time. In wetland sites 55-78% of samples were WCF and SpCr Fall were 2nd highest at all but one site. Up Col R Su/F were highest at that site and minor contributors at other sites. Otolith Analysis Residence times in 2004>2003>2005, all sig, and ranged from 1-176d. 72%, 68%, 86% otoliths showed Sr increase in '03, '04, '05. 30-55% of fish stayed in the estuary a month or more. At estuary entry fish were 34-178mm. Nearly 50% were <60mm. Back-calculated size at estuary entry increased with time. Size at estuary entrance was negatively correlated with estuary residence time. Fish that entered the estuary May-Aug had higher growth rates than fish entering Jan-Apr. No year or year \* season effects were found. Estuary residents were mainly SpCr Fall and WCF. Mean wetland residence times were 7d and 5d; residences ranged from 1-27d. Residence time was positively correlated size increase (sig) and rate of growth (NS).

**Comments**: Looks like it summarizes a lot of research on Chinook use of estuarine habitat; provides evidence for importance of estuarine habitat, discusses reduction in extent of, and access to this habitat due to dikes and tide gates. No tide gates mentioned. Current overview of juvenile Chinook use of the shallow water habitats in the Columbia R estuary.

Boumans, R.M.J., D.M. Burdick, and M. Dionne. 2002. Modeling habitat change in salt marshes after tidal restoration. Restoration Ecology 10(3): 543–555.				
Keywords: tide gate replacement salmon	<b>Type</b> : Peer-reviewed journal article		Publication Date: 2002	
Include: Yes	<b>Reason</b> : Shows impact of incomplete restoration. Removing a tide gate but leaving a culvert: marsh vegetation and wetting level were not restored because tidal flow was still restricted.		Relevance: Moderate	
Location & Species: New England tidal salt marshes		Ecosystem(s):	salt marsh	
Reference Source:				

**Abstract**: Salt marshes continue to degrade in the United States due to indirect human impacts arising from tidal restrictions. Roads or berms with inadequate provision for tidal flow hinder ecosystem functions and interfere with self-maintenance of habitat, because interactions among vegetation, soil, and hydrology within tidally restricted marshes prevent them from responding to sea level rise. Prediction of the tidal range that is expected after restoration relative to the current geomorphology is crucial for successful restoration of salt marsh habitat. Both insufficient (due to restriction) and excessive (due to subsidence and sea level rise) tidal flooding can lead to loss of salt marshes. We developed and applied the Marsh Response to Hydrological Modifications model as a predictive tool to forecast the success of management scenarios for restoring full tides to previously restricted areas. We present an overview of a computer simulation tool that evaluates potential culvert installations with output of expected tidal ranges, water discharges, and flood potentials. For three New England tidal marshes we show species distributions of plants for tidally restricted and nonrestricted areas. Elevation ranges of species are used for short-term (5 years) predictions of changes to salt marsh habitat after tidal restoration.

FROM STUDY SITE DESCRIPTIONS: The present culvert under Drakes Island Road is 0.9 m in diameter and open. It was originally installed in the 1950s as a 1.2-m diameter flap gate culvert to exclude salt water, but inserts used to repair the pipe reduced the diameter. The flap gate fell off in March 1988, the date we consider as time 0 for this inadvertent and unplanned tidal restoration.

**Results Summary**: Field measurements were done to determine the relationship between water level and volume. This data populated a predictive model which accurately simulated tidal exchange. Low marsh habitat predicted was not present until 5 and 6 years after tide gate removal. At Mill Brook tidal flow is not restricted after restoration. At Drake Island water inflow and outflow were still restricted by an undersized culvert. However, restoring tidal flux is predicted to have a negative impact on salt marsh vegetation because the marsh surface has subsided.

**Broad Outcomes**: The model accurately simulated tidal exchange.  $r^2$ = 0.97 for DI and OK.  $r^2$  = 0.92 for MB (tidal flow not restricted after restoration). DI: present culvert does not allow sufficient tidal inflow or outflow. MB: Vegetated areas were flooded 20% of the time. OK: 8% of upper marsh area covered 25% of tidal cycle.

**Detailed Outcomes**: Model predicted area of elevation in each marsh after restoration. Authors overlayed vegetation data from downstream sites on upstream sites to predict the percent occurance of high and low marsh habitat. The model predicted MB would be mostly low marsh. This was not the case in the first 2 years when high and low marsh was present but in years 5 and 6 low marsh plants dominated. The authors used the model to evaluate several restoration and flood control options to determine if they would provide the desired outcomes for stakeholders. They also used the model to predict the long term outcomes of marsh restoration because marshes may look different in the interim than at the end without moving along a clear trajectory.

**Effects Modifiers**: Flap gate was removed in DI but culverts remained so tidal inflow and upland water outflow was still restricted.

**Intervention**: Drakes Island: diked in 1848, road with water control measures replaced dike in early 1900's. Present culvert installed in 1950's with flap gate. Repair inserts have reduced pipe diameter. Flap gate fell off in 1988. (inadvertent and unplanned restoration)

Mill Brook: bridge replaced with culvert and flap gate in 1960's. 1993 larger arched culvert with no gate was installed. Oak Knoll: present culvert configuration installed circa 1930. No restoration planned at the time of research

Conditions: DI: unplanned	MB: planned	OK: none	Duration:	
---------------------------	-------------	----------	-----------	--

**Study Design**: Each study marsh was paired with an unimpounded marsh downstream as reference. Water depth was calculated using pressure loggers, elevations were measured with transit and rod using standard survey methods. Determined the hypsometric curve - relationship between water level and volume. Surveyed 5-6 transects across channel beginning and ending in upland vegetation. Plotted against h-curve. Field data was used to populate the model directly or estimate values for the model. Measured sediment accretion over 2 years.

**Statistics**: Built a model to predict how successful a project would be in returning a site to full tidal inundation.

**Comments**: This paper focuses on restoring tidal inflow and outflow and the subsequent amount of marsh that would support high and low marsh vegetation and whether that was similar to a nearby reference marsh. I would not put too much emphasis on the model output. The 'future' habitat conditions they predicted were for the same years that data was collected to calibrate the model.

confined to freshwater tributaries of estuaries.				

Abstract: Dispersal is a critical ecological process in which individuals move within and between populations, as well as colonising new habitat. Habitat fragmentation, in combination with habitat loss, detrimentally affects dispersal success with associated impacts on biodiversity. Within New South Wales (NSW) alone, there are over one thousand floodgates which fragment important coastal habitats and have had negative impacts on fish and crustacean assemblages. Importantly, 99% of all these floodgates are considered modifiable to enhance connectivity. When such works occur, however, they are rarely accompanied by rigorous monitoring of fish and crustacean responses. In collaboration with managers and land holders, tidal flushing and connectivity was restored through opening of floodgates at three tidal creeks in the Macleay and Clarence Rivers in northern NSW. Changes in fish and crustacean assemblages were evaluated by regular sampling over a two-year period. Changes in assemblages in managed creeks were compared to those in reference creeks (i.e., without floodgates) and control creeks (with closed floodgates). Following floodgate opening, managed creeks showed an immediate shift in assemblage composition to closely resemble those in reference creeks, which was sustained for the duration of the study in at least two out of the three creeks. This change was driven primarily by an increase in the number of estuarine-marine species (including commercially important fish and prawn species) and was clearly a result of floodgate opening, as similar shifts were not observed in (un-gated) reference and (gated) control creeks in either estuary. Our study demonstrates that restoration of connectivity in tidal creeks through regular and frequent opening of floodgates leads to strong, rapid and sustained recolonisation of habitats. Hence, implementation of management solutions associated with improving connectivity, particularly those that consider differences in the dispersal capabilities of animal, will significantly benefit coastal aquatic biodiversity and fisheries production. Our study

strengthens the case for robust experimental design of restoration studies to ensure that ecological objectives are being achieved and success (or otherwise) is quantified.

**Results Summary**: In Macleay Creek there was a significant shift in fish assemblage making it similar to reference creeks after treatment. The number of species increased, especially estuarine-marine species. In Clarence Creek active tide gate management resulted in more species upstream, again driven by estuarine-marine species. This brought the treatment sites closer to reference conditions. However, one of the Clarence creeks diverged again over time. There were not temporal differences in fish assemblage for reference or control creeks. Tide gate management did not affect salinity or pH.

**Broad Outcomes**: Macleay: MG1 had a significant shift in assemblage, making it similar to reference creeks after treatment. Treatment effect on pH, but not on salinity or DO. Clarence: MG2 and MG3 assemblages shifted after treatment and became closer to the reference creeks.

**Detailed Outcomes**: Macleay: The number of species increased to become similar to the reference creeks - increases were due to more estuarine-marine species being present. However, there were temporal differences noted at MG1 - one post-treatment sample was similar to some pre-treatment samples. Clarence: MG3 became closer to Reference creeks shortly after treatment, but over time diverged again. In MG2 and MG3 treatment resulted in more species upstream, which was driven by estuarine-marine species. Treatment did not affect salinity or pH. Both: there were not temporal (treatment) differences in fish assemblage for reference or control creeks. When open, MG creeks resembled reference creeks most in spring and early summer. The authors noted that to have the largest effect, the tide gate opening should correspond to marine larvae settlement events so coastal floodplain habitats are available.

**Effects Modifiers**: MG1 and MG2 creeks were directly connected to the main river channel. MG3 was at the end of a large lake, was shallower and more removed from potential recruits, upstream habitat was more degraded, and its floodgate type (pipe culvert) differed from MG1 and MG2 (box culverts).

 Intervention: Manage gated creeks by retrofiting with a small flap gate (structural) or intermittent opening with manual winching (operational)

 Conditions:
 Duration: Macleay: 20 months 2007-2008 Clarence: 21 months 2000, 2001, 2002

**Study Design**: Monitor and compare faunal taxa in managed-gated creeks with faunal taxa in referance (ungated) creeks (Macleay and Clarence), and control (gated, unopened) creeks (Clarence). The focus was on fish and crustacean samples.

**Statistics**: Nonparametric permutation analysis of variance was used. They tested for changes in the managed creeks over time relative to reference and control creeks.

**Comments**: The species assemblage in the managed creeks differed after treatment. These changes can be attributed to tide gate management because no differences were noted in the references or controls. This study also points out the important consideration of in-stream habitat degredation and distance of the stream from the river or source of potential resident organisms.

Boys, C.A. 2015. Changes in fish and crustacean assemblages in Hexham Swamp following the staged opening of the Ironbark Creek floodgates. NSW DPI – Fisheries Final Report Series No. 145. 50 pp.

Location & Species: Ironbark Cree Swamp, a wetland system in the H NSW, Australia. Estuarine-marine including commercially important Eastern king prawn, yellowfin bre mullet, and silver biddy.	Hunter River, species, school prawn,	Ecosystem(s):	Rivers/Estuaries	
Reference Source:				

**Abstract**: [Non-technical summary clips] The Hunter River has experienced intensive flood mitigation over the past century, with 175 floodgates and hundreds of kilometers of levee banks and drainage canals being constructed. These developments have reduced the extent and biodiversity of the adjacent coastal wetlands such as Hexham Swamp. This Ramsar-listed wetland, located in the Hunter River estuary, was degraded by the installation of floodgates on Ironbark Creek in the early 1970s. The Hexham Swamp Rehabilitation Project was established to promote the long-term rehabilitation of this important estuarine wetland ecosystem. The project has involved the staged opening of eight floodgates at the downstream end of Ironbark Creek to increase tidal flushing of the swamp and inundate low-lying lands with saline water. This involved three stages: one gate opened (Stage 1), three gates opened (Stage 2), six to eight gates opened (Stage 3).

This report documents the changing assemblage of aquatic fauna (fish and crustaceans) in Hexham Swamp over an 11-year period, between April 2004 and April 2014. It also outlines which of those changes, if any, may be attributed to the staged opening of the Ironbark Creek floodgates. To investigate the changes, seine netting was used to sample fish and crustaceans in tidal creeks above and below the Ironbark Creek floodgates. The catches were compared to nearby natural, un-gated reference creeks and a control creek that remained closed by a floodgate throughout the entire study.

After the floodgates were opened, significant recovery was noted in the upper site, which was more degraded than the lower site. Recovery was observed in both water quality and assemblage composition; by the end of the study, the upper site resembled the un-gated reference creeks. Most importantly, this response was not seen in the control creek where the floodgates remained closed. This provides strong evidence for the recovery being related to the opening of the floodgates. The recovery did not occur until all eight floodgates were opened in Stage 3.

#### **Results Summary:**

**Broad Outcomes**: Overall, 54 fish and 14 decapod species were collected. Two-thirds were mainly estuarine-marine dwellers and one-third moved between freshwater and estuary conditions. Nearly a third were juveniles of commercially important species. The restored creek assemblage changed from similar to the control gated creek to the ungated reference creeks after stage 3 completion. Species richness doubled, many species had significantly greater abundance, and water quality improved, especially in the upper reaches.

**Detailed Outcomes**: Species assemblage shifted from similar to control to similar to reference and below gate sites after stage 3 and persisted for the duration. The control site remained distinct throughout. Eight new species were seen in upper Ironbark, mostly estuarine-marine but also freshwater-estuarine, including several commercially important species. 25 species explained 92% of the post-stage 3 change. Abundance increased for estuarine-marine species but decreased for half of the freshwater-estuarine species. pH and dissolved oxygen improved with each opening stage; salinity did not improve until after stage 3 (10-15 ppt to ~25 ppt). Lower Ironbark remained similar to lower reference reaches. Because there were no differences before gate opening the gates were likely leaky or had been opened in the past. Temperature changes in the managed creek followed estuary-wide patterns. Habitat degradation may also have contributed to faunal assemblage changes. Restricting fish movement limits the export of their productivity. Tide gate opening also resulted in decreased abundance of Mosquitofish (invasive), which can alter food webs and impact nutrient cycling, and whose prey includes eggs and tadpoles of endangered frogs. Two commercially important prawn species received special interested because the Hexham Swamp was considered a historical nursery area.

#### Effects Modifiers:

<b>Intervention</b> : Floodgates at the downstream end of Hexham Swamp were opened in three stages to increase inundation and tidal flushing.		
<b>Conditions</b> : Nursery habitat functions of the estuary were degraded by the presence of the tide gates.	Duration: 11 years	
<b>Study Design</b> : Compared samples taken in Hexham Swamp to samples taken in reference creeks and in control creeks that remained gated. Samples were collected above and below each tide gate and in upper reaches of each restored and control creek and in upper and lower reaches of ungated reference creeks (18 samples - 2x9sites - per time). Fish and crustaceans were seined before (3 yrs), during (3 yrs) and after (2 yrs) staged gate opening. Individuals were identified to species and measured. Surface and bottom pH, dissolved oxygen, and salinity were measured at each site.		
<b>Statistics</b> : Multivariate analyses on fourth-root transformed data. Fish and crustacean assemblage changes visualized with NMDS; PERMANOVA was used to determine if site changes were significant at each stage of gate opening. If main effects showed response, pairwise comparisons were done among stages. For largest response, SIMPER determined relative contribution of species groups (estuarine-marine, freshwater-estuarine, freshwater). Calculated species richness for species groups, total species, and commercially important species and plotted by site and project stage. Water quality measures plotted by site and stage.		

**Comments**: The fact that significant assemblage change did not occur until after all 8 gates were open, is evidence for a threshold response. For restoration projects, ecosystem processes or faunal assemblages may not respond until an appropriate restoration threshold is met (such as inundation or tidal flushing).

Brophy, L. S., S. van de Wetering, M.J. Ewald, L. A. Brown, and C.N. Janousek. 2014. Ni-les'tun Tidal Wetland Restoration Effectiveness Monitoring: Year 2 Post-restoration (2013). Corvallis, Oregon: Institute for Applied Ecology.

Location & Species: Ni-les'tun tidal wetland restoration site, Bandon National Wildlife Refuge, Coquille River Estuary, Oregon. Monitoring focused on tidal hyrdology and plant communities.Ecosystem(s): tidal wetland			
Reference Source: http://appliedeco.org/wp-content/uploads/ Nilestun_Year2_EM_report_FINAL_20140730-3_bkmks.pdf NOTE: OWEB-FUNDED.			

**Abstract**: Purpose, approach, presentation and results are all similar to Brown et al. 2016, which includes these results and results for the 2 subsequent years.

**Results Summary**: Post-restoration tidal exchange was restored and tide height closely resembled mainstem. Channel morphology changed slightly - channels deepened, fine sediment increased, downcutting began in lower reaches. Percent total cover and non-native cover and species richness decreased. Pasture grass had died back and plant community was moving toward reference site. Soil salinity and percent C increased. Mean peak CPUE in the restoration site was lower than reference pre-removal and higher post-removal for Chinook, staghorn sculpin, and was higher in the restoration site pre- and post-removal for stickleback. Restoration significantly affected sculpin, and wood significantly affected Chinook and sculpin.

Broad Outcomes: Mean daily maxiumum water level was higher after restoration. Tidal exchange was restored and tide height closely resembled mainstem. Transect elevations were 1.5 -2.5 m, avg 2.1 m in 2010 with no significant changes in 2013. Channel morphology changed slightly - channels deepened, fine sediment increased, downcutting had begun in lower reaches. Percent cover and percent nonnative cover and species richness decreased. Soil salinity and %C increased at the restored site. Groundwater levels and amplitude of tidal amplification of groundwater level increased at the restoration site. Groundwater levels were higher than at the reference site and tidal influence was similar to the reference site (subsidence evidence). Salinity increased at the restoration site - increases were highest farthest from channel mouths. T (mean and daily maximum) was lower in upper channel reaches after restoration. Soil salinity, shallow groundwater duration, prevalence index, and plant species richness were correlated with percent inundation - soil salinity was higher where brackish flows inundated more frequently, groundwater related to inundation frequency, prevalence index higher in wet frequently inundated areas, species richness lower in harsh (brackish/very wet) conditions. Restoration increased fish access (2% pre, 27% post). Fish access at channel mouth was higher in the restored site. Periods of time at >18C were reduced. Wooded reaches had higher channel morphology complexity. Benthic macroinvertebrate richness increased in the mid and upper sections but decreased

in the lower (Sig). Shannon-Weiner diversity index decreased (Sig), community index decreased (Sig) and abundance increased (NS) in all sections. Data suggest that all restored sub-basins had higher taxa richness than adjacent river sites. There was little difference between restoration and reference sites. S-W index and abundance differences were driven by Corophium, which is a preferred prey of age-O Chinook and staghorn sculpin, the two most abundant fish species. This increased the restoration site fish capacity (and likely increased survival and production in the system). Chinook occupancy post restoration increased in all months in 2 subbasins and increased in some months in the third. Staghorn sculpin occupancy increased after restoration. Stickleback occupancy increased at two of three restoration sub-basins post-restoration and decreased in the third. Mean peak CPUE in the restoration site was lower than reference pre-restoration and higher post-restoration for Chinook, staghorn sculpin, and was higher in the restoration site pre- and post-restoration for stickleback. BACI showed significant effects of restoration on sculpin and significant effects of wood on Chinook and sculpin. Peak migration increased in the 3 restoration subbasins, but not in the reference site.

**Detailed Outcomes**: Tidal maximum increased from 1.29 m (2009) to 2.09 m (2013). Restoration daily MHHW was within 9 cm of river mainstem. Tidal inundation was higher in winter. Channel deepened 12-24 cm in most channels. Fine sediment was 5-23 cm in excavated channels, 38-60 cm in pre-existing. Percent bare ground increased - pasture grass died back and not yet replaced. NMDS suggested that plant community was moving toward reference community composition. Abundance of specific plant species did not show a clear pattern with restoration - not yet equilibrated with new salinity/hydro scape. 2013: restoration site 86.2 ha native dominated, 103.0 ha non-native dominated; reference site - 81.4 ha native, 9.5 ha non-native.

**Effects Modifiers**: Restoration site historically was high marsh so used high marsh transects at reference site but restoration site has undergone subsidence and is currently in the low marsh elevation range. Non-excavated (natural) channels at restoration site were not sampled prior to restoration. Changes in individual channel cross-sections are not testable. Pre-and post: channel width and width:depth could not be compared b/c field methods differed.

**Intervention**: Dikes and tide gates removed. Major ditches filled, minor ditches disked. Tidal channels excavated.

Conditions: Final removal of tide gates and dikes was Aug 2011	Duration: 1 year pre and 1 year
	post restoration (2 years
	subsequent to removal)

**Study Design**: Water level was logged every 15 minutes and was used to calculate tide height maxima and inundation.Surface inundation was logged in groundwater wells. Wetland surface elevations were measured. Channel cross-sections measured (depth, fine sediment, longitudinal flow path profile - wood and no wood placements). Physical/biological metrics measured: plant community composition and extent, soil carbon, salinity, pH, groundwater levels, surface water salinity and T. Estimated amount of habitat available to juvenile salmonids using tidal elevation data. Benthic macroinvertabrates were sampled (abundance by taxon, taxon richness, S-W diversity index, community structure index) at one restoration sub-basin. Determined juvenile fish habitat use by counting fish present during low tide (multiday residents) and determining migration movement into and out of the estuary.

Statistics: BACI (2-way ANOVA) with site and year as independent variables: tested if restoration

affected maximum tide height; with wood presence and channel reach as fixed effects: tested channel depth differences and fine sediment thickness. Plant community variables (cover - total, natives, nonnatives, species richness) and Soil metrics (salinity, organic matter, carbon, pH) were compared seperately with restoration vs reference site and year as categorical variables. Restoration effect on groundwater daily maximum was tested with a 3-way ANOVA with site, year and season as independent categorical variables. Linear regression on inundation vs soil C, soil salinity, shallow groundwater duration, prevalence index (proportion wetland tolerant species), total plant cover, native cover, plant species richness. Benthic macroinvertebrates: general linear mixed model with pairwise comparisons of means. CPUE was analyzed with a hurdle model (binomial and count models incorporated), BACI for month effects with covariates of time (pre/post), month, sub-basin, treatment (reference/restoration). Linear model for effects of year, location, and interaction on fish abundance of age-0 salmon, shiner perch, three-spine stickleback, sculpin.

**Comments**: Data are presented from before and after dike and tide gate removal - tidal inundation, plant community cover and mapping, fish utilization - abundandance and timing. We should use this report for the fish data. The Brown et al. 2016 paper has plant community and hydrology data from an additional sampling year. The authors recommend using simple wood placements meant to develop scour pools for low tide refuges instead of the complex log jams used in stream restorations.

<b>Reference Source</b> : <b>Full text</b> : http://appliedeco.org/wp-content/uploads/ Nilestun_Year4_EM_report_20160221_FINAL.pdf NOTE: OWEB-FUNDED.			

**Abstract**: PURPOSE: This report describes results of effectiveness monitoring of tidal hydrology, plant community composition, and plant community extent (vegetation mapping), at the Ni-les'tun tidal wetland restoration site, Bandon NWR, Coquille River Estuary, Oregon. Parameters monitored are a subset of the full suite of parameters that have been monitored at Ni-les'tun during baseline and post-restoration periods. Monitoring described in this report was conducted during 2015, the 4th year after the site's dikes and tide gates were removed, restoring tidal flows to the site. Effectiveness monitoring was designed to determine whether the project is meeting its goals, and to provide information to help guide other restoration projects. Results and "lessons learned" through monitoring at this landmark project are already helping to advance restoration science at many projects in Oregon, the PNW, and beyond.

APPROACH and PRESENTATION: To determine project effectiveness, we used a BACI approach, comparing 2015 and 2013 data to baseline (pre-restoration) data collected in 2010-2011(or earlier) at Ni-les'tun and the Bandon Marsh Unit reference site. Year 4 post-restoration monitoring of tidal hydrology was conducted from late winter/early spring through summer 2015 (March-September); vegetation was monitored during August 2015. This report provides summaries, representative results, and interpretation of the 2015 monitoring. Additional data are available from the Estuary Technical Group upon request. Throughout this report, we focus on year 4 post-restoration monitoring results, highlighting key comparisons to pre-restoration and year 2 post-restoration conditions. Further details on pre-restoration conditions are contained in the baseline monitoring report (Brophy and van de Wetering 2012), and details on year 2 post-restoration monitoring (which included the full suite of parameters) can be found in Brophy et al. (2014).

SUMMARY OF RESULTS: Post-restoration monitoring in 2015 showed a consistent trajectory towards full recovery of tidal wetland functions at Ni-les'tun. Tidal hydrology was completely restored to the site, with daily maximum tides matching precisely between Ni-les'tun and the adjacent Coquille River. Plant communities remain very dynamic in response to reintroduction of tidal hydrology and salinity, with salt-tolerant early colonizers spreading across the site and pasture grasses continuing to decline. Plant

community changes observed between 2013 and 2015 indicate that plant communities are far from stabilization and can be expected to continue to change substantially for a number of years.

**Results Summary**: Daily maximum water levels were similar inside and outside and inundation and exchange were restored at even the two highest elevation transects in the restoration site by 2015. Surface elevations were higher in the restored and reference marsh in 2015 (post) than in 2011 (pre). Elevation change was similar between marshes. Species richness was lower at the restoration site and did not change at the reference site post-restoration.Percent cover (total, native, non-native) did not differ between sites or among years. However, salt-tolerant plants were increasingly present. Native-dominated communities increased and non-native-dominated communities decreased from 2013 to 2015. The large changes in specific salt-tolerant early colonizers suggest that the plant community is not yet close to a stable state. Additional evidence: spatial distribution seemed based on individual plant tolerances rather than clear zonation.

**Broad Outcomes**: Daily maximum water levels were similar inside and outside the restoration site in 2015 for periods of sampling overlap in all 3 yrs (Mar 1 - Jul 8, Aug 29 - Oct 1). Tidal inundation and exchange was restored at even the two highest elevation transects by 2015. Surface elevations were higher in the restored and reference marsh in 2015 (post) than in 2011 (pre). Elevation change was similar between marshes. Species richness was lower at the restoration site and did not change at the reference site post-restoration. Percent cover (total, native, non-native) did not differ between sites or among years. However, salt-tolerant plants were increasing present. Bare ground increased immediatedly after restoration but decreased slightly and did not differ from pre-restoration by 2015. Plant community is moving toward low salt marsh composition. Native-dominated communities increased and non-native-dominated communites decreased from 2013 to 2015. The large changes in specific salt-tolerant early colonizers suggest that the plant community is not yet close to a stable state. Additional evidence: spatial distribution seemed based on individual plant tolerances rather than clear zonation.

**Detailed Outcomes**: In 2009 water levels were lower inside, in 2013 they were higher than prerestoration but lower than outside, in 2015 they were not significantly different inside and outside the restoration site. Tidal inundation at the two lowest elevation transects increased from negliglibe (3.9% and 0.6%) in 2009 (leaky tide gate) to 28% and 19% in 2015 and the two highest were inundated 0.2% and 0.9% of the time. Elevations at specific transects increased an average of 4.9 cm (restored) and 3.6 cm (reference) post-restoration. Non-native salt-tolerant plants that have colonized are not expected to be obstacles to restoration - they are often out-competed by later colonizing native salt-tolerant plants. NMDS showed that restoration plant community was moving toward low salt marsh found at the reference site. Broad spatial patterns were visible at the 'alliance' level but at the higher-resolution 'association' level there were a large number of associations shifting gradually making mapping difficult at this resolution.

**Effects Modifiers**: Elevation increases could have been caused by measurement or equipment differences, accretion, or a combination (if only accretion it would be more than twice as high as other reference marshes along the coast). Low salt marsh was not sampled in the reference marsh because transects were designed to be similar elevation to the original high marsh at the restoration site prior to diking.

Intervention: Dike and tide gates removed - completed 2011		
Conditions:	Duration: 2010, 2013, 2015	
<b>Study Design</b> : Measured tidal hydrology with a electric water level logy ear in 2010-11, 2012, 2013, and 7 months in 2015. These data were restoration data. Calculated % inundation and daily water level maxi Sampled plant community composition 1 time each in 2010, 2013, and species randomly within 30x150 ft permanent plots (14 restoration, each plant community over the entire restoration site using high rest field truthing. *mapping was not done at the reference site in 2015 k showed no changes since 2013. Elevations along transects were mean	compared to 2009 pre- mum for 2009, 2013, 2015. nd 2015. Measured % cover by 4 reference). Mapped area of plution aerial photography and pecause field reconnaissance	
<b>Statistics</b> : Water level analyses completed in R with daily maximum water level as dependent variable. Elevation change with mean transect elevation modeled with regression in R. Plant community: species richness, total % cover, and native & non-native percent cover were analyzed using BACI (2-way ANOVA) with site (restoration vs reference) and year (2010, 2013, 2014) as categorical independent variables. NMDS summarized plant community composition differences among transects pre- and post-restoration. Linear regression was used for the relationship between elevation and species richness at reference and restoration sites. R was used for all analyses - dependent variable was % cover per transect.		

**Comments**: This paper includes data before and after dike and tide gate removal, specifically tidal inundation, plant species percent cover and community mapping.

23037.pdf

**Abstract**: [CLIPS FROM ABSTRACT]...The purpose of the research reported herein was to evaluate the effect on listed salmon of the restoration effort currently being conducted under the auspices of the federal Columbia Estuary Ecosystem Restoration Program (CEERP). Linking changes in the quality and landscape pattern of tidal wetlands in the lower Columbia River and estuary (LCRE) to salmon recovery is a complex problem because of the characteristics of the ecosystem, the salmon, the restoration actions, and available sampling technologies. Therefore, we designed an evidence-based approach to develop, synthesize, and evaluate information to determine early-stage (~10 years) outcomes of the CEERP...Our evidence-based approach to evaluate the primary hypothesis incorporated seven lines of evidence, most of which are drawn from the LCRE, and included: spatial and temporal synergies, cumulative net ecosystem improvement, estuary-wide meta-analysis, offsite benefits to juvenile salmon, landscape condition evaluation, and evidence-based scoring of global literature...We concluded that all five lines of evidence from the LCRE indicated positive habitat-based and fishbased responses to the restoration performed under the CEERP, although tide-gate replacements on small sloughs were an exception.

**Results Summary**: All three historically reconnected sites are now emergent marshes. Water temperatures were similar to reference sites and were suitable for juvenile salmon for most of the year. Data and observations show no barrier to accessibility. Water depth is a minimum of 50 cm in 95-100% of all slough channels. At the more recent restoration site (with no tide gate present) the habitat and

fish measures are trending toward reference site values. In 2008 at Karlson Island small numbers of Chinook were caught in May, Jun, Sep; chum were also caught in May. No juvenile salmonids were collected at Haven Island in 2009. Each site was sampled once and the amount of available data did not allow for strong conclusions on the benefit of dike breach and tide gate removal for juvenile salmon. However, no evidence was found to contradict the hypothesis.

**Broad Outcomes**: Data and observations show no barrier to accessibility. Minimum depth of 50 cm present 100% (H), 99.7%(FC), and 95.4(K)%. Main wetland channel depth was 2.3 m - 4.2 m (mean 3.4 m). Mean width:depth ratio was 8.6. Water temperature variation patterns were similar to nearby reference sites and are suitable for juvenile salmon for most of the year but exceed 17.5C 7DADM in May or Jun (the WA State criterion for favorable salmon rearing). Salmon presence: FC - not sampled, H - none, K - 83 Chinook and 2 chum, 20 Chinook, 3 Chinook in May, Jun, Sep. Complete habitat metrics results were reported in Diefenderfer 2013 PNNL-22667 %TOC floodplain - averaged 4.86, 4.84-4.88, n=2; channel - averaged 3.25, 1.34-5.16, n=2 \* More complete data is available in Diefenderfer 2013 PNNL-22667.

**Detailed Outcomes**: Accessibility of juvenile salmon to reconnected wetlands is positively related to the degree to which natural hydrologic function is restored. All three historically reconnected sites are now emergent marshes. At more recent restoration site (with no tide gate present) the habitat and fish measures are trending toward reference site values. The amount of data available did not allow for a strong conclusion of benefit for juvenile salmon, but no evidence was found to contradict that hypothesis. Secondary production in restored marshes is exported to nearby areas and can benefit juvenile salmon, albeit likely for only a short time, even when they do not enter the marshes.

# Effects Modifiers: Field sites were not sampled multiple times

**Intervention**: Some data were collected at historically breached dikes that had never been repaired. Haven Island, Fort Clatsop, Karlson Island.

**Conditions**: The breaching occurred without human action (weather, flooding, erosion...?)

Duration: 2007, 2008

**Study Design**: Evaluated fish presence - beach seine? (2replicate hauls at Haven Island Jun and Aug 2009, 3 hauls at Karlson Island May, Jun, and Sept 2008), channel morphology - ground survey or photo , frequency 50 cm depth - depth logger set at 1-hr intervals and channel cross sections survey transects at data logger locations, %total organic C in upper 10cm sediment - I can't find this methodology. Data collection methods followed protocol described in Roegner et al. 2009. No paired reference sites were available, and an evaluation of published reference sites found no suitable comparisons so the authors reported their findings with no reference comparisions.

**Statistics**: Used descriptive statistics. Did not have paired reference sites. Did not sample each site more than once.

**Comments**: The data summarized above are novel. Other syntheses are not summarized because three of the primary sources that this data was drawn from are included in our review and synthesis (J. Johnson et al. 2008, 2009, 2011); the other is a section of an earlier report from this meta-project (Thom et al. 2012). In three sloughs tide-gate replacement did not substantially improve habitat or salmon presence. In all but two instances, data is either not supportive of a benefit to salmon, or is inconclusive.

Diefenderfer, H.L., G.E. Johnson, R.M. Thom, K.E. Buenau, L.A. Weitkamp, C.M. Woodley, A.B. Borde, and R.K. Kropp. 2016. **Evidence-based evaluation of the cumulative effects of ecosystem restoration.** Ecosphere 7(3) :e01242.

Abstract: This study adapts and applies the evidence-based approach for causal inference, a medical standard, to the restoration and sustainable management of large-scale aquatic ecosystems. Despite long-term investments in restoring aquatic ecosystems, it has proven difficult to adequately synthesize and evaluate program outcomes, and no standard method has been adopted. Complex linkages between restorative actions and ecosystem responses at a landscape scale make evaluations problematic and most programs focus on monitoring and analysis. Herein, we demonstrate a new transdisciplinary approach integrating techniques from evidence-based medicine, critical thinking, and cumulative effects assessment. Tiered hypotheses about the effects of landscape-scale restorative actions are identified using an ecosystem conceptual model. The systematic literature review, a health sciences standard since the 1960s, becomes just one of seven lines of evidence assessed collectively, using critical thinking strategies, causal criteria, and cumulative effects categories. As a demonstration, we analyzed data from 166 locations on the Columbia River and estuary representing 12 indicators of habitat and fish response to floodplain restoration actions intended to benefit culturally and economically important, threatened and endangered salmon. Synthesis of the lines of evidence demonstrated that hydrologic reconnection promoted macrodetritis export, prey availability, and juvenile fish access and feeding. Upon evaluation, the evidence was sufficient to infer cross-boundary, indirect, compounding, and delayed cumulative effects, and suggestive of nonlinear, landscape-scale, and spatial density effects. Therefore, on the basis of causal inferences regarding food-web functions, we concluded that the restoration program is having a cumulative beneficial effect on juvenile salmon. The lines of evidence developed are transferable to other ecosystems: modeling of cumulative net ecosystem improvement, physical modeling of ecosystem controlling factors, meta-analysis of restoration action effectiveness, analysis of data on target species, research on critical ecological uncertainties, evidence-based review of the literature, and change analysis on the landscape setting. As with medicine, the science of ecological restoration needs scientific approaches to management decisions, particularly because the consequences affect species extinctions and the availability of ecosystem services. This evidence-based approach will enable restoration in complex coastal, riverine,

and tidal-fluvial ecosystems like the lower Columbia River to be evaluated when data have accumulated without sufficient synthesis.

[Systematic review portion] 2 searches (2012) in Web of Science: 1) salmon AND (dike\* OR dyke\* OR levee\* OR tidegate\* OR tide gate\*); and 2) salmon AND (restoration\* OR creat\*) AND (estuar\* OR river\* OR floodplain\* OR tid\* OR slough). 27 of 709 papers returned by searches appeared to meet three criteria: 1) included original data on juvenile Pacific or Atlantic salmon; 2) pertained to tidal ecosystems including tidal freshwater and estuaries; and 3) concerned an anthropogenic action for restoring aquatic habitat connectivity or an analogous habitat change.

**Results Summary**: The mean above ground biomass values for restored marshes were about threequarters those of the emergent reference marshes. Chironomids were typically the most abundant prey and their densities at restored sites were half those at emergent marshes. Therefore, the reconnection of ~3% of the recoverable area was estimated to have resulted in substantial increases in plant biomass and prey production in the Lower Columbia River Estuary. Significantly more juvenile salmon were actively feeding in the Columbia River Estuary than in the reaches above the 2 lowermost dams. Fish sampled at rkm 15 included individuals from the Willamette R, lower, mid, and upper Columbia R, and Snake R basins; those sampled in shallow-water areas as far downstream as rkm 4 included fish from the Snake R, Deschutes R, and mid and upper Col R basins (all interior stocks - this relates to the question of whether upriver stocks utilize the estuary habitats or simply pass through quickly to reach the ocean). Landscape change: in contributing watersheds - net loss of 189 km<sup>2</sup>, cumulative loss of 642.7 km<sup>2</sup>; on the floodplain - net loss of 13.3 km<sup>2</sup>, cumulative loss of 17.7 km<sup>2</sup>.

**Broad Outcomes**: The mean above ground biomass values for restored marshes were about threequarters those of the emergent marshes. Chironomids were typically the most abundant prey and their densities at restored sites were half those at emergent marshes. Therefore, the reconnection of ~3% of the recoverable area was estimated to have resulted in substantial increases in plant biomass and prey production in the Lower Columbia River Estuary. Hydrodynamic modeling of the Gray's River estimated that half of the particulate organic matter exported from the study site would travel 7-8 km to the mainstem Columbia R. It also indicated that wetted area was affected by dike breach configuration, and that the increase in the amount of wetted area per dike breach decreased after about a quarter of the dikes were breached. Of 24 restored sites, 3 were supportive and 10 suggestive that condition is moving toward reference. 6 sites had inadequate evidence and 6 (all tide-gate replacements) showed no trend. Because of this, tide gate replacement projects have been deprioritized in the Lower Columbia River Estuary.

**Detailed Outcomes**: Significantly more juvenile salmon were actively feeding in the Columbia River Estuary than in the reaches above the 2 lowermost dams. Fish sampled at rkm 15 included individuals from the Willamette R, lower, mid, and upper Columbia R, and Snake R basins; those sampled in shallow-water areas as far downstream as rkm 4 included fish from the Snake R, Deschutes R, mid, and upper Columbia R basins (all interior stocks - this relates to the question of whether upriver stocks utilize the estuary habitats or simply pass through quickly to reach the ocean). Landscape change: in contributing watersheds - net loss of -189 km<sup>2</sup>, cumulative loss of -642.7 km<sup>2</sup>; on the floodplain - net loss of -13.3 km<sup>2</sup>, cumulative loss of -17.7 km<sup>2</sup>. **Effects Modifiers**: When calculating future prey and vegetation biomass production in restored sites the authors assumed that there would be uniform distribution and used the mean densities present in reference sites although prey is known to be patchy. Restoration project areas were estimated in some cases.

Intervention:	
Conditions:	Duration:
<b>Study Design</b> : meta-analysis with 7 restoration/reference paired site reference-restoration design; aggregated PIT-tag and GSI data to doo salmon in shallow-water habitats; sampled for stomach fullness at Jo near the mouth (rkm 15); modeled net ecosystem improvement; evid examined landscape cover change; cumulative effects evaluation usi	cument presence of juvenile ohn Day and Bonneville dams and dence-based literature review;
Statistics:	

**Comments**: There is novel data on 3 sites that were reconnected to the tidal floodplain a decade or several before the study takes place. There is also some limited data on tide gate replacement, however, this seems to be from papers we are including in our analysis. We don't want to include the same studies twice (directly and indirectly). However, we may want to mention that these authors also reviewed them and concluded that they should deprioritize tide gate replacement projects. This paper is essentially the same as the Diefenderfer 2013 project annual report. I would lean toward using this one because it is more recent so analysis should be most complete and it has undergone peer review, however the original data is presented in more detail in the annual report.

Abstract: Dramatic declines in salmon populations in the Pacific Northwest have brought new attention to the importance of estuarine rearing habitats. Levees and tide gates used to convert estuarine wetlands into farmland have reduced available habitat by more than half of historical levels. Recent efforts to restore estuarine habitats include tide gate replacement, though this method has been poorly studied. As a key indicator of salmon habitat suitability, temperature was used to evaluate the effects of tide gate replacement in a tidally influenced freshwater slough in the Lower Columbia River estuary. Three tide gates in the largest slough on Tenasillahe Island were replaced in 2007 with side-hinged aluminum gates. As managed during the data collection periods, the new tide gates did not allow tidal inflow into the slough. The study employed a Before-After, Control-Impact (BACI) approach, collecting data seasonally two years before and after replacement at the impact site and at the control site, a relatively unaltered slough on nearby Welch Island. Randomized Intervention Analysis and Monte Carlo tests revealed no significant difference in slough water temperatures after tide gate replacement, although minimum temperatures dropped up and downstream of the tide gates. Although the new tide gates did not have a significant effect on water temperature, the lower minimum temperatures may have been caused by a slight increase in tidal circulation. This result suggests that slough temperatures would decrease if the tide gates were managed to increase tidal inflow, and thus improve the quality of salmon rearing habitat.

**Results Summary**: Tide gate replacement had no significant effect on the mean water temperature or on the difference between the control sites and the section upstream of the tide gate. Mean temperature and minimum tempurature decreased at all sites after replacement. The number of days in which water temperature exceeded EPA limits decreased in all sections after replacement. This may have been due to La Nina conditions present in 2008. The main change caused by replacement was an 'increase in frequency, duration and width of tide gate openings during ebb tides'. More Chinook salmon juveniles were detected (PIT tag array) moving upstream of tide gates after replacement.

**Broad Outcomes**: Tide gate replacement had no significant effect on the mean water T. No change in the T difference between the control and the section upstream of the tide gate was caused by tide gate

replacement. However, the change in difference between the downstream T and the control T was significant. Main change caused by replacement was 'increase in frequency, duration and width of tide gate openings during ebb tides'. More Chinook salmon juveniles were detected (PIT tag array) moving upstream of tide gates after replacement. The new gates may have increased drainage, including warm surface waters - the old gates mostly drained cooler water at depth because they were top-hinged.

**Detailed Outcomes**: Mean and minimum T decreased at all sites after replacement. T upstream of tide gates were higher than in other sites, downstream T were lower, and control T lowest (natural variation). T at all sites followed a similar pattern over time. T in 2008 differed from all other years, no other pairs were significantly different. Water T variation at a specific site was most explained by waterT of nearby water bodies and by air T. Discharge and precipitation had very low correlation with other variables. Salmonid habitat via T: Daily range did not increase with replacement. In general, T increased as depth decreased. The number of days in which water temp exceeded EPA limits decreased in all sections after replacement.

**Effects Modifiers**: In 2008 there was a La Nina during data collection which affected all sites equally. The analysis used the difference between sites. Therefore, the La Nina did not bias the results because all sites were influenced evenly. Upstream site is affected by cattle grazing, which has a net warming affect. Downstream site is influenced by Clifton Channel and outflow. LWS influenced by Clifton Channel and Columbia River, and is unimpeded. Only one control site was available, so natural range of variability was not known - high variability among sites and years may have obscured any effect of replacement on temp.

Intervention: August 2007 Tenasillahe Island - 3 top-hinge cast-iron tide gates replaced with sidehinged aluminum tide gates with a manually operated fish orifice (this could allow upstream inflow and fish passage, but they were closed during data collection) Seperately, in 2007 2 culverts (one on each branch of the slough ~3km upstream of the fork) were replaced with bridges

**Conditions**: marsh habitat nonexistent, water table lowered, grazing/upland habitat present

Duration: 4 years

**Study Design**: water T and depth, daily discharge, daily precipitation data measured seasonally for 2 years before and 2 years after tide-gate replacement at the impact site and a nearby similarly sized slough that had minimal impacts. Calculated daily T range, relationship between T and depth, number of days T exceed EPA standards

**Statistics**: BACI study design. Monte Carlo and Randomized Intervention Analysis (RIA) were used to determine if tide gate replacement affects water T. Also used Spearman Rank Correlation to get correlation values for water T up- and downstream, in CVS, in Clifton channel, air T, precipitation, Columbia R discharge. Also used for hourly T and depth at all sites.

**Comments**: This thesis focused entirely on water quality and connectivity. The Johnson et al. 2008 report was more comprehensive and included data on gate opening, fish presence and movement, and chemical and physical habitat metrics. It seems that the data presented by Ennis is not represented in the Johnson et al. report, She reports on differences before and after replacement while Johnson et al. 2008 report on differences between restored and reference conditions.

Abstract: Tide and flood gates are used widely throughout the world to facilitate drainage of lowland areas and provide flood protection to valuable agricultural land and human infrastructure. However, these structures can impact on aquatic communities by disrupting connectivity and altering physical habitat conditions. Complete removal is rarely feasible in the short-term because of the competing flood mitigation and land use interests. However, in many cases it is likely that the structure and/or its operation can be modified to enhance connectivity for migratory species and reduce the severity of impacts on instream habitats. This study describes the results of a short-term trial investigating the effects of modified tide gate management on instream habitat and fish communities in a small tidal stream in the North Island of New Zealand. The study site was located upstream of the saline limit and thus does not directly address this potential limitation on managing the effects of some tide gates. The main objective of the study was to understand whether improvements in tidal flushing could mitigate the negative effects of tide gates on upstream habitats, thus improving their suitability for native fish communities. The trial demonstrated that in impacted lowland river reaches, the reintroduction of limited tidal exchange upstream of tide gates reduced negative impacts on instream habitat by restoring hydrological variability, increasing minimum dissolved oxygen concentrations and potentially also reducing water temperatures. However, it was also shown that the recovery may not be uniform and can be dependent on interactions with other stressors. The trial illustrated the potential for using modified tide gate management to mitigate the environmental effects associated with their operation, and to restore habitat conditions so that they are more favourable for the persistence of native fish species.

**Results Summary**: Opening one tide gate reintroduced tidal inundation in the lower reaches and improved instream habitat characteristics. Mean daily temperature and mean daily maximum temperature decreased at all sites after gate opening. Macrophyte cover decreased in upstream areas closest to the tide gates. Dissolved oxygen was stable at sites below the tide gates and above tidal reach. At the two upstream sites nearest the tide gates dissolved oxygen increased after gate opening. However, dissolved oxygen at the next two sites upstream decreased. Above the tide gates all but one native species were diadromous. All native species were found in the lower reaches of the stream. Even so, they comprised just over half of the species collected. Total species richness averaged 7.6 whereas species richness of native species averaged 4.1.

**Broad Outcomes**: Instream habitat characteristics were improved with gate opening management action. T and dissolved oxygen improved. Macrophyte cover decreased in upstream areas closest to the tide gates. Responses were not uniform throughout the study area. Diamdromous species were found in sites upstream of the tide gate - however the upstream migration opportunity is likely limited.

**Detailed Outcomes**: Water Quality Pre action daily water level only varied with tidal activity at K1. Water level increased at K2-K5 after gate opened and tidal inundation was reintroduced. Water stayed within the banks of the channel with limited riparian inundation. Prior to gate opening dissolved oxygen above the tide gates was lower than the threshhold for faunal protection. No difference in dissolved oxygen at K1 (below gate), K6, K7 (above tidal influence). Dissolved oxygen increased (sig) at K2 and K3 and decreased (sig) at K4 and K5. Water T was above preferred T for most native species and approached lethal levels for some. Mean daily T decreased at all sites post gate opening (sig at K1, K2, K3). Mean daily max T reduced at all sites (sig at K1, K2, K4, K5). Fish Community 14 species collected, 8 natives. At K1-K7 species richness averaged 7.6. Native species richness averaged 4.1. K7 had the most native species. K6 was the only lower-reach site with no non-natives. No non-natives were found at K8-K11. All native species above the tide gates were diadromous except Cran's bully (only at K11). Inanga used as an indicator species. Juveniles at K1 peaked in Dec - upstream migration timing. Adults found in Feb and Mar at K1, K6, K7 and in Mar only at K5.

**Effects Modifiers**: Dissolved oxygen levels dropping could be caused by high nutrient sediment in K4 and K5 being resuspended by increased tidal inundation. It is difficult to determine if species are not using habitat because it is degraded or because the tidegates represent a physical barrier.

**Intervention**: triple 1.5 m diameter twin-pipe double-hinge, top-hung wooden tide gates (6 gates). Modification: manually open one tide gate.

Conditions: A summer storm forced closure of the gate for one	Duration: 6 months
week midway through the trial for storm protection.	

**Study Design**: BACI design. Stream conditions and fish communities were monitored at 7 sites: 1 below tidegate, 2-5 above and within expected tidal influence, 6-7 above tidegates and expected tidal influence. Sites 8-11 were only sampled for use by adults of diadromous species. Logged water level, T, dissolved oxygen. Collected fish via trap, fyke net, electrofishing. All fish were ID'd, counted, measured.

**Statistics**: Analyses were limited to the 10-d period before tide gate opening and the 10-d immediately following commencement of the trial (to avoid impact of flood(flushing) and season). Shapiro-Wilk tests determined normality of pre and post T and dissolved oxygen. Dissolved oxygen was analyzed with Kruskal-Wallis rank sum test, T analyzed with ANOVA. CPUE calculated as total catch/set by site.

**Comments**: This study found that active management of a tide gate can have a positive impact on water temperature, dissolved oxygen, and fish community composition. The gate was manually held open, not retrofit with a mechanism.

**Abstract**: We assessed restoration of a 21 ha diked pasture in the Salmon River estuary to a naturally functioning estuarine salt marsh in 1988, eleven years after partial dike removal in 1978. Diane Mitchell (1981) collected base line data, established an intensive sampling system of permanent plots in the diked pasture and flanking 'intact' control marshes, and analyzed restoration progress from 1978 to 1980. Our report continues Mitchell's earlier research by evaluating the composition, structure, function, and long term prospects for the restored wetland.

**Results Summary**: Immediately after restoration upland species died back in both the 1978 and 1987 marshes. In the 1978 marsh resultant bare ground was colonized quickly by mainly annual species whose presence was ephemeral and were replaced by later arriving permanent colonizers. Restoration and control sites displayed vegetative zoning. The restoration area elevations had increased 2-7 cm between 1979 and 1988. One of the control sites also increased in elevation 6-10 cm. Elevation increased more in areas of lower elevation and in areas with greater inundation. Mean biomass decreased after restoration as upland species died back but had increased to more than double the control sites by 1988. Communities showing a stronger increase were dominated by colonizing rather than residual species. Creeks with high connectivity and tidal exchange narrowed and deepened. Creeks with low connectivity and limited tidal exchange had slight downcutting or sedimentation.

**Broad Outcomes**: Immediately after restoration upland species died back in both the 1978 and 1987 marshes. In the 1978 marsh resultant bare ground was colonized quickly by mainly annual species whose presence was ephemeral and were replaced by later arriving permanent colonizers. Subsidence during the diked period that 11 years after breaching the restoration site elevation was 34.9 cm below that of the control sites. Elevation increased more in areas of lower elevation and in areas with greater inundation. The marsh productivity was similar to the control marshes before restoration. Immediately after breaching productivity decreased but then increased substantially and was >2x that of the controls. The authors argue that the goal of restoring areas to a 'pristine', unaltered condition are unrealistic. Some reasons provided include the inabilativ to alter some upland and hydrologic changes, the difficulty in knowing what pre-alteration conditions were, and not having unaltered controls for comparison.

**Detailed Outcomes**: Upland species have not returned. The two major residual species decreased from ~40% to ~8% cover. Soon after restoration some colonizers established in bare ground but by 1988 these were gone (ephemeral) and other colonizers had established themselves (permanent). The

proportion of bare ground, which increased after restoration and was present in 1984, was gone by 1988. The current study described 8 plant communities in the restored and control areas. Five of these communities are present in both restoration and control sites although at differing levels. One intertidal community is only present in the restoration site and both extratidal communities are only present in the control areas. Restoration and control sites displayed vegetative zoning. The restoration area elevations had increased 2-7 cm between 1979 and 1988. One of the control sites also increased in elevation 6-10 cm. Accretion was negatively correlated with elevation in the restoration site. Most plant communities had significantly different mean elevations and the two that were similar had different substrates. Plant species on the leveled dikes in 1980 were still present in 1988 but high salt marsh communties had formed at the most elevated and least inundated sites. Creeks with high connectivity and tidal exchange narrowed and deepened. Creeks with low connectivity and limited tidal exchange had slight downcutting or sedimentation. Immediately after restoration salinity increased from 0 to 18-33 ppt. In 1988 salinity was 22-44 ppt and averaged 31.5 ppt. The amount of organic material increased with elevation and salinity increased with percent sand. Mean biomass decreased after restoration as upland species died back but had increased to more than double the control sites by 1988. Communities showing a stronger increase were dominated by colonizing rather than residual species.

## **Effects Modifiers**:

**Intervention**: In 1978 the dike was partially removed, a tide gate was removed, and tidal creeks were reconnected at the dike breach and through the dike, where necessary. In 1987 dikes were removed from a 63 ha marsh on the opposite river bank.

Conditions:	Duration: 1 year
<b>Study Design</b> : Plots from Mitchell 1989 were sampled and new plots each plot they measured percent cover of vascular plants, above-gro texture and organic content, accretion since 1978, and elevation. So cores.	ound biomass, soil salinity, soil
Statistics:	

**Comments**: This paper summarizes Mitchell's 1981 results and includes an additional 3 years of data collected by Mitchell (1981, 1982, 1984) and one year of data these authors collected (1988). It describes changes in a restored marsh over a decade relative to more undisturbed sites. However, the authors do point out that the 'control' sites are dynamic as well.

Goertler, P. 2014. Juvenile Chinook salmon (*Oncorhynchus tshawytscha*) life history diversity and growth variability in a large freshwater tidal estuary. M.S. Thesis, School of Aquatic and Fishery Sciences, University of Washington, Seattle, WA. 97 pp.

Reference Source:			

Abstract: [Clips from ABSTRACT]...thesis focuses on juvenile Chinook salmon and their use of estuarine wetlands as nursery habitat. ..used otolith microstructural growth estimates and prey consumption to measure rearing habitat quality...sampling was designed to target as much genetic diversity as possible...individual assignment to regional stocks of origin was used to describe diversity of juvenile Chinook salmon groups inhabiting the estuary. ...addresses how juvenile salmon growth changes among a range of wetland habitats in the freshwater tidal portion of the Columbia River estuary and how growth variation describes and contributes to life history diversity. ...incorporated otolith microstructure, individual assignment to regional stock of origin, GIS habitat mapping and diet composition, in three habitats (mainstem river, tributary confluence and backwater channel) along ~130 km of the upper estuary. Employed a generalized linear model to test three hypotheses: juvenile Chinook growth was best explained by 1) temporal factors, 2) habitat use, or 3) demographic characteristics, such as stock of origin or the timing of seaward migration...variation in growth was best explained by habitat type and an interaction between fork length and month of capture. Juvenile Chinook salmon grew faster in backwater channel habitat and later in the summer. ...mid-summer and late summer/fall subyearlings had the highest estuarine growth rates. ...survival studies from the system elucidated a possible tradeoff between growth and survival in the Columbia River basin...findings [illustrate] the complexity in understanding the influences of the many processes that generate variation in growth rate for juvenile anadromous fish inhabiting estuaries. ... used otolith microstructure and growth trends produced in a dynamic factor analysis (DFA, a multivariate time series method only recently being used in fisheries) to identify the life history variation in juvenile Chinook salmon caught in the Columbia River estuary over a two-year period (2010-2012). DFA estimated four to five growth trends were present in juvenile Chinook salmon caught in the Columbia River estuary.

**Results Summary**: Juvenile Chinook growth rate increased with month and was higher in backwater than mainstem habitat. Mid-size juveniles caught in mid to late summer had the fastest growth rates. The volumetric percentage of planktonic prey decreased with month while emergent prey increased.

Emergent prey were especially important in backwater habitats. Juvenile salmon were present year round with a consistent stock composition pattern. All month/year capture groups were characterized by 4 or 5 growth pattern trends. These trends were not grouped by stock in any capture period. However, in May of both years hatchery fish grouped tightly. Therefore, hatchery fish may not experience the same breadth of growth rate patterns as wild fish.

**Broad Outcomes**: Ch 1. 1 86 prey items found in stomach contents. The model that best explained growth included habitat, length, month, year, and length x month – but habitat has less support. Growth rate increased with month and was higher is backwater habitat. Mid-size juveniles caught in mid to late summer had the fastest growth rates. Planktonic prey volume decreased with month while emergent prey increased. Fish from backwater habitat had more emergent prey by number, weight, Index of relative importance. Chinook did not get terrestrial flux from flood events. Ch 2. Juveniles were present year round with consistent pattern in stock composition. Upper Columbia Spring, Snake Spring and Fall, Deschutes stocks much less frequently caught. 40% of all fish had a 'growth check' that may show habitat transition. The check was most often at ~1 month age but a 50-100 d check was also common. DFA: All month/year groups were best explained with 4 or 5 growth pattern trends. In 2010 and 2011 May growth fit 4 trends and Jul and Sep fit 5 trends – fish did not group by stock in any capture period. Hatchery fish grouped tightly in May of both years - hatchery fish may not experience the same breadth of growth rates as wild fish.

**Detailed Outcomes**: Ch 1 The interaction between length and month for growth rate is interpreted as an idicator of life-history type/strategy being present in the Columbia R estuary.

**Effects Modifiers**: DFA models took a long time to converge - may not be appropriate for otolith growth because of large sample size. The author was not able to catalog and quantify life-history diversity.

Intervention: None

**Comments**: The growth data for the Columbia River estuary is very interesting. Also of noteis that the different life-history strategies identified by DFA did not cluster by genetic stock. I don't know if this is because fish in each stock are employing multiple strategies, if more than one stock is employing each strategy, or both. I would suspect that although we tend to generalize about the life-history strategies of different stocks that there is a great deal of overlap.

Gordon, J., M. Arbeider, D. Scott, S. Wilson, and J. Moore. 2015. When the Tides Don't Turn: Floodgates and Hypoxic Zones in the Lower Fraser River, British Columbia, Canada. Estuaries and Coasts 38: 2337 - 2344.

Abstract: Floodgates are common flood control structures in coastal river systems, which allow tributary drainage into river main stems and decrease flooding risk of land upstream of diking systems. Floodgates have been shown to impact upstream aquatic habitats and alter organismal community structures in some systems by impounding water and acting as a physical barrier to migratory species; their impacts on water quality have been less well described. This study investigated water quality in tidal creeks with and without floodgates on the lower Fraser River, British Columbia, Canada. There are an estimated 500 floodgates in this region. Water quality measurements were taken upstream and downstream at three floodgate sites and three reference sites across a 10-day period in July/August. The average dissolved oxygen (DO) concentration upstream of floodgates was 2.47 mg/L and fell as low as 0.08 mg/L, which was significantly lower than the comparable region of reference sites (8.41 mg/L) during this sampling period. In contrast, the average DO concentration downstream of floodgates was 7.38 mg/L and in reference sites 8.35 mg/L. All DO concentration measurements upstream of floodgates in July and August fell below the 6-mg/L minimum set by the Canadian Council of Ministers of the Environment. These hypoxic zones extended at least 100 m upstream of floodgates. Thus, floodgates may be facilitating the occurrence of local hypoxic zones in summer months in these locations. Floodgate-induced hypoxia may not only cause local exclusion of sensitive native fishes but may also act as a chemical barrier that decreases connectivity among aquatic systems. Understanding these environmental impacts associated with floodgates can inform floodgate design and post-installation management, which is an increasingly important issue as coastal municipalities across the world deal with aging floodgate infrastructure and sea level rise.

**Results Summary**: Dissolved oxygen was lower in gated streams than reference streams and dissolved oxygen concentrations were lower above tide gates than below. Upstream dissolved oxygen was always below the 6 mg/L water quality threshhold. The model that best predicted dissolved oxygen included temperature, depth, and an interaction between stream type and distance from the tidegate. Water temperature did not differ between site types. Reference sites had lower salinity and conductivity and higher pH.

**Broad Outcomes**: Dissolved oxygen concentrations were lower above tidegates than below and were lower above tidegates than in reference streams. Upstream dissolved oxygen was always below the

6mg/L minimum quality threshhold. Dissolved oxygen downstream of tidegates was slightly lower than reference streams. Agriculture and other human use covered the majority of the areas sampled of both types.

**Detailed Outcomes**: The best predictive model included water T, depth, the interaction between stream type and distance from tidegate. Those variables plus distance from tidegate were highly significant. Dissolved oxygen comparisons between site type at each distance relative to tidegate showed that dissolved oxygen was lower in gated streams at all relative distances except 100 m below the gate. There were no trends in water T between locations or site types. Salinity and conductivity were lower in reference sites and downstream reaches than upstream of gates. pH was lower at gated streams.

**Effects Modifiers**: Only sampled during summer. Tide gates likely did not open for the duration because the Fraser River freshet held the gates closed.

Intervention: None				
Conditions:	Duration: < 1 month			
<b>Study Design</b> : Dissolved oxygen, T, conductivity, salinity, pH measured dusk and dawn 5, 10, 25, 50, and 100 m up and downstream of tide gates or reference points. Hourly weather and precipitation data were collected from weather stations. Determined area and land uses for watersheds.				
<b>Statistics</b> : Linear mixed effects model examined relationship between dissolved oxygen and site type. Co-variables: conductivity, salinity, pH, air T were related to water T. Water T, depth, sample time, site type and either distance from gate or reference point or upstream/downstream location included as fixed effects and creek as random effect in model testing. Also included an interaction term between site type and either distance or location relative to gate. Used AlCc to determine most parsimonious model. Tukey's planned contrasts examined interaction effect.				

**Comments**: This paper provides an example of an issue not often focused on - basically non-functional tide gates. It focused on water quality differences between sites with and without tide gates. However, the authors point out that the gates might not open during the entire study period because the spring freshet is high enough to keep them closed. Therefore there is no drainage or interchange.

Abstract: For an estuarine restoration project to be successful it must reverse anthropogenic effects and restore lost ecosystem functions. Restoration projects that aim to rehabilitate endangered species populations make project success even more important, because if mis-judged damage to already weakened populations may result. Determining project success depends on our ability to assess the functional state or 'performance' and the trajectory of ecosystem development. Mature system structure is often the desired 'end point' of restoration and is assumed to provide maximum benefit for target species; however, few studies have measured linkages between structure and function and possible benefits available from early recovery stages. The Salmon River Estuary, Oregon, U.S.A., offers a unique opportunity to simultaneously evaluate several estuariene restoration projects and the response of the marsh community while making comparisions with a concurring undiked portion of the estuary. Dikes installed in three locations in the estuary during the early 1960s were removed in 1978, 1987, and 1996, creating a 'space-for-time substitution' chronosequence. Analysis of the marsh community responses enables us to use the development state of the three recovering marshes to determine a trajectory of estuarine recovery over 23 years and to make comparisons with a reference marsh. We assessed the rate and pattern of juvenile salmon habitat development in terms of fish density, available prey resources, and diet composition of wild juvenile Oncorhunchus tshawytscha (Chinook salmon). Results from the outmigration of 1998 and 1999 show differences in fish densities, prey resources, and diet composition among the four sites. Peaks in Chinook salmon densities were greatest in the reference site in 1998 and in the youngest (1996) site in 1999. The 1996 marsh had higher densities of chironomids (insects; average 864/m<sup>2</sup> and lower densities of amphipods (crustaceans; average 8/m<sup>3</sup>) when compared with the other sites. Fauna differences were reflected in the diets of juvenile Chinook with those occupying the 1978 and 1996 marshes based on insects (especially chironomids), whereas those from the 1987 and reference marshes were based on crustaceans (especially amphipods). Tracking the development of recovering emergent marsh ecosystems in the Salmon River estuary reveals significant fish and invertebrate response in the first 2 to 3 years after marsh restoration. This pulse of productivity in newly restored systems in part of the trajectory of development and indicates some level of early functionality and the efficacy of restring estuarine marshes for juvenile salmon habitat. However, to truly know the benefits consumers experience in recovering systems requires further analysis that we will present in forthcoming publications.

**Results Summary**: Important insect prey species density was negatively correlated with recovery age but important benthic invertebrate density was positively correlated with recovery age. If fish diet composition is generally similar to prey community composition then fish growth will differ among sites with prey energetic content. In this study, metrics for capacity, opportunity, and fish performance differed between recovery sites and the reference site even after two decades. Foraging opportunities may still exist for juvenile salmonids during early restoration but the benefits may be modulated by lower quality habitat.

**Broad Outcomes**: Pacific staghorn sculpin and three-spine stickleback were the most abundant fish species and the sculpin densities were an order of magnitude higher than juvenile Chinook densities. Juvenile Chinook salmon were most abundant in the REF marsh and second most abundant in the 1996 marsh. There were no differences among sites in total density of invertebrates collected in fall traps but there were important differences in community composition. Chironomids and certopogonids, which are important Chinook prey items, were negatively correlated with marsh recovery age. This may point to differences in marsh function as relating to foraging and prey availability. Benthic macroinvertebrates were most dense in the REF marsh with no differences among the recovery marshes. Community composition differed among marshes. Corophium and Eogammarus species (amphipods) were rare in the 1996 marsh and amphipod density was positively correlated with marsh recovery age. Differences among sites in the biotic structure may lead to differences in fish growth if fish diet reflects available prey and there are differences in the energetic content of prey.

Detailed Outcomes: In 1998 and 1999 Pacific staghorn sculpin was the most abundant species in the REF, 1978, and 1987 marshes. Three-spine stickleback were most abundant in the 1996 marsh. Chinook salmon were similarly abundant in the REF, 1987, and 1996 marshes, and less abundant in the 1978 marsh. Peak density and timing differed between years. No pattern was found for overall density of insects among marshes in 1998, however in 1999 the 1987 hi marsh had lower abundances. Chironomidae and Ceratopogonidae dipteran families were most abundant and were assessed futher. In both years chironomidae were most abundant in the 1996 marsh. In 1998 there were no differences in density of ceratopogonids among marshes but in 1999 their density was significantly greater in the 1996 marsh. Chironomids were negatively correlated with marsh age in both years and ceratopogonids were in 1999. Ceratopogonids were not correlated with recovery age in 1998 and total insect density was not correlated with recovery age in either year. For benthic invertebrates a positive relationship between density and recovery age was only found for one species in one year. When two amphipod species from both years were considered together there a slight positive trend was indicated. Juvenile Chinook diets were most similar between the REF and 1987 marshes (they consisted mostly of crustaceans). Diets from the 1978 and 1996 marshes were mainly insects. Chinook were preying selectively on trichoptera, corophium spp, chironomid larvae, and dipterans. The average percent similarity between diet and available prey was 38%.

**Effects Modifiers**: Long term monitoring has not been completed. Changes in marsh habitat, prey production, or foraging have not been documented. Bioenergetic sampling was not done - similarity in diets between sites does not necessarily translate to similar energetic benefits.

Intervention: Dikes and associated tide gates removed from three marshes in 1978, 1987, and 1996.		
Conditions:	Duration: 2 6-mo sampling	

seasons

**Study Design**: The 3 restoration sites and a reference site were sampled Mar-Jul. Fish were collected twice monthly by fyke net with pole seine. Fork length and wet weight were collected for all salmonids. A subsample of juvenile Chinook were kept for stomach analysis. Fullness and digestion stage were rated. Prey was sorted and each category was counted and weighed (frequency of occurance and gravimetric composition). Marsh insects and benthic invertebrates were sampled monthly. Insects were collected in fallout traps and benthic invertebrates in sediment cores with five replicates taken at each sample site. Individuals were identified and counted.

**Statistics**: Fish abundance was standardized to the estimated surface area sampled and reported as average density per m<sup>2</sup>. Insect and benthic invertebrate abundances were standardized to sample area or core volume and reported as inverts per m<sup>2</sup> or m<sup>3</sup>. Kruskal-Wallis comparison of means was used to test intergroup differences at each site. Linear regression was used to test relationship between density of groups to recovery time in restored sites. Index of relative importance was calculated for prey types, percent similarity index determined diet similarity among areas and overlap between diet and available prey. Standardized forage ratios were used to determine selectivity of certain prey. Stomach fullness was used as a measure of relative consumption rate among marshes.

**Comments**: This paper is interesting becasue the marshes were restored over two decades, which allows some investigation of restoration over time. Even though it is three different marshes, their close proximity makes comparisons possible. The two sites with freshwater input had higher densities of insects and insects were more important in the Chinook diets. Perhaps it is not just the recovery age, but also the connection to upland habitats that is important for the prey types available to juvenile salmonids. This study does not determine if insects or benthic invertebrates are more beneficial energetically to juvenile salmonids.

Greene, C., J. Hall, E. Beamer, R. Henerson, and B. Brown. 2012. <b>Biological and Physical Effects of</b> <b>"Fish-Friendly" Tide Gates.</b> Final Report for the Washington State Recreation and Conservation Office, January 2012.

**Abstract**: [From SUMMARY] Findings indicate that self-regulating tide gates (SRTs) vary substantially based on design and operation and consequently vary in performance, depending upon the metric of interest. For estuarine-dependent species in general and juvenile Chinook salmon in particular, SRTs support habitat use above gates much less than natural channels and a little better than traditional flap gates. For other anadromous salmon species that may spawn in creeks above tide gates, SRTs do not appear to strongly inhibit passage or juvenile rearing density. These findings suggest that estuary restoration with SRTs will have limited benefits for juvenile Chinook salmon and other estuarine-dependent species, but can result in some improvement in connectivity and rearing habitat quality compared to traditional flap gate designs. SRT designs and operation standards that maximize connectivity, and site selection criteria that focus on reconnection of large amounts of habitat may overcome some of the limitations of reduced habitat use associated with SRT installation. These potential reductions can successfully be evaluated by comparing the benefits of SRT installation with those of other estuary restoration techniques (e.g., dike breaching or setback).

**Results Summary**: Time open at side-hinged self-regulating tide gates (SRT's) was half that of reference sites and top-hinge flap gates were more restrictive. SRT's had twice the connectedness of flap gates and half that of reference sites. Water elevations at flap gate systems were 2-6 times lower than reference sites, and 1/3 to 5 times lower than at SRT's. Chinook salmon densities were more than 4 times greater at reference sites than at SRTs or flap gates (which were similar). Stickleback densities were higher at flap gates than reference sites; densities at SRT's were similar to flap gates. Cumulative densities at all tide gates were at least 8 times lower than at reference sites.

**Broad Outcomes**: Time open at SRT's was half of reference sites; flap gates were more restrictive. SRT's had twice the connectedness of flap gates and half that of reference sites. Connectedness, leakiness, and mean surface elevation, varied with site type. Elevation was lower above tide gates. Salinity and T varied with site type but also with visit (time) and system. Water elevations at flap gate systems were 2-6 times lower than reference sites, and 1/3 to 5 times lower than at SRT's. SRT water levels were 50% of reference levels. Chinook salmon densities were >4x greater at reference sites than at SRTs or flap gates (which were similar). Chinook also differed by system and time, and their interaction. Stickleback densities were higher at flap gates than reference sites; SRT densities similar to flap gates. Species

groups did not show systematic variation among site types, except estuarine-dependent species. Densities were an order of magnitude greater at reference sites than SRT's or flap gates. At Fornsby after installation of SRT, door opening % and % time upstream movement possible increased.Tidal muting decreased after SRT installation. Cumulative densities at all tide gates were at least 8 times lower than reference sites. Post SRT installation cumulative densities increased at Fornsby but decreased at Fisher. At McElroy cumulative densities were low (no pre SRT data).

# **Detailed Outcomes:**

# **Effects Modifiers**:

**Intervention**: Fisher: 3 door side-hinged self-regulating tide gates (SRTs) with 2 small submerged flap gates replaced passive side-hinged system with manual opening during spring McElroy: post-treatment monitoring of a side-hinged SRT and 3 flap gates replacing 3 flap gates Fornsby: side-hinged SRT replaced a flap gate, channel modification, revegetation

Conditions:	Duration: 3 2-week data
	collection periods
<b>Study Design</b> : 1) investigate physical and ecological characteristics of reference sites (spatially extensive) 2) describe Chinack density the	

reference sites. (spatially extensive) 2) describe Chinook density thru rearing season at 3 SRT's in multiple years surrounding tide-gate change compared to open channel reference sites. (temporally extensive). Measured salinity, water level, water T up- and downstream, tide-gate tilt, water velocity with data loggers. Collected biological samples with beach seine, fyke nets, neuston traps. All fish were counted and up to 25% were measured. Densities were calculated from counts and net areas. Invertebrates >500 µm categorized as estuarine/marine or freshwater.

**Statistics**: Tilt data classified gate open/closed, and with elevation determined connectedness. Calculated leakiness index. Calculated density of each species. Focused on Chinook, 3-spine stickleback, all anadromous fish, estuarine-dependent species, non-native species, % neuston that are estuarine. Log- transformed data to reduce variation among systems. Effects of site type on connectedness, water level, salinity, T, and fish indicator groups were examined with general linear models. Leakiness and velocity were examined with ANOVA. Temporal study analyzed SRT function in Chinook habitat over time. Focused on variation in measures of connectivity and surface water elevation. Calculated cumulative density up- and downstream, divided above by below for a comparable ratio across sites. Used Pearson correlations among physical metrics describing connectivity and water elevation, determined if these are correlated with logRatio of cumulative density.

**Comments**: This report investigated side-hinged self-regulating gates in comparison to traditional flap gates and reference sites. The summary conclusions of relative impacts or benefits to juvenile salmon are useful and relevant to our questions. One caveat is that we have included reports focused specifically on Fisher Slough. We should be careful to include the data from the other systems but not to double count Fisher.

Greene, C., E. Beamer, and J. Anderson. 2016. Skagit River Estuary Intensively Monitored Watershed Annual Report April 2016. NOAA Northwest Fisheries Science Center, Skagit River System Cooperative, and Washington Dep't. of Fish and Wildlife. 25 pp.

Abstract: The goal of the Skagit River Intensively Monitored Watershed (IMW) Project is to understand changes in population characteristics (primarily abundance, productivity, and life history diversity) of wild Chinook salmon in response to reconnection and restoration of estuarine habitat. To accomplish this goal, we are monitoring the Skagit River Chinook salmon population at four stages of their migration: the mainstem Skagit River near estuary entry, the tidal delta, nearshore, and offshore. These monitoring programs allow us to examine changes in body size, abundance, and life history variation as fish migrate out of the estuary. The long time series of monitoring data allows us to examine the effects of large restoration projects in the tidal delta, which commenced in 2000 and will continue in future years. Additional status and trends monitoring of adults returning to the Skagit River provides a further reference to evaluate whether the cumulative amount of restoration projects, methodologies, and results of the Skagit system-wide monitoring. In doing so, we address how our methodologies are answering two general questions relevant to monitoring the population response of Chinook salmon to estuary restoration:

1) do salmon exhibit limitations during estuarine life stages related to capacity and connectivity, and

2) has estuary restoration resulted in population-or system-level responses?

This report is primarily a summary of previous knowledge gained about Chinook use of estuarine habitats in the Skagit River estuary and delta, and study plan for future post-restoration monitoring, but also includes some post-restoration results. Results are not presented for individual tide gate projects, but rather for the larger system and restoration effort as a whole which includes several different kinds of actions. Does include some discussion of "what works, what doesn't".

**Results Summary**: Almost 290 hectares were restored in the Skagit River South Fork between 2000 and 2012. Density decreased and residence increased after restoration. Each restored hectare provided habitat for ~690 daily residents at high outmigrations. Additionally, cohort residency would increase by 15 days for each 200 ha restored. Fry migrant abundance and the smolt-to-adult ratio did not seem to be influenced by restoration. Additionally, average length did not increase with restoration. Different

types of projects provided different restoration results. Projects associated with dike setback, dike breach, and fill removal had juvenile Chinook densities comparable to reference sites. Self-regulating tide gate sites had Chinook densities an order of magnitude lower than reference sites although they did perform about twice as well as traditional flap gates. Individual projects are contributing to the overall estuary goal. Data from systems in which abundannce has been quantified and carrying capacity estimated show that Chinook are more abundant than project design estimates.

**Broad Outcomes**: Projects associated with dike setback, dike breach, fill removal had juvenile Chinook densities comparable to reference sites. Self-regulating tide gate sites had an order of magnitude lower Chinook densities than reference sites although they did perform about twice as well as traditional flap gates. Individual projects are contributing to overall estuary goal. Systems in which abundannce has been quantified and carrying capacity estimated, Chinook are more abundant than project design estimates. Density decreased and residence increased after restoration.

**Detailed Outcomes**: Between 2000 and 2012, nearly 290 hectares were restored to tidal inundation in the Skagit River South Fork. Post-restoration densities decreased and residencies increased. The added capacity translated into approximately 690 daily residents per restored hectare at high outmigrations. Residency significantly increased as a function of restoration ( $R^2 = 0.25$ , p < 0.05), such that a 200 ha restoration effort would result in an average increase in cohort residency of 15 days within the tidal delta. Fry migrant abundance and SAR did not seem to be influenced by restoration. Additionally, average length did not increase with restoration.

## **Effects Modifiers**:

Intervention: Various		
Conditions:	<b>Duration</b> : Sampling has been done for 14-23 yrs on different segments of the study	
<b>Study Design</b> : Collect fish with downstream migrant trap, fyke net (tidal delta), beach seine (nearshore), townet (offshore), adult returns. Measure FL, calculate density and cumulative density, migrant timing, and recruits per spawner.		
Statistics:		

**Comments**: This paper summarizes results from several restoration projects in one large river delta and estuary. The authors can make comparisons about outcomes based on the type of restoration completed (dike setback or removal, tide gate replacement) and compare to reference and traditionally gated marshes.

Guimond, E. 2010. <b>Courtenay River Estuary (Dyke Slough) Biophysical Assessment 2009–2010.</b> Prepared For Living Rivers – Georgia Basin/Vancouver Island and BC Conservation Foundation, Nanaimo, BC. 39 pp.

<b>Location &amp; Species</b> : Courtenay River estuary, BC. Dyke Slough - 2 tributariess: Glen Urquhart (4.7 km <sup>2</sup> ) and Mallard (2.8 km <sup>2</sup> ) creeks		Ecosystem(s): marsh		
Reference Source:				

Abstract: Paraphrased EXECUTIVE SUMMARY: Dyke Slough on the Courtenay River estuary receives inflows from 2 main tributaries – Glen Urquhart and Mallard creeks, and discharges to the estuary through floodboxes under Comox Road. Connectivity of this habitat to the estuary and its value as estuarine wetland habitat for juvenile salmonids is influenced by operation of 2 side-hinged and 1 tophinged tide gate on the floodboxes. In 2009 a biophysical assessment of this habitat was initiated to establish baseline water quality conditions and seasonal utilization by juvenile salmonids and to guide future conservation and rehabilitation activities in the estuary. Five water quality sampling sites were monitored Aug 2009-Sept 2010. Two were located in the marsh (lower & middle), one in each of two tributaries (Mallard & Glen Urguhart Creeks) at their confluence with the marsh, and one downstream of Comox Road in the estuary. Temp was monitored using continuous recording instruments (15-30 min intervals) installed at 4 sites. Other environmental parameters were monitored during monthly (or 2X monthly) visits to each site including temp, DO, conductivity, salinity and pH. Discharge was measured periodically in tributaries further upstream from their confluence with the marsh, whereas discharge from Dyke Slough was calculated from measurements taken at the two lower elevation floodboxes (circular concrete culverts) at Comox Road. Water samples were collected at two sites in Oct 2009 and monthly from March-Sept 2010 for analysis of nutrients. Daily average water temperatures at all sites ranged from 0.7C to 28C. The warmest temperatures were recorded during summer at Site 3, located in the middle of the marsh, while Site 5 (Mallard Creek) had the coolest temperatures throughout the year. DO values at all sites averaged 5.98-9.64 mg/l with Site 5 lowest. It is suspected that groundwater seepage into Mallard Cr contributes to the cooler temps and lower DO, particularly during low summer flows which are predominantly groundwater sources. Site 3 had the greatest diurnal DO variation due to photosynthesis/ respiration of aquatic flora and fauna, reaching oxygen saturation values of 160% in summer. Water level recorders were installed downstream and upstream of the floodboxes at Comox Road to evaluate operation of the tide gates. Tide gates operate automatically as a result of water level differences upstream and downstream of the gate, closing during incoming tides and opening during ebb tides. By design, side-hinged tide gates require less force to open, thus remain open for longer periods. Water level data, recorded every 15 min, indicates that on average, duration of an OPEN cycle is ~6-8 hrs. However, tidal cycle and magnitude, and inflows upstream of the gates influence the hydraulic head differential, and therefore duration and frequency of the OPEN cycle. Water velocity and

depth through the culverts will determine suitability of conditions for upstream fish passage. Based on fish passage criteria in culverts in the literature, the opportunity for juvenile passage at the Comox Road floodboxes is generally limited to brief periods when the tide is flooding upstream through the floodboxes, before the gates close. Results from catch data (Gee trapping) indicate juvenile salmonid abundance was greatest in the lower tributaries of the slough with the highest catches occurring in Feb. No salmonids were captured at Site 3. Average length and weight of all coho captured in Gee traps was 93mm (range 46–144 mm) and 9.42g (range 0.9 - 32.1 g), respectively. High numbers of coho juveniles were captured in pools downstream and upstream of the floodboxes at Comox Road in Oct 2010. The presence of one adipose clipped coho fry (2010 hatchery release) upstream provides evidence of successful passage through the floodboxes.

**Results Summary**: Both Glen Urquart and Mallard creeks had measureable flow all year. Water temperature was generally between 5°C and 16°C Oct to Jun. Dissolved oxygen varied but was above the optimum survival threshhold of 8mg/L at all but one site. Salinity decreased with distance upstream. Nitrogen was below the threshhold for aquatic and animal protection. Phosphorus was higher than threshhold criteria at two sites. The tide gates only open if the low tide passes below a certain point. Between Oct 2009 and Jun 2010 the gates were open ~44% of the time. Gate open time was 0.5 to 18.75 hours per open cycle. This may influence juvenile migration but not likely adult migration. Most salmonids were collected at sites 4 and 5. None were caught at site 3. From Sep 2009 to Sep 2010 98 coho and 1 steelhead were collected. Condition factor was near or above 1 for all fish. During Oct 2010 nomad sampling more than 65 coho fry were collected below the gates and 32 were collected above. Fulton's condition factor was 0.8 to 1.64 for all fry and did not differ above and below the gates.

Broad Outcomes: Habitat Both tributaries had measurable flow all year. Flows were highest Nov - Apr in tributaries and Oct-May in Dyke Slough. T was similar at all sites mid-Oct to early Jun. Site 3 was warmest in Aug-Sep and Jun-Aug. Site 5 was coolest throughout the year with biggest differences Aug-Oct and Jul-Sep. T was generally between 5°C and 16°C Oct-Jun. Dissolved oxygen samples ranged from 1.8 to 12 .74. Average dissolved oxygen was above optimum survival threshhold (8 mg/L) at all sites except 5. Site 5 groundwater likely influenced cool T and low dissolved oxygen. Sites 1-3 were saline or brackish (conductivity 18,900 - 41,660) and 4-5 were freshwater (conductivity <266). pH ranges overlapped at all sites. Salinity decreased with distance upstream, ending in the middle marsh. Nutrients: No measure of nitrogen was higher than threshhold criteria for fish and aquatic animal protection. Phosphorus was 0.028-0.134 mg/L at site 3 and 0.02-0.051mg/L at site 4, higher than the threshhold criteria of 0.005-0.015. Discharge and velocity: The tide gates only open if the low tide passes below a certain point not reached on all tides. Oct 2009 - Jun 2010 the gates had 43 open and close cycles per month and gates were open ~44% of the time. Gate open time was 0.5 to 18.75 hours per open cycle. Means for all months were > 6 hours. However, it is not clear what proportion of that time would be suitable for juvenile migration. Adult migration is not likely to be impacted. Fish: Most salmonids were collected at sites 4 and 5. None were caught at site 3. Stickleback dominated at all sites. Prickly sculpin and Pacific staghorn sculpin were found at site 2.98 coho and 1 steelhead were collected Sep 2009 - Sep 2010. Coho FL ranged from 46 to 144 mm, weight from 0.9 to 32.1 g, and condition factor was >1 for most fish (min 0.92) showing fish were adequatley nourished. Oct 2010 nomad sampling: collected >65 coho fry below and 32 coho fry above (1 ad marked - migrated upstream) tide gates. Nomad size and condition: Below - FL 62-107 mm, weight 2.1-13.7 g, K 0.84-1.64, Above - FL 79-113 mm, weight 5.6-17.0 g, K 0.80-1.42.

## **Detailed Outcomes**:

## Effects Modifiers:

Intervention:				
<b>Conditions</b> : the slough is regulated with 2 side-hinged and 1 top- hinged tide gates at the junction with Comox Road	Duration: 1 year			
<b>Study Design</b> : Habitat: Logged water surface elevation and T, measu oxygen, conductivity, salinity, pH at all sites. At tributary outflows minitrate, total phosporus, ortho-phosphate, pH. Juvenile fish were co (baited, 24 hr soak) at sites 2, 3, 4, 5 bimonthly Sep - Nov 2009, mon Fish were ID'd, salmonids were measured (mm) and weighed (g). Sca Jun 2010 for age composition. Fish: Fish were beach seined at sites 1 tide gates) in Oct 2010 with focus on coho nomads. All fish were ID'd inspected for marks and a subset were measured and weighed.	easured total nitrogen, ammonia, illected in 15-30 minnow traps thly Feb - Sep 2010 excluding Jul. ale samples collected in Mar, Apr, . and 2 (up and down stream of

Location & Species: Fisher Slough, S River, WA Chinook salmon	South Fork Skagit	Ecosystem(s):	freshwater tidal wetland	
<b>Reference Source</b> : http://skagitcoop.org/wp-content/uploads/2015MonitorReport_Final_062316.pdf				

**Abstract**: [Paraphrased from introduction] The Nature Conservancy's Fisher Slough Tidal Marsh Restoration Project has been monitored to document conditions in the original and restored freshwater tidal habitats following reintroduction of tidal hydrology and reconnection of stream floodplains on the site in order to evaluate success of restoration efforts. This monitoring report compares established baseline (pre-project) conditions with changing-project conditions, to test hypotheses derived from project objectives....In 2009, existing floodgates at the Pioneer Highway crossing were replaced with new self-regulating floodgates to allow greater tidal exchange and fish access upstream of the floodgate, while still providing flood protection to adjacent farmland. The new floodgate is designed and operated to maximize tidal exchange (i.e. open for a longer timeframe during the year) and also to improve fish access during spring migration for Chinook salmon. At the same time, a small flapgate located below the south floodgate was retrofitted with a gate that can be propped open to allow fish passage in summer when water levels drop below the floodgate sill. [The project also included ditch realignment and excavation, a levee setback and plantings. All work was completed in 2011.] Data in this report are presented for the fourth water year after restoration construction was completed.

Parameters measured include water elevations, tidal amplitudes, water temps, dissolved oxygen, vegetation cover, sediment accretion, Chinook density.

**Results Summary**: Tidal amplitude increased upstream of tide gates post restoration. Area inundated at MHHW increased and the inundation curves up and downstream became more similar. However, 55.7 acres were inundated instead of the expected 60 acres. The plant community changed to freshwater tidal composition covering 99.6% of the tidal floodplain. Species richness of native vegetation increased and transitioned to late succession plants - however, it remained distinct from the reference site. The area covered by reed canary grass (RCG) decreased, but at bit more was observed in 2015 than 2012 and the density of RCG did not decrease at all elevations as targeted. Total channel length, channel area, channel density, and channel depth increased.

**Broad Outcomes**: Tidal amplitude increased upstream of tide gates post restoration. Tidal amplitude immediately upstream of gates matched that below gates. MHHW at Nav88 >/= 8.88 ft and immediately upstream of tide gate >/= 9.5 ft. Dissolved oxygen was below 8mg/L in all years, fell below the critical

level in late spring or early summer (the goal of >8mg/L may be unrealistic because tidal inundation might not be the driving force). 7-DADM T goal was exceed every year. The area inundated at MHHW increased and the inundation curves up and downstream became more similar. 55.7 ac were inundated instead of the expected 60 ac. The percent of time wetland is inundated and the area inundated at 9.5 ft NAVD88 increased. Mean sedimentation rates were positive and more pins showed accretion than erosion by 2015. Plant community changed to freshwater tidal composition covering 99.6% of the tidal floodplain. Species richness of native plants increased and transitioned to late succession plants - however it remained distinct from the reference site. Vegetation elevation ranges in 2015 were similar to target. The area covered by reed canary grass (RCG) decreased, however at bit more was observed in 2015 than 2012. RCG density did not decrease at all elevations, as targeted. Percent cover of RCG was not measured in 2015. Total channel length, area, channel density, and channel depth increased. Relative Chinook juvenle density above floodgates increased. Density and connectivity were within the scatterplot of long-term monitoring sites by 2015. Floodgate doors were open 5 deg once a day on most but not all days Oct-Feb. After sill removed at Big Ditch the channel was deeper with a more natural profile. Flood storage increased by 245 acre-feet.

# **Detailed Outcomes:**

Effects Modifiers: Sedimentation rates may not be accurate because not all stakes stayed upright.

Intervention: Replaced tide gates with self-regulating gates. Re-routed big ditch, filled old ditch channel. Built new dike farther back, removed old dike. Excavated new tidal channels.		
<b>Conditions</b> : goal is to evaluate success of restoration treatment <b>Duration</b> : 12 months		
<b>Study Design</b> : Measured surface and ground water levels, dissolved oxygen, T, vegetation, marsh elevation, channel cross-section. Monitored fish.		
Statistics:		

**Comments**: Earlier reports suggest that the dike setback had more positive influence than gate replacement, but new gate is self regulating and does remain open longer. This report focuses on tidal amplitude, inundation, and plant community composition. Beamer et al. 2016, which also reports on the Fisher Slough restoration, focuses on juvenile Chinook population abundance and response to environmental factors.

Abstract: Tidal wetland channels provide rearing habitat for juvenile Chinook salmon as they emigrate from freshwater habitat and prepare to enter the ocean. Widespread diking and drainage of estuarine marshes for agricultural and urban development may have contributed to a decline in salmon abundance in the Pacific Northwest, prompting efforts to restore estuarine salmon habitat in the region. I investigated the growth and residence patterns of age-0 Chinook salmon in two blind tidal channels in the Salmon River estuary, Oregon. One channel drained a natural high salt marsh in "reference" condition, and the other channel was in an adjacent salt marsh, restored to tidal inundation in 1996 after being diked and controlled by a tide gate for thirty five years. Recapture of individually marked fish indicated salmon growth rates were similar in the two channels, though growth rates varied more seasonally in the restored site. Average minimum residence times of individual fish were approximately ten days in each channel, and individual salmon were observed up to 79 and 117 days after initial marking in the reference and restored channels, respectively. To characterize movement of age-0 salmon within tidal channels, I tested the feasibility of stationary Passive Integrated Transponder (PIT) detection within a small (approximately 8m wide) tidal channel within the natural marsh system. I found that a stationary PIT detector was an effective tool for monitoring tagged fish movement in a brackish water channel network. Salmon movements in the channel were asymmetrical about high slack tide, with peak movement frequency occurring late during both flood and ebb tide periods. Most movements were in the direction of tidal currents, but 20% of individuals entered the channel against the ebbing tide. Individuals occupied the intertidal channel for a median 4.9 hours and as long as 8.9 hours per tidal cycle, and few were detected moving when water depth was <0.4m. Some individuals used the channel on multiple successive tidal cycles, and others entered intermittently over periods up to 109 days. This research used individual-based fish marking methods to quantify juvenile Chinook salmon behavior and performance within tidal marsh channels, assessing functional equivalence of natural and restored sites and demonstrating the value of such habitats for conservation and restoration of salmon populations.

**Results Summary**: Peak CPUE was late May/early Jun 2003 and late Jun/early Jul 2004, before peak temps and increased salinities for both reference and restored channels, although Chinook were collected into the fall in both sites. Growth, condition, and residence time did not differ significantly

between the channels. Density was higher closer to the tidal refuge of the mainstem. 7-9 years after dike breaching and tide gate removal the marsh seemed to be functionally equivalent to the reference marsh in terms of growth, residence and density. However, with lower abundance smaller fish. In 2004 fish growth was modeled using bioenergetics. Measured growth was lower than modeled growth. The authors argue that models are good for comparing growth potential but not realized growth and may not make accurate predictions of growth.

**Broad Outcomes**: Peak CPUE was late May/early Jun and late Jun/early Jul in 2003 and 2004. Both before peak temps and increased salinities although Chinook were collected into the fall in both channels. Growth, condition, and residence time did not differ significantly between the channels. Density was higher closer to the tidal refuge of the mainstem. 7-9 years after dike breaching and tide gate removal the 1996 marsh seemed to be functionally equivalent to the reference marsh in terms of growth and residence. However, abundance was lower (smaller size too though), the fish were smaller in one year but densities were similar. \*\*\*\*in 2004 fish growth was also modeled using bioenergetics. The actual measured growth was lower than modeled growth. Therefore, models may be good for comparing actual growth potential but not realized growth and may not make accurate predictions of growth.

Detailed Outcomes: Chinook were present Apr/May - Aug/Sep but CPUE was low after mid-Jul (water temp peaked then). CPUE was negatively correlated with the distance from the main stem river during peak abundance. In 2004, peak abundance and density were estimated as 1812 fish and 0.09 (95% CI 0.01 - 0.16) fish/m<sup>2</sup> in the reference and 563 fish and 0.04 (95% CI 0.01 - 0.07) fish/m<sup>2</sup> in the 1996 marsh. Water temperature increased throughout the sampling season. Reference: surface T ranged from 10.5 to 23 C at all sites and bottom T ranged from 9.2 to 18.9 C at high tide. Difference between surface and bottom generally greater. 1996: surface temps ranged from 9.5 to 23 C, bottom temps were 10.8 to 21.1 C. Salinity varied with the tidal cycle and rainfall, and generally increased through the summer but not consistently greater than 10 C until early Jul. Salinity was often 2 to 3 PSU greater in the reference marsh - likely because it was closer to the ocean. Fish were almost always recaptured in the channel where they were tagged (3 fish, <0.01%, switched) so growth attributed to channel. Growth was not significantly different between channels or among years but in 2004 (the best sampled) FL averaged 6.5 mm less. Individual PIT growth ranges: -1.31 - 2.10 mm/d; biomass growth -2%/d to 4.2%/d (1996marsh) and to 11%/d (reference). Condition was similar between channels in all years. Median measured residence in the reference marsh were 3d, 10d, and 8d in the 3 years. 1996 only measured in 2004 - 10d median residence. Longest residence: reference - 79d, 1996 - 117d (both 2004).

**Effects Modifiers**: Abundance estimates were likely postively biased because the populations were not closed as assumed; however, effect should be same in both channels. Growth calculations excluded recaptures after </= 48 hours. CPUE was positively correlated with abundance estimators. Differences in capacity or rearing potential are influenced by landscape position and land use/restoration history. Rearing capacity may be additive at the estuary level with additional marsh restoration creating habitat for additional cohorts.

Intervention: tide gate removal some years prior, compared to a reference never gated marsh			
<b>Conditions</b> : the restored marsh was diked for 35 years but by the time the study was undertaken a native salt marsh plant	Duration: 3 years		

community was forming.

**Study Design**: Sites within each channel were beach seined at high tide. Sampling frequency was highest and most even in 2004. Fish (naturally-produced) were collected and counted. 2003: 195 >/= 60mm in reference were weighed, measured, and PIT-tagged; 2004: all fish weighed and measured, 671 in reference and 319 in restored PIT-tagged; 2005: all reference fish weighed and measured, 569 PIT-tagged. Surface temperature, and salinity were recorded at each seining site at each sampling. Water temp was logged continuously in each channel.

**Statistics**: CPUE=relative abundance - spatial and temporal distribution. Abundance estimates: maximum likelihood Lincoln-Peterson estimator (program NOREMARK). Population level growth was calculated as the slope of the regression of length or weight on time and the change in size from first to last capture of PIT-tagged fish. Fish condition was estimated as the slope of the regression of logWeight on logLength. PIT data was used to calculate growth rates in length (mm/d), weight (g/d), and specific growth rate (%biomass/d). In 2004 growth was estimated for 2-wk intervals also. The median minimum residence time in a channel was used as an index of residence time. Report maximum time between first and last capture in each channel.

**Comments**: No data before restoration except the plant community description. Chapters 2 and 3 of this thesis are individual papers. Only chapter 2 includes data from a previously diked and gated marsh and contains the data I have summarized here.

Johnson, J. and T.A. Whitesel. 2012. Julia Butler Hansen National Wildlife Refuge: Post-Construction Assessment of Fishes, Habitats, and Tide Gates in Sloughs on the Mainland. Draft 2011 Annual Report. U.S. Fish and Wildlife Service Columbia River Fisheries Program Office, Population & Habitat Assessment Program, Vancouver, WA. 30 pp.					
Keywords: tide gate replacement salmon	<b>Type</b> : Annual report. (Copy on file is listed as "draft".)		Publication Date: 2011		
Include: Yes	<b>Reason</b> : Directly relevant to question of tide gate replacement.		Relevance:		
<b>Location &amp; Species</b> : Mainland sloughs at Julia Butler Hansen NWR, lower Columbia River; juvenile Chinook, coho and chum salmon		Ecosystem(s): Columbia River estuary			
<b>Reference Source</b> : https://www.salmonrecovery.gov/Files/2011%20APR%20files/ New%20Folder%203/Johnson_and_Whitesel_2012_JBH_NWR_2011Monitoring.pdf					

**Abstract**: GOAL: The primary goal of this study is to assess the effect of habitat restoration on fish, fish communities and aquatic habitat at Julia Butler Hansen National Wildlife Refuge. Habitat restoration is focused on replacement of traditional style tide gates with side-hinged, self-restrained tide gates and installation of these new style tide gates at sloughs without connection to the Columbia River.

# OBJECTIVES

1. Assess the periods, frequency, and duration that tide-gates (as presently configured, after modifications, and newly installed) are conducive to passage by juvenile and adult salmonids, specifically during October-June.

2. Describe presence, distribution, and biological characteristics (e.g., species, size) of fish inhabiting mainland sloughs at Julia Butler Hansen NWR (pre-and-post construction) and compare to that observed at reference sloughs.

3. Characterize habitats of mainland sloughs at Julia Butler Hansen NWR and compare to that observed at reference sloughs (pre-and post-construction).

4. Quantify changes in fish community and habitat quality with the re-introduction and/or improvement of the return of tidal exchange.

**Results Summary**: Juvenile salmonids: Chinook, coho, chum, cutthroat, were collected in all reaches of all sloughs except mid Indian Jack, which was previously closed. More juvenile salmon were collected in a greater number of reaches of previously closed sloughs after tide gates reconnected access. The similarity index increased in previously closed sloughs relative to both control and reference sloughs. However, for sloughs with replacement tide gates the similarity indices did not increase relative to reference or control sloughs. There were no differences in dissolved oxygen among individual sloughs, but when grouped dissolved oxygen was higher in reference sloughs than in either treament. Dissolved oxygen was above critical levels in all sloughs.

**Broad Outcomes**: Passage: 532 juvenile coho and Chinook were caught entering a gated previously closed and a reference slough. Stickleback most abundant, juvenile Chinook 2nd. Community: 5710 fish in 25 taxa collected. Juvenile salmon (including Chinook, coho, chum, cutthroat trout) were collected in all reaches of all sloughs except mid Indian Jack (prev closed) and 3 of 5 reaches in closed control. More juvenile salmon were collected and in more reaches of previously closed sloughs post-contruction. The similarity index increased post-construction in previously closed compared to reference and control sloughs. There was no similarity index increase in previously gated sloughs compared to reference or controls. Habitat: Dissolved oxygen did not differ among individual sloughs; when grouped dissolved oxygen was higher in reference sloughs than treatment. Dissolved oxygen was not below critcal levels in any slough.

## **Detailed Outcomes:**

**Effects Modifiers**: All gated and closed sloughs were on the mainland and all ungated sloughs were on islands. Data are from 2 years pre and 2 years post restoration. Variable catches and weather make it difficult to make conclusions about treatments.

**Intervention**: Replaced top-hinge tide gates with side-hinged self-restrained aluminum tide gates at 3 sloughs. Installed side-hinged self-restrained aluminum tide gates at 3 closed sloughs with no current connection to the Columbia River. One gated and one closed slough had no treatment, and 2 reference sloughs were monitored.

Conditions:	Duration: 4 months			
Study Design: Compare habitat conditions, fish communities in treatment sloughs to control and				
reference sloughs before and after treatment. Each slough was divided into 50- or 25-m reaches.				
Sampling order randomized, all surveyed twice. Passage was determined with hoop nets. Community				
and distribution measured with beach seine. Fish ID'd, counted; salmonids weighed, measured,				
examined for marks, scanned for PIT-tags. Measured dissolved oxygen, conductivity.				

**Statistics**: Calculated Sorensen Similarity Index for seine data 2007-2011 to compare fish community among sloughs grouped by slough type.

**Comments**: This is an interesting study because it looks at tide gate replacement and tide gate insertion. Replacement of top-hinge gates with side-hinge self-restrained gates did not provide positive benefit for fish or habitat. However, positive results were seen in sloughs with newly installed gates that had been previously completely disconnected.

Abstract: [From introduction] In an attempt to improve conditions for fish, in 2007 the U.S. Army Corps of Engineers (USACOE) replaced the three top-hinge steel tide gates controlling tidal action on the largest Tenasillahe Island slough with side-hinge aluminum gates equipped with a manually controlled fish orifice. This action was to improve aquatic habitat conditions and to improve fish passage for juvenile salmonids while balancing the needs of the endangered white-tailed deer found on the island. It is unclear whether these modifications will result in improved fish passage into and out of the sloughs or in changes to aquatic habitat conditions. The U. S. Fish and Wildlife Service, Columbia River Fisheries Program Office (CRFPO) is evaluating this project with the goal of assessing the effects of the USACOE restoration actions at Tenasillahe Island. This project will compare slough conditions in Tenasillahe Island sloughs before and after restoration and among treatment and reference sites in Welch Island sloughs. Pre-construction assessment began in 2005. Activities associated with this assessment provided insights into logistical constraints such as access to sample sites and fish sampling methods amenable to conditions within the sloughs. Data collected March through June 2006 and March through May 2007, before gates were replaced, show elevated gated slough water temperatures, more non-native species present in gated sloughs, and limited opportunity for juvenile salmonids to enter gated sloughs. Activities in 2008 focused on collecting post-construction data needed to assess effects of the new tide gates. The following objectives were addressed during 2008 field season: 1. Assess fish passage conditions; 2. Describe fish distribution among treatment and reference sloughs; 3. Characterize aquatic habitats of treatment and reference sloughs; 4. Measure juvenile salmonid growth rate and residence time in treatment and reference sloughs.

**Results Summary**: Replacement side-hinged tide gates opened on 64% of the low tides and were open an average of 3.4 hour per opening. No salmon were collected entering Large Tenasillahe Slough, however juvenile Chinook and coho were caught exiting the slough. PIT-tagged fish released in LTS remained throughout the summer and grew well. Water quality differed for some factors and was similar for others. Gated sloughs had higher water temperature, lower percent dissolved oxygen, and more emergent aquatic vegetation. However, pH was similar in all sloughs and turbidity and transparency ranges overlapped. Conductivity was similar among sloughs except Large Tenasillahe Slough, which had much higher values. The reference sloughs on Welch Island had larger proportions of native species.

**Broad Outcomes**: Passage: 12 species entered LTS (no salmonids). 13 species exited LTS (including Chinook and coho). Community structure: 48,879 fish, 20 species collected. 99.4% of fish were native species. 255 salmonids captured - 231 Chinook (85% not ad-clipped), 23 chum, and 1 steelhead 7-DADM reached 16C twice in all sloughs between Mar 20 and Jul 10 (with decrease between - remained above for total of 47d in LTS and STS, 26d in LWS and 24d in SWS. 65.6% of PIT-tagged fish released were detected leaving LTS. Gated sloughs have higher water T, lower dissolved oxygen, and more emergent aquatic vegetation. PIT-tagged fish released in LTS remained throughout the summer and grew well.

Detailed Outcomes: Replacement tide gates opened 64% of the low tides and were open an average of 3.4 hr/opening. (Avg of 1.3 opening/d, 4.4hrs open/d). 3-spine stickleback dominated species entering LTS (78.6% and 89% of two traps) and no salmon. 3-spine stickleback comprised 92% fish exiting LTS, 27 Chinook (12 PIT-tagged) and 1 coho exited. Community: Native species - LWS: 8/10, SWS: 8/9, LTS: 5/12, STS: 3/8. Water Quality: LTS and STS (gated) had smaller T ranges than LWS and SWS (reference). LTS also had a smaller T range than STS (but not sig). Percent dissolved oxygen ranges overlapped in gated and reference sloughs. Conductivity was higher in LTS (2700 uS) than in other sloughs (128.9 uS - 167.2 uS). pH was 6.19-8.04 in all sloughs. Turbidity was higher in LTS (10-40 JTU), but overlapped other sloughs (5-10). Transparency was slightly higher in reference sloughs but all ranges overlapped. Habitat: Silt dominated all reaches. Reference sloughs predominantly shrub and forb-grassland. STS was shrub and trees, LTS was grassland-forb and shrub. LTS and STS cover dominated by aquatic veg. LWS and SWS cover provided by overhanging trees/shrubs and woody debris. Residence was 1-119d, median 41d to 45d for 4 release groups, 64-67% were detected leaving. 43% of total had one detection. Time between 1st and last detection ranged from 1 to 61.5d. 150 fish had detections >24hrs apart. 10 recaptures were in culvert fyke traps and growth rate was 1.29 - 1.62 mm/d and 0.51 - 0.79 g/d. Growth rates of penned fish were lower (-0.07-0.12 mm/d in LWS and 0.02-0.26 in LTS - sig higher in LTS).

# Effects Modifiers:

**Intervention**: Tenasillahe: Replaced three top-hinge steel tide gates on the larger slough with sidehinge aluminum tide gates with a manually controlled fish opening. The smaller slough retains its single top-hinged steel tide gate

Conditions: Attempt to improve fish passage and habitat while	Duration: 3years
maintaining habitat for endangered Columbia white-tailed deer	

**Study Design**: 25-m transects in a large and small slough on each of Tenasillahe and Welch Islands. Large Tenasillahe Slough (LTS): 8, Small Tenasillahe Slough (STS): 3, Large Welch Slough (LWS): 5, Small Welch Slough (SWS): 2 Calculated water level differential needed to open the gates, then used to estimate total openings and durations. Fyke nets were installed to capture incoming (2 gates) and outgoing (1 gate) fish in LTS. Fish were identified and counted, and salmonids were measured. Fyke nets and beach seines were used in all reaches of all sloughs to determine fish community composition. Seine area size was estimated to quantify effort. All fish were identified and counted. Salmonids were measured and weighed and those >60mm were scanned for a PIT-tag. Habitat data (water T, atmospheric pressure, dissolved oxygen, specific and relative conductivity, pH, turbidity, water transparency, wetted width, mean depth, substrate, riparian vegetation, percent shade, and physical channel cover) were recorded for each site once Mar-Apr and once May-Jun. In reference and gated sloughs water temp and depth were recorded hourly in lowest and highest reach and temp only was recorded in the middle reach. 7-DADM for temperature were calculated. Residence time was determined by releasing 1500 (LWS) and 1000 (LTS) PIT-tagged sub-yr fall Chinook, which were recaptured with seining, fyke traps, and PIT antennas. To compare growth rates and survival PIT-tagged fish were held in enclosures in 3 reaches each of LWS and LTS for 1.5 months (50 fish/reach).

**Statistics**: BACI, tested for sig diff in mean percent dissolved oxygen using ANOVA with Bonferroni multiple comparisons.

**Comments**: This report describes one of the few tide gate replacement projects in the Columbia River Estuary. It is also useful because it does not include other restoration actions. The effects are all related to the tide gate treatment. This is an example of other 'uses' requiring less change - the Columbia White tail deer habitat on the island needs to be maintained and protected.

Johnson, G.E., N.K. Sather, A.J. Storch, J. Johnson, J.R. Skalski, D.J. Teel, T. Brewer, A.J. Bryson, E.M. Dawley, D.R. Kuligowski, T. Whitesel, and C. Mallette. 2013. **Multi-Scale Action Effectiveness Research in the Lower Columbia River and Estuary, 2012.** PNNL-22481, final annual report submitted to U.S. Army Corps of Engineers, Portland District, Portland, OR, by Pacific Northwest National Laboratory, Richland, WA. 172 pp.

Abstract: The study reported herein was conducted for the U.S. Army Corps of Engineers, Portland District by researchers at the Pacific Northwest National Laboratory (PNNL), National Marine Fisheries Service (NMFS), Oregon Department of Fish and Wildlife (ODFW), University of Washington (UW), and U.S. Fish and Wildlife Service (USFWS). The goal of the study was to evaluate the ecological benefits of restoration actions for juvenile salmon in the lower Columbia River and estuary (LCRE; rkm 0–234). This multi-year study (2011–2018) addresses the ecological benefits of restoration actions at multiple spatial scales over time. The spatial scales include the 1) site scale as a result of an individual project, 2) landscape scale as a result of multiple restoration actions located within a ~50-km segment of the LCRE, and 3) estuary scale as a result of the cumulative effects of multiple restoration actions estuary-wide. 2012 Objectives: Objective 1, Site Scale – a) Continue pre-restoration action effectiveness research to evaluate effects of the upcoming dam removal/rechannelization at the Sandy River delta; b) continue post-restoration action effectiveness research to evaluate effects of the tide gate replacements at the Julia Butler Hansen National Wildlife Refuge (JBHNWR) mainland and Tenasillahe Island.Objective 2, Landscape Scale – a) Estimate juvenile salmon density in shallow water habitats between St. Helens and Longview (rkm 110–141); b) estimate residence time for tagged juvenile Chinook salmon during winter 2012 in Carroll's Channel behind Cottonwood Island. Objective 3, Estuary Scale – Prepare a compendium of tag release-recapture technologies to inform planning for future action effectiveness studies.

[TIDE GATE RELATED FINDINGS] Comparison of the presence and distribution of fish inhabiting mainland and Tenasillahe Island sloughs at JBHNWR to those observed at reference sloughs showed that 1) juvenile salmon had increased access to sloughs after installation of self-regulating tide gates at JBHNWR, and 2) juvenile salmon were captured in more treatment sloughs after self-regulating tide gates were installed. Water temperatures of sloughs at JBHNWR were similar to reference sloughs with 7-DADM exceeding 18°C in the same months and at similar cumulative days.

**Results Summary**: Installation of side-hinged, self-restrained tide gates improved fish passage and distribution, and water quality at Julia Butler Hanson National Wildlife Refuge. Juvenile salmon were collected in all reaches in all reference, gated, and control sloughs after hydrologic connectivity was

restored. Pre-restoration, juvenile salmon were only caught in reference sloughs. At Tenasillahe Island replacement of top-hinged gates with side-hinged tide gates with manual fish orifices did not improve fish passage or water quality. There were no differences in temperature pre- and post- replacement. No juvenile salmon were collected in gated sloughs.

**Broad Outcomes**: Side-hinged, self-restrained tide gate installation improved fish passage and distribution, and water quality at JBHNWR. Side-hinged tide gates with manual fish orifice did not improve fish passage or water quality at Tenasillahe Island.

Detailed Outcomes: Ch 3 JBH: 26,004 fish (21 taxa) were collected. 22,832 (87.8%) were stickleback. In reference 82% of species were native, in gated sloughs 50% were native, at control sites 47% were native. Juvenile salmon were collected in all reaches in all reference, gated, and control sloughs. Mostly Chinook (684), and coho (126), but some chum (3) were collected in May. 7-DADM T was below 18°C threshhold until May in all sloughs, Jun in Winter, and Jul in Indian, South Hunting, and Ellison. T remained high through Aug and Sep in all sloughs and into Oct for Winter, South Hunting, and Steamboat. Tenasillahe: 10,930 fish (18 taxa) collected, 9947 (91%) stickleback. In reference 80% of species were native, in gated 38% were native. No juvenile salmon were collected in gated sloughs. In Welch reference sloughs Chinook (121) and coho (1) were collected. Appendices - pre-and postrestoration data: JBH Pre-restoration water T surpassed 18°C later in the season in reference sloughs. In 2007 reference sloughs had more salmon species (chum not collected in closed or gated sloughs). Reference: 66 Chinook, 1 chum, 3 coho; Gated: 87 Chinook, 12 coho; Closed: 1 Chinook, 1 coho. Gated and closed had more species, especially non-natives. 2010 fish community: 3430 fish caught in Control (22 Chinook, 2 chum, 9 coho), 6773 fish caught in gated (314 Chinook, 2 chum, 41 coho), 4590 fish collected in Reference (62 Chinook, 18 coho). Tenasillahe: Pre-restoration water T surpassed 18°C earlier in May at Tenasillahe than Welch. Relative abundance and %native species were higher in Welch sloughs. Salmon were never collected in Large Tenasillahe when tide gate was operating. In Welch sloughs 270 Chinook, 6 chum, and 1 coho were collected. Post-restoration no difference in water T. 2008 fish community: Large Tenasillahe: 475 fish (2 Chinook), Small Tenasillahe 447 fish (0 salmon). Large Welch 35,428 fish (175 Chinook), Small Welch 12,529 fish (54 Chinook, 1 Sthd). Large Tenasillahe gate only opens when water is higher in slough (~20% of time) and fish have to swim against the flow.

# **Effects Modifiers**:

**Intervention**: JBHNWR: In 2009 two sloughs were reconnected to the Columbia River with culverts and side-hinged gates, one top-hinge aluminum gate at Brooks was replaced with a side-hinge aluminum gate. Tenasillahe: in 2007 three top-hinge steel gates were replaced with three side-hinge aluminum gates in Large Tenasillahe Slough.

Conditions:	Duration: 10 months	
Study Design: Ch 3 Fish were collected in beach seines, counted, measured, and weighed (stickleback		
not measured and weighed). Recorded T and calculated 7-day maximum daily average.		
Statistics:		

**Comments**: Chapter 3 is pertinent to our questions. Data from Tenasillahe and Welch are in Johnson et al. 2008 but the data presented here was collected in 2012 and 2013. The other chapters are not summarized here.

Abstract: This study evaluated estuarine habitat use, life-history composition, growth and survival of four successive broods of coho salmon Onchorynchus kisutch in Salmon River, Oregon, U.S.A. Subyearling and yearling O. kisutch used restored and natural estuarine wetlands, particularly in the spring and winter. Stream-reared yearling smolts spent an average of 2 weeks in the estuary growing rapidly before entering he ocean. Emergent fry also entered the estuary in the spring, and some resided in a tidal marsh throughout the summer, even as salinities increased to >20. A significant portion fo the summer stream-resident population of juvenile O. kisutch migrated out of the catchment in the autumn and winter and used estuary welands and adjacent streams as alternative winter-rearing habitats until the spring when they entered the ocean as yearling smolts. Passive integrated transponder (PIT) tag returns and juvenile life-history reconstructions from otoliths of returning adults revealed that four juvenile life-history types contributed to the adult population. Estuarine-associated life-history strategyies accounted for 20-35% of the adults returning to spawn in the four brood years, indicating that a sizable proportion of the total *O. kisutch* production is ignored by conventional estimates based on stream habitat capacity. Juvenile O. kisutch responses to the reconnection of previously unavailable estuarine habitats have led to greater life-history diversity in the population and reflect greater phenotypic plasticity of the species in the U.S. Pacific Northwest than previously recongnized.

**Results Summary**: Overwinter habitat was generally low except in a few areas in the same sections of high spawner abundance. Spawning, freshwater rearing, and quality overwinter habitat were concentrated in the upper Salmon and Little Salmon rivers and Bear Creek. Summer juvenile abundance and density increased with spawner abundance. Juvenile size was similar among years and did not vary with abundance. Juveniles demonstrated 4 migrant patterns and these 4 patterns were present in the adult spawners that returned (all as 3 year olds). Three of the rearing patterns included estuary residence: fry migrants, fry-nomad migrants, and parr migrants. These three life history strategies together comprised 20-35% of the returning spawner population. Based on PIT detections survival rates could be calculated for some groups: fry migrants - 1.5%, parr migrants - 3.2%, yearling migrants - 4.4%. Growth rates in the estuary were high compared to the freshwater habitats. The authors argue that estuarine habitat restoration has increased the productivity of the population by increasing off-channel rearing opportunities which the coho population has responded to by expressing estuarine-dependent life-history strategies. The authors also mention that production models that do not consider the

contributions of estuarine rearing may be missing a portion of the population. Multiple life-history strategies also increase the resilience of a population.

**Broad Outcomes**: Spawning, freshwater rearing, and quality overwinter habitat were concentrated in the upper Salmon and Little Salmon rivers and Bear Creek. Juvenile size was similar among years and did not vary with abundance. Juveniles demonstrated 4 migrant patterns and these 4 patterns were present in the adult spawners that returned (all as 3 year olds). Three of the rearing patterns included estuary residence: fry migrants, fry-nomad migrants, and parr migrants. These three life history strategies together comprised a fifth to a third of the returning spawner population. Based on PIT detections survival rates could be calculated for some groups: fry migrants - 1.5%, parr migrants - 3.2%, yearling migrants - 4.4%. Growth rates in the estuary were high compared to the freshwater habitats. The authors argue that estuarine habitat restoration has increased the productivity of the population by increasing off-channel rearing opportunities which the coho population has responded to by expressing estuarine-dependent life-history strategies. The authors also mention that production models that do not consider the contributions of estuarine rearing may be missing a portion of the population. Multiple life-history strategies also increase the resilience of a population.

Detailed Outcomes: Adults: Spawning occurred mid-Sep to early Jan and peaked in Nov. Most spawning was in upper main-stem Salmon and Little Salmon rivers and Bear Creek. Juveniles: Summer juvenile abundance and density increased with spawner abundance. Juvenile abundance was high in the upper Salmon River and Bear Creek, two of the spawning concentrations. Freshwater fork length was 42-109 mm in all years and mean size was 70.6 0 76.7 mm. Juveniles were significantly larger in 2008, the year with lowest densities, and smaller in 2011, although density was not much higher in that year and years with higher densities also had larger mean sizes. Overwinter habitat was generally low except in a few areas in the same sections of high spawner abundance. Juvenile Outmigration: Age 0 migrated Mar-Jun and late-Sep. Age 1 outmigration began in Mar and peaked in Apr or May. Age 1 migrants were 63 -151 mm, averaging 104mm. Up to 40% of the summer coho population may have moved to the estuary in the winter when the trap was not operated. Estuary Rearing and Growth: Age 0 spring migrants resided in the estuary 31 - 147 d. Age 0 fall migrants were detected for 6 days but some were detected again in spring, evidence of overwintering. Nearly all Age 0 were caught in the upper and mid estuary. Fish growth was higher in the estuary than upriver and this difference was significant in winter. Age 1 migrants were collected in all areas of the estuary. Their estuary residence was 2 - 34 d, average 13 d. 27% were detected in the marsh outfitted with a PIT array. Life-History Diversity: PIT and juvenile otolith data showed 4 migrant types: yearling, fry, fry-nomad, parr. 18% of the otoliths were fry-nomad and parr migrants. Nomads estuary entry size was 60mm median and parr migrants entered at median 97 mm and resided for up to 101 d. Juvenile Rearing Patterns of Returning Adults: yearling migrants comprised 65-80% of the spawner population and combined Age 0 migrants contributed 20-35%. Fry, fry-nomad, and parr migrants were represented. Survival rates: fry migrant - 1.5%, parr-migrant - 3.2%, yearling - 4.4%.

**Study Design**: Spawning surveys were conducted at sites in 15-20% of available habitat at least every 10d. Otoliths were collected from natural origin spawners. A PIT antenna recorded tagged adult and juvenile migrants. Juveniles were sampled with backpack electrofishers, abundance was standardized to fish per m or km. Coho were counted, measured, and weighed. Individuals >65 mm (71-79%) were PIT tagged. Downstream migrants were screwtrapped and those > 65 mm were PIT tagged. Rearing capacity was estimated for summer and winter periods. Estuary residents were beach seined in mainstem and wetland channel habitats twice monthly. Separate sampling was done to monitor ocean entry Apr - Nov.

**Statistics**: Spawner abundance was estimated for the entire available habitat using AUC. Age 0 rearing abundance was determined with the LNB estimator then expanded to spawning and rearing habitat in the basin. Fish size and timing at trapping were representative of estuary entry because of the nearness to the estuary. PIT detections were used to determine residence time, growth, migration time, juvenile to adult survival, and spawner age. Size and growth differences by year and location were analyzed with ANOVA and Dunnett-Tukey-Kramer pairwise multiple comparisons. Juvenile migration histories of spawning adults were determined using otolith Sr:Ca. Juvenile sizes and timing of ocean entry were calculated from juvenile otoliths collected at the estuary mouth. Sr:Ca increase relative to annulus formation was used to determine season of estuary/ocean entry. Spawner age was determined from scale analysis.

**Comments**: This paper describes the presence and contribution of 4 life-history strategies. Three of them are estuary dependent and are expressed in response to estuary restoration. This restoration was described in other studies we included. This study is especially helpful because it describes the life-history variation in the juveniles and then demonstrates the existence of all 4 strategies in the returning adult population.

Reference Source: http://www.ecologyandsociety.org/vol14/iss1/art4/			

**Abstract**: The downstream movement of coho salmon nomads (age 0), conventionally considered surplus fry, has been an accepted characteristic of juvenile coho salmon for the past 40 to 50 yr. The fate of these nomads, however, was not known and they were assumed to perish in the ocean. Several studies and observations have recently provided new insights into the fate of nomads and the role of the stream- estuary ecotone and estuary in developing this life history strategy that promotes coho resilience. Chinook and sockeye salmon have developed the ocean-type life-history strategy to exploit the higher productivity of the estuarine environment and migrate to the ocean at age 0. Nomad coho can acclimate to brackish water, and survive and grow well in the stream-estuary ecotone and estuary, but instead of migrating to the ocean they return upstream into freshwater to overwinter before migrating to the ocean as smolts. Nomads may enter the estuarine environment from natal or non-natal streams, rear there throughout the summer, and then emigrate to a non-natal stream for overwintering and smolting in the spring. These estuarine and overwintering habitats have enabled coho to develop this unique nomad life history strategy that may help to ensure their resilience. Restoring estuarine habitats may be essential to the recovery of depressed populations of coho.

**Results Summary**: Nomads (age-0 coho migrants) migrate downstream and use the estuary similarly to age-0 Chinook and sockeye but overwinter in freshwater tributaries including non-natal streams. Coho cannot survive direct migration to ocean salinities but do survive and grow in some estuarine salinities. Nomad migration increases the available rearing area, food, and growth potential for coho populations and increases overall productivity. However, it is difficult to determine nomads' contribution to the population because freshwater and estuarine growth are not readily distinguishable in scales. Recommends reconnecting freshwater/estuarine habitats by removing tide gates and dikes to allow these kinds of up and downstream migrations.

**Broad Outcomes**: Nomads (age-0 coho migrants) likely migrate downstream in response to carrying capacity being met. They use the estuary similarly to age-0 Chinook and sockeye but overwinter in freshwater tributaries. Coho may overwinter in non-natal streams (moving upriver or downriver to get there). Coho cannot survive direct migration to ocean salinities but do survive and grow in some estuarine salinities (some describe as tidal-fresh to tidal-brackish transition zone) - habitat for osmoregulatory change. Estuaries increase rearing area, food available, growth potential for coho populations and increase overall productivity - may also allow recovery of depressed populations or repopulate streams whose runs had been extirpated. It is difficult to determine contribution to the population because freshwater/estuarine growth is not readily distinguishable in scales. Recommends

reconnecting freshwater/estuarine habitats by removing tide gates and dikes to allow these kinds of up and downstream migrations.

**Abstract**: Paraphrased from SUMMARY: This paper summarizes and translates, into less technical language, a scientific report: Biological and Physical Effects of 'Fish-Friendly' Tide Gates (in the PNW). This work was commissioned in 2009 by the WA Estuary and Salmon Restoration Program (ESRP) and completed by NOAA's Fisheries Science Center via an Interagency Agreement with the WA Recreation and Conservation Office. The final product was a technical report (Appendix B). This investigation was a first step toward comprehensive evaluation of the effectiveness of tide gates in providing benefits to fish. We expect the results of this study will be of interest to the broader restoration community. During review and early circulation of this report a number of important questions were raised provoking a useful dialogue about the current state of knowledge and remaining data gaps. Much of this dialogue is preserved in Appendix A as a technical Question and Answer (Q&A) session between authors, reviewers and ESRP staff. We have provided this information to help answer common questions, to clarify some uncertainties presented in the report and to identify priority data gaps need to better inform policy and restoration practice.

Contents of this document:

- Background and context on the tide gate study, including description of the study objectives
- Summary of findings, policy implications and recommendations on future inquiries and applications
- Appendix A: Q & A section in which the study authors address questions about the study design, findings, and interpretation of results. Also included are recommendations on future monitoring and research needs
- Appendix B: The final report on tide gates delivered to ESRP by NOAA as a contract deliverable

**Results Summary**: Summary: Site type (type of gate, reference) had a larger influence on juvenile Chinook density than habitat water quality characteristics. However, habitat characteristics are important when they are above or below threshholds for stress or survival (likely leading to avoidance before mortality). Dike setback is more beneficial to juvenile salmon than tide gate replacement by increasing the amount of habitat available without traversing any obstacles. Recomendations: Maximize gate opening width and time and maximize culvert width, and increase upstream depth at high tide. Additionally, perform studies to tease apart the limiting factors of connectivity and habitat quality, and evaluate benthic conditions, riparian cover, and prey availability.

**Broad Outcomes**: Direct measurements of door openness angle and gate type. Site type (type of gate, reference) was a larger influence on juvenile Chinook density than habitat water quality characteristics. However, habitat characteristics are important when they are above or below threshholds for stress or survival (likely leading to avoidance before mortality). The authors suggest a suite of sites that experimentally vary the operation of several tide gates types to determine the influence of operation and design on fish usage. The authors present some general operation considerations to maximize benefit for juvenile salmon. 1) maximize gate opening width and time 2) maximize cumulative width of culverts 3) keep the culvert low in the channel (minimize the height of culvert invert) 4) increase upstream depth at high tide (trade-off between drainage and rearing hab) 5) gate operation and design should be adjustable. Collect habitat data using loggers up and down stream. Sample fish community biweekly up and downstream. Recommend performing studies to tease apart the limiting factors of connectivity and habitat quality. The report demonstrates that dike setback is more beneficial to juvenile salmon than tide gate replacement - increases the amount of habitat available without traversing any obstacles. Recommend considering rearing habitat characteristics 1) connectivity 2)maximum production possible from restored area (using some expected density level) 3) habitat quality. Additional habitat measures to evaluate are benthic conditions, riparian cover, prey availability.

# **Detailed Outcomes:**

**Effects Modifiers**: The study was unable to address the question of how much tide gate functionality can be influenced by design and operation - what are the limits or expected levels of change with this approach?

ence=1

Abstract: A 22 ha, 15-year old, diked permanent pasture in the Salmon River estuary in Lincoln County, Oregon, was chosen for a study to determine the potential for natural salt marsh restoration with dike breaching. Two undiked fragments of relatively undistrubed sal marsh, one at each end of the study site, were used as 'control' marshes. A permanent plot-permanent transect system was set up for vegetation and soils sampling before and after dike breaching. Three pasture communities, the Potentilla pacifica community, the Agrostic alba-Holcus lanatus community, and the Holcus lanatus community, were described before dike breaching. Elevational means for each community were not significantly different, and spatial distribution appeared to be most influenced by cultural practices. Vegetative cover in 49- $1.0m^2$  permanent plots was also recorded for comparison with post-dike breaching data. Half the dike was leveled in September 1978 and tidal creeks reopened. Vegetation resampling in 1979 and 1980 has shown that upland pasture-type species suffered close to 100% mortality by 1979. Somewhat salttolerant residual species, mainly Agrostis alba and Potentilla pacifica, either expanded into areas previously occupied by upland species or died back depending on degree of flooding and/or drainage within a local area. Permanent plots were grouped into four persistence classes (P.C.) based on cover of residual species. They ranged from P.C. I with 100% cover in 1979 and 1980 to P.C. IV with 30% mean cover of residual species by 1979. P.C. I permanent plots average 10-15 cm higher than P.C. IV plots, and are furthest from tidal creeks and/or locally better drained. Intensive sampling of colonizing species was done in 1979 and 1980 on over 3000 m<sup>2</sup> using the permanent plot system. By 1980, in areas of high residual species cover (P.C. I and II), the most successful colonizers were Atriplex patula (up to 18% cover locally), Hordeum brachyantherum (11%), and Carex lyngbei (to 6%). In P.C. III and IV areas, where there was mostly bare mud, Spergularia marine (to 11%) and Salicornia virginica (to 12%) have colonized most rapidly. Because of 0.30-0.40 m subsidence of the diked site below the elevation of the 'control' marshes, intertidal to low-transitional salt marsh is expected to develop. Future net primary productivity is projected to be in the 1200-1800 g/m<sup>2</sup>/yr range, compared to 800-1200 g/m<sup>2</sup>/yr for the higher transitional marshes on undisturbed Salmon River sites. Soils changes on the study site include increase in interstitial soil water salinity from zero on the diked site to 18 to 30 ppt summer salinity (5-10 ppt higher than 'control' marshes). Soil pH which was lower (4.7) on the diked site than the 'control' marshes (5.5) has returned to the level of the 'control' marshes. Higher concentrations of NH4 on the breached site indicate more anaerobic conditions with increased flooding and poorer drainage.

**Results Summary**: After restoration Upland species cover decreased from 85% in 1978 to near 0% in 1979 and remained low in 1980. Residual species cover decreased somewhat, colonizing species increased cover to ~20% and bare ground increased from near zero to ~45%. For residual species, those that persisted after breaching and tide gate removal, the percent cover decreased in areas that flooded most and increased in areas with less flooding. After dike breaching the proportion of biomass represented by residual species increased from about 50% to 97% and 80% in 1979 and 1980. The percent cover of residual species is related to elevation, distance from a tidal channel, and drainage efficiency because they cannot tolerate flooding. Colonization occured more in persistence classes with a greater degree of flooding. The colonizing species differed with the degree of flooding as well. In areas with the most bare ground plant vigor was lowest. Concentrations of several extractable bases ( K, Ca, Mg, Na, B) and ammonia increased after breaching while nitrate and Potassium decreased. After breaching the study site had higher ammonium and sodium compared to control sites and Potassium and Magnesium had increased to control site levels. Organic material is high 25-40% over the site with very little stratification.

**Broad Outcomes**: For residual species, those that persisted after breaching and tide gate removal, the percent cover decreased in areas that flooded most and increased in areas with less flooding. After dike breaching the proportion of biomass represented by residual species increased from about 50% to 97% and 80% in 1979 and 1980. The percent cover of residual species is related to elevation, distance from a tidal channel, and drainage efficiency because they cannot tolerate flooding. Concentrations of several extractable bases and ammonia increased after breaching while nitrate and P decreased. After breaching the study site had higher ammonium and sodium compared to control sites and Potassium and Magnesium had increased to control site levels. Organic material is high 25-40% over the site with very little stratification.

**Detailed Outcomes:** Within the study areas there were three plant community types: those dominated by Patentilla pacifica (silverweed), Agrostis alba (black bent/redtop) / Holcus lanatus (velvet grass), and Holcus lanatus. The P. pacifica community sections had 75-100% cover and 99-100% frequency of the dominant species. The A. alba / H. lanatus community had patches of Ranunculus repens, Alopecurus geniculatus and Trifolium repens. These shorter grasses may have been maintained by cattle grazing. The H. lanatus community included tall weed species such as Senecio jacobea, Epilobium watsonii, and Cirsium vulgare and was patchier - indicative of its use as horse graze land. H. lanatus, A. alba, and P. pacifica had overall frequencies of 90%, 74%, and 65% respectively. The three plant communities had overlapping elevational means ranging from 1.08 m to 1.14 m above MLLW. Upland species cover decreased from 85% in 1978 to near 0% in 1979 and remained low in 1980. Residual species cover decreased somewhat, colonizing species increased cover to ~20% and bare ground increased from near zero to ~45%. The crop biomass in 1979 and 1980 was 59% and 28% that of 1978. Biomass decreased less quickly than cover, mostly driven by residual species. 1978 biomass was about half upland and half residual species but after dike breaching residual species made up 97% and 80% of the biomass. Residual species had complete mortality in areas flooded often, some mortality and low vigor in areas of moderate flooding, and increased cover in areas flooded infrequently. Colonization occured more in persistence classes with a greater degree of flooding. The colonizing species differed with the degree of flooding as well. In areas with the most bare ground plant vigor was lowest.Percent cover of colonizers was 30% in two intertransect types by 1980. Pre-restoration sampling found more colonizing species in creek samples than in transect samples. Post-restoration upland species had high mortality except along

the highest creek banks. After breaching three of the 8 tidal creeks experienced downcutting erosion. Two years after restoration the net primary productivity was ~50 - 33% of that of the natural marshes. Soil salinity pre-breaching was 0 ppt in all areas except near the leaky tide gate. Post restoration soil salinity ranged from 11 to 39 ppt and averaged 25 ppt over the entire site. Control site soil salinities were lower. Soil pH increased after dike breaching to a value near that of the control sites. Concentrations of K, Ca, Mg, Na, B, and ammonium increased. Nitrate and phosphorus decreased.

# **Effects Modifiers**:

**Intervention**: The tide gate and half of the dike around the pasture was leveled in Sep 1978. Additional material was removed to restore connectivity of tidal creeks where they intersected with the leveled or intact dike.

**Conditions**: The study site was diked ~1963. It was bordered on either side by areas of relatively intact salt marsh.

Duration: 3 yrs

**Study Design**: Vascular plant species cover was sampled along a total of 20 permanent transects in in the study site in 1978 (pre) and 1979-1980 (post), and in one year in each of the control sites (1 in 1978 and 1 in 1979), in 102 permanent plots created along the transects (minimum of 3 plots per transect), and along the permanent profiles. Permanent profiles were created across tidal creeks. Plant species mean height was also recorded within plots. In 1979 1-m wide belts were sampled every 10 m between plots on adjacent transects or between a plot and another permanent marker. Above ground biomass was measured in permanent plots once each summer. Water elevation in the river upstream of the study site was recorded May 1979 to Aug 1980. Elevations were determined for all permanent transects, plots, and profiles. Soils were sampled for salinity, pH, strata delineation, and from each strata: bulk density and organic matter measurements.

**Statistics**: 1978 study sites were classified into clusters by the dissimilarity of vegetative species cover. Mean cover of each species was calculated across all samples, and within upland species, residual species, colonizing species, and bare ground categories for each year. Permanent plots were assigned to persistence classes based on the timing and degree to which the pre-restoration vegetation broke up and exposed bare ground. Mean cover of residual species and frequency of colonizing species were calculated by persistence class. Intertransect belts were classified by persistence class and mean cover and frequency of colonizing species was calculated. Standing crop biomass and net primary productivity were determined for the control sites. Monthy averages were calculated for 5 tide height categories and reduced to the Metonic cycle using Garibaldi tide data. Radiocarbon dating was performed on samples of seaside arrowgrass found in the soil samples.

**Comments**: This is the first of several studies on restored marshes in the Salmon River delta. It is nice to have papers that examine the effects of restoration at different points in time. One side note: It seems odd to classify the colonization and species of occurrence by persistence class because the persistence classes are defined by the amount of bare ground and colonization.

Nordholm, K.E. 2014. Contribution of subyearling estuarine migrant coho salmon (Oncorhynchus kisutch) to spawning populations on the southern Oregon coast. M.S. Thesis, Dep't. of Fisheries and Wildlife, Oregon State University, Corvallis, OR. 81 pp.

Abstract: The typical coho salmon life history has been characterized by juvenile fish that spend their entire first year in freshwater habitats before migrating into estuaries as smolts. However, reports of early migrating coho fry (age 0), including migration downstream to estuarine habitats, date back to the 1960s. Until a few years ago, these individuals were considered to be displaced surplus fish with low chances of survival. Recent studies have suggested that subyearling estuarine migrating coho salmon could be an alternative life history in coastal populations, but their return as jacks or mature adults needed to be documented for this life history to be considered a viable strategy. The goal of our study was to track the return of spawning coho salmon that had been individually tagged in either estuarine or riverine nursery habitats, and determine return percentages for each life history strategy as well as independently verify the presence of subyearling estuarine migrating coho salmon through otolith analysis on spawning populations. We used Passive Integrated Transponder (PIT) tags to identify individual fish as they passed through a series of antennas deployed in two coastal lowland streams on the southern Oregon coast. Percentage return of estuary tagged parr (fish  $\geq$  60 mm tagged in spring and summer of their first year) was variable between years and streams. For the 2010 return year, subyearling estuarine migrants was 2.5 times higher than stream residents in Palouse Creek. Fork length at estuary entrance was reconstructed for one return year of spawning fish based on otolith Sr:Ca and Br:Ca. Four main life history strategies were identified based on their fork length at time of estuary/ocean entrance: early migrating fry (< 60 mm fork length), early migrating parr (60 - 70 mm fork length), early migrating parr that returned to freshwater before migrating as yearlings ("nomads"), and yearling migrating smolts (> 70 mm fork length). Overall, 30% (Larson Creek) to 42% (Palouse Creek) of the 2009 spawning run was made up of fish that displayed evidence of estuarine residence during their first year. This study confirms that subyearling estuarine migrating coho salmon survive to reproductive age and contribute to subsequent generations. The survival of this life history type likely varies between years with changing ocean and stream conditions. It is hypothesized that their life history serves as a "bet hedging" strategy that supports coastal populations in years of poor stream conditions. In the face

of rising sea levels, this life history may represent a key to the future viability of coho salmon stocks in coastal watersheds.

**Results Summary**: In this system the Sr:Ca in the estuary was distinguishable from that in the ocean. Three subyearling estuarine life-histories were identified: estuarine fry migrants, estuarine parr migrants, estuarine nomads (migrated to estuary as fry, migrated back to freshwater as parr and overwintered before returning to estuary as smolts). Return rates by life-history type were 2.81%, 1.81%, and 0.78% for smolts, estuary subyearlings (fry and parr migrants and nomads), and stream parr. Stream resident smolt migrants were also identified. Of the adults spawning in Palouse and Larson creeks, 58 and 69% had been yearling smolts, 21 and 16% were estuary parr, estuary fry were 15 and 13%, nomads were 6 and 2%.

**Broad Outcomes**: Estuary Sr:Ca distinguishable from ocean ratio. Return rates by life-history type: smolts (2.81%), estuary parr (1.81%), stream parr (0.78%). Three subyearling estuarine life-histories were identified - estuarine fry migrants, estuarine parr migrants, estuarine nomads (migrated to estuary as fry, migrated back to freshwater as parr and overwintered before returning to estuary as smolts). Stream resident smolt migrants were also identified. Of the adults spawning in Palouse and Larson creeks, yearling smolts were 58 and 69%, estuary parr were 21 and 16%, estuary fry were 15 and 13%, nomads were 6 and 2%.

# **Detailed Outcomes:**

## **Effects Modifiers**:

Intervention: None				
Conditions:	Duration:			
<b>Study Design</b> : Fish collected via screw trap, seine, electrofishing - all trapped and subsample of other YOY and smolts PIT-tagged. PIT arrays set in double rows to determine directionality. Adults were recovered as antenna detections and as carcasses on the spawning grounds. Water samples were collected to predict the elemental ratios expected in the otoliths.				
<b>Statistics</b> : Return rate, odds of returning calculated for each creek. Odds ratios were used to determine if subyearling estuarine migrants differed significantly from stream residents. Calculated detection efficiencies for each array. Used regressions to determine relationship between otolith width (OW) and FL, then back-calculated fish length at estuarine entry.				

**Comments**: These tide gates had no modifications; one is top-hinged and one is side-hinged. However, this study presents conclusive evidence for the contribution of at least four life-history types to the coho spawning population.

Poirier, J., S. Lohr, T.A. Whitesel, and J. Johnson. 2009. Assessment of Fishes, Habitats, and Fish Passage at Tide gates on Deer Island Slough and lower Tide Creek. USFWS, Columbia River Fisheries Program Office, Population & Habitat Assessment Program, Vancouver, WA. 41 pp.			
Keywords: N/A.Type: 2009 Project ReportPublication Date: 2009			
Include: Yes	<b>Reason</b> : For discussion of estuary usage by juvenile salmon.		Relevance:
Location & Species: Deer Island, Lower Columbia River, Deer Island Slough and Lower Tide Creek		Ecosystem(s):	
Reference Source: https://www.fws.gov/columbiariver/publications/Deer_Island_Report_2009.pdf			

Abstract: Deer Island is located at river kilometer 125-130 along the south shore of the lower Columbia River near the town of St. Helens in Columbia County, Oregon. The area encompasses over 1,821 hectares within the Columbia River floodplain, which historically consisted of tidally influenced backwater and slough habitats (i.e., Deer Island Slough), as well as stream habitats in relatively small tributaries adjacent to the area (e.g., Tide and Merrill creeks). Presently, the value of these habitats for anadromous salmonids has been reduced by such activities as dike construction, tide gate installation, and stream channelization, resulting in restricted access by fish and degraded habitat conditions. However, anadromous fish continue to use the area....In spring 2009, the USFWS, Columbia River Fisheries Program Office (CRFPO), contributed to these efforts by monitoring biological and physical attributes of Deer Island Slough and lower Tide Creek for the preparation of this biological assessment. The ultimate goal of this assessment was to provide information concerning fish presence, aquatic habitat conditions, and fish access to habitats that would assist with the identification and prioritization of future restoration actions intended to improve juvenile salmonid habitats and access to habitats, as well as providing information useful for describing baseline conditions prior to implementing restoration actions. Our monitoring efforts occurred during the time when juvenile salmonids were likely to be in the area, March-June.

**Results Summary**: Water elevation was higher inside the gates. The gates were perched 46% of the time during adult migration and 5% of the time during juvenile migration. 73 juvenile salmon were captured during fish passage trials: 83.6% in Apr. Chinook comprised 98.6%. In Apr 29.4% were captured upstream and in Jun 41.7%. Juvenile salmonids entered the slough only in Apr. Length frequencies suggest subyearling and yearling Chinook and coho were present. In North Deer Island Slough 10,125 fish were collected and 4/13 species were native. No salmonids were collected. In South Deer Island Slough 4,104 fish were collected and 10/20 species were native. Chinook and coho were collected. In Tide Creek 1,250 fish were collected and 10/15 species were native. Coho, cutthroat, and steelead were collected. North Deer Island Slough had lower dissolved oxygen and higher temperature and conductivity. Tide creek had lower turbidity. Transparency and pH did not differ among systems.

**Broad Outcomes**: 73 juvenile salmon were captured during fish passage trials, 83.6% in Apr. 98.6% were Chinook. 29.4% were captured upstream in Apr and 41.7% in Jun. Salmonids only entered the slough

during the Apr trial. Chinook were 62-141 mm in Apr and 51-104 mm in Jun. The length-frequency distribution suggests subyearlings and yearlings were present.

Detailed Outcomes: Water elev higher inside gates. During adult migration time the gate was perched 46% of the time, during juvenile migration time the gate was perched 5% of the time. Fish Community North Deer Island Slough10,125 fish in 13 taxa - 81.5% hoop netted, 18.5% in minnow/crayfish traps. Stickleback were most abundant (97.5%), oriental weatherfish were 2nd most abundant (0.7%) 4/13 species were native (97.7% total catch) - excluding stickleback native species were 9.0%. No salmonids. South Deer Island Slough 4,104 fish in 20 taxa - 74.8% hoop net, 21.2% seine, 18.5% traps. Stickleback 84.5%, sculpin 3.0%. 10/20 species were native (94.3% total). Excluding stickleback, natives were 63.0%. 71 salmonids were collected. Chinook comprised 66.2%. Of salmon 81.7% seine, 12.7% hoop nets, 5.6% traps. Chinook 71-125mm ad marked, 40-79mm unmarked, coho 39-152mm. Coho length-frequency suggests subyearlings (66.7%) and yearlings. Tide Creek 1,250 fish in 15 taxa - 92.3% hoop net, 6.7% seine, 1.0% trap. Stickleback 63.0%, coho 18.8%. 10/15 species were native (94.7%). 243 salmonids. Coho 96.7%, cutthroat 2.5%, steelhead 0.8%. 90.5% coho in hoop net, 9.5% seine. Coho were 37-142 mm, cutthroat 120-217 mm, steelhead 176, 180 mm. Coho length-frequency suggests subyearlings (55.7%) and yearlings. Habitat Substrate was silt and sand in all areas. Shrubs and trees dominated in North and South Deer Island sloughs. Grass/Forb dominated in lower Tide Cr. Percent shade 9-16%. Overhanging tree/shrub, woody debris, aquatic vegetation dominated in North and South Deer Island Slough. Reed canary grass, woody debris, overhanging tree/shrub dominated in lower Tide Cr. 7DADM in Deer Island Sloughs <16.8°C until late May. Dissolved oxygen was lower at N Deer Island Slough. T and conductivity were higher at N Deer Island Slough. Turbidity was lower at Tide Cr. Transparency and pH did not differ.

# **Effects Modifiers**:

Intervention: None			
Conditions:	Duration:		
<b>Study Design</b> : Fish passage trials - seine in- and out-side gates, net attached to culvert upstream. Water depth and T were logged. Dissolved oxygen, conductivity, pH, turbidity, transparency, mean wetted width, mean depth, substrate, riparian veg, percent shade, physical channel cover were measured. Sampling was spatially balanced among the 3 water bodies. Fish were seined and hoop netted. Fish were ID'd, counted, salmon were also weighed, measured, checked for marks, and >60 mm scanned for PIT tag.			
<b>Statistics</b> : Estimated gate openings and 'perched culverts'. The T range was compared between sloughs using Kruskal-Wallis ANOVA on ranks and Dunn's multiple comparison procedure. Mean daily T compared with Kruskal-Wallis ANOVA with Holm-Sidak multiple comparison. Dissolved oxygen compared with ANOVA and Holm-Sidak, conductivity compared with ANOVA on ranks and Dunn's multiple comparison.			

**Comments**: This paper reported on physical conditions in sloughs with salmon present and absent. Data novel to this paper were the proportions of time when the gate was 'perched', i.e. when the culvert was above the water level, that adult and juvenile salmonids were able to successfully pass upstream.

Location & Species: Freshwater Creek, Humboldt County, CA coho salmon		Ecosystem(s):		
Reference Source:				

Abstract: Salmon monitoring programs often measure juvenile production by operating migrant traps downstream of spawning and rearing areas during smolt migration. However, this approach does not account for individuals that move downstream of trapping locations prior to smolt sampling. We used a mark-recapture study with passive integrated transponder tagging to estimate the proportion of coho juveniles, tagged in the fall in a N. California stream, that migrated to rearing habitat downstream of a seasonally operated trap before spring smolt sampling. Emigrants were detected by using the migrant trap, located near the upstream limit of tidal influence, and continuously operated antennas located in tidal wetlands downstream of the trap. For all three cohorts sampled (2010, 2011, 2012), we identified two distinct emigration periods (not including fry emigrants that emigrated in spring at a size too small to tag): a fall-winter period, when early emigrant parr moved into a restored tidal wetland (early emigrants); and a spring period, when smolts emigrated (smolt emigrants). There was little movement in the intervening period. Emigration timing varied depending on the location in the basin where fish were tagged; locations in the lower main stem generally produced more early emigrants, while locations in the upper basin produced more smolt emigrants. Across locations, early emigrants accounted for 2–25% of the fall-marked juveniles from 2010, 8–29% from 2011, and 7–13% in 2012. Smolt emigrants accounted for 15–49% of the fall-marked juveniles from 2010, 13–14% from 2011, and 3–35% from 2012. The consistent occurrence of early emigration in this and other recent studies brings into question estimates of smolt abundance and demographic rates (e.g., overwinter and marine survival) that do not account for this [early emigrant] life history variant.

**Results Summary**: Coho emigrated at two times, in winter as early emigrants and in spring as smolts. Whether larger fish were early emigrants or smolts differed by year. Early emigration imparted a growth benefit in one of the two study years. Growth rates were more variable for early emigrants.

**Broad Outcomes**: Early emigrants left during high flow events in late fall and winter. Smolts emigrated in April. Larger fish were more likely to be early emigrants in one year and smolt migrants in two years. Growth rates were more variable for early migrants. Wood Creek was suitable habitat for overwinter growth and survival. Early emigration had growth benefits in 2010 and deficits in 2011.

## **Detailed Outcomes:**

#### Effects Modifiers:

 Intervention:
 Duration: 3 years

 Conditions:
 Duration: 3 years

 Study Design: Fish were beach seined within stream reaches, measured, weighed, PIT-tagged. Fish were recaptured with PIT arrays (in a tributary) or at a weir migrant trap. Recaptures were measured and weighed

 Statistics: Used Cormac Jolly Seber mark recapture to estimate probability of early emigration and of

smolts emigrating each year. Comments: While this paper describes coho early migrant life-history and growth benefits associated

**Comments**: While this paper describes coho early migrant life-history and growth benefits associated with this strategy in some years, it did not sample the adult population to determine what the importance of each life-history type was to the spawning population.

Roegner, G.C., E.W. Dawley, M. Russell, A. Whiting, and D.J. Teel. 2010. Juvenile Salmonid Use of Reconnected Tidal Freshwater Wetlands in Grays River, Lower Columbia River Basin. Transactions of the American Fisheries Society 139 (4): 1211 - 1232.				
Keywords: tide gate removal salmonType: Peer-reviewed journal articlePublication Date: 2010				
Include: Yes	<b>Reason</b> : Directly focused on review questions.		Relevance: High	
<b>Location &amp; Species</b> : Grays River tidal freshwater system, WA USA coho, chum, and Chinook salmon		Ecosystem(s): tidal freshwater river		
Reference Source:				

Abstract: Degraded wetland systems with impaired hydraulic connections have resulted in diminished habitat opportunity for salmonid fishes and other native flora and fauna in the Pacific Northwest. Many of these lost habitats were once intertidal freshwater marshes and swamps. Restoration of these systems is effected in part by reestablishing tidal processes that promote connectivity, with a central goal of restoring rearing habitat for juvenile Pacific salmon Oncorhynchus spp. In the Grays River tidal freshwater system of Washington, we measured hydrologic changes that resulted from the removal of tide gates from diked pastureland and we determined the subsequent time series of salmonid abundance and size frequency in the restoring marshes. Dike breaching caused an immediate return of full semidiurnal tidal fluctuations to the pasturelands. Juvenile Pacific salmonids quickly expanded into this newly available habitat and used prey items that were presumably produced within the marshes. Habitat use varied by species and life history stage. Fry of chum salmon O. keta migrated rapidly through the system, whereas populations of Chinook salmon O. tshawytscha and coho salmon O. kisutch resided from March to at least July and were composed of fry, fingerlings, and (for coho salmon) yearlings. Based on salmon size at date and the timing of hatchery releases, we concluded that most salmon sampled in restored and reference sites were the progeny of natural spawners. However, the presence of adipose-fin-clipped Chinook salmon indicated that hatchery-raised fish originating outside the Grays River system also used the restoring wetland habitat. Because of extensive mixing of stocks through hatchery practices, genetic analyses did not provide additional insight into the origins of the Chinook salmon but did reveal that out-migrating juveniles were an admixed population composed of lower Columbia River ancestry and nonindigenous Rogue River stock. Restoration of tidal wetlands in the Columbia River estuary will improve overall ecosystem connectivity and reduce habitat fragmentation and may therefore increase survival of a variety of Pacific salmon stocks during migration.

**Results Summary**: At the Kandoll Farm site hydraulic patterns more closely followed tidal fluctuations after removal. Fish species number and community compsition more closely matched reference sites after removal. Johnson was not sampled pre-removal. Life-history stage and size range similar at all sites: chum were fry, and coho were fry and fingerlings (2005 2006, 2007), also smolt (2007), Chinook were less abundant and were fry and fingerlings. 7d average maximum temperatures were similar among years and sites. At the downstream site T was above 16 deg earlier and for longer periods and went over 20 deg more often than upstream sites. Chinook and chum were most abundant below 16 deg but coho were most abundant at 16-18 deg. Salmonids in restoration sites had more diverse diets.

**Broad Outcomes**: Hydraulic patterns more closely followed tidal fluctuations after removal. Fish species number and community compsition more closely matched reference sites after removal. For Chinook: fry and fingerlings, chum: fry, coho: fry and fingerlings (2005 2006, 2007), also smolt (2007). 7DAM T were similar among years and sites but were higher downstream. Downstream sites were above 16 deg earlier and for longer periods and went over 20 deg more often. Salmonids in restoration sites had more diverse diets.

**Detailed Outcomes**: Kandoll: water level fluctuations changed to fully tidal pattern immediately, water levels increased within two weeks. Combined restoration and control: 93.6% of all fish were 3-spine stickleback. Of the remaining species, chum salmon were 32.7%, coho salmon were 13.4%, and Chinook salmon were 8.3%. Banded killifish, prickly sculpin, and peamouth were also nonincidental collections. Before restoration only killifish were collected at Kandoll. After treatment: 9 species including Chinook, chum, and coho were present. In 2005 and 2006 10 and 11 species were present at Johnson. Total catch and #species were lower in 2007. Salmonid catch by T varied with species: Chinook CPUE peaked between 11-15 deg, chum were not present above 16 deg and were most common between 9 and 12 deg, coho were most abundant between 16 and 18 deg but were present up to 23 deg. Insects were the most important prey at all sites. Annelids, amphipods, cladocerans, mysids, fish, and isopods were also eaten.Most Chinook were either Rogue River or West Cascades Tributary (Columbia R) stock but some had a mixture from both stocks.

# Effects Modifiers: Chinook salmon numbers were very low after 2005

**Intervention**: Kandoll Farm: two 4.2 m culverts were installed in the dike to reconnect to Seal Slough in 2004. Johnson Farm: a tide gate along the Grays River was breached in 2005. In both cases historic channel reaches were reconnected and pasture surfaces were flooded tidally.

Conditions: land aquired by conservation organizations and	Duration: 2005, 2006, 2007
subsequently restored	

**Study Design**: Water level change showed hydraulic connectivity (Kandoll only). Used water T to determine conditions adequate for salmonid rearing. Sampled fish communities (CPUE, #species, S-W diversity index), tracked salmonid migration stage and timing (time series of relative annual abundance), tested for thermal restraints,gastric lavaged large coho and Chinook to sample diet (%IRI, and proxy for habitat use), noted ad-marks, performed genetic analysis of salmonids (2006-2007, genetic stock ID, estimated Columbia R ancestry for each fish).

**Statistics**: All statistics are descriptive.

**Comments**: We should keep in mind that one of the marshes in this study had dike breaches to reconnect tidal channels, but not a tide gate treatment. The other included a tide gate removal.

Scott, D.C., M. Arbeider, J. Gordon, and J.W. Moore. 2016. Flood control structures in tidal creeks associated with reduction in nursery potential for native fishes and creation of hotspots for invasive species. Canadian Journal of Fisheries and Aquatic Sciences 73(7): 1138-1148.			
Keywords: tide gate replacement salmon	Type: Peer-reviewed journal articlePublication Date: 2016		
Include: Yes	<b>Reason</b> : Clear difference in fish community in gated and reference channels.		Relevance:
Location & Species: Lower Fraser River delta, BC		Ecosystem(s): tidal creeks	
Reference Source: http://summit.sfu.ca/item/15346			

**Abstract**: Habitat connectivity is important for maintaining biodiversity and ecosystem processes yet globally is highly restricted by anthropogenic actions. Anthropogenic barriers are common in aquatic ecosystems; however, the effects of small-scale barriers such as floodgates have received relatively little study. Here we assess fish communities in ten tributaries over the spring– summer season of the lower Fraser River (British Columbia, Canada), five with floodgates and five reference sites without barriers, located primarily in agricultural land use areas. While the Fraser River supports the largest salmon runs in Canada, the lower Fraser river–floodplain ecosystem has numerous dikes and floodgates to protect valuable agricultural and urban developments. Floodgate presence was associated with reduced dissolved oxygen concentrations, threefold greater abundance of invasive fish species, and decreased abundances of five native fish species, including two salmon species. These findings provide evidence that floodgates decrease suitable habitat for native fishes, and become hotspots for non-native species. Given climate change, sea-level rise, and aging flood protection infrastructure, there is an opportunity to incorporate biodiversity considerations into further development or restoration of this infrastructure.

**Results Summary**: Gated and reference sites were similar in size and land use proportions. T did not differ between gated and reference sites. Salinity and conductivity were negligible at all sites. Sites above tide gates had lower dissolved oxygen, especially later in the season (Jul, Aug ). 30,759 fish from 21 species were collected, including 674 juvenile salmon from 5 species. Stickleback dominated at all sites. Other abundant native species were northern pikeminnow, prickly sculpin, and peamouth chub. During summer reference sites shifted away from salmon communities to a higher abundance of minnows and prickly sculpin. Communities at gated sites transitioned to higher abundances of sunfish and brown bullhead. Juvenile salmon were collected at all reference and two gated sites but abundances were 2.5 times higher at reference sites. Abundance of other natives (exculding stickleback) was also higher at reference sites. Non-native species were 3.1 times more abundant at gated sites.

**Broad Outcomes**: Gated and reference sites were similar in size and land use proportions. T increased with date, but there was no affect of tide gates. Salinity and conductivity were negligible at all sites. Sites above tide gates had lower dissolved oxygen, especially later in the season (Jul, Aug - below safe min in Aug). 30,759 fish collected (21 species), 674 juvenile salmon (5 species), 29,351 'other natives' (10 species), 734 non-natives (6 species). Stickleback dominated (27,791 individuals). Other abundant native species: northern pikeminnow, prickly sculpin, peamouth chub. Non-natives included: pumpkinseed,

largemouth bass, common carp, brown bullhead, black crappie, weather loach. Fish community difered by date, gate presence, and interaction. During summer, reference sites shifted away from salmon communities to higher abundance of minnows and prickly sculpin. Gated site communities moved to higher abundances of sunfish and brown bullhead. Juvenile salmon were collected at all reference and two gated sites - abundances 2.5x higher at references. For individual salmon species abundance was 11.7x (coho -sig), 1.5x (chum-sig), and 2.2x (Chinook-NS) higher at reference sites. Abundance of other natives (exculding stickleback) was also lower at gated sites: Prickly sculpin (37.2x -sig) and minnows (11.7x -sig for peamouth and pikeminnow). Non-native species had 3.1x higher abundance at gated sites. Largemouth bass was the only non-native not more abundant at gated sites.

# **Detailed Outcomes:**

# **Effects Modifiers**:

Intervention: None		
Conditions:	Duration: 5 months	
<b>Study Design</b> : Fish were seined in first 150 m upstream of gates or confluence or were trapped overnight (avg 18 hr). Fish were ID'd and measured. Recorded salinity, T, dissolved oxygen, and conductivity. Determined watershed area and land use proportions.		
<b>Statistics</b> : Fish community composition among sites and sampling times and between site types was analyzed with NMDS. Used Generalized additive models to test gate presence on fish abundance by species. Salmon data were log(x+1) transformed.		

**Comments**: This study compared gated sites to ungated reference sites. It shows very clear differences in the fish community composition and fish density between the two types. It does not, however, include any restoration action or treatment.

Seifert, R.E. 2016. Floodgate Operations and Implications for Tidal Creek Fish Communities. 2016. MRM Research Project Report No. 646, School of Resource and Environmental Management, Simon Fraser University, Vancouver, BC. 72 pp.			
Keywords: tide gate replacement coho	Type: Master's thesisPublication Date: 2016		
Include: Yes	<b>Reason</b> : It may be useful for expanding on our understanding of how tide gates affect water quality and fish community.		Relevance:
Location & Species: Lower Fraser River, BC Canada Ecosystem(s):			
Reference Source: http://summit.sfu.ca/item/16240			

**Abstract**: Tidal creeks represent important fish habitats that are often highly modified by human activities. Floodgates can protect developed areas but also restrict connectivity of tidal creek habitats; however, floodgate operations and their effects are not well quantified. I used time-lapse cameras to quantify the timing of gate openings for 22 tributaries of the Lower Fraser River in British Columbia, Canada, and related these operational data to dfferences in fish communities above and below floodgates. I found that floodgate operations varied substantially, with some floodgates opening daily while others opened less than 20% of the day. Where floodgates opened infrequently, I found lower upstream dissolved oxygen concentrations, greater differences in fish communities, and lower native species richness relative to sites where floodgates opened more. Thus, improvements in floodgate operation will likely benefit fish communities. These data can inform management activities to balance fish and flood protection in the region.

**Results Summary**: Almost half of the gates opened for less than 20% of the day and 40% opened less than 10% of the time. However, 30% of gates were open more than half the day. Opening time was not related to tide gate type. The gates opened more when mainstem flows were lower and at sites farther from the ocean. Fish communities above and below gates were more different at gates that opened less. When gates rarely opened native species richness was ~32% lower upstream. Prickly sculpin seem particularly vulnerable - where gates rarely or never open, abundance above was 1/4 of that below. Dissolved oxygen was lower above gates that opened infrequently. However, temperature, salinity, and conductivity did not differ with gate openess.

**Broad Outcomes**: Almost half of the gates opened for less than 20% of the day. The gates opened more when mainstem flows were lower and at sites farther from the ocean. Tide gate type was not related to openess (maybe because there were just a few top-mounted and manual gates). Fish communities were more different above and below gates than opened less. When gates rarely opened native species richness was ~32% lower above. Prickly sculpin seem particularly vulnerable - where gates rarely or never open, abundance above was 1/4 of that below.

**Detailed Outcomes**: 40% of floodgates opened less than 10% of the time while 30% of gates were open more than half the day - high variability. Opening patterns differed seasonally and regionally - only Fraser discharge consistently explained patterns - many gates were closed during the freshet, which could impact juvenile salmon outmigration and geographic redistribution. More than 50% fish collected were 3-spine stickleback (>4000). Next were juvenile cyprinids (>1000). Other species with >100 individuals were pumpkinseed, northern pikeminnow, prickly sculpin, and peamouth chub. Collected only 11 chum and 17 coho. Up- and downstream communities differed more where gates opened less. Gates open more had higher relative native species richness. However, neither floodgate openess nor site characteristics explained differences in fish counts, biomass, or taxonomic richness. When gates opened less, fewer prickly sculpin were collected above the gates. Dissolved oxygen was lower above gates that opened infrequently. Temperature, salinity, and conductivity did not differ based on gate openess.

**Effects Modifiers**: Most gates were side mounted (13), while 2 were top-mounted, and 3 were manual. When gates are open there may be barriers to fish passage (velocity, installed too high or low, opening too small for larger fish).

Intervention:			
Conditions:	Duration: 1 year		
<b>Study Design</b> : Time-lapse camera of tide gate opening to compare opening time with fish communitiy composition above and below tide gates			
<b>Statistics</b> : Used general linear mixed-effects models to determine if site characteristics affected time open. Calculated difference between up and downstream communities using a dissimilarity matrix. Then used linear models to see if the community differences and water quality are related to gate openness.			

**Comments**: This is an interesting study looking at whether the amount of time tide gates are open affects fish community and water quality above relative to below. However, there were no modifications done prior to monitoring.

Silver, B.P., J.M. Hudson, and T.A. Whitesel. 2015. <b>Bandon Marsh National Wildlife Refuge</b> <b>Restoration Monitoring, Final Report.</b> U.S. Fish and Wildlife Service, Columbia River Fisheries Program Office, Vancouver, WA. 49 pp.

<b>Location &amp; Species</b> : Ni-les'tun Unit within the Bandon Marsh National Wildlife Refuge in the Coquille River estuary		<b>Ecosystem(s)</b> : intertidal and freshwater marsh, 2 creeks at rkm 5 and 8 (of the Coquille)	
<b>Reference Source</b> : https://www.fws.gov/Columbiariver/publications/Bandon%202015%20Final%20Report.pdf			

Abstract: Bandon Marsh National Wildlife Refuge (BMNWR) completed construction of a large-scale tidal marsh restoration project on the Ni-les'tun Unit within the Coquille River estuary in 2011. This monitoring project is focused on changes in the aquatic species community before and after the restoration construction. [p. 6: Construction actions included dike and tide gate removals, culvert replacements, and channel and wetland construction.] Stream sections were sampled on Fahys Creek and Redd Creek within the restoration site, reference areas in the Bandon Marsh Unit, and along the Coquille River. Fish were sampled by double hoop net, seine, and backpack electrofisher from 2007 to 2013. Invertebrates were collected and archived from the restoration area and reference area before and after construction. Biodiversity was assessed by community, species richness, distribution, relative abundance, and frequency of occurrence. The project positively benefits salmonids and juvenile estuarine fish by creating habitat and increasing access to the refuge. The overall assemblage of the fish community was not substantially different after construction; however, the number of estuarine species increased by 80% (4/5). Change in the Simpson Diversity Index differed by site, sample method, and season. Tidally influenced areas saw a decrease in richness where upper stream areas saw an increase. Salmonids were found in all areas of the refuge. Chinook (age-0), coho (age-1), and an increased number of sea-run coastal cutthroat trout were found primarily in tidally influenced areas. Newly constructed channels were occupied and used seasonally. Species found in these new channels include salmonids, introduced species, and estuarine species. Three spine stickleback and species of sculpin dominated the restoration area and reference area in abundance and capture frequency. Among salmonids, coastal cutthroat trout and coho had the highest frequency of occurrence and relative abundance before and after construction. After construction, estuarine fish increased in both abundance and frequency. Changes are likely due to improved access and changing habitat created by the reintroduced tidal regime. Future assessment of the Ni-les'tun Unit would continue to focus on changes in the aquatic species community over time for further evaluation of the success of the restoration.

**Results Summary**: 21 fish species were collected over all sampling events. Of these, 13 were present pre- and post-restoration, 3 pre- only, and 5 post- only. The proportion of unique species differed between restoration and reference sites pre- and post-resoration, but to a lesser degree post-restoration. Life-history diversity, as measured by size classes, did not change with restoration.

Ecological classisfications were similar in the restoration and reference sites. Greater abundance of estuarine species, subyearling Chinook, and sea-run cutthroat trout in the restored area increased the similarity post-restoration. The distribution of estuarine and salmonid species changed after restoration. Coho moved farther upstream and more estuarine species were present in the creeks.

**Broad Outcomes**: 21 fish species were collected over all sampling events. 13 present pre and post, 3 pre only (carp, small mouth bass, steelhead), 5 post only (anchovy, American shad, bay pipefish, starry flounder, crappie). Jaccard's similiarity coefficient not substantially different pre and post in the Niles'tun Unit. More estuarine species present post. Jaccard's coefficient for Ni-les'tun and Reference differed pre and post, but to a lesser degree post. Species richness index increased slightly for Fahys electrofishing, Redd double hoop, reference seine (Coquille R), decreased for Fahys double hoop (sig) and reference marsh double hoop. LH diversity Redd - 2 size classes of coho pre and post. Fahys - mult size classes cutthroat, 1 size class coho above N Bank Lane pre and post; mult size classes cutthroat, 2 size classes coho and Chinook pre and post below N Bank Lane. Reference - 2 size classes coho and Chinook pre and post estimilar in reference and restoration sites. Changes post restoration were mainly due to greater abundance of estuarine species (although some no longer seen), subyearling Chinook, and sea-run cutthroat; the restoration sites became more similar to the reference site. Estuarine and salmonid distributions changed after restoration. Coho moved farther upstream. More estuarine species were present in the creeks.

# **Detailed Outcomes:**

Effects Modifiers: channels only sampled at low tide

**Intervention**: removed 3 tide gates, excavated 5 km tidal channels, lowered dikes, improved culverts, filled large ditches, disrupted small ditches

**Duration**: 7 years

Conditions: Completed 2011	
<b>Conditions</b> . Completed 2011	

**Study Design**: Restored creeks and reference sites sampled with double hoop nets overnight (avg 21 hrs). Upper reaches of Fahys electrofished. REF-1 switched to seine in Fall 2009. Coquille River sites seined. Newly restored (excavated) channels seined. Measured T, conductivity, salinity at each site. All fish were ID'd and counted and up to 20 per species were measured. Salmonids were weighed (up to 20). Macroinvertebrates were netted (surface and water column) in Fahys and REF-1.

**Statistics**: Jaccard's coefficient calculated the proportion of unique species pre and post restoration. Simpson's diversity index was used for species richness. ANOVA tested differences in mean Simpson Diversity Index of double hoop values between Fahys, Redd, Reference pre- and post- construction. Salmonids were categorized into age classes using length frequency histograms with 50 mm bins by species, area, construction phase. Mean FL calculated by sample area. Used % frequency of occurence and average relative abundance to classify species as dominant, common, occasional, rare by area, sampling method, construction phase. BACI design.

**Comments**: The authors equate life-history diversity with the size classes present. However, this may not be the whole story. Coho distribution changed after removal. This may be evidence that life-history diversity is beginning to increase even with no change in size classes. The plant community evaluation and hydrology of the Ni-les'tun restoration project are described in Brophy et al. 2014 and Brown et al. 2016.

Tryon, L. 2011. Investigation of Restoration and Protection Options for Juvenile Salmonids in the **Courtenay Estuary.** BC Fish and Wildlife Compensation Program Project # 10.PUN.08. Prepared for Comox Valley Project Watershed Society by Lake Trail Environmental Consulting, Cumberland BC. 149 pp.

<b>Keywords</b> : Found while searching for "Comox Road Dyke Slough tide gate modifications".	<b>Type</b> : Report		Publication Date: 2011
Include: Yes	<b>Reason</b> : Includes recently gathered (2010) data on coho use of estuary habitat. Also some discussion of tide gates.		Relevance:
<b>Location &amp; Species</b> : Courtenay River estuary, BC. Chinook, coho		<b>Ecosystem(s)</b> : river estuary from tidal fresh to subtidal	
Reference Source: http://a100.gov.bc.ca/appsdata/acat/documents/r40301/ 10.PUN.08_Courtenay_1386168826750_6166228483.pdf			

**Abstract**: [Paraphrased from exec summary:] Study goal was to provide a foundation for future restoration and protection of important salmon habitats and their supporting food webs in the Courtenay River estuary. The study produced an ecological characterization of the estuary and developed restoration and protection options. Estuary characterization involved a field investigation of habitat requirements of juvenile salmonids from the upper to the lower estuary over the spring and summer of 2010. We used chinook and coho fry as indicator species. Fry stages were marked and monitored for recaptures, fish were identified and counted, water conditions were recorded, snorkel counts were conducted and habitats were mapped. Data from past studies were analyzed to identify changes in residency period and salmon size classes. Chinook and coho fry stages were more dependent on the estuary than smolts, which moved through the estuary quickly. Chinook and coho fry were in the estuary by early spring. Coho fry were found into December. Most chinook fry left by early July.

NOTE: Didn't find much mention of tide gates until the "Management Recommendations" (Appendix 9, p. 99-111) where tide gate impacts and mitigation actions are discussed.

**Results Summary**: Length frequencies indicated two age classes of both Chinook and coho were present. Subyearlings of both species stayed in the estuary longer than smolts. Most Chinook had left by Jul but coho remained in Oct and Dec. Chinook subyearlings preferred upper ecotone habitats near freshwater input. Coho subyearlings were collected in areas with good refuge and freshwater inflow. Additionally, estuary rearing coho grew faster than those that stayed in freshwater. Chinook growth rate was slower than coho growth rate in May and Jun below the tide gate. Chinook were mainly preying on insects (not prevalent) and coho were eating gammarid amphipods (prevalent). Water T increased throughout the season, surpassing optimal conditions in May but never reached lethal levels. Mark-recapture data indicated that coho subyearlings had site fidelity within the estuary.

### **Broad Outcomes:**

**Detailed Outcomes**: Chinook and coho subyearlings stayed in the estuary longer than smolts. Chinook were mostly gone by Jul but coho were still left in Oct and Dec. Chinook fry preferred upper ecotone habitats near freshwater input. Coho fry were found in areas with good refuge and freshwater inflow - they grow faster than those that stayed in freshwater. In May and Jun below the tide gate Chinook growth rate was slower than coho. Chinook were mainly preying on insects (not prevalent) and coho were eating gammarid amphipods (prevalent). May CPUE was highest for Chinook and coho - sites 1-4 were the most used. Other relatively abundant species collected: chum, steelhead, sea-run cutthroat, sculpins, stickleback, perch. Two age classes of Chinook and coho were indicated by length frequency analysis in most months. Diet composition varied by species and month. Chinook selected for copepods and then insects and against amphipods, isopods, and ostracods. Coho selected for amphipods and mysids, then amphipods and insects, and against ostracods, isopods, and amphipods (in Jun). Water T increased throughout the season, surpassing optimal conditions in May but never reached lethal levels. Growth rate varied with time and site. Mark-recapture data showed that coho fry had site fidelity within the estuary. Residence times in Jun were 23, 41, and 66 days in areas 2, 4, and 5.

#### **Effects Modifiers**:

<b>Reference Source</b> : https://www.researchgate.net/publication/287686888_Importance_of_the_stream- estuary_ecotone_to_juvenile_coho_salmon_Oncorhynchus_kisutch_in_Humboldt_Bay_California			

Abstract: Recent studies have shown the broad role estuaries play in juvenile coho salmon (Oncorhynchus kisutch) life history; however, most of these studies were limited to the PNW and did not include information from the southern end of its range in California. We sampled the stream-estuary ecotone (SEE) of numerous Humboldt Bay tributaries from 2003 to 2011 to document use by juvenile coho salmon. We sampled fish using seine nets and baited minnow traps and found that young-of-theyear (YOY) and yearling plus (1+) coho salmon reared primarily in freshwater or tidal freshwater habitat in the SEE. We detected three basic life history strategies employed by juvenile coho salmon regarding their use of the SEE. The first group were YOY fish that arrived in the spring and resided mostly in mainstem channel habitat in the summer and early fall; the second group of nearly 1+ fish arrived after the first large stream flow event in the fall and resided extensively in smaller tributary and off-channel habitat during the winter and spring; and finally a third group of stream-reared 1+ coho salmon emigrated through the SEE quickly during the following spring. Juvenile coho salmon resided in the SEE an average of one to two months but some individuals reared there for over a year. We found that about 40% of the coho salmon smolt production from Freshwater Creek, Humboldt Bay's largest tributary, originated from the SEE. Juvenile coho salmon rearing in the SEE were larger than their cohorts rearing in stream habitat upstream of the SEE. Our results demonstrate that juvenile coho salmon utilize portions of the Humboldt Bay SEE in ways similar to those reported in Pacific Northwest estuaries, and suggest that the SEE of Humboldt Bay provides quality rearing habitat—especially over winter rearing habitat—for those juveniles. By incorporating this knowledge into habitat eestoration plans we can design effective habitat restoration projects to improve habitat conditions and non-natal rearing for juvenile coho salmon.

# **Results Summary:**

**Broad Outcomes**: Subyearling and 1+ coho reared for extensive periods on sampled sections of Humbold Bay stream-estuary ecotone. Subyearlings were mostly in upper sloughs in spring and summer. The mean residence was 1-2 months, but some individuals reared there for over a year. Age1+ used small downstream non-native tributaries mostly in winter (age classification changed at end of calendar year) and residence varied (1-9 months). Lower sloughs were mostly used in spring by both subyearlings and yearlings. Some subyearlings moved into tributaries after spending some time in the brackish water. Yearling fish in the lower sloughs were significantly larger than those in the upper sloughs. Likewise, subyearlings rearing in the SEE were larger than those rearing upstream. Juveniles rearing in the SEE tended to move more during winter than spring and summer. The authors did not comment on possible causes (two examples are life stage and seasonal habitat differences).

# **Detailed Outcomes:**

# **Effects Modifiers**:

Intervention: None				
Conditions:	Duration: 2003-2011			
<b>Study Design</b> : Stream sections were sampled 4-8 years with seines and traps at set sites within the range of tidal influence. Fish were weighed (0.1g), measured FL (mm), and checked for tags. All untagged coho were PIT-tagged if large enough - migration and growth rates determined for recaptures. Downstream migrant traps were used to geographically partition juvenile production and PIT antennas were used to capture movement and residence data.				
<b>Statistics</b> : Calculated residence time in the stream-estuary ecotone (SEE), and growth rates for fish at large for >12 days. Used ANOVA for spatial and temporal differences of mean size in different areas of the SEE and between the SEE and upper reaches. Tukey-Kramer used for post-hoc comparisons.				

**Comments**: Tide gates were mentioned in the abstract and very briefly in the discussion but this study was not set up to evaluate effects, did not alter any stream reaches or impediments in any way, and did not discuss the habitat conditions that were most beneficial to juvenile salmon. However, it does provide additional evidence for fish moving into the lower stream reaches and mildly brackish habitats as both subyearlings and yearlings.

Location & Species: Palouse Creek, Coos Bay, OR		<b>Ecosystem(s)</b> : freshwater and tidally influenced streams	
Reference Source:			

Abstract: Juvenile salmonids display highly variable spatial and temporal patterns of early dispersal that are influenced by density-dependent and density-independent factors. Although juvenile coho salmon (Oncorhynchus kisutch) movement patterns in streams and their relationship with body mass and growth have been examined in previous studies, most observations were limited to one season or one stream section. In this study, we monitored the movement of juvenile coho salmon throughout their period of residence in a coastal basin to identify prevalent dispersal strategies and their relationships with body mass, growth rates and survival. Our results revealed seasonally and spatially variable movement patterns. Juvenile coho salmon that dispersed to tidally affected reaches soon after emergence remained more mobile and expressed lower site fidelity than those individuals that remained in upper riverine reaches. We did not detect significantly different growth rates between sedentary and mobile individuals. Although a greater proportion of sedentary than mobile fish survived winter to emigrate from the creek in the spring, reach of residence at the onset of winter influenced these survival estimates. Hence, apparent summer-to-smolt survival for mobile individuals was greater than for sedentary fish in tidally influenced reaches, whereas in riverine reaches the sedentary strategy seemed to be favoured. Our research identified complex movement patterns that reflect phenotypic and life history variation, and underscores the importance of maintaining diverse freshwater and estuarine habitats that support juvenile coho salmon before marine migration.

**Results Summary**: In summer ~75% of the fish were sedentary and in the winter ~70% were mobile. In summer the mobile fish originated mainly in the lower reaches; in winter they were from all reaches. Of the 64 fish captured in both seasons, the fish sedentary in summer split about evenly between sedentary and mobile classes in winter but for those mobile in summer the majority became sedentary in winter. There was no overarching relationship between growth rate and movement pattern. Winter survival depended on collection reach and movement class in both seasons. Completely sedentary fish had higher apparent survival.

**Broad Outcomes**: In summer ~3/4 of the fish recovered were sedentary and in the winter ~70% of recovered fish were mobile. The summer mobile fish originated mainly in the lower reaches. The winter mobile fish were from all reaches. 64 were captured in both seasons - of these the summer sedentary split about evenly between sedentary and mobile classes in winter but for those mobile in summer the majority became sedentary in winter. Growth rate differences between sedentary and mobile fish

depended on reach and season - no common pattern. Winter survival depended on movement class in summer and winter, and sample reach. Completely sedentary fish had higher apparent survival.

## **Detailed Outcomes**:

# Effects Modifiers:

Intervention:			
<b>Conditions</b> : 2 wood top-hinge flap-doors - last refurbished 1985 - large scour holes allow upstream movement of estuarine water	Duration: 2 years		
<b>Study Design</b> : Water T and salinity recorded. BY '08, '09 coho PIT tagged and tracked. Fish collected, ID'd, counted, subsample tagged, measured (mm), weighed (0.1g). Fish were recaptured physically and by PIT array to track movement. Fish classed as sedentary or mobile by capture location relative to tagging location.			
<b>Statistics</b> : Calculated instaneous growth rate for recaptures. Used a t-test to determine if body size predicted movement class. Tested if growth differed between movement classes. Estimated winter survival.			

**Comments**: This paper includes very interesting data on coho movement within the freshwater/brackish environment prior to estuary emigration. However, the only affect of the tide gate is to create a brackish pool upstream that coho use for rearing.

G.V. Wright, R.M. Wright, and P.S. Kemp. 2014. Impact of tide gates on the migration of juvenile sea trout, <i>Salmo trutta</i> . Ecological Engineering 71(October): 615–622.

Include: Yes	<b>Reason</b> : Based on data for individual fish.		Relevance:
Location & Species: The River Meon, UK; juvenile sea trout, Salmo trutta		<b>Ecosystem(s)</b> : Tidally influenced river channel and canals	
Reference Source:			

**Abstract**: As part of flood protection and land reclamation schemes, tide gates allow rivers to discharge to sea when open, and prevent salt water intrusion when closed. Their impact on diadromous fish migration between essential spawning and rearing habitats, and the effectiveness of mitigation measures, have received little consideration. The River Meon, UK, discharges to sea through four tophung counterbalanced tide gates. In March 2012, the gates were replaced with new ones of the same design, but with an orifice installed in two of them partly to improve fish passage. Sixty downstream migrating juvenile sea trout, Salmo trutta, were trapped approximately 4.9 km upstream of the tidal limit and tagged with acoustic transmitters in April 2011 (n = 30) and 2012 (n = 30). Tagged individuals were detected by acoustic receivers placed near the tide gates before (year 1) and after (year 2) orifice installation. Of the fish that approached the tide gates, 95.8% and 100.0% successfully passed in years 1 and 2, respectively. The speed of migration at the gates was slower than for upstream and downstream reaches, and was positively related to percentage of time the gates were open. Presence of the orifices did not influence delay. Overall, top-hung tide gates delayed sea trout migration, potentially increasing the risk of predation and energy expenditure during the vulnerable juvenile life stage.

Study highlights: •First study to quantify fish passage efficiency and delay at tide gates. •Smolt passage past the tide gates was high. •Smolts migrated slower through the gates than surrounding river reaches. •In year 2, orifices were installed in 2 gates to increase connectivity. •Mean migration speed past the gates did not differ between years.

**Results Summary**: 25 of 30 tagged smolts survived to the study area each year. Passage efficiency at the tide gates was 95.8% and 100% in years 1 and 2. Tide gates delayed migration downstream. Orifices in the gates did not decrease the delay caused by the gates. The proportion of time the gates were closed was the most significant factor in migratory delay. Of the time that each fish spent in the tide-gated reach the proportion of time that was night was also significant.

**Broad Outcomes**: Tide gates delayed migration downstream. Orifices in the gates did not decrease the delay caused by the gates. The proportion of time the gates were closed was the most significant confounding factor in migratory delay.

**Detailed Outcomes**: 25 of 30 tagged smolts survived to study area each year. Passage efficiency at the tide gates was 95.8% and 100% in years 1 and 2.Confounding factors accounted for 19.8% above and

40.8% in the treatment reach when years were combined. In the treatment reach, the proportion of time that was night was also significant.

Effects Modifiers: River discharge was significantly lower in year 2.

**Intervention**: 2 of 4 tide gates (counterbalanced, top-hinge) were modified with the addition of a 300 mm diameter orifice which remains open during the full tidal cycle.

**Conditions**: The 4 tide gates are deployed in a row across the culvert. The orifices were installed in the outer two (end) gates.

**Study Design**: 30 smolts captured each year, acoustic tagged, released to migrate to the ocean. 6 acoustic recievers were set up to create 3 reaches, one above and two below the culvert and tide gates. Migration timing (delay) and efficiency were determined. Water conductivity, T, pressure, and barometric pressure were measured above (2012) and below (2011, 2012) the tide gates. Tide gate angle and upstream river discharge were also recorded. Migration time = distance between receivers/time between first detections. Mean discharge (Qfish) and T (Tempfish) in each reach, along with % time gates were open (GO%), and % night (N%) were calculated for each fish.

**Statistics**: Kolmogorov-Smirnov for normal distribution, Bonferroni correction applied to Qfish and Tempfish for subsequent pairwise comparisons. Multiple regression to explored speed of migration and FL, Qfish, Tempfish, GO%, N% in reaches A & B when combined and within a year. Used t-tests to test influence of tide gate postition and time of day on migration speed, and to compare upstream and downstream conductivity and water T.

**Comments**: This paper is not from the PNW, but may be helpful. It shows that fish passage orifices do not decrease the migration delay caused by tide gates for outmigrating juveniles. There is a companion paper focused on adults.

G.V. Wright, R.M. Wright, B. Bendall, and P.S. Kemp. 2016. Impact of tide gates on the upstream movement of adult brown trout, <i>Salmo trutta</i> . Ecological Engineering 91(June): 495–505.				
Keywords: tide gate removal salmon	<b>Type</b> : Peer-reviewed journal article		Publication Date: 2016	
Include: Yes	Reason:		Relevance:	
<b>Location &amp; Species</b> : River Stiffkey UK; Brown trout, anadromous for trout		Ecosystem(s):	river	
Reference Source:				

Abstract: Tide gates, used to regulate tidal flow as part of land reclamation programmes, temporally block fish movement by closing during the flood tide. Their impact on the upstream movement of brown trout, Salmo trutta, and other fish species has received little consideration. The River Stiffkey, UK, discharges into the North Sea via three top-hung tide gates, one counterbalanced (Gate 1), and two not (collectively referred to as Gate 2). Three-hundred adult trout were caught between 0.5 and 6.0 km upstream from the gates on 20 separate days between July and December 2011 (n = 15 per day) and implanted with 23 mm half-duplex Passive Integrated Transponder (PIT) tags before being released 15 m downstream from Gate 1 where PIT antennas were located on either side. Overall, gate attraction (percentage of fish released that were detected by at least one antenna) and passage efficiencies (number of fish that passed Gate 1 reported as a proportion of those that approached) were 96.7% and 92.4%, respectively. The operation of an orifice, installed to improve connectivity for adult trout and juvenile eels, did not influence passage efficiency or delay. Of the fish that passed Gate 1 when the orifice was operational, 42.6–55.7% approached the orifice entrance and 70.6–92.3% of these passed through. Individuals that passed through the orifice were larger than those that did not. Movement past the tide gates (median duration = 6.04 h) took 6 times longer than passage through two unimpeded reaches upstream. Duration of passage through the gates was predominately related to the mean angle of gate opening during the time prior to passage, followed by water temperature. Overall, a counterbalanced top-hung tide gate delayed the upstream movement of brown trout, highlighting a need to assess and potentially mitigate the impact of gates with more restrictive opening apertures and durations.

Study highlights:

- Diadromous fish passage at tide gates has received little consideration.
- Upstream adult brown trout, Salmo trutta, passage at a tide gate was high.
- Adult trout moved 6 times slower past the gate than through unimpeded river reaches.
- An orifice modification did not improve passage or decrease delay.
- Smaller gate apertures and higher temperatures were related to longer passage times.

**Results Summary**: Migration speed was 6 times slower in the tide gate reach than in upstream unimpeded reaches. The orifice did not improve attraction, passage efficiency, or delay. Larger fish used

the orifice when it was available. No fish passed through the orifice when the tide gate was closed. The time to pass the gate was negatively correlated with temperature downstream, temperature upstream, and discharge.

**Broad Outcomes**: Migration speed was 6 times slower in the tide gate reach than in upstream unimpeded reaches. The orifice did not improve attraction, passage efficiency, or delay. Larger fish, on average, used the orifice. No fish passed through the orifice when the tide gate was closed.

**Detailed Outcomes**: 290 of 300 PIT tagged trout were detected at least once. 251 passed through Gate 1 (91.6% efficiency). Fish had no apparent preference for passing at flood or ebb tide stage. Fish made a median of 8 approaches (no difference with orifice status). No fish returned downstream after passage. More fish passed at night. Fish that used the orifice were larger than those that passed at the gate when the orifice was open. No fish used the orifice when Gate 1 was closed. Gate angle during each fish's passage time had the most influence on passage duration when the orifice was non-operational and fish specific T had the most influence when the orifice was operational. Migration speed was lower in the impeded (tide gate) reach than in unimpeded reaches upstream. Reach A migration duration did not differ between fish that passed through the orifice and those that used Gate 1. # Gate 1 approaches was positively correlated with duration of migration through Reach A, negatively correlated with angle width. Reach A passage duration was negatively correlated with with T downstream, T upstream, discharge at release.

## Effects Modifiers:

**Intervention**: A submerged fish passage orifice with a float controlled bottom-hinged flap gate was installed under tide gate 1. Tide gate 1 is top-hinged with a counterbalance weight to increase opening time and width.

**Conditions**: Some of the river discharge also flows through Tide gate 2 - two paired top-hinge tide gates operated passively.

Duration: 5 months

**Study Design**: Collected, measured (mm), weighed (g), and PIT tagged adult upstream migrant brown trout. The fish passage orifice was allowed to operate passively or was clamped shut - alternated on every 2nd tidal cycle. 6 PIT tag detectors installed in River Stiffkey lower reaches recorded movement up- and downstream. The orifice was monitored with a IR-LED video camera. Only fish passing through Gate 1 were included in analyses. Categorized fish behavior at the passage orifice. Logged condutivity, T, pressure, barometric pressure. Calculated water depth and salinity. Recorded gate opening angle, river discharge, dissolved oxygen, velocity at Gate 1.

**Statistics**: Calculated speed of migration through each reach for each fish and determined the mean opening angle, discharge, T, % of time it was night during passage through each reach. Wilcoxon signed-rank test and Friedman's ANOVA were used to test for between reach differences in migration speed, discharge, T for each fish. Assessed the influence of orifice status and environmental variables on delay in Reach A (the location of the tide gate).

**Comments**: This study is outside the PNW and focused on adults instead of juveniles. However, I think it would be a good piece of information to include. Many of the studies on juveniles assume that adults will be able to better traverse tide gated reaches and impoundments.

**Study Description**: Fisher Slough, Skagit River estuary, Washington. In 2009 barn style doors were replaced with 3 tidegates with floats to self-regulate. There are two lower submerged tidegates on the headwall. The tide gates were monitored for water velocity and depth, water surface elevation, and gate openness during water years 2012 and 2013. Monitoring results were compared to operational criteria for both flood protection and fish passage. The authors pointed out that successful floodgate operation must include monitoring of current conditions and appropriate response to achieve desired outcomes.

Location & Species: Lone Tree Lagoon, Lone Tree Creek		Ecosystem(s): supstream of a r	easonal non-natal stream natural lagoon	
Reference Source:				

**Study Description**: A culvert (no tide gate) was removed between Lone Tree Lagoon and stream and replaced with a bridge. The channel was deepened and several culverts were replaced with wider shorter versions. For 6 years fish were sampled with beach seine, fyke net, and electrofisher and water quality was measured. Identified and counted all fish, sub-sampled length by species. Tide gauges logged water level in the lagoon. Standardized abundances between lagoon and stream and compared pre- and post-restoration.

**Results Summary**: The channel and lagoon had similar species present, and included juvenile Chinook, chum, and pink (even years). The stream catches included subyearling Chinook, coho, chum, rainbow trout, and yearling coho. After culvert replacement the standardized abundance of staghorn sculpin, chum, and shiner perch in the channel increased by orders of magnitude but that of Chinook and stickleback did not change.

<b>Reference Source</b> : http://skagitcoop.org/wp-content/uploads/FisherSlough2009Report_Final.pdf				

**Study Description**: The Fisher Slough tide gate is 3 openings in a concrete sill, each with paired sidehinge doors. The gates open and close with the tide for flood control fall, winter, and spring but are tied open in summer for irrigation. Fish passage is possible only when gates are open. Collected fish up and downstream of the tide gate. Identified fish and counted by species. Measured 20 individuals per site each sampling period. Measured water quality variables and documented substrate and vegetation. Analyzed fish density and environmental variables among sites and dates with ANOVA.

**Results Summary**: Under normal operation water level changes upstream were less extreme than downstream, mean T was similar up and downstream, and passage opportunity (gate open, water velocity low) was 49%. During irrigation operation water level changes were similar up and downstream, mean T was ~2°C higher upstream, and passage opportunity (water velocity low) was 73%. Chinook threshholds were exceeded ~5% of the time up and downstream. Wild Chinook were present up and downstream in Feb, persisted upstream until mid-July and downstream at least until Aug 12. All upstream Chinook had passed the tide gate; there are no Chinook spawning upstream of the tide gate.

Location & Species: River Emån, southeastern Sweden. Sea-run brown trout		Ecosystem(s):	freshwater river		
Reference Source:					

**Study Description**: This project focused on sea-run brown trout passage around turbines on the River Emån, Sweden. Monitoring was conducted during 2 years. Upstream migrating adults were PIT-tagged, downstream migrating smolts were tagged with radio transmitters. Monitored movement with fixed telemetry stations and PIT arrays. Two-way ANOVA tested for differences in size by sex, year, tag type. Calculated fishway attraction effeciencies for spawners with radio tags and passage efficiency with radio and PIT tags.

**Results Summary**: Most adults stopped at spawning sites below the second turbine. Median travel time between the two turbines for adults was approximately a month in both years. Fish that had previously made the spawning migration were more likely to migrate to fishways. Approximately half of the smolts migrated downstream past both turbines in each year. Losses were from turbines, predation, desmoltification. The key points seem to be that both upstream and downstream passage issues need to be addressed and that connectivity needs to be addressed holistically.

**Study Description**: Three sites were 'restored' by creating embayments or estuaries and planting riparian species. Three restoration sites and adjacent paired reference sites (linear rip-rap segments) were sampled with enclosure nets. Fish were identified and counted; salmonids were checked for hatchery origin, at least 5 of each species and origin type were measured, weighed, and lavaged (chum were preserved whole for diet). 5 additional reference sites were beach seined and fish sampled as above except all diet samples were preserved in whole fish. Measured water quality variables, analyzed diet, and modeled growth.

**Results Summary**: Fish densities were similar between restored and reference areas at the two upriver sites but lower in the restored site at the lower river location. At a given date chum were smaller than Chinook and consumed smaller prey species. Chinook diets differed between restored and reference sites. However, modeled growth rates did not differ systematically between restored and reference sites. Growth rate of co-occurring wild and hatchery Chinook varied with season and were highest during peak densities. Inartaneous ration and estimated growth rates were higher at the Turning Basin sites than at other locations. Location of restoration projects in the estuary is key to their success providing habitat and forage for juvenile salmon migrants. Coho, sockeye, pink, steelhead, cutthroat were present at low numbers but not included in analyses.

David, A.T., C.S. Ellings, I. Woo, C.A. Simenstad, J.Y. Takekawa, K.L. Turner, A.L. Smith, and J.E. Takekawa. 2014. Foraging and growth potential of juvenile Chinook salmon after tidal restoration of a large river delta. Transactions of the American Fisheries Society 143(6):1515-1529.

Reference Source: http://afs.tandfonline.com/doi/abs/10.1080/00028487.2014.945663				

**Study Description**: Dike sections were removed in 1996, 2002, 2006, and 2009 restoring tidal inundation to 364 ha. Sampled 2006 and 2009 restored and 2 reference sites, 1 channel per site. T was logged. Fish were collected Apr-Jul, counted by species, and diet analyzed for up to 10 hatchery and 10 natural-origin Chinook. Stomach contents were weighed, and sorted by taxa (each counted and weighed). Fish density was calcuated for each site. Diet similarity was calculated and regressed against time since restoration. Stomach fullness, daily ration, diet energy density, and fish energy density were calculated. A growth potential (g/g\*d) bioenergetics model was run with consumption, energy density of diet and fish, fish mass, and temperature as inputs. Of the model inputs only gastric evacuation rate was derived from literature values while the rest were based on measurements from fish collected in the sample area.

**Results Summary**: Chinook were the most often collected salmonid. Other salmonids were collected seasonally (chum and pink), or rarely (coho and cutthroat). Chinook density differences between restored and reference channels decreased through time but density remained higher in reference channels, especially during May and Jun. The energetic density of the diet decreased with increasing fish density. Diet similarity between restored and reference channels increased with time since restoration. Bioenergetics modeling indicated that the potential for growth was similar in the restored and reference channels after the first year post-restoration. However, the increased temperature range in the restored channels led to larger potential growth ranges and indicated that channels in the restored marshes had not reached reference conditions.

Diefenderfer, H.L., A.M. Coleman, A.B. Borde, and I.A. Sinks. 2008. Hydraulic geometry and microtopography of tidal freshwater forested wetlands and implications for restoration, Columbia River, U.S.A. Ecohydrology and Hydrobiology 8(2): 339-361.

Reference Source: http://fulltext.	study/download/4	388250.pdf		

**Study Design**: Restoration sites: culvert installation(tide gate removal) or dike breaching - intended to restore flows and forest cover. Marsh mitigation: tide gate replacement - enhance hydrologic connectivity and still control flooding for airport. Measured sediment accretion, water level, and elevations along cross-section transects. Cross-sections represented areas closest to, farthest from restoration point and a point between the two. Calculated cross sectional area. Derived contributing catchment area and total channel length in network for inundation. Calculated topgraphic roughness of the floodplain surface and area-time inundation index.

**Results Summary**: Hydrological reconnection immediately influences inundation frequency and areatime. Channel density was similar between restoration and reference sites. Most change in channel cross-section and incision was at the mouth. Catchment area, channel length, and cross-sectional area at outlet were correlated in reference but not restoration sites. From the analyses it is difficult to determine differences between dike breach, culvert installation (tide gate removal), and tide gate replacement (top hinge with side hinge) because restoration sites were grouped.

Diefenderfer, H.L., A.B. Borde, and V.I. Cullinan. 2013. A synthesis of environmental and plant community data for tidal wetland restoration planning in the Lower Columbia River and Estuary. <b>Reference Source</b> : http://www.pnnl.gov/main/publications/external/technical_reports/PNNL-22667.pdf				

**Study Description**: Data from 55 studies was combines and reanalyzed to describe plant community composition and hydrologic change after restoration. Summarized data on plant communities and distribution, non-native species, transect slope, hydrologic regime, sediment accretion, temperature, channel morphology and inundation. The results are organized to provide guidance to those planning restoration projects so that measures can be taken to increase project success. Determined if wetland metrics were related to disturbance level.

**Results Summary**: Elevation and inundation are related. Within an estuary zone elevation can serve as a proxy for inundation. Vegetation data is organized to show the horizontal and vertical distributions and to provide data on whether each species is native, its wetland status (facultative, obligate), and whether it is invasive/weedy. Transect slope did not differ among wetland types and was not related to plant community metrics. Sediment accretion did not differ with estuary zone or weland type. Water temperature differed with rkm in some years and some seasons. Morphology and inundation did not differ except between tributaries and mainstem for inundation. Marsh elevation and proportion of low marsh differed among disturbance categories. Sediment accretion and grain size did not differ among disturbance categories.

Reference Source: https://walrus.wr.usgs.gov/reports/reprints/Ellings_RE24.pdf				

**Study Description**: This study focused on marshes with dike removals in 2006 and 2009. Measured channel morphology, tidal inundation, and water quality variables. Fish were identified, counted, 10 individuals of each species were measured (mm). Hatchery had 95% mark rate so all unmarked fish assumed natural origin. Calculated index of fish use for each site - proportional presence - number months fish present at site relative to number of sampling months fish present in the delta for fyke net data. Calculated mean catch per set by month across all sites for beach seine data.

**Results Summary**: The time that marsh habitat was available increased from 30% to 75% postrestoration. Dike removal increased connectivity, accessibility for juvenile salmon, tortuosity, and, for some sloughs, the number of connection pathways. There were no changes in channel sinuosity for major or minor channels. However, channel area, length, and edge all increased after restoration. Channel depth increased at restored sites, but to a greater degree on the west side of the river and especially at seaward and midland sites. Reference sites showed little change. Water temperature was stable at reference sites while restored sites had lower temperatures. Inland sites were warmer with larger fluctuations throughout the year. Salinity was 3ppt higher at reference sites. Natural origin and hatchery Chinook and chum were caught in restored channels during the first post-restoration sampling year. Proportional use by hatchery and natural origin Chinook was highest at the Nisqually Ref and 2009 Restoration sites. Proportional use by chum was highest at the Nisqually Ref and Red Salmon Ref sites. Catch per set was generally lowest for chum at the 2009 Restoration site and for Chinook at the 2006 Restoration site. The capacity of the marshes to support foraging and growth were not estimated.

Reference Source: http://dx.doi.org/10.1080/24705357.2016.1252251					

**Study Description**: This paper focuses on juvenile Atlantic salmon passage of sluices on River Dee, North Wales. Sluices are undershot guillotine style gates. The study was meant to ascertain local impacts of flow-control gates on behavior and survival of juveniles. Smolts were caught by fyke nets and 94 were tagged with coded acoustic tags. Six discrete receiver arrays detected tags as the fish emigrated.

**Results Summary**: A majority of fish (91% hatchery and 88.9% wild) successfully passed the gates. There was no difference between hatchery and wild fish in the control or gate reaches. Fish preferentially passed at night. Migration speed was positively influenced by flow and by the gate opening apertures. Fish origin and size, and temperature did not influence migration speed. Migration speed was delayed by the presence of the sluice gates.

Reference Source: https://www.nwfsc.noaa.gov/assets/11/7388_06272014_140450_Greene.and.Beamer.2012.pdf				

**Study Description**: A large-scale effort to restore Skagit delta habitat was begun in 2000. These 7 projects represent >750 acres restored. They have fulfilled ~10% of the restoration called for in the Skagit Recovery plan. Juvenile Chinook were sampled in freshwater, blind channel, shoreline, and subtidal habitats. Estimated abundance and density for resident and migrant fish. Investigated 3 density-dependent relationships: tidal delta density vs total migrants, delta fry size vs total migrants, shorline cumulative density vs delta density. Calculated connectivity index based on distance from mainstem and channel width at sample site; compared with local density.

**Results Summary**: Fry size, outmigrant abundance, and cumulative density were density dependent. Fish density was dramatically higher and relatively stable at sites closer to the mainstem and with wider channel mouths. Local densities increased after restoration actions at two sites. At sites with low connectivity indices fish densities were low but at connectivity indices above ~0.02 fish density was relatively stable around 10,000 fish/ha. The South Fork Skagit cumulative density decreased relative to the North Fork Skagit after South Fork restoration actions, evidence of increased rearing capacity. However, the density of juvenile Chinook in the shoreline of Skagit Bay and the fry to adult return rate remained density dependent. Additional restoration efforts are needed to increase recruitment.

Location & Species: Skagit Bay and Skagit River tidal delta		<b>Ecosystem(s)</b> : intertidal and tidally-influenced freshwater river delta		
Reference Source: http://www.rco.wa.gov/doc_pages/other_pubs.shtml#salmon				

**Study Description**: The Skagit River is an Intensively Monitored Watershed, which means that several of its tributaries, sloughs, and river sections are sampled each year. Systems had been sampled for 14-23 years. Depending on the sampling area fish were collected by downstream migrant trap, fyke net (tidal delta), beach seine (nearshore), or townet (offshore). The authors calculated density and cumulative density, measured FL, and documented migrant timing. They aimed to determine the effectiveness of different restoration designs by summarizing data from projects throughout the watershed.

**Results Summary**: Projects associated with dike setback, dike breach, and fill removal had juvenile Chinook densities comparable to reference sites. Self-regulating tide gate sites had much lower Chinook densities than reference sites although they did perform better than traditional flap gates. Individual projects are contributing to overall estuary goal. As capacity increased after restoration, densities decreased and residency time increased.

<b>Reference Source</b> : http://projec Tide-Gates-Modelling-Update-D		content/uploads	s/2010/10/300174-Comox-Road-		

**Study Description**: Modeled hydrologic effects of increasing tailrace riffle elevations downstream to -0.6 or -0.4 m and installing permanent holes 40x80mm or 200x300 mm in one of three tide gates. Used graphical comparison and calibration of modelled and actual water levels.

**Results Summary**: At high flow conditions there were no differences among model simulations. At low flow conditions model outputs differed. Higher water elevations were achieved with the 200x300mm hole and were not strongly influenced by the riffle tailwater increase although the -0.4 m tailwater and 200x300 mm combination produced the highest water elevation during low water conditions. 200x300 mm hole is also large enough for juveniles and adults to pass through.

Johnson, J., J. Poirier, R. Horal, and T. Whitesel. 2007. <b>Reference Source</b> : https://www.fws.gov/Columbiariver/publications/Johnson_Tenasillahe_2007.pdf				

**Study Description**: Sampled one large and one small slough each on Tenasillahe and Welch islands. Determined tide gate opening. Recorded water T, dissolved oxygen, conductivity, pH, turbidity, water transparency. Described physical attributes of each reach. Fish were collected in fyke nets, minnow traps, crayfish traps, and beach seines. They were then identified, weighed, measured, examined for marks, and scanned for PIT tag if >60mm.

**Results Summary**: Of 100 tides, 42% failed to open the tide gate at Large Tenasillahe and the Small Tenasillahe gate was blocked shut by debris twice. Maximum daily temperature was similar in the two sloughs, but the daily minimum was lower in Welch sloughs. Dissolved oxygen was higher in Welch sloughs (always above 6 mg/L). Cover in Tenasillahe sloughs changed from woody debris and trees early to aquatic vegetation later. Welch sloughs were dominated by woody debris throughout study. Substrate was silt and sand for all sloughs throughout. Three-spine stickleback comprised >97% of the catch. 279 Chinook, chum, coho were collected. No salmon were collected in Tehasillahe sloughs, which had higher non-native percentages and lower abundances than Welch sloughs.

Johnson, G.E. (ed.) 2007. Evaluating Cumulative Ecosystem Response to Restoration Projects in the Columbia River Estuary, Annual Report 2006. PNW National Laboratory, PNNL-16561. Report to the U.S. Army Corps of Engineers, Portland District. 118 pp.

Location & Species: Columbia River estuary		<b>Ecosystem(s)</b> : Vera Slough, Young's Bay, OR - brackish marsh; Kandoll Farm, Gray's River, WA - freshwater swamp;both tidally influenced			
<b>Reference Source</b> : http://www.pnl.gov/main/publications/external/technical_reports/PNNL- 16561.pdf					

**Study Description**: At Vera Slough tide gates were replaced and at Kandoll Farm tide gates were removed. Surveyed plant community composition and cover. Measured water depth, velocity, salinity, organic carbon, inorganic nutrients, chlorophyll a, and chlorophyll fluorescence. Collected fish and prey (insects, benthos, neuston). Measured fish, checked for tags, and lavaged a subset.

**Results Summary**: Plant species increased from 27 to 41 from 2005 to 2006. Six species had cover >10% while 51% had cover <1%. Velocity did not differ with tidal cycle or water column strata. Treatment and elevation influenced plant species composition. Chinook diet was mainly insects and amphipods. Chum and coho ate mostly insects. Salmon were collected inside and outside tide gates and at reference sites. Chum were present only at small sizes early in the season. Coho were present during all sampling dates outside tide gates and at reference sites. Chinook were collected upstream of tide gates Apr-Jun. More salmon were upstream of Kandoll tide gates post restoration. Dissolved nutrients were higher at Vera than Kandoll and nitrogen:phosphate at Vera was closer to reference levels.

Johnson, J., J. Poirier, S. Ennis, and T. Whitesel. 2009. Julia Butler Hansen National Wildlife Refuge: Assessment of Fishes, Habitats, and Tide gates in Sloughs on the Mainland 2007, 2008 Progress Report. <b>Location &amp; Species</b> : Lower Columbia River estuary, Julia Butler Hansen NWR		<b>Ecosystem(s)</b> : 8 tidally-influenced sloughs, 4 gated, 4 with dikes closing them off from the Columbia R, and 2 pristine reference sloughs on nearby islands		
Reference Source: https://www.f	ws.gov/columbiari	ver/publications,	/jbh_2009.pdf	

**Study Description**: Sloughs were divided into 50- or 25-m reaches. Sample closest to the mouth, tidegate, or historic connection to Columbia R. was sampled. All slough reaches were seined. Additional reaches were selected to be spatially balanced and representative of all habitats. Fish passage potential was measured by sampling up and downstream of tide gates. Reference streams were sampled at the mouth. All fish were counted by species. Salmonids were measured, weighed, and checked for marks. Those >60mm were scanned for PIT tags. In each slough and reach environmental variables were recorded.

**Results Summary**: Reference sloughs had only native species in both years. Gated sloughs had 5/10 and 8/13 native species and closed sloughs had 6/13 and 3/9 native species in the two years. In reference, gated, and closed sloughs juvenile salmon were 19.1%, 25.8%, and 1.5% of the total catch, respectively, in 2007 and 1.5%, 5.1%, and 0%, respectively, in 2008. Temperature passed 16°C in May in most sloughs and remained high. Dissolved oxygen was lower in closed sloughs in 2008; otherwise, it was similar among slough types. In both years Chinook, coho, and chum were present. In 2008 steelhead were also collected. Reference sloughs contained 72% and 92% of the juvenile salmonids in the two years. Reference sites had more woody shrubs and woody debris both years.

Lohr, S., J. Poirier, S. Castle, B. Silver, G. Silver, J. Johnson, J.M. Hudson, J. Jolley, D. Allard, A. Hortsman, M.L. Koski, and T.A. <b>Location &amp; Species</b> : 6 miles N of Eureka, CA Tributary to Humboldt Bay Historically had coho salmon, steelhead, and anadromous cutthroat spawning populations		<b>Ecosystem(s)</b> : freshwater stream, borders tidal zone, tidal inundation in first 1700 ft. Tide gate at 600 ft is leaky so seawater moves farther upstream but all anadromous fish passage is blocked.	
Reference Source: http://www.coastalwatersheds.ca 4.pdf	a.gov/portals/0/hum	boldtbay/monit	or/docs/Hydro_McBTrush_rocky_

**Study Description**: This project was meant to improve passage for anadromous fish, especially naturally producing salmonid populations (coho and steelhead) while still providing flood protection. The tophinged wooden tide gate at Rocky Gulch, Humboldt Bay, CA was replaced with a side-hinged aluminum tide gate with an adjustable 'guillotine' auxillary door, mounted on the existing wingwalls. The restoration also included excavation of aggraded fines, reconstruction/rerouting of 2,800 ft of channel, relocating some dikes and rehabbing others, installing riparian fencing, and planting native species. The report includes a fairly detailed description of the tide gate that was subsequently replaced, and evidence and reasoning for concluding that it effectively blocked passage for migrating salmonids.

**Results Summary**: The tidal portion of Rocky Gulch was surveyed as part of a larger survey of Humboldt Bay that found coho and steelhead. However because they did not survey higher reaches they could not determine if they were produced in the system or nearby watersheds. There is a blurb about the project on the USFWS site that says coho and steelhead were found in Rocky Gulch within a year of the project completion.

Thom, R., N. Sather, G. Roegner, and D. Bottom. 2013. <b>Columbia Estuary Ecosystem Restoration</b> <b>Program: 2012 synthesis memorandum.</b> Pacific Northwest National Laboratory Report # PNNL- 21477 FINAL.

Location & Species: Lower Columbia River; coho salmon (among other species)		Ecosystem(s): tidally influenced shallow river, side channels, and peripheral embayments	
Reference Source: http://cdm16021.contentdm.oclc.org/cdm/ref/collection/p16021coll3/id/94			

**Study Description**: This is a literature review of the Lower Columbia River Estuary with 3 questions focused on juvenile salmon (migration patterns by habitat and salmon species, facors limiting salmon recovery, restoration and salmon performance) and one question focused on the estuary status holistically. It discusses the effects of a number of restoration actions in particular locations in the LCRE, including several tide gate projects.

**Results Summary**: In general, yearling coho use main channel habitat during spring and have longer residence in side channels and tributaries in winter (24-34 d) and subyearling coho used lower sections of tributary rivers. Coho did not frequent wetland channels and were only abundant in the main channel but did use side channels and tributaries in winter. Chinook were found in all habitats sampled and abundance generally increased after restoration. Increased access does not guarantee increased use. Upstream sources differ and use by migrants is often determined by proximity to the migration channel (mainstem or tributary). Tide gate replacement with more 'fish friendly' gates and systems increase water quality, inundation, and fish presence, but not to the level of ungated systems.

Reference Source: http://www.edc.uri.edu/nrs/classes/nrs555/assets/readings_06/CR_RestEcol_warren.pdf			

**Study Description**: Marshes were diked between 1900 and 1954 and restored between 1978 and 1991. Surveyed plant community composition, cover density, and shoot height. Measured soil water and surface salinity, surface elevation. Sampled macroinvertebrates, fish, macrocrustaceans, and birds. Not all restoration sites had paired or nearby reference sites. One reference site was used for 4 restored sites.

**Results Summary**: Marshes were recovering quickly or slowly (order of magnitude difference in rate). There was no relationship between recovery rate and time since restoration. Fast recovery marshes had higher water tables. Salinity did not differ among marshes. Typical fish assemblages are present soon after restoration but abundances are lower for a number of years. For birds, generalists return first while specialists return longer periods after restoration. Restoration to complete parity with reference sites may take decades and different functions and attributes have independent trajectories and rates.

Weybright, A.D. 2011. Juvenile coho salmon movement, growth and survival in a coastal basin of southern Oregon. M.S. Thesis, Dep't. of Fisheries and Wildlife, Oregon State University, Corvallis, OR. pp. 127 pp.			
Keywords: tide gate replacement salmon	<b>Type</b> : M.S. Thesis		Publication Date: 2011

Location & Species: Palouse Creek, Coos Bay, OR		Ecosystem(s): freshwater and tidally influenced streams	
Reference Source: http://www.cooswatershed.org/Publications/WeybrightAdamD2011Thesis.pdf			

**Study Description**: Over two years the authors seined fish in stream sections/habitat units. Sampling sites were described and environmental variables measured. Fish were identified and counted – a subset of the coho were PIT tagged, measured, and weighed. PIT recaptures were by seining and array readings. Movement was characterized by season and fish were classified as sedentary or mobile based on movement between reaches. Survivorship was based on PIT detections. Logistic regression examined association between winter survival and winter movement, late summer location, active channel width, late summer size, density. All models evaluated with AIC.

**Results Summary**: Most fish (>70%) were sedentary in summer, mobile in winter. Sedentary fish in summer or winter had higher winter survival. Winter survival was related to late summer distance from tide gate, late summer FL, Rkm\*FL. Dispersal was not likely associated with competition or discharge. Most reach1 (tide gate) fish moved upstream in late summer (avoiding salinity or temperature?). Growth rates higher in early summer and near the estuary.

Estuary: Coos	Name: Willanch Creek Fish Passage and Habitat Improvements		
Type: Restoration	Action: Upgrade	<b>Grant</b> #: 210-2024- 7458	<b>OWRI</b> #: 20110069
Grantee: Coos Watershed Association		<b>OWEB</b> : \$105,504 (\$48,713 on OWRI)	<b>Total</b> : \$161,956 (\$87,965 on OWRI)

**Summary**: Willanch Creek is a tributary to Coos Bay that supports coho and Chinook salmon, steelhead, and cutthroat trout. The old tide gate was top-hinged made from wood and steel I-beams. It was very heavy and only partially opened during low ebb tides and closed quickly due to its mass. This caused limited opening times and hydraulic conditions unfavorable to passage even when the gate was open. Additionally, historic land management contributed to a lack of instream large wood. A 2001 survey found that the volume of large wood, and pool depth and frequency did not meet state benchmarks. This project aimed to improve fish passage and increase stream complexity in the lower gradient spawning and rearing reaches. The tide gate was replaced with a lighter side-hinged gate equiped with a muted tide regulator. Large wood was added to improve summer and winter habitats and increase complexity. In Dec 2014 willow were planted in one section to stabilize the banks and improve fish habitat.

### Aerial Images:

**Restoration Metrics**: 2 tide gates (fish passage non-crossings) replaced or modified, 7.24 fish passage non-crossing miles

Monitoring Focus: N/A	<b>Study Design</b> : No monitoring was described. The tide gate has been visually inspected to be sure that it is functioning properly.
Parameters: N/A	Species Monitored: N/A

**Project Findings**: A 2016 inspection confirmed that the tide gate was performing as expected and the muted tidal regulator is allowing the gate to stay open for longer periods. Log placements were also found to be performing as designed by retaining bedload, providing cover habitat, and creating complex pools. Many of the sites have recruited gravel and additional woody debris. Project sites have not required any maintenance or modification.

**Lessons Learned**: Partnering with timber companies for large wood placements may require site tours with local timber placement experts for ecologically successful placements. The timber company that was willing to place wood on their property was primarily concerned with liability and damage if wood broke free and getting successful placements was difficult.

#### Data Gaps:

Project Reports: Final Completion Summary, 2015. Post-Implementation Status Report, 2016

**Associated Publications & Reports**: Coos Watershed Association. Willanch Creek Project Effectiveness Monitoring & Stream Temperature Study, 1997-2005. 2006.

Estuary: Coos	Name: North Slough Restoration Project		
Type: Restoration	Action: Upgrade	<b>Grant</b> #: 212-2022- 8872	<b>OWRI</b> #: 20150414
Grantee:		<b>OWEB</b> : \$195,514	<b>Total</b> : \$275,653

**Summary**: The North Slough sub-watershed is a tributary to the Coos River estuary. The previous tide gate was a heavy top-hinged wooden design that impeded juvenile and adult fish passage and did not permit cool estuary water to pass upstream. Several tributaries also ran through under-sized culverts that impeded fish passage. In January 2013 new lightweight tide gates with a muted tidal regulator were installed. This was intended to increase fish passage and tidal inundation. Additionally, three culverts were upgraded and four ditch relief culverts were installed to improved fish passage and reduce sediment transport to the streams. These actions will restore access to and water quality in 510 acres of marsh and ~12 miles of stream channel.

## Aerial Images:

**Restoration Metrics**: 3 culverts (passage crossings) replaced with embedded or flat culverts, 1.62 fish passage crossing miles, 1 tidegate replaced/ modified (fish passage non-crossing), 22 fish passage non-crossing miles, 4 permanent cross-drains added above stream crossings - improve surface drainage (4 road sd structures)

Monitoring Focus: N/A	Study Design: N/A
Parameters: N/A	Species Monitored: N/A
Project Findings: N/A	

**Lessons Learned**: When permitting for the culverts was submitted the fish passage criteria had changed so this aspect was redesigned in coordination with NFMS and ACOE. Being up to date on fish

passage design and permitting requirements is important.

Data Gaps: N/A

Project Reports: Project Completion Report

Estuary: Coos	Name: Coos Watershed Tide Gate Replacement Project Effectiveness Monitoring		
Type: Monitoring	Action: Upgrade	Grant #: 204-289	OWRI #: N/A
Grantee: Coos Watershed Association		<b>OWEB</b> : \$115,880	Total:

**Summary**: Effectiveness monitoring began in 2004, three years after the Larson top-hinged gate was replaced with a side-hinged gate. This project aimed to understand the function and impacts of the new tide gate compared to a top-hinged gate, describe the coho populations, and discuss the influence of the gates on water quality and habitat.

Restoration Metrics:	
<b>Monitoring Focus</b> : Tide Gate, Biological, Water Quality	Study Design: Not described
<b>Parameters</b> : Tide gate: water surface elevation upstream, downstream; open and closed cycles, duration of open cycle Habitat: temperature, vegetation surveys, limiting factors anaysis on available habitat Coho: adult weir counts, spawning ground surveys, mark-recapture, coho population abundance, total egg deposition estimates, juvenile screw traps, freshwater and marine survival	Species Monitored: Coho juveniles and adults

**Project Findings**: Tide gate: Larson gate opening time is influenced by tidal fluctuation and streamflow, and so is seasonally dependent: winter - ~3 hrs, summer - ~1 hr; Mar-May smolt outmigration gate opens once per day during spring tides. Late summer gate opened once per day regardless of tide cycle because of low inflow, complete drainage, and low sill height; Coho: Spawner estimates were 341-787 in Larson and 587-1915 in Palouse, freshwater survival was <1% for both years estimated; Habitat: in Palouse summer rearing area (T considered) is most limiting while in Larson winter rearing area is most limiting, temperature increased downstream in both creeks and limited use of lower stream reaches, especially in Palouse, which was above 70F Jul-Aug, no juvenile coho were found in either tide gate pool in summer but some moved back into Palouse pool after temperatures decreased (no mention of sampling in Larson).

**Lessons Learned**: Opening times could be increased by locking one side gate closed. Brackish backflow could be accomplished with a mitigator to hold the gate open for more of tidal cycle.

## Data Gaps:

Project Reports: Project Completion Report, 12/2006

Estuary: Coos	Name: Coos Watershed Tide Gate Replacement Project Effectiveness Monitoring		
Type: Monitoring	Action: Upgrade	Grant #: 206-244	OWRI #: N/A
Grantee: Coos Watershed Association		<b>OWEB</b> : \$80,229	Total:

**Summary**: The Larson Creek tide gate was replaced and the sill lowered 3 ft in 2001 to improve fish passage conditions and water drainage between stream and estuarine areas. Monitoring was begun in 2004, to evaluate the effectiveness of the new tide gate. In addition to monitoring Larson Creek tide gate function, CoosWA has conducted monitoring efforts of stream conditions immediately upstream of the tide gate and of coho populations in Larson and Palouse Creek.

Restoration Metrics:	
<b>Monitoring Focus</b> : Tide Gate, Water Quality (as habitat), and Biological	<b>Study Design</b> : To assess the effectiveness of the Larson Creek tide gate replacement and to monitor the production and survival of coho salmon populations in each stream. Post-project conditions at the Larson Creek tide gate were compared to conditions at the Palouse Creek tide gate in order to assess potential differences between side- and top-hinged tide gate structures. Palouse Creek tide gate is assumed to be representative of pre-project conditions at the Larson Creek tide gate.

<b>Parameters</b> : Tide gate: water surface elevation upstream, downstream; open and closed cycles, duration of open cycle Habitat: salinity, aquatic vegative cover, water velocity, water temperature; amount of existing habitat Coho: adult weir counts, spawning ground surveys, mark-recapture, coho population abundance, total egg deposition estimates, juvenile screw traps, freshwater and marine survival	Species Monitored: Coho juveniles and adults
--	--

**Project Findings**: Tide gate: Larson gate generally opens twice daily but this influenced by tidal fluctuation and streamflow, duration of opening seasonally dependent: winter - 3+ hrs, summer - <90 min, and driven by streamflow. Opening frequency and time were higher during spring tides. Habitat: after replacement salinity was higher and velocity lower than before and Palouse 2008, pre-replacement patchy eel grass beds and algae present, post-replacement rushes, grasses, small algae patches along margins. Temperature was generally lower in Larson than Palouse and generally lower after replacement, T may reduce habitat availability especially in Palouse. Habitat in the two basins was comparable but capacity was higher in Palouse. Coho: 2001-2004 spawner counts were similar to historic levels but have since declined. Smolt abundance, freshwater and marine survival were similar in the two basins.

Lessons Learned: N/A

Data Gaps: juvenile coho distribution, utilization of reservoir habitats

**Project Reports**: Project Completion Report, 8/2008

Estuary: Coos	Name: Coos Watershed Tide Gate Replacement Project-Effectiveness Monitoring		
Type: Monitoring	Action: Upgrade	Grant #: 207-238	OWRI #: N/A
Grantee: Coos Watershed Association		<b>OWEB</b> : \$170,642	Total:

**Summary**: The CoosWA initiated Life Cycle Monitoring efforts in Palouse and Larson subbasins to augment the existing ODFW monitoring project by providing annual estimates of coho abundance and survival in lowland coastal streams. They used passive integrated transponder (PIT) technology to tag and remotely track individual fish, which complemented standard ODFW Life Cycle Monitoring procedures. Estimating coho salmon abundance and survival in Oregon coastal subbasins is an integral part of maintaining sustainable coho populations.

Restoration Metrics:		
Monitoring Focus: Biological, Water Quality	<ul> <li>Study Design: Adult population was sampled with weirs and spawning ground surveys and abundance estimated with mark recapture and area under the curve methods. Total egg depostition was estimated. The juvenile population was sampled with rotary screw traps. A portion of each catch was measured, marked, and released upstream for efficiency calculations. Abundance was estimated. Freshwater and marine survival were calculated. A portion of fish</li> </ul>	

	were PIT tagged to examine freshwater migration and habitat use and to complement survival estimates. Water quality parameters temperature, dissolved oxygen, conductivity/salinity were measured.
<b>Parameters</b> : Adult abundance, juvenile abundance, PIT recaptures and resights	Species Monitored: Coho juveniles and adults

**Project Findings**: Adult spawner abundance decreased '01-'04 and increased in '05 and '06. From lifecycle monitoring, freshwater survival was <3% for all brood years but '07 and marine survival was <2% in '04 and >6% for '07 and '08 for both creeks. Based on PIT data freshwater survival was ~30% in Palouse and 20% and 9% in Larson. Marine survival was 5% in Palouse in '05. <2% of the run returned as jacks in any year for both streams. Fish PIT tagged in tidally influenced areas moved extensively while those tagged in riverine reaches were mostly sedentary. Growth rates decreased throughout the season. Mobile juveniles' growth rates were more variable than those of sedentary juveniles.

Lessons Learned: N/A

## Data Gaps:

Project Reports: Project Competion Report, 11/2010

**Associated Publications & Reports**: Bass, A.L. 2010. Juvenile coho salmon movement and migration through tide gates. M.S. Thesis, Dep't. of Fisheries and Wildlife, Oregon State University, Corvallis, OR. 124 pp.

Estuary: Coos	Name: Coho Life History in Tide Gated Lowland Streams		
Type: Monitoring	Action: Upgrade	Grant #: 210-2071	OWRI #: N/A
Grantee: Coos Watershed Association		<b>OWEB</b> : \$169,813	Total:

**Summary**: The coho salmon Life Cycle Monitoring project in Palouse and Larson Creeks is a long term monitoring study initiated in 2004 to examine coho salmon survival, production, and habitat use in tide gated coastal lowland streams. Coastal lowland streams are critical for the sustainability of Oregon Coast coho, but it is unclear how tide gates may affect coho movement, habitat use, and survival. This project is intended to describe variations in juvenile coho life histories, including the nomad strategy, and their contribution to adult spawning populations.

Restoration Metrics: None available	
Monitoring Focus: Biological	Study Design: Adult population was sampled with weirs and spawning ground surveys and abundance estimated with mark recapture and area under the curve methods. Total egg deposition was estimated. The juvenile population was sampled with rotary screw traps. A portion of the juveniles were measured and fin- clipped for trap efficiency. Egg deposition and smolt abundance were estimated. Freshwater and marine survival were calculated. A portion of fish were PIT tagged to examine freshwater

	migration and habitat use and to complement survival estimates. Otolith microchemistry to determine fish size at migration. DNA samples taken and candidate gene analysis performed.
<b>Parameters</b> : Adult abundance, juvenile abundance	Species Monitored: Coho juveniles and adults, Chinook, steelhead

**Project Findings**: Spawner abundance decreased '01 to '04, increased to '07, and was about average in '08. Smolt abundance increased '04 to '09 and was lowest in '10. Freshwater survival was <3% except in '07 it was >6%. Marine survival varied from 1.6% to 18.2% in Palouse and 1.3% to 8.7% in Larson. Survival rates in both streams were within the ranges of other life cycle monitoring sites. PIT data: freshwater survival ~11% to >40% in both creeks, jack returns were <2% of the run in all years, marine survival was 5% in Palouse for the one year with data. Juveniles in lower reaches before their first October were considered early migrants. In '07 early migrants had the highest percent return. In summer ~3/4 of the fish were sedentary and in winter ~3/4 were mobile. In summer mobile fish were mainly in the lower two reaches. In winter mobile fish were distributed throughout the stream. Growth rate was influenced by water temperature, coho density and habitat complexity. Fish sedentary in summer or winter had higher winter survival, however, in reaches 2 and 3 no sedentary fish survived. Survival was higher for larger fish and for fish farther upstream. Total growth in the estuary was higher for estuary-rearing fish - longer time. High levels of interrelatedness were found in Larson so could not look for genetic differences in residents and nomads.

Lessons Learned: N/A

#### Data Gaps:

**Project Reports**: Project Completion Report, 10/2013

**Associated Publications & Reports**: Weybright, A.D. 2011. Juvenile coho salmon movement, growth and survival in a coastal basin of southern Oregon. M.S. Thesis, Dep't. of Fisheries and Wildlife, Oregon State University, Corvallis, OR. pp. 127 pp. Weybright, A.D., and G.R. Giannico. 2017. Juvenile coho salmon movement, growth and survival in a coastal basin of southern Oregon. Ecology of Freshwater Fish. 2017:1–14.

Estuary: Coos	Name: Coho Life History in Tide Gated Lowland Coastal Streams			
Type: Monitoring	Action: Upgrade         Grant #: 212-2044         OWRI #: N/A			
Grantee: Coos Watershed Association		<b>OWEB</b> : \$148,962	<b>Total</b> : \$307,482	

**Summary**: Coos Watershed Association's (CoosWA) coho Life Cycle Monitoring Project (LCM) is a continuation of a long-term monitoring study initiated in 2004 to examine coho salmon abundance, survival, life histories and habitat use in two tide gated coastal lowland streams, Larson and Palouse Creeks. Productive utilization of these remarkable habitat types is critical for the recoverey and sustainability of Oregon Coastal coho. Specifically, this project developed, and adapted innovative mark recapture techniques using PIT tags to monitor the coho life cycle, further evaluated over-winter rearing strategies in relation to temporal and spatial habitat use and continued project effectiveness monitoring in these study streams. In addition, coho diet analyses were designed and conducted and will be analyzed in relation to seasonal and diurnal variations in environmental factors in order to assess proximal causes of habitat productivity.

Restoration Metrics: None available	
Monitoring Focus: Biological	<b>Study Design</b> : To determine the extent to which tide gates alter the trophic ecology of juvenile salmonids and how they affect coho ontogeny life cycle monitoring was completed in Palouse and Larson creeks. Spawner surveys and abundance estimates were completed. Outmigrant trapping allowed smolt estimates. Used PIT tags to assist

	with population estimates and efficiency calculations.
<b>Parameters</b> : spawner surveys, outmigrant trapping, female ratio, calculate adult spawner population (AUC estimates), egg deposition estimates, marine and freshwater survival estimates	Species Monitored: Coho juveniles and adults

**Project Findings**: Palouse Cr freshwater survival followed the same pattern as Larson Cr and other LCM sites in the Coos River watershed. Marine survival was variable with some years below 7% and others 13-18%. Larson Cr freshwater survival was variable, and closely tracked the survival at other LCM sites. Marine survival was 1-10% and within the range of other Coos watershed LCM sites. The pattern of survival was similar that that of the Smith River LCM site. Fork length distribution provided evidence for two age classes. Fish size distribution was similar in freshwater and brackish habitats. Adult spawner estimates vary up and down, a few years in each direction following the same pattern as other Coos LCM sites, especially Smith River.

**Lessons Learned**: Female coho spawner number is inversely related to smolt abundance - suggests density dependence. Screw traps are difficult to use in these creeks because of sandstone geology. Low capture rates lead to abundance estimates that may not accurately reflect the population. Future sampling will couple screw traps and PIT antennas. NOAA has increased the min size for 12mm PIT tags; this may affect long term data sets - 8mm tags have lower detection.

Data Gaps: 3000-4000 smolts need to be PIT tagged to estimate smolt to jack survival successfully

**Project Reports**: Project Completion Report, 3/2015, and Final Completion Summary

**Associated Publications & Reports**: Nordholm, K.E. 2014. Contribution of subyearling estuarine migrant coho salmon (Oncorhynchus kisutch) to spawning populations on the southern Oregon coast. M.S. Thesis, Dep't. of Fisheries and Wildlife, Oregon State University, Corvallis, OR. 81 pp.

Estuary: Coos	Name: Coho Life History in Tide Gated Lowland Coastal Streams 2014-2016			
Type: Monitoring	Action: Upgrade         Grant #: 214-2031         OWRI #: N/A			
Grantee: Coos Watershed Association		<b>OWEB</b> : \$145,361	<b>Total</b> : \$248,657	

**Summary**: Coos Watershed Association's (CoosWA) coho life history in tide gated lowland coastal streams, a life cycle monitoring (LCM) project, adapts and advances a long-term monitoring study initiated in 2004 to explicitly examine coho salmon abundance, survival, life histories and habitat use in tide gated coastal lowland streams. Evidence from this project and across the range of coho strongly indicates that connectivity in diverse and dynamic tidal habitats provides alternative rearing pathways critical for the sustainability and recovery of Oregon Coastal (OC) coho stocks. Specifically, this project reestablished innovative PIT tag mark recapture techniques to monitor coho movements and migrations. Temporal and spatial components of over-winter rearing strategies, in relation to habitat use and project effectiveness monitoring, is the focus in these paired study streams. Notably, monitoring was shifted to Willanch Creek from Larson Creek. Juvenile coho diet analyses revealed seasonal and diurnal variation in foraging strategies between early migrating sub-yearlings and yearling smolts across their range in estuarine habitats. These results reveal the fundamental mechanisms that promote increased juvenile coho growth and survival in the estuarine ecotone. In conjunction with prior and current data, results highlight the critical importance of these diverse habitats for recovering viable OC coho populations.

Restoration Metrics: None available	
Monitoring Focus: Biological	Study Design: Assess the effect of tide gates on
	habitat characteristics and the consequences for

	juvenile coho ontogeny, and the extent to which tide gates alter trophic and migratory ecology. Palouse (top-hinge) and Willanch (side-hinge muted tide regulator) creeks were monitored. Installed gate angle sensors, pressure transducers inside and outside, water quality sonde, HDX PIT array at Willanch. PIT array provides mark-recap closure and monitors juvenile migratory behavior. Switching to Willanch from Larson diminishes the long-term tracking ability but increases sampling ability - Larson was not completely accessible because of landowner restrictions.	
<b>Parameters</b> : spawner surveys, adult abundance (AUC) estimates, female ratio, egg deposition estimates, juvenile outmigrant trapping and tagging, juvenile abundance estimates, freshwater and marine survival	Species Monitored: Coho juveniles and adults	
<b>Project Findings</b> : Willanch data set shorter but tracks other Coos River systems at lower levels. Palouse peak spawner counts are influence by ocean conditions in the north Pacific - PDO, NPGO. Palouse fry and smolt estimates were lower in 2016 than 2015. Willanch fry and smolt estimates were both higher in 2016 than 2015. Palouse marine survival oscillated between high and low values. Freshwater survival was generally <5% with the exception of 2007, which was above 20%. No estimates could yet be made for Willanch Cr. Growth rates from PIT data for periods longer than 30 days show a growth rate reduction and then recovery at interval times >90 days for both length and weight. Juveniles residing in the stream-estuary ecotone exist in stressful conditions but they have increased growth rates relative to upstream rearing fish.		
<b>Lessons Learned</b> : all equipment should be securely anchored to withstand high water conditions and to deter theft		
<b>Data Gaps</b> : Winter habitat usage and growth are not measured because of seasonal sampling difficulties		
Project Reports: Project Completion Report, 12/20	16 and Final Completion Summary	

Estuary: Coos	Name: Coho Life History in Tide Gated Lowland Streams 2016-2018			
Type: Monitoring	Action: Upgrade         Grant #: 216-2068         OWRI #: N/A			
Grantee: Coos Watershed Association		<b>OWEB</b> : \$139,441	<b>Total</b> : \$273,621	

Summary: This project is a continuation of a long-term monitoring study initiated in 2004 to examine coho salmon survival, life histories and habitat use in tide gated coastal lowland streams. The objectives of the proposed project are to 1) obtain robust freshwater and marine survival estimates for coho salmon that can calibrate limiting factors models and identify habitat and or life history bottlenecks, 2) monitor migratory patterns, survival and growth rates of coho salmon populations in lowland stream systems where restoration projects have improved habitat connectivity. 3) Assess fish utilization and passage through a state-of-the-art tide gate in Willanch Creek in comparison to similar previous efforts of this project (Bass et al. 2012). Objective 1 expands ODFW Coho Life Cycle Monitoring sites from seven to nine and enhances the ability to identify trends in coho survival and abundance by adding critical data from productive tidal lowland coastal streams. Objective 2 will characterize habitat use by juvenile salmonids within the lower tidal and upper freshwater reaches of lowland coastal streams. Continuous mark-recapture methods will more fully elucidate seasonal variability and proportional utilization of the freshwater and estuarine rearing life histories previously characterized by this project and others. This monitoring strategy will also provide ongoing assessment of the effectiveness of past and current restoration projects and identify future potential restoration needs. Objective 3 provides critical baseline information for ODFW on fish passage statutes (HB 3002: 2001). Connectivity of rearing and migratory habitats within and between subbasins has been identified as the limiting factor in these systems. Restoration in the tidal ecotone is presumed to strengthen population resiliency in light of continued habitat alteration and climate change and associated interactions.

Restoration Metrics: None available			
<b>Monitoring Focus</b> : This project is a continuation of a long-term monitoring study initiated in 2004 to examine coho salmon survival, life histories and habitat use in tide gated coastal lowland streams. The tidal ecotone habitats of these streams are critical for the sustainability of Oregon Coastal coho.	<b>Study Design</b> : This project uses continuous PIT tag mark-recapture methods to monitor coho life cycles, to evaluate over-winter habitat use and for project effectiveness monitoring in Palouse and Willanch Creek subbasins.		
<b>Parameters</b> : Gate open duration and water velocities (i.e., fish passage criteria). Effects of MTR tide gates on water quality (salinity, temperature). Freshwater and marine growth and survival rates for coho salmon. Freshwater rearing habitat quantity and quality. Adult and juvenile fish abundance and distribution.	<b>Species Monitored</b> : Coho juveniles and adults, Chinook, steelhead

Estuary: Coquille	Name: Coquille Valley Wetland Conservation and Restoration Project/ China Camp Creek/ Winter Lake Restoration		
Type: Restoration	Action: Upgrade	<b>Grant</b> #: 215-2000- 11256, 211-115-10755	OWRI #: N/A
Grantee: Beaver Slough Drainage District		<b>OWEB</b> : \$2,626,604	<b>Total</b> : \$3,422,854

Summary: The project area is located in the Coquille River Estuary, approximately 3 miles west of Coquille, Coos County, Oregon. The area has been diked and drained for agricultural purposes for nearly a century. The Beaver Slough Drainage District was formed in 1906, and encompasses over 1,700 acres of tidally influenced land. The tide gate structures are reaching the end of their design life and the drainage district has developed a project to allow access for native migratory fish and restore wetland habitat while providing agricultural uses. The project will replace a metal culvert and wooden tide gate with a concrete box and aluminum tide gate structure. The project area will be divided into three parcels, two of which will be managed for agricultural activity and the center one for wetland habitat and restoration. The central parcel will be isolated with a berm and each parcel will have dedicated side-hinge tide gates. The Winter Lake restoration project is the result of long term collaboration between the Beaver Slough Drainage District, The Nature Conservancy, Oregon Department of Fish and Wildlife, China Camp Creek Gun Club and other public and private stakeholders. The project has the opportunity to build resilience and balance between agricultural use of historic tidelands and restoration of tidal wetlands to benefit Coho salmon and other wetland dependent species. The project has a detailed monitoring program to measure the ecological changes and evaluate the effectiveness of the effort, OWEB funds will be used for the completion of the infrastructure. This project is a continuation of grants 215-2000 and 211-215.

Restoration Metrics: Not available		
Monitoring Focus: Biological	<b>Study Design</b> : In the spring and summer the outer parcels will be managed for flood protection and drainage. In the winter the entire area floods and creates one large lake.	
<b>Parameters</b> : spring and summer channel connectivity, fish passage, off-channel rearing habitat, and forested wetland habitat	Species Monitored: coho	
Project Findings: In progress.		
Lessons Learned: In progress.		
Data Gaps: In progress.

Estuary: Coquille	Name: Ni-les'tun Tidal Marsh Restoration, Bandon Marsh National Wildlife Refuge		
Type: Restoration	Action: Removal	<b>Grant</b> #: 210-2032- 7450	<b>OWRI</b> #: 20140361
Grantee: Ducks Unlimite	d	<b>OWEB</b> : \$893,365	<b>Total</b> : \$2,588,169.58

**Summary**: The Coquille River Estuary has lost the highest proportion of marsh habitat of any in Oregon. Dikes and tide gates have contributed to wetland loss. The Ni-les'tun Unit of the Bandon Marsh National Wildlife Refuge is 582 acres and was established in 2000 to protect and restore intertidal marsh, freshwater marsh, and riparian areas, provide habitats for migratory birds and songbirds, and to restore intertidal marsh habitats for anadromous fish such as steelhead, cutthroat trout, and chum, Chinook, and coho salmon. Restoration completed in 2011 increased Coquille River estuary tidal marsh habitat by 400 acres. Restoration involved removing levees and three tide gates, discing and filling ditches, constructing sinuous tidal channels, increasing culvert size, reconnecting small coastal streams, large wood placements, native plantings, non-native and invasive vegetation control, and power line relocation. This project is described as the largest of its kind in Oregon, with multiple partners. OWEB funded vegetation and tidal hydrology monitoring (next two entries in this appendix); USFWS funded pre- and post-project fish monitoring (see Silver et al. 2015, Appendix A).

Aerial Images (see 2 pages subsequent).

**Restoration Metrics**: 418 estuarine acres improved by channel modification, estuarine connection restored to 418 acres by dike/ berm removal/ modification

<b>Monitoring Focus</b> : No monitoring under this restoration grant. Monitoring funded separately.	Study Design: N/A
Parameters: N/A	Species Monitored: N/A

**Project Findings**: Effectiveness monitoring indicated that the vegetative cover was moving toward native-dominated tidal marsh communities. Additionally, marsh use by native fish and aquatic invertebrates, and migratory shorebirds and waterfowl increased. Hydrology and channel morphology have also become more similar to reference conditions. Full tidal exchange has been restored. Tidal marsh function indicators are approaching or within the range of conditions at reference sites.

**Lessons Learned**: The potential to create mosquito breeding areas should be considered during the design phase, and will depend on the speicies present. 80,681 linear feet of tidal channel were excavated to alleviate water retention caused by restoration activity. A high priority should be placed on effective distribution of channels to provide adequate drainage for all areas of the site. Develop cost contingencies to support unexpected issues.

Data Gaps:

NOTE: This report summarizes USFWS-funded fish monitoring.

Ni-les'tun Tidal Marsh Restoration – Before (5/26/1994):

Ni-les'tun Tidal Marsh Restoration – After (5/21/2015):

Estuary: Coquille	Name: Ni-les'tun Tidal Wetland Restoration Effectiveness Monitoring		
Type: Monitoring	Action: Removal         Grant #: 210-2032         OWRI #: N/A		
Grantee: Ducks Unlimited		<b>OWEB</b> : \$150,234.5	<b>Total</b> : \$150,234.5

**Summary**: The final completion summary stated that the effectiveness monitoring project will determine rates of juvenile salmonid use within a) the three 6th field sub-basins and b) the complex (wood) and non-complex habitats located within the 430 acre Coquille River/Ni-les'tun restoration unit. Physical 'controlling factors' ('ecosystem drivers') and resulting biological characteristics that create desired wetland functions will be monitored. Ecosystem services provided, such as carbon sequestration in soils (tons), wildlife habitat (acres), and native plant community support (acres) will be quantified. Baseline data will be compared to post-restoration data to document restoration trajectory. The 'controlling factors' which structure the wetland and create valued biological functions will be tracked, including tidal inundation, groundwater hydrology, soil salinity, and soil organic mattter. Survival of woody plantings will be measured. However, in this project year only tidal hydrology and emergent vegetation were monitored. The only post-project fish focused monitoring was done in 2013 and is included in the following reference.

Restoration Metrics: None available		
Monitoring Focus: Water Quality, Biological	Study Design: Logged tidal hydrology for 1 year in 2010-11, 2012, 2013, and 7 mos in 2015. Compared the data to 2009 pre-restoration data. Calculated % inundation and daily water level maximum for 2009, 2013, 2015. Single plant community composition sample in 2010, 2013, and 2015. Measured % cover within 30x150 ft	

	permanent plots (14 restoration, 4 reference). Summarized data with NDMS. Mapped area of each plant community over the entire restoration site using high resolution aerial photography and field truthing. Mapping was not done at the reference site in 2015 because field recon showed no changes since 2013. Surface elevation measured along transects in 2011 and 2015.	
<b>Parameters</b> : Percent inundation, daily maximun water level, transect elevation, groundwater hydrology, soil salinity, soil organic matter, Plant community: species richness, total percent cover, and native and non-native percent cover, woody planting survival Ecosystem Functions: quantify carbon sequestration in soils (tons), wildlife habitat (acres), native plant community support (acres)	<b>Species Monitored</b> : Vegation community composition	
<b>Project Findings</b> : Daily max water levels were similar inside and outside and inundation and exchange were restored at even the two highest elevation transects in the restoration site by 2015. Surface elevations were higher in the restored and reference marsh in 2015 (post) than in 2011 (pre). Elevation change was similar between marshes. Species richness was lower at the restoration site and did not change at the reference site post-restoration. Percent cover (total, native, non-native) did not differ between sites or among years. However, salt-tolerant plants were increasingly present. Native-dominated communities increased and non-native-dominated communities decreased from 2013 to 2015. The large changes in specific salt-tolerant early colonizers suggest that the plant community is not yet close to a stable state. Additional evidence: spatial distribution seemed based on individual plant tolerances rather than clear zonation. Elevations at specific transects increased an average of 4.9 cm (restored) and 3.6 cm (reference) post-restoration. NMDS showed that restoration plant community was moving toward a low salt marsh community as found at the reference site.		
Lessons Learned:		
<b>Data Gaps</b> : Results are not conclusive on the recovery of the estuary marsh in terms of fish use, fish habitat opportunity and capacity, prey availability, forested wetland plant communities, channel morphology, salinity, water temperature, groundwater, and soils.		
Project Deports Vear 4 Dest restaration (2015) 2/	2016	

Project Reports: Year 4 Post-restoration (2015), 2/2016, revised 12/2016

Estuary: Coquille	Name: Ni-les'tun Tidal Wetland Restoration Effectiveness Monitoring		
Type: Monitoring	Action: Removal         Grant #: 212-2068         OWRI #: N/A		
Grantee: Ducks Unlimited		<b>OWEB</b> : \$157,117	Total:

**Summary**: This report describes the results of effectiveness monitoring at the Ni-les'tun tidal wetland restoration site, Bandon National Wildlife Refuge, Coquille River estuary, Oregon. The monitoring described in this report was conducted during 2013, which was the 2nd year after the site's dikes and tide gates were removed, restoring tidal flows to the site. Effectiveness monitoring was designed to determine whether the project is meeting its goals, and to provide information to help guide other restoration projects. The results and 'lessons learned' through monitoring at this landmark project are already helping to advance restoration science at many projects in Oregon, the Pacific Northwest, and beyond.

Restoration Metrics: N/A			
Monitoring Focus: Water Quality, Biological	Study Design: Measured plant community composition and extent, soil carbon, salinity, and pH, groundwater levels, surface water salinity and temperature. Estimated amount of habitat available to juvenile salmonids. Sampled benthic macroinvertabrates (abundance by taxon, taxon richness, S-W diversity index, community structure index) at one restoration sub-basin. Determined habitat use by juvenile fish and movement into and out of the estuary.		

Parameters: N/A	Species Monitored: Benthic macroinvertabrates,
	Chinook, Pacific staghorn sculpin, three-spine
	stickleback (3 most abundant species).

**Project Findings**: Post-restoration tidal exchange was restored and tide height closely resembled mainstem. Channel morphology changed slightly - channels deepened, fine sediment increased, downcutting began in lower reaches. %cover and %non-native cover and species richness decreased. Pasture grass had died back and plant community was moving toward reference site. Soil salinity and %C increased, maybe caused by evaporation and plant die-back. Groundwater level and amplitude of fluctuation increased. Channel salinity increased; temperature was more similar to reference. Fish access to the channels increased from 2% to 27%. Benthic macroinvertabrate abundance increased and diversity decreased - dominated by Corophium. Mean peak CPUE in the restoration site was lower than reference pre-removal and higher post-removal for Chinook, staghorn sculpin, and was higher in the restoration site pre- and post-removal for stickleback. Restoration significantly affected chinook and sculpin. Peak migration increased in the 3 restoration subbasins, but not in the reference site. Increased resilience to climate change and ability to moderate flooding.

**Lessons Learned**: Restoration site was historically high marsh so used high marsh transects at reference site but restoration site has undergone subsidence and is currently in the low marsh elevation range. Non-excavated (natural) channels at restoration site were not sampled prior to restoration. Changes in individual channel cross-sections are not testable. Pre-and post: channel width and width:depth could not be compared because field methods differed.

Data Gaps:

Project Reports: Year 2 Post-restoration (2013), 7/2014, revised 5/2016

**Associated Publications & Reports**: Brophy, L. and S. van de Wetering. 2012. Ni-les'tun Tidal Wetland Restoration Effectiveness Monitoring: Baseline (2010-2011).

Estuary: Lower Columbia	Name: Thousand Acres Floodplain Restoration Project		
Type: Restoration	Action: Removal	<b>Grant</b> #: 214-3032- 10845	<b>OWRI</b> #: 20150139
Grantee: Lower Columbia Estuary Partnership		<b>OWEB</b> : \$82,566	<b>Total</b> : \$682,879

Summary: The Thousand Acres site is located on USFS land and is part of the 1,500 acre natural area at the confluence of the Sandy and Columbia rivers known as the Sandy River Delta in the lower Columbia River estuary. The site was historically a dynamic alluvial floodplain with two distributaries of the Sandy River flowing across it and a mosaic of bottomland forests, wetlands and meadows. This area provided valuable habitat for many species, including rearing and refuge habitat for juvenile salmon. A combination of river flow regulation and human manipulation of natural hydrology at the site resulted in the disconnection of the floodplain channels, ponds, and wetlands. The system lacked habitat complexity and was dominated by noxious non-native invasive plants. An old tide gate and water control structure between the ponds and the Columbia River were removed creating an uninhibited flow path from the bluff through to the river. Excavation in the ponds and channels expanded the wetland and off channel juvenile salmonid habitat area. Additional enhancements include recontoured slopes, large wood placements, and planting riparian vegetation on 35 acres. The project followed several years of reforestation efforts by Lower Columbia Estuary Partnership, USFS and other partners. The project restored natural hydrology and access for juvenile salmonids and reestablished the site's native plant communities. These habitat enhancements will also benefit many regionally important species of birds, amphibians and reptiles.

#### Aerial Images:

**Restoration Metrics**: 0.3 instream miles, 2 riparian miles, 52 riparian acres, 3 fish passage crossings, 2 fish passage crossing miles, 20 wetland acres, 3 culverts removed, 792 feet in 1 main channel created/

modified, 22 structures (key piece logs) placed - not anchored, 2 miles-2 stream sides-52 acres treated for non-native/ noxious plants, conifer and hardwood riparian trees planted and riparian shrubs or herbaceous vegetation planted/ reseeded, 20 wetland acres treated for non-native or noxious plant species, returned to shrub/scrub wetland, wetland vegetation planted

Monitoring Focus: N/A	Study Design: No monitoring was described.	
Parameters: N/A	Species Monitored: N/A	

**Project Findings**: The project continues to be extremely effective at increasing access, as the removal of the former passage barriers allowed unimpeded fish access to the channels and wetland vegetative communities to provide shade and cover. Large numbers of juvenile salmonids were observed above the former passage barriers each year since the project was implemented. The revegetation of the 70 acres of riparian and wetland areas was implemented at the site as well, and plants were in the establishment phase. In most areas the plantings were growing rapidly and the goals were anticipated to be met by this portion of the project as the plants continued to grow to mature height.

**Lessons Learned**: Consider additional costs when planning and budgeting, particularly for organizing, storing, delivering, and distributing plants. Bare root timing is critical because they should not dry out or be exposed to harsh weather. When excavcating, apply herbicide to germinating weeds prior to planting because it can be done with large equipment. Once plantings are done all herbicide application will need to be done by hand.

## Data Gaps:

Project Reports: Project Completion Report, 2015. Post-Implementation Status Report, 2016.

NOTE: Detailed project description, with several photos.

http://www.estuarypartnership.org/news/sandy-river-delta-thousand-acres-restoration-project-rfp-released

<b>Estuary</b> : Lower Columbia	Name: Thousand Acres Floodplain Restoration Project, Plant Establishment		
Type: Restoration	Action: Removal	<b>Grant</b> #: 214-3032- 11263	OWRI #: N/A
Grantee: Lower Columbi	Columbia Estuary Partnership <b>OWEB</b> : \$44,933 <b>Total</b> :		Total:

**Summary**: 35 acres of the Thousand Acres site in the Sandy River Delta of the lower Columbia River estuary were planted with native riparian species. Plant establishment activities began in spring 2015 and will continue until spring 2018. Maintenance includes herbicide and mowing.

## Aerial Images:

Restoration Metrics: None available		
Monitoring Focus: N/A	Study Design: No monitoring was described.	
Parameters: N/A Species Monitored: N/A		
<b>Project Findings</b> : Plantings in the lower wetland area have been very successful. Survival ranged from		

**Project Findings**: Plantings in the lower wetland area have been very successful. Survival ranged from 75% in the two drier zones to 90% in the wetter lower wetland zone. Willow plantings were growing well and on a trajectory to out compete the reed canarygrass in areas where it persisted.

**Lessons Learned**: In areas where grading was completed to expand the estuary and improve channel bank morphology it would have been ideal to add a layer of topsoil for plantings. Costs were prohibitive for this project. Awareness of post-restoration conditions and plant sensitivity is important for success of plantings. Cottonwood appears to be better adapted to harsh conditions than dogwood. During drought conditions the option to irrigate from an existing well was considered. However, it became apparent that the willow plantings were accessing enough water in the soil and irrigation was not needed. Data Gaps:

Project Reports: Post-Implementation Status Report, 2016

<b>Estuary</b> : Lower Columbia	Name: Tide Gate Effectiveness Monitoring, Columbia River Tributaries		
Type: Monitoring	Action: Upgrade	Grant #: 204-277	OWRI #: N/A
Grantee: Clatsop Coord	itee: Clatsop Coordinating CouncilOWEB: \$25,134Total:		Total:

**Summary**: This project was intended to demonstrate the effectiveness of newer 'fish-friendly' tide gates to allow passagefor rearing salmonid juveniles, collect data on water quality changes, and establish a volunteer training template.

Restoration Metrics: None available		
Monitoring Focus: Biological, Water Quality	<b>Study Design</b> : Sub-yearling salmonids were collected via fyke-net migrating out of gated tidal channels during ebb tides. Water quality measurements were performed weekly, temperature logged continuously	
<b>Parameters</b> : Fish: crew, time, species, number of fish, fish size, hatchery marks for all salmonids and a 30-ind subsample of other species; Water Quatlity: dissolved oxygen, salinity, turbidity,	Species Monitored:	

conductivity, temperature	
---------------------------	--

**Project Findings**: Fish: Barrett Slough: sampled once - no salmonids and vegetation clogged the net. Larson Slough: Stickleback dominated all samples. Mainly warm water fish were collected as well as a few Chinook and coho. These samples were from below the tide gate; very few fish were collected above the tide gate and conditions did not seem conducive (thick mud substrate). Water quality: Vera Slough: Upstream water level and tidal amplitude increased after gate replacement. Preliminary data - temperature decreasing, salinity increasing and fluxing with tides. Blind Slough: Water quality did not change significantly after replacement. Temperature above the tide gates averaged higher than below. Warren Slough and Johnson Creek (Young's Bay): dissolved oxygen are similar above and below the tide gates at both sites, and temperature is similar above and below at Johnson Creek. Once equilibrium is established there will not be large above/below changes.

**Lessons Learned**: Landowners may be reluctant to actively manage tide gates, even after cooperating on replacement. Therefore tide gate improvements are underutilized.

## Data Gaps:

**Project Reports**: Project Completion Report, 8/2007.

Estuary: Nehalem	Name: McDonald Slough Reconnection Project		
<b>Type</b> : Restoration	Action: Upgrade	<b>Grant</b> #: 215-1017- 11365; 215-1017- 11607	OWRI #: N/A
Grantee: Lower Nehalem Watershed Council		<b>OWEB</b> : \$331,365 (\$36,362 for Monitoring (ID 11607)	<b>Total</b> : \$478,551 (ODFW: \$613,370.65)

**Summary**: McDonald Slough drains into the North Fork Nehalem River and is one of the largest sloughs in the estuary. It was historically disconnected from the river by two top-hinge tide gate structures (default closed) critical to the operation of surrounding agricultural land. The structures impaired access to over 1.5 miles of spawning and rearing habitat for salmonids, including 16 acres of slough habitat, disrupted the natural hydrology and nutrient exchange, and limited tidal influence in the slough. The top-hinged gates were replaced by two side-hinged epoxy-coated aluminum gates with muted tidal regulators. The new system is default open - the MTRs keep the gates open until the inside inundation level reaches a set height. Large woody debris placements were made in four locations within the slough near the old and new gates and downstream of the new gate.

# Aerial Images:

**Restoration Metrics**: 0.5 instream miles, 1 fish passage non-crossing, 1.5 fish passage non-crossing miles, 1 tidegate replaced/ modified, 20 rootwads placed - not anchored

Monitoring Focus: Tide Gate, Water Quality	Study Design: N/A
(Project ID 11607 monitoring is focused on the	
gate that will be replaced and is occurring after	
completion of the associated restoration project)	

**Parameters**: gate duty cycles, inundation levels upstream of gate, water quality: T and salinity up and downstream

**Project Findings**: Installation of the new structure has improved access to 1.5 miles of freshwater and forested/shrub and freshwater emergent wetland habitat to benefit coho, Chinook, and steelhead. The MTR tide gates allowed for more tidal flushing resulting in greater dissolved oxygen, decreased water temperatures, and improved water quality in McDonald Slough. The new tide gate system also provided improved fish passage. The large wood placements created complex habitat within the slough and North Fork Nehalem River, providing cover, encouraging pool scour, providing hard surfaces for aquatic invertabrates, and providing additional habitat for other aquatic and terrestrial species.

**Lessons Learned**: It is imperative that project partners and permitting agencies establish a clear protocol for communication and outline expectations at the outset of a project. The federal and county permitting processes were delayed by lack of clear requirements and staff turn-over at the permitting agencies. The project was pushed back a year because the in-water work window was missed due to permitting delays. Developing an acceptable modeling approach, metrics to be evaluated, and conditions that will be accepted is key to successful permitting and project completion.

#### Data Gaps:

Project Reports: Final Completion Summary

**Associated Publications & Reports**: ODFW R & E Grant Application, 13 Biennium, Project Information: McDonald Slough Reconnection Project

http://www.dfw.state.or.us/fish/RE/projects/cycle\_13-4\_applications/13-

062%20submitted%20Application%20Dec13%20w%20attachments%20for%20web.pdf

NOTE: Detailed project background and description. Funding details differ from OWEB records -states that the project had \$578,370.65 in Match Funding (partly OWEB) for a total of \$613,370.65. OWEB docs say \$331,364.93 OWEB funding, total project cost \$478,550.93.

Estuary: Nestucca	Name: Little Nestucca River Restoration		
Type: Monitoring	Action: Removal	Grant #: 207-261	<b>OWRI</b> #: 20070106
Grantee: Ducks Unlimited		<b>OWEB</b> : \$146,691 (\$170,616?)	<b>Total</b> : \$640,697

**Summary**: [USFWS] Nestucca Bay, at 1,202 acres, is the largest refuge within the Oregon Coastal Refuge Complex. Located where the Nestucca and Little Nestucca rivers converge and debouch into the Pacific, the refuge is managed to provide wintering habitat for six subspecies of Canada Geese, including Aleutian and Dusky Canada Geese. The refuge also hosts several species of dabbling ducks, shorebirds and raptors on at least seven distinct habitat types. In 2007 an 83-acre tidal marsh restoration project was completed on the Little Nestucca River Unit of the refuge constituting a 30% increase in tidal marsh habitat in the estuary. The project is already benefiting juvenile salmonids, waterfowl and other species.

[N. Coast Citizen 3-14-2008] The area was diked and drained for agricultural use during the early 1900s and remained in pasture prior to restoration, said [ODFW Fish Biologist] Steve Pribyl. The project entailed 3,000' of levee removal and removal of two tide gates to restore full tidal inundation to the site, reconstruction of 3,700' of tidal channels, filling 2,800' of drainage ditches, and the placement of large woody material to stabilize the reconstructed tidal channels while enhancing juvenile salmonid habitat. To allow reconnection of the historic tidal channels and full tidal inundation to the west side of the project area, decommissioned Old Highway 101 was breached in three locations with each breach being excavated to a depth of 5' and a width of 55'.

In 1996 a dike breached naturally, leading to limited tidal influence. The 2007 project was undertaken to fully reestablish tidal exchange and wetland habitat over 87 acres of estuary. Two tide gates and parts of the dike were removed, the levee and an old road were breached, ditches were filled and tidal channels were excavated. Wetland use and function were monitored. Additionally, this project focused on the role of woody debris in estuaries for habitat formation and fish utilization.

Aerial Images (see next page)

**Restoration Metrics**: 0.84 instream miles, 3 fish passage noncrossings, 1.4 fish passage non-crossing miles, 82 estuarine acres, 2 tidegates removed and 1 other diversion modified, 3462 feet in 3 main channels modified/ created, 9 log weirs installed(not below culverts), 20 anchored habitat structures placed, 0.2 miles grass seeding and mulching, 10 stations(1000 ft) road effectively closed to public use, 2 stations (200 ft) road obliterated, decommissioned, or vacated, estuarine connection restored to 82 acres and .64 miles by dike/ berm modification/ removal

Monitoring Focus: Biological	<b>Study Design</b> : Vegetation was monitored using standard transects with quadrats. Plant communities were mapped over whole site. Evaluated change in plant community composition since 2001 baseline. Fish distribution was determined with seine sampling across a tidal cycle in Jun, Aug, and Oct. Tidal migration patterns were examined with underwater videography during the spring peak usage period. Macroinvertabrate distribution and abundance were described.
------------------------------	---

**Parameters**: Vegetation cover, frequency. Fish tidal migration, distribution, use of large woody debris. Macroinvertebrate abundance and distribution.

Species Monitored: N/A

**Project Findings**: 2008/2009: The amount of estuary covered by brackish tolerant plants increased dramatically post-restoration. Non-native, freshwater wetland, and pasture plant species decreased significantly. Reed canarygrass is no longer dominant but is still present at the highest elevations. The plant community was quite dynamic but on a trajectory toward typical native tidal marsh community. Fish use was significantly different post-restoration. Species composition was more similar to other marshes. Significantly more juvenile salmon were present during key rearing periods. After tide gates were removed the number of tidal migrants and the period of migration increased. Complex habitats with large wood placements had 10x more usage than non-complex habitats. Macroinvertabrate community was transitional - not similar to natural or degraded systems. 2011-2013: Native estuary plants are present over much of site. Most of the rest of the plant species are transitional brackish-tolerant. Tidal channels drained on falling tides and pools had formed around large woody debris placements. Reed canarygrass is still high density at highest elevations. In 2016: There were no noted changes from 2013.

**Lessons Learned**: There are few contractors experienced in tidal area construction, but these people/groups are very valuable for restoration projects. Providing flexibility for a good contractor can achieve design goals while saving money and improving production and product. All utilities should be moved prior to restoration activity. Full time inspection helps achieve unfamiliar restoration goals.

#### Data Gaps:

Little Nestucca River Restoration – Before (5/6/1994).

Little Nestucca River Restoration – After (8/23/2016).

Estuary: Salmon	Name: Tamara Quays Dike Removal and Fish Passage Culvert		
Type: Restoration	Action: Removal	<b>Grant</b> #: 208-1040, 208-1061-7658	<b>OWRI</b> #: 20090336
Grantee: Salmon Drift Creek Watershed Council		<b>OWEB</b> : \$232,614	<b>Total</b> : \$529,200
Summer Tomore Output was to achie here and automatic related infractive turns was			

**Summary**: Tamara Quays vacant mobile home park and extensive related infrastructure were removed. The tide gate was removed, undersized culverts were replaced with a 20' fish passage culvert. Ditches were filled, and dikes and fill removed. Reed canarygrass sod was removed and covered with landscape cloth. Some large woody debris and log jams were placed. Native tree species were planted. To discourage illegal entry by vehicles, gates, logs, and boulders were installed.

Aerial Images: (see next page)

**Restoration Metrics**: 1 fish passage crossing, 1 fish passage crossing mile, 1 fish passage non-crossing, 1.25 fish passage non-crossing miles, 13 estuarine acres, 1 culvert replaced with open bottom arch culvert, 1 tidegate removed, 8.7 acres existing estuary vegetaion planted and improved by channel modification, estaurine connection restored to 4.3 acres restored by dike/ berm removal/ modofication

Monitoring Focus: N/A	Study Design: N/A
Parameters: N/A	Species Monitored: N/A

Project Findings: N/A

**Lessons Learned**: A more thorough walk through of the site prior to plan development would have made work and equipment estimates more accurate. A chain of command for responsibilities, delineating roles and an accounting system to share cost estimates clearly organizing and managing multiple fund sources are important for partnership no-cost agreements. Communication management is time consuming but necessary. Completion celebration with contributor and partner acknowledgement was an important component.

## Data Gaps:

NOTE: Includes site history, project details, pictures, and additional "lessons learned".

Tamara Quays Dike Removal and Fish Passage Culvert – Before (5/5/1994).

Tamara Quays Dike Removal and Fish Passage Culvert – After (8/18/2016).

Estuary: Salmon	Name: Pixieland Phase 1 - Restoration		
Type: Restoration	Action: Removal	<b>Grant</b> #: 208-1061- 8288	<b>OWRI</b> #: 20110314
Grantee: Salmon Drift Creek Watershed Council		<b>OWEB</b> : \$183,815 (\$183,186 on OWRI)	<b>Total</b> : \$313,249 (\$302,886 on OWRI)

**Summary**: The Pixieland parcel of the Salmon River estuary was developed as an amusement park and then purchased by USFS as part of the Cascade Scenic Research Area. Development included dikes, a tide gate, grading, fill, non-native plantings, buildings, and roads. Restoration involved removing roads and buildings, excavating fill, removing dikes, filling ditches, removing the tide gate, and invasive plant control.

Aerial Images (see next page).

**Restoration Metrics**: 1 instream miles, 40 estuarine miles, 5280 feet in 1 main channel modified/ created, esuarine connection restored to 40 acres by dike/ berm removal/ modification

Monitoring Focus: N/A	<b>Study Design</b> : At the time of the report restoration was ongoing. No monitoring was described.
Parameters: N/A	<b>Species Monitored</b> : steelhead, chum, Chinook, coho, sculpin, cutthroat,

Project Findings: N/A

**Lessons Learned**: Cost-effectiveness of different grading equipment was examined. An excavator and dump trucks were more efficient than a scraper. Coordination between disciplines is very important. Grading equipment and fish evacuation schedules had to be timed precisely. Grading work was divided among contractors, which made oversight and scheduling difficult.

## Data Gaps:

**Project Reports**: Final Report and Accounting, 2/2012

**Associated Publications & Reports**: Brown, L. and L. Brophy. 2015. 2015 Monitoring Report: Pixieland Tidal Wetland Restoration. Prepared for Salmon-Drift Creek Watershed Council, Neotsu, Oregon. Corvallis, Oregon: Green Point Consulting, Estuary Technical Group, Institute for Applied Ecology.

Ellingson, K.S. and B.J. Ellis-Sugai. 2014. Restoring the Salmon River Estuary: Journey and Lessons Learned Along the Way 2006-2014. Report to Siuslaw National Forest, Corvallis: OR.

Pixieland Phase 1 Restoration – Before (5/5/1994)

Pixieland Phase 1 Restoration – After (8/18/2016)

Estuary: Salmon	Name: Pixieland Tidal Wetland Restoration		
Type: Restoration	<b>Action</b> : Removal and site grading, excavation	<b>Grant</b> #: 208-1061- 8321	OWRI #: N/A
Grantee: Salmon Drift Creek Watershed Council		<b>OWEB</b> : \$30,752	<b>Total</b> : \$172,152

**Summary**: Monitor the Pixieland site elevation to ensure that the grading plan is adhered to and the final desired elevations are achieved, as well as to assess pre- and post-wetland delineation. Assess vegetation changes and conduct water quality testing for temperture, dissolved oxygen, and salinity. It is uncertain whether vegetation in this area will stabilize as tidal marsh so will investigate herbaceous and woody plantings for reed canarygrass control.

## Aerial Images:

Restoration Metrics: Not available		
Monitoring Focus: Biological, Water Quality	Study Design: Vegetation was monitored using standard transects, shrub plots, and reed canarygrass control experiment plots - 4 treatments. Percent cover, percent frequency, species richness were measured. Plant community composition was evaluated using NMDS. Soil salmples were collected from transects and analyzed for conductivity (for salinity), pH, %organic matter. Salinity and water temperature were measured in a separate contract. Water depth was logged in an internal channel and the river near the creek mouth.	

**Parameters**: Vegetation cover, frequency, density. Water depth, salinity. Soil salinity. Community composition.

**Project Findings**: Vegetation performance standards: The average cover of native herbaceous plants is higher than that of invasive species in the herbaceous but not the shrub zone. Cover of invasive species (except reed canarygrass) is <10% in all habitats. The moisture index is <3.0 for all habitats. In shrub habitats native woody species are >1600 stems/acre and no invasive trees or shrubs were present. Total plant cover is moving toward reference conditions. Hydrology performance standards: Tidal exchange moves freely. Vegetation change: Plant composition was largely unchanged and comprised of native species; but decrease in Baltic rush and increase in tall-fescue (non-native). Cover of litter, wood, moss, and open space increased. In control plots opportunistic colonizers were most prominent. Ratio of native to non-native species did not differ among treatments. NMDS showed separation between years in community composition. Soils and Water Quality: Salinity was high at some reed canarygrass plots - low willow survival and large decline in reed canarygrass. Summer salinity was high (15-20 psu) in tidal channels.

**Lessons Learned**: Inundation and water levels were higher than anticipated. Resultant high salinity and failure of willow plantings in tidal marsh zone were also not anticipated.

Data Gaps:

Project Reports: Monitoring Report and Final Completion Summary, 12/2013

**Associated Publications & Reports**: Ellingson, K.S. and B.J. Ellis-Sugai. 2014. Restoring the Salmon River Estuary: Journey and Lessons Learned Along the Way 2006-2014. Report to Siuslaw National Forest, Corvallis: OR.

Estuary: Salmon	Name: Pixieland Phase II		
Type: Restoration	Action: Removal	<b>Grant</b> #: 208-1061- 8990	<b>OWRI</b> #: 20140003
Grantee: Salmon Drift Creek Watershed Council		<b>OWEB</b> : \$213,016	<b>Total</b> : \$469,516 (\$350,205 on OWRI)

**Summary**: The Pixieland Restoration project is the site of the former amusement park. Phase II of the restoration focused on hydrological connectivity. The work involved removal of the remaining infrastructure, including a large dike and a tidegate. Ditches were filled, Fraser Creek was remeandered, spruce trees were removed and used for wood placements. Native vegetation was planted and managed while invasives were controlled.

## Aerial Images: see next page

**Restoration Metrics**: 1 fish passage non-crossing, 5 fish passage non-crossing miles, 10 estuarine acres improved by channel modification, 1 tidegates removed, estuarine connection restored to 10 acres and 0.5 miles by dike/ berm removal/ modification

Monitoring Focus: Biological	Study Design: No monitoring was described.	
Parameters: N/A	<b>Species Monitored</b> : native vegetation, coho, Chinook	

## Project Findings: N/A

**Lessons Learned**: If water control devices are removed before all ground work is completed efforts must be made to keep water and fish out of the work area. A settlement curtain should be used to keep sediment from escaping downstream.

Estuary: Siuslaw	Name: Waite Ranch Tidal Wetlands Restoration: Infrastructure Demolition		
Type: Restoration	Action: Removal	<b>Grant</b> #: 212-8004- 9544	<b>OWRI</b> #: 20130356
Grantee: Ecotrust		<b>OWEB</b> : \$33,960	<b>Total</b> : \$110,635

**Summary**: The Siuslaw Basin historically was one of the most productive for anadromous fish in the Pacific Northwest. The long-term goal of the Waite Ranch Tidal Wetlands Restoration Project is to improve habitat and restore tidal exchange between the Siuslaw River and approximately 211 acres of estuarine wetlands previously altered for agricultural uses. Waite Ranch is being managed and restored to maximize ecological benefits. Agricultural ditches will be filled, meandering tidal channels excavated, the tide gate removed, and levees breached in order to reestablish natural inundation and kick-start processes that create high-quality estuarine wetland habitat for numerous fish and wildlife species. This first phase of the project was comprised of the safe and efficient removal of farm infrastructure covering ~1.5 acres, prior to ditch filling and channel excavation. It was completed in 2013.

## Aerial Images:

Restoration Metrics: 1.5 estuarine acres improved by debris removal

Monitoring Focus: N/A	Study Design: N/A	
<b>Parameters</b> : wetland area, groundwater recharge, groundwater containment, water quality	Species Monitored: N/A	
Project Findings: N/A		
<b>Lessons Learned</b> : Major cost savings were realized by hiring a local demolition company with knowledge of the site and a commitment to working efficiently. Additionally, enrollment in the local		

fire department's 'Burn to Learn' program was a cost-effective way to dispose of buildings with the added benefit of providing training opportunities for local volunteer fire fighters. If possible give preference to competent local contractors. Their intimate knowledge of the project area can result in benefits such as cost savings and positive grass roots public relations.

Ecotrust: Waite Ranch Tidal Wetland Restoration Project DATA SHARING PLAN http://www.habitat.noaa.gov/pdf/NA13NMF4630130WaiteDataSharingPlan.pdf

Estuary: Tillamook	Name: Kilchis Estuary Preserve Restoration; Kilchis Wetlands Conservation and Restoration Project		
Type: Restoration	Action: Removal	<b>Grant</b> #: 214-1034- 10974	OWRI #: N/A
Grantee: The Nature Conservancy		OWEB:	<b>Total</b> : \$1,325,246

**Summary**: [NOAA] This project will restore freshwater and tidal connections on a Nature Conservancy (TNC) acquistion located on the banks of the lower Kilchis River in the Tillamook Bay watershed. This project will remove fill from Stasek Slough, remove the Kilchis River dike, remove tidegates, elevate subsided lands, and construct tidal channels to restore the connection between Kilchis River and Stasek Slough and to restore tidal exchange to Stasek Slough. Restoration planting and control of invasive plant species will occur in tidal spruce swamp, riparian forest, and scrub-shrub tidal marsh. The removal of culverts within the dike and the removal of debris are incidental to the stream and tidal channel work. The project incorporates projected climate change impacts by designing the restoration with sea level rise and precipitation changes in mind.

The primary project purpose is to restore tidal wetlands on 66 acres in the salt-freshwater transition zone that will provide off channel habitat for salmon and steelhead. A primary limiting factor for salmonids in the Kilchis system is availability of off-channel habitat in low-lying areas, especially habitat in the salt-freshwater transition zone of the estuary. The restored habitats will benefit all salmonid species present in the Kilchis system and will represent a large percentage increase in transition zone habitats in natural condition. Spruce swamps and riparian habitats will benefit salmonids by shading streams and channels, supporting food webs for prey for fish, and serving as a source of large wood for the system. Tidal wetland habitat will provide additional cover for salmonids along tidal channels.

[TNC] After removing dikes and re-creating tidal channels, water has returned to Kilchis Estuary Preserve near Tillamook Bay. And with the water, came newfound beaver activity and spawning chum salmon— exciting to see at a marsh that had been disconnected from the tides for nearly 100 years. With channel work complete, staff is now focused on stabilizing and restoring the preserve by planting native trees and shrubs, such as Sitka spruce, Hooker's willow, twinberry and spiraea. During the next two years, the TNC hopes to plant a total of 200,000 native plants, including 120,000 willows and 8,000 Sitka spruce trees.

**Restoration Metrics**: Acres protected, acres restored, acres of potential salmonid rearing habitat restored.

Monitoring Focus	Study Design NOTE: This is an extensively studied site,
Monitoring Focus:	with numerous reports. At least some of the available monitoring data was gathered using a Before/After/Reference/Restoration (BARR) study design, comparing the Kandoll Farm site with a reference site in Seal Slough.
	[Johnson et al. 2012] Fish abundance was monitored before (2005) and after (2006–2009) tide gate removal. From 2005 through 2007, we compared the fish community inside the Kandoll Farm site to sites in Seal Slough. During 2008 and 2009, we concentrated on fish distributions at dual trap net locations within the KF wetland.
	[Monitoring history from Schwartz et al. 2013; vegetation composition, terrestrial macroinvertebrates.] The US Army Corps of Engineers' Cumulative Effects Team intensively sampled the Kandoll Farm Restoration Site in 2005 (pre-restoration),

	2006 (year 1), and 2009 (year 4). Additional metrics (and more intensive sampling of standard metrics) were also sampled in dissertation research by Heida Diefenderfer at this site starting in 2005. Kandoll Reference Site (Seal Slough Swamp): The Corps of Engineers' Cumulative Effects Team intensively sampled Kandoll Reference Site 2005-2009 as a paired site for Kandoll Farm Restoration Site. The 2009 sampling was also included as part of an LCRE-wide suite of sites for the Estuary Partnership/BPA Reference Sites project. Additional metrics (and more intensive sampling of standard metrics) were also sampled in dissertation research by Heida Diefenderfer at this site starting in 2005.
<b>Parameters</b> : Juvenile salmonids, vegetation, terrestrial macroinvertebrates	Species Monitored: coho, chum, Chinook salmon

**Project Findings**: NOTE: Selected results from Johnson et al. 2012. This is an extensively studied and documented site. These are selected results, not a complete summary. [Location and synthesis of of all available data is beyond scope of this review.]

Before the Kandoll Farm (KF) tide gate removal, no fish other than stickleback were found inside the tide gate controlled area (Figure 2.36), while at Seal Slough reference sites we captured seven species, including coho (N = 418, H' = 0.92). In 2006, after tide gate removal at the KF site, trap net samples yielded nine species, three of which were salmonids (N = 19575, H' = 0.07). Diversity remained low due to the high numbers of stickleback. Species counts and total individuals decreased at trap net sites in 2007 with the loss of incidental species and decline in the number of stickleback (N = 1330, S = 6, H' = 0.72). In comparison, the mean values of S and H' from beach seine samples at lower Columbia River main stem freshwater sites from 2002 to 2008 were 13.1 and 0.55, respectively. However, note that overall salmonid abundance remained relatively high in the restoration sites. During the post-breach period from 2006-2009, chum and coho made extensive use of the reconnected wetland. Chinook, chum, and coho exhibited different patterns of habitat use. Chinook were not abundant in the wetland in any year, but had a relatively wide temporal window extending from February-June. Chum were very abundant each year, especially during 2009 when over 1000 individuals per tide were captured in one trap net. We likely sampled during the peak migration period. Chum had a relatively narrow window lasting ~6 weeks each year; overall occupation of the wetland was from mid-February-late April with a maximum in early April. Coho were moderately abundant each year with a variable maximum. Overall distribution was wide and extended from March-June (and possibly later). Chinook were present at 7-DAM temperatures between 6 and 21°C, chum in the range 7 to 16°C, while coho exhibited the warmest and narrowest range between 13 and 21°C.

## Appendix C. Summaries of Non-OWEB tide gate projects, 2006 – 2016.

Estuary: Lower Columbia	Name: Tenasillahe Island Slough, Julia Butler Hansen NWR	
Type: Replacement (3 gates)		Total Cost:

**Summary**: Tenasillahe Island is located in the Columbia River Estuary in Clatsop County, OR. It is downstream of Puget Island and the town of Cathlamet, WA, separated from the mainland and the unincorporated community of Clifton, OR by the Clifton Channel, and from nearby Welch Island by the Red Slough. In 2007 the U.S. Army Corps of Engineers (USACOE) replaced the three top-hinge steel tide gates controlling tidal action on the largest Tenasillahe Island slough with side-hinge aluminum gates equipped with a manually controlled fish orifice. This action was to improve aquatic habitat conditions and to improve fish passage for juvenile salmonids while balancing the needs of the endangered white-tailed deer found on the island.

Data collected March-June 2006 and March-May 2007, before gates were replaced, show elevated gated slough water temperatures, more non-native species present in gated sloughs, and limited opportunity for juvenile salmonids to enter gated sloughs. Activities in 2008 focused on collecting post-construction data needed to assess effects of the new tide gates. Objectives addressed during 2008 field season: 1. Assess fish passage conditions; 2. Describe fish distribution among treatment and reference sloughs; 3. Characterize aquatic habitats of treatment and reference sloughs; 4. Measure juvenile salmonid growth rate and residence time in treatment and reference sloughs.

Aerial Images:

Restoration Metrics: Water temp, juv Chinook #s, TG opening parameters		
Monitoring Focus: Biological, fish passage at tide gates	<b>Study Design</b> : BACI study design. Monte Carlo and Randomized Intervention Analysis (RIA) were used to determine if tide gate replacement affects water temperature. Also used Spearman Rank Correlation to get correlation values for water temp up and downstream, in CVS, in Clifton channel, air temp, precip, Col. R discharge. Also used for hourly temp and depth at all sites.	
<b>Parameters</b> : Water temp, juv Chinook, TG opening frequency, duration, width	Species Monitored: Chinook	

**Project Findings**: Ennis thesis: Tide gate replacement had no significant effect on mean water temperature or on the difference between control sites and the section upstream of the tide gate. However, the change in difference between the downstream temps and the control temps was significant. Mean temperature and minimum tempurature decreased at all sites after replacement. The number of days in which water temp exceeded EPA limits decreased in all sections after replacement. This may have been due to La Nina conditions present in 2008. The main change caused by replacement was an increase in frequency, duration and width of tide gate openings during ebb tides. The new gates may have increased drainage, including warm surface waters - the old gates mostly drained cooler water at depth because they were top-hinged. More Chinook salmon juveniles were detected (PIT tag array) moving upstream of tide gates after replacement.

2013 PNW National Lab report: At Tenasillahe Island replacement of top-hinged gates with sidehinged tide gates with manual fish orifices did not improve fish passage or water quality. There were no differences in temperature pre and post replacement. No juvenile salmon were collected in gated sloughs.

2008 USFWS monitoring report: Replacement side-hinged tide gates opened on 64% of the low tides and were open an average of 3.4 hour per opening. No salmon were collected entering Large Tenasillahe Slough, however juvenile Chinook and coho were caught exiting the slough. PIT-tagged fish released in LTS remained throughout the summer and grew well. Water quality differed for some factors and was similar for others. Gated sloughs had higher water temperature, lower percent dissolved oxygen, and more emergent aquatic vegetation. However, pH was similar in all sloughs and turbidity and transparency ranges overlapped. Conductivity was similar among sloughs except Large Tenasillahe Slough, which had much higher values. The reference sloughs on Welch Island had larger proportions of native species.

At Tenasillahe Island replacement of top-hinged gates with side-hinged tide gates with manual fish orifices did not improve fish passage or water quality. There were no differences in temperature pre and post replacement. No juvenile salmon were collected in gated sloughs.

**System Effects**: The following reference incorporated findings from monitoring at this site with other sites to address the following objective: "Objective 3, Estuary Scale – Prepare a compendium of tag release-recapture technologies to inform planning for future action effectiveness studies."

## Appendix C. Summaries of Non-OWEB tide gate projects, 2006 – 2016.

Estuary: Lower Columbia	Name: Mainland Unit Restoration, Julia Butler Hansen NWR	
Type: Replacement (3 gates)		Total Cost:

**Summary**: In 2010 the Corps worked with the USFWS to replace three tide gates and repair a failing culvert at the Julia Butler NWR at RM 36 in Wahkiakum County, near Cathlamet WA. The project replaced a derelict top-hinged tide gate with a hydraulically-efficient side-hinged tide gate to provide improved fish passage and water quality. In addition, the Corps installed two new side-hinged tide gates on a blind slough on the Refuge, restoring a muted tidal signal and facilitating fish passage in shallow-water habitat. The project restored 110 acres of slough/wetland habitat and 210 acres of riparian forest habitat.

NOTE: Listed in Lower Columbia Estuary Partnership site as having been done in 2003 to 2009.

Appendix C. Summaries of Non-OWEB tide gate projects, 2006 – 2016.

Estuary: Lower Columbia	Name: Ft. Clatsop, South Slough	
Type: Removal (replaced by a bridge)		Total Cost:

**Summary**: In 2007, Lower Columbia River Estuary Partnership (EP) and its partners replaced a failing tide gate with a bridge at Lewis and Clark National Historic Park's Fort Clatsop in order to reconnect South Slough (and 45 acres of diked pastureland) with the tidal influence of the Columbia River. Water velocities in the culvert were elevated, potentially limiting fish passage into the slough. A reconnection of the tidal influence to the slough had the potential to both open up access to the habitats in the slough for fish and improve those habitats.

Aerial Images:

**Restoration Metrics**: Salmonid abundance, proportion of non-native species, water quality (temp)

Monitoring Focus: Fish community assemblages,<br/>size class, and residency; for water quality<br/>conditions including temperature, tidal<br/>range/depth, dissolved oxygen and conductivity.Study Design: BACI. In 2007 the Columbia River<br/>Estuary Study Taskforce (CREST) implemented pre-<br/>project monitoring as a baseline for characterizing<br/>CREST performed post-project effectiveness<br/>monitoring in 2008, 2009, 2010, and 2011 as part<br/>of the EP's Action Effectiveness Monitoring<br/>Program. (From methods section) This synthesis

	report summarizes monitoring results between 2007 and 2011 from South Slough and discusses South Slough before and after restoration, and in the context of Alder Creek, its reference site. (2012 annual report is also available.) Pre-restoration sampling 2007. Post-restoration sampling 2008, 2009, 2010, 2011. Jan - Aug 2007-2011. 2007, 2008, 2011 sampled twice per month. 2009, 2010 sampled once per month. Some sampling in 2012
<b>Parameters</b> : From 2007-2010, a trap-net was employed at Ft Clatsop South Slough. Sampling from high tide to low tide we capture upriver salmon stocks, marine and freshwater fishes as well as resident juvenile salmon that use the off- channel habitat during the flood tide and return to the mainstem Lewis and Clark River on the ebb.	Species Monitored:

**Project Findings**: Abundance of salmonids and other native fishes increased at South Slough after restoration. The proportion of non-natives decreased at both the restoration and reference sites; the fish community at South Slough fluctuated similarly to the reference site. Peak abundance was later post restoration, however, a distinct trend was not described because sampling methods did not capture fish holding in the tidal channels during all years. Multiple size classes of Chinook and coho were caught in South Slough post-restoration indicating the presence of at least two life-histories. Chum salmon were most abundant in March-April as at other sites in the lower Columbia River Estuary. Chinook and coho were much more abundant in South Slough than Alder Creek and peak abundance was later. The two species' prey prefrences overlapped potentially indicating competition. Restoration increased tidal inundation, lowered temperatures, and altered channel morphology increasing available habitat spatially and temporally.

[Notes from Powerpoint] "Salmonid mean lengths, post-restoration, Ft. Clatsop South Slough, 2008. After restoration, more natural sized Chum are using the system. Encouraging since Chum were once thought to be absent from the system. Source unknown; too small to be hatchery strays from Gray's Bay; no fin clips either. Obviously establishing some spawning in the system again, but only genetics would enable stock identification. Some yearling Chinook in the system early and again late; all naturally produced and pelvic fin clips genetic analysis will determine stock source. Subyearling coho and some yearling steelhead also using the system. No genetics as of yet, but despite the lack of adipose fin clips, which would suggest these are naturally produced fish, the proximity to CEDC net pens in Young's Bay prevents the application of 'wild' rear type. Salmonids more numerous after bridge installation, and species more diverse (steelhead and cutthroat trout new this year)."

NOTE: Powerpoint presentation with pictures of the TG removal site and new bridge, and discussion of monitoring results. Presented to Northwest Power & Conservation Council(?)

Estuary: Lower Columbia	Name: South Tongue Point Restoration - Liberty Lane	
Type: TG removal		Total Cost: \$70,772
<b>Summary</b> : The South Tongue Point Restoration site is located along the southwest shoreline directly off Cathlamet Bay in the Columbia River Estuary (mile 18) and is owned by the State of Oregon (DSL). The site was historically a brackish wetland fed by a 95-acre tributary basin to the southeast. During		

the late 1940s, the site was partially disconnected from the bay by placement of dredge spoils to expand the fleet facility at the Tongue Point Naval Base. Later, Liberty Lane was constructed as an access road to buildings and docks on the eastern portion of the dredge materials. Installation of a tide gate and culvert under a road at the entrance disconnected the wetland complex from the bay, severely restricting tidal connection and eliminating fish access. The project restored tidal connection to a 10-acre diked tidal wetland [BPA-USACE EA says 15 acres]. The project included installation of a 10' diameter countersunk HDPE culvert under Liberty Lane, removal of the existing tide gate and undersized culvert, excavation of the wetland channels and large woody debris placements in the new channels. The existing 36" culvert was plugged and abandoned in place. Culvert replacement, large wood placement and wetland grading took place July-October 2012. Planting and invasive controls took place 2012-2013. The culvert invert was lowered from 5.8' to 0.5' outside the tide gate. Stream bed rock was placed in the culvert to create a low flow channel at elevation 3.5', the existing channel elevation downstream of Liberty Lane. Concrete masonry head walls were installed to minimize the length of channel enclosed in culvert. Approximately 950' of inter-tidal channels were excavated below the existing marsh surface. These channels range from a thalweg elevation of 3.5' at the upstream culvert end to 5.0' at the south end of the channels and from 4-6' in depth from the marsh surface. Channel bottom width ranges from 3-6'.

Estuary: Lower Columbia	Name: Wallooskee-Youngs Confluence Restoration Project	
<b>Type</b> : Removal (two tide gates, as part of levee breaching)		Total Cost: \$7,600,000 (Source says \$4,500,00 expended as of 7-31-17) https://www.cbfish.org/Contract.mvc/Summary/ 62692

**Summary**: Wallooskee-Youngs Confluence Restoration Project is located at the confluence of the Wallooskee and Youngs Rivers five miles from the Columbia River near Astoria, Oregon. The project will involve modifying a levee to inundate historic wetlands, creating a network of tidal channels within the project site, and restoring native vegetation. The project will enhance estuary rearing habitat for juvenile salmon and steelhead, as well as provide habitat for wildlife such as deer, elk, and river otter. The project will also help BPA meet its obligations under the Endangered Species Act. An existing BPA transmission line and access road on the property will be modified to withstand the new tidal regime. Structures on the property - a house, barn, and out buildings - will be removed and the upland area returned to a natural condition.

Levee was breached in June 2017, and included removal of two tide gates.

EA p. 2-11: The levee would be breached in five locations. Each breach would have a main breach opening, with benches at the floodplain elevation on either side, before sloping to meet the top of levee elevation (8.5 feet in areas next to the breaches following restoration activities). Both of the site's tide gates are located at proposed breach locations and would be removed during the levee breaching. The Crosel Creek tide gate under OR 202 would not be modified.

Aerial Images: see next page.

**Restoration Metrics**: [Inferred] Acres of tidal wetland restored; Acres of native plant communities restored; Acres of off-channel salmonid habitat restored

Monitoring Focus:	Study Design:
Parameters:	Species Monitored:

**Project Findings**:

**System Effects**: NO ACTION: Sea-level rise would likely still affect the project area and the likelihood that the site would convert to mud flats or open water, in a self-breaching scenario due to sea level rise, would be much greater since soils would continue to be lost through the tide gates. (EA P. 2-39)

PROPOSED ACTION: The proposed action would better position the site to respond to sea level rise since tidal process would be restored and the site would begin to accrete sediment. (EA P. 2-39)

The restored tidal wetland would act as a carbon sink and capture carbon through increased vegetation growth and accretion. Restoration of a functioning wetland plant community would help buffer the effect of rising sea levels by attenuating wave action and storm surges. (EA P. 2-39)

Lessons Learned:

**Funders**: Bonneville Power Administration (BPA)

**Partners**: Astoria Wetlands, LLC, an environmental resources company, currently owns the property and will conduct the restoration work. The Cowlitz Indian Tribe will assist in project implementation and provide long-term stewardship to ensure permanent protection of the property.

Wallooskee-Youngs Confluence, mid-project prior to dike breaching (3/20/2016)

Estuary: Lower Columbia	Name: Chinook River Restoration	
Type: Tide gate upgrades (2)		Total Cost:

**Summary**: The Chinook River flows into the north side of the Columbia River 5 miles upstream from the Pacific Ocean. The project area is located at the mouth of the Chinook River and consists of approximately 1,050 acres of estuarine and riparian wetlands surrounding a complex network of tidal channels. Historically, the Chinook River supported populations of five anadromous salmonid species, and its estuary is an important rearing habitat for juvenile salmonids from the Columbia River basin. The reduction in species abundance from historic levels is attributed to elimination of the tidal action since the construction of a tide-gate at the mouth of the Chinook River in the 1920s. The objective of the Chinook River Restoration Project is to recover the natural estuarine and riparian wetlands habitat by restoring tidal flows through the study area.

Washington Department of Fish and Wildlife began developing a restoration concept for this area in 1997. In 2001, the Columbia Land Trust acquired a large parcel of land, which was transferred to WDFW to become the Chinook unit of the St Johns Wildlife Area. Partial restoration including retrofit of internal tidegates was undertaken from 2005-2007. New restoration planning and implementation is being undertaken from 2011-2014, including an additional acquisition to the north (Mattson property).

[Juel doc] In September of 2006, two large GH-52SC tide gates were installed where the Chinook River passes beneath Hwy 101 southeast of Ilwaco WA. This tide gate is essentially a top-hinged flap gate mounted on a frame with a mechanical lift that allows the flap gate to be raised and lowered. When fully raised, the flap gate is completely above the opening in the headwall, allowing unimpeded tidal exchange. When partially raised, the flap gate allows throttled backflow through a submerged orifice when the tidal water level downstream is higher than the water level upstream from the flap gate. When completely lowered, this is simply a top hinged flap gate that allows no backflow. The aluminum flap gate is very light weight and opens wide under moderate out flow. Golden Harvest does not show this tide gate in their on-line tide gate catalog. (It does not function well at the Chinook River, so they presumably do not market this design.)

#### Aerial Images:

Restoration Metrics:		
<b>Monitoring Focus</b> : Chinook - Lower Columbia River ESU; Coho - Lower Columbia River ESU; Chum - Columbia River ESU; Cutthroat Trout, Coastal - Southwest Washington/Columbia River ESU; Steelhead - Lower Columbia River DPS	<b>Study Design</b> : Hydrologic and hydrodynamic modeling were conducted by Pacific Northwest National Lab to assess project feasibility and alternatives. A follow-up modeling study was apparently done to assess various scenarios and combinations of operating the new tide gates.	
Parameters:	<b>Species Monitored</b> : Chinook, coho, coastal cutthroat trout.	
<b>Project Eindings:</b> In 2002, DNNL staff conducted a hydrodynamic and hydrologic modeling analysis to		

**Project Findings**: In 2003, PNNL staff conducted a hydrodynamic and hydrologic modeling analysis to evaluate the feasibility of restoring natural estuarine functions and tidal marine wetlands habitat in the Chinook River estuary, located near the mouth of the Columbia River in Washington. The reduction in salmonid populations is attributable primarily to the construction of a Highway 101 overpass across the mouth of the Chinook River in the early 1920s with a tide gate under the overpass. This construction, which was designed to eliminate tidal action in the estuary, has impeded the upstream passage of salmonids. The goal of the Chinook River Restoration Project is to restore tidal functions through the estuary, by removing the tide gate at the mouth of the river, filling drainage ditches, restoring tidal swales, and reforesting riparian areas. The hydrologic model (HEC-HMS) was used to compute Chinook River and tributary inflows for use as input to the hydrodynamic model at the project area boundary. The hydrodynamic model (RMA-10) was used to generate information on water levels, velocities, salinity, and inundation during both normal tides and 100-year

storm conditions under existing conditions and under the restoration alternatives. The RMA-10 model was extended well upstream of the normal tidal flats into the watershed domain to correctly simulate flooding and drainage with tidal effects included, using the wetting and drying schemes. The major conclusion of the hydrologic and hydrodynamic modeling study was that restoration of the tidal functions in the Chinook River estuary would be feasible through opening or removal of the tide gate. Implementation of the preferred alternative (removal of the tide gate, restoration of the channel under Hwy 101 to a 200-foot width, and construction of an internal levee inside the project area) would provide the required restorations benefits (inundation, habitat, velocities, and salinity penetration, etc.) and meet flood protection requirements. The alternative design included design of storage such that relatively little difference in the drainage or inundation upstream of Chinook River Valley Road would occur as a result of the proposed restoration activities

## System Effects:

**Lessons Learned**: [Clip from a newspaper story about a project in a nearby area] "...a dispute about modifying the tide gates at the mouth of the Chinook River. There were serious concerns raised about some aspects of that project. 'We had some initial public hearings held at the Sea Resources classrooms,' said Osborner, 'And we had some lower river homeowners that got their hackles raised when they thought the whole Lower Chinook River was going to be flooded.'"

Estuary: Bear River (WA)	Name: Greenhead Slough Restoration, Willapa NWR	
<b>Type</b> : Removal	<b>Total Cost</b> : According to NOAA Fisheries: \$752,284 (Willapa Bay NWR: \$1,009,524)	
<b>Summary</b> : Greenhead Slough is located in Pacific County, WA, Willapa Bay, just east of Bear River. The project is part of an overall Bear River Estuary plan to restore 649 acres and 6 streams. This area historically supported large numbers of chum, coho, Chinook, cutthroat trout and steelhead; their numbers have dramatically decreased due to poor land management. Since 2003, Willapa Bay National Wildlife Refuge (NWR) worked with partners to remove fish travel barriers in the 3.74 square mile (2,317 acre) watershed from tributaries to Willapa Bay Estuary. Culverts on 4 streams (North, Lost, Chum and South Creeks) were replaced by bridges and 10 miles of stream habitat were enhanced. The last partial obstacle, a culvert/tide gate on Greenhead Slough was removed in 2015.		
Greenhead Slough was modified in the 1940s when the WA State Dept of Transportation (WDOT) re- routed four streams along State Route 101. A culvert/tide gate was later installed to allow road access to private timberlands. In 2003, Willapa NWR purchased the property with an existing NRCS Wetland Reserve Program easement as well as a right-of-way easement to WDOT for State Route 101 and to Bonneville Power Administration (BPA) for power lines and transmission towers.		
existing channel and adding woo ensure stabilization, and installin to uplands. Native trees will be p realigned and the old road was o fresh and salt water, and growth rich nutrients that provide essen cutthroat. Hundreds of other spe birds and mammals. Tributaries	included abandoning the blocking culvert/tide gate, realigning the of for habitat complexity, re-sloping a portion of a steep bank to og a 70-foot, single lane, steel bridge over the new channel for access blanted later this year [2016?]. Also, the BPA access road was lecommissioned. Post-project, the daily influence of tides, mix of of salt-tolerant plants, algae, and phytoplankton will create cycles of tial food, spawning, and nursery habitat for chum, coho and ecies will also benefit, such as invertebrates, migratory and resident North, Chum, Lost and South Creeks- are monitored by Refuge staff g surveys have consistently documented chum, coho, and cutthroat.	

Aerial Images: (3/20/2016)

**Restoration Metrics**: Length of stream made accessible; Length of stream treated/protected; Instream pools created/added; Number of structures placed in channel; Number of blockages/barriers removed

Monitoring Focus:	Study Design:
Parameters:	Species Monitored:

**Project Findings**: Reopened several hundred acres of former saltwater marsh to full hydrology, and improved fish passage to several streams. Chum and coho salmon returned to these streams in 2016. Anecdotal Nov. 2016 [http://columbiacoast.blogspot.com/2016/11/]: "Chum salmon came back to their natal streams this season in large numbers. Commercial fishermen caught their quota, and still the salmon kept coming. Last year, refuge stream walkers did not see any chum or coho salmon. This year, chum have returned to all the streams they monitor. Today I saw two streams with chum in them, splashing as they mated and dug out redds to lay eggs. There were dead fish too; I could smell the dead fish as I approached."

## System Effects:

**Lessons Learned**: Daily Astorian article on need to be opportunistic with funding for large-scale projects; may have to get them done piecemeal: [Willapa NWR] "...over the years has picked away at fish passage projects upstream when money [was] available, restoring four different streams...10-miles of spawning habitat for...salmonids. But the final piece, the old culvert, was more complicated. Various groups held easements or right-of-ways...BPA and WDOT...also, over the years, people interested in pushing the project through have come and gone..was the same for funding..."Ideally we

would have proceeded from downstream to upstream [with habitat] improvements," [Sustainable Fisheries Foundation's Cleve Steward] "But because of funding and mechanics of getting all this work done, it didn't work out that way. With these kinds of large, expensive, long-term projects, you have to be opportunistic."

Estuary: Tillamook	Name: Southern I	Flow Corridor Project-Wilson River
Type: Removal (setback levee)		Total Cost: \$10,645,736
<b>Summary</b> : Construction began in summer 2016; completion is slated for late September 2017. The primary intent of Southern Flow Corridor (SFC) Landowner Preferred Alternative Project is to remove manmade impediments to flood flows to the maximum extent possible in the lower Wilson River floodplain by extensive removal of existing levees and fill. New setback tidal dikes are required to protect adjacent private lands from inundation from daily tides. The SFC creates a "natural overland floodway" by removal of numerous old levees, dikes and fill (including 15 tide gates) around the Trask and Wilson Rivers and the smaller sloughs and setting back remaining levees in order to provide an unobstructed flow corridor. This is expected to reduce flood levels over a wide area in the lower Wilson floodplain and, to some degree, the lower Trask and Tillamook River systems. Although the SFC was developed as a flood project, it also restores tidal wetland habitats and ecological function as a direct consequence of removing levees and reconnecting 14 miles of ancient channels to the river systems.		
Areas outside the setback levees were restored to tidal marsh. Working with a diverse set of partners, Tillamook County permanently protected and restored 522 acres of tidal marsh habitats at the confluence of the Bay's two most productive salmon systems, the Wilson and Trask Rivers. This represents 10% of the watershed's historic tidal acreage and a far greater percentage of "restorable" tidal lands. Prior to restoration the site contained an expansive mosaic of tidal wetlands, disconnected freshwater wetlands and drained pasture lands. Once restored to a tidal regime, the resulting habitats (mud flats, aquatic beds, emergent marsh, scrub-shrub wetlands, forested wetlands and sloughs) will provide substantial babitat benefits to not only threatened cobe, but also chum and Chinook salmon		

provide substantial habitat benefits to not only threatened coho, but also chum and Chinook salmon, and cutthroat trout.

Further questions may be directed to Project Manager Aaron Palter at 503 842-2413 x116.

Southern Flow Corridor project area at beginning of construction, showing locations of new tide gates (8/23/2016):

**Restoration Metrics**: Levee/road Removal-9 miles; levee, dredge spoil, & fill removal-195,000 yd<sup>3</sup>; levee modification-2.8 miles; new levee-1.5 miles; tide gates removed -15; new floodgate/drainage tide gates-1/8; structures removed-1 house, 3 barns; ditches filled-4.6 miles; channel reconnections-18; channel construction-5.5 miles; natural channel restoration-14 miles.

Monitoring Focus:	Study Design:
Parameters:	Species Monitored:

**Project Findings**: The Southern Flow Corridor has successfully restored more than 500-acres of tidal wetland and reopened nearly 14 miles of historical tributaries that will serve as important wintering habit for juvenile salmon. The project has resulted in significant flood reduction benefits over a 3,000-acre area, giving the Tillamook community a projected \$9.2 million in avoided flood damages over 50 years.

ODFW estimates that the restored wetland will annually produce 6,000-9,000 adult coho salmon (average) and 9,000-14,000 with good ocean conditions. Long-term ecological and socio-economic outcomes include 1) reduced flooding in the Highway 101 business corridor and adjacent residential/agricultural lands, including measureable reductions in flood elevation and duration; 2) improved freshwater and estuarine water quality, including reductions in temperature, dissolved oxygen, and turbidity; 3) increased habitat complexity and availability across the range of tidal wetland habitats; and 4) enhanced ecological function benefitting other aquatic, terrestrial, and avian species. **System Effects**: In addition to salmonid habitat benefits, project provides substantial public benefits via reduction of flood risks to life and property, and improvement of water quality. Over time, should also provide sea-level rise and climate change adaptation benefits.

**Lessons Learned**: Tillamook Fire Department conducted a practice burn on the house slated for removal on project site. SFC project managers and Thompson Bros. Excavating actively monitored the site over winter [2016/17] and responded to minimal storm-related impacts during that time. During the lifetime of the project it provided an estimated 50 jobs to the area.

**Funders**: FEMA-\$3,225,000; NOAA-\$2,700,000; OWEB-\$1,522,144; OR State Lottery Bonds-\$1,075,000; OR Business Development Dept-\$1,050,974; USFWS-\$822,618; Loren Parks Foundation -\$250,000

## [Total: \$10,645,736]

**Partners**: Work completed by: "On April 27 [2016] contract was signed with Thompson Brothers Excavating, Inc. (TBE) of Vancouver, WA for \$5,500,930." [Tillamook Herald 6/2016] TBE has completed similar projects along the Columbia River and elsewhere, including work for ODOT.

Estuary: Salmon	Name: Salmon River Estuary, Oregon	
<b>Type</b> : Dikes removed 1978, 1987, 1996. At least two TGs removed 1987, 1996. TG removed at Tamara Quays 2008. TG removed at Pixieland 2011.		Total Cost:
<b>Summary</b> : NOTE: Restoration from 1978-1996 appears to have been funded by the US Forest Service. Restoration at Tamara Quays and Pixieland was funded by OWEB. So this project area is included in both OWEB funded and non-OWEB funded summaries.		
The Salmon River Estuary has been extensively restored in distinct periods of activity over several decades. Between 1954 and 1974 most of the estuary had been diked and ditched to create pastures, with the majority of dike building in the early 1960s. From 1978 to 1996 a series of land acquisitions and intertidal marsh restoration projects restored 339 acres of tidal marsh and over 3 miles of sinuous tidal marsh channels. A dike was removed in 1978; a dike and tide gate were removed in 1987, and another dike and tide gate were removed in 1996. Projects from 2007-2014 (which included OWEB funding) were more complex - included Rowdy Creek marsh restoration and dismantling a trailer park housing development (Tamara Quays, 2008-2009) and an amusement park (Pixieland, 2010-2011) built directly on tidal marsh land. Projects from 2007-2014 restored tidal influence to 108 acres; restoring 2.5 miles of stream channel and floodplain; removing 2 miles of dikes, failing septic systems, underground infrastructure and 3 tide gates, multiple complex ditches, and a boat basin carved into the marsh floor and restoration of native marsh and upland plants.		

Aerial Images (after Flitcroft et al., 2016):

#### **Restoration Metrics**:

Monitoring Focus:	Study Design:
Parameters:	Species Monitored:

**Project Findings**: [2014 Powerpoint] Restoring estuary habitat has enhanced life history expression in both Chinook and coho salmon. Coho that leave natal streams as subyearlings are not lost to the population but use the estuary. Estuary life histories linked to restored wetlands contributed 25-40% of adult Chinook and 20-35% of adult Coho produced in Salmon River. Life history diversity (and the habitat opportunities that support it) is fundamental to the productivity as well as the resilience of salmon populations.

Estuary: Siuslaw	Name: Phey Lane Tide Gate Replacement	
Type: Replacement with MTR ac	dition	Total Cost:

**Summary**: The Phey Lane tide gate is a project on the Siuslaw River (approximately two miles west of Mapleton, Oregon). Phey Lane was funded by the Phey Lane Homeowners Association.

[Greg Apke-ODFW] "ODFW purchased and deployed equipment to monitor hydraulic and water chemistry parameters on the tide gate system to further ODFW's understanding of fish passage hydraulics in tide gate controlled water bodies. The project has been collecting data for two and a half months and we are observing good results that are revealing how tidal cycles and stream flows interact and we are able to draw conclusions about the time available for fish to pass into and out of the impounded water body."

Estuary: Coos Bay	Name: Kentuck Slough Tide Gate Replacement		
<b>Type</b> : 4 tide gates replaced with MTR addition <b>Total Cost</b> : \$2,321,000			
Mettman Creeks. These streams the Coos estuary. The watershee From the tide gate at East Bay D	<b>Summary</b> : The Kentuck sub-basin is oriented east to west, with 2 major tributaries, Kentuck and Mettman Creeks. These streams converge in the lowlands to form Kentuck Slough, which drains into the Coos estuary. The watershed drainage area is about 10,637 acres, with about 60 miles of streams. From the tide gate at East Bay Drive, Kentuck main stem is approximately 13 km (8.1 mi) long, and Mettman Creek main stem is 5.47 km (3.4 mi) long. The elevation in the basin ranges up to 406.60 m		

The Kentuck Slough Bridge is located along the northeastern side of Coos Bay near North Bend, OR. The existing bridge did not meet current design standards and needed to be replaced. Attached to the downstream side of the existing bridge was a set of three 7.5-ft wide by 10-ft high top-hinged tide gates. One of the tide gates was wedged in the gate slot and completely inoperable. The other two gates functioned, but leaked significantly during flood tides. Additionally, the gates were frequently overtopped during high tides.

The leaky gates have allowed for salt-water intrusion into the slough, which has re-created an important estuarine habitat. However, this has also resulted in an increase in the amount of salt water that intrudes into adjacent land via groundwater flow. This has negatively affected the quality of the soil during the summer months when there is little freshwater inflow to the slough to help dilute the salt concentrations from the bay water. The local landowners have indicated that the current volume of saltwater influx to the slough is tolerable, but any increase would not be acceptable. WEST developed an HEC-RAS unsteady flow hydraulic model of the tide gate designs to accommodate and improve upon conditions that encourage the estuarine habitat, while at the same time, will not increase the volume of salt-water influx to the slough over the existing conditions.

The old tide gates were replaced in 2007 by 4 Nehalem Marine gates.

Estuary: Coquille River	Name: Bandon N	larsh Restoration Monitoring
Type: Removal		Total Cost: \$9,500,000+

**Summary**: The Ni-les'tun Unit of Bandon Marsh contains portions of floodplain lowlands from three drainages, Fahys, Redd, and Overlook creeks. The restoration was undertaken to restore over 400 acres of marsh habitat in the Coquille River estuary. Short term goals included providing habitat for juvenile salmon and reintroduce unresticted tidal inundation. Long term goals were to create estuary-wide improvements in water quality and estuarine marsh habitat and to increase the amount of wetland habitat in the estuary. Restoration actions included removing tide gates, lowering or removing dikes, filling large ditches, disrupting small ditches, installing upgraded culverts, and excavating 5 miles of tidal channels. Monitoring was performed to determine changes in aquatic species communities after restoration.

Fish were collected in each of the three tributaries to the marsh, newly created tidal channels, reference streams and tidal channels, and the Coquille River. All fish were identified and counted and up to twenty of each species were measured. Up to twenty of each salmonid species were also weighed. Macroinvertebrates were collected in surface and water column nets in Fahys Creek and one reference creek.

This project focused on fish and wildlife. Plant community responses were documented in an OWEBfunded study. Those results are available in Brophy et al. 2014 and Brown et al. 2016, which are included in Appendix A and Appendix B.

Bandon Marsh Restoration – Before (5/26/1994):

Bandon Marsh Restoration – After (5/21/2015):

Restoration Metrics:		
Monitoring Focus: Biological, Chemical	Study Design: BACI	
<b>Parameters</b> : Species frequency and abundance, species richness, community similarity, salmonid age-classes (assigned by length-frequency). Frequency categories for fish species: dominant, common, occasional, and rare.	<b>Species Monitored</b> : Chinook and coho salmon, cutthroat trout, sculpins, stickleback, additional fish species and aquatic macroinvertebrates	
<b>Project Findings</b> : Twenty-one fish species were collected over the course of the study. Of these, 13 were collected both before and after restoration. Three species were only collected prior to		

were collected both before and after restoration. Three species were only collected prior to restoration and five were only collected after restoration. Of the species only collected after restoration, 80% (4/5) were estuarine. Fish distributions differed after restoration. Species richness increased in upstream areas and decreased in tidally influenced areas. The fish communities in the treatment and reference marshes differed before and after the restoration. However, the degree of difference was smaller post-restoration.

<b>Parameters</b> : juv Chinook density. Recorded fish catch #'s by species, water temp, salinity, DO, seine depths, velocity. Vegetation ground cover, species composition	<b>Species Monitored</b> : Fish: recorded all species, focused on juv Chinook Vegetation: Seaweed species- green tuft, witch's hair, sea lettuce, green string lettuce, nori. Salt
	marsh species- pickleweed, seashore saltgrass,

brass buttons

**Project Findings**: FISH: Prior to restoration only stickleback were caught in Crescent Marsh. After restoration 10-16 species were caught including subyearling Chinook (wild and hatchery), subyearling and yearling coho, pink, chum, yearling sockeye, cutthroat, and native char (Salvelinus sp). Pink salmon fry timing did not differ inside and outside the marsh. Chum fry abundance peaked inside the marsh earlier than the adjacent beaches but densities were similar inside and outside. Wild Chinook were collected mainly in the adjacent beaches and main marsh, but were also collected in the creek. Fish size was negatively correlated with outmigrant abundance. Density was higher in the marsh than at adjacent beaches, which follows a pattern seen at natural pocket marshes in Puget Sound but the difference is smaller.

VEGETATION: Pre-project communities had mix of high and low estuarine salt marsh, and upland vegetation. Reintroduction of tidal influence resulted in large dieback of existing vegetation. By 2014, most of site was in mudflats that supported various types of seaweed and large shellfish populations. Channel size has increased, which could be allowing more water to enter during tidal inundation. The increased energy could be scouring the marsh surface, removing sediment faster than it is being replaced. Pickleweed and saltgrass dominate the highest sites, but brass buttons- an annual and pioneer species- has been encroaching further onto the mudflats. It remains to be seen if the site will continue to be dominated by bare ground, or if the marsh surface will continue to expand as soil organic matter lost through scouring builds-up in the remaining substrate over time.

**System Effects**: Electrofished and sampled water quality in Crescent Creek above the salt marsh Project also examined vegetation effects

**Lessons Learned**: In Crescent Harbor Salt Marsh, there is a declining order of wild juvenile Chinook salmon density associated with connectivity of marsh lobes. Water quality data and juvenile Chinook results suggest that restrictions in hydraulic connectivity between marsh lobes may be driving this. Hydraulic connectivity improvements within Crescent Harbor Salt Marsh (i.e., between marsh lobes) would likely allow for improved water quality and better use of this habitat by fish.

Salt marsh formation after restoration was limited by elevation. Post-restoration vegetation conditions are still changing in response to restoration of tidal flow, and appear not to have stabilized yet.

The Crescent Harbor Salt Marsh Restoration project, constructed during the summers of 2008-2009 using SRFB and other funding, has restored more than 200 acres of pocket estuary habitat to tidal inundation and fish access. During the initial project design, great care was taken to model post-restoration conditions. However, the dynamic nature of the natural processes interacting within the site make it difficult to account for all the ways in which conditions will evolve following exposure to tidal and wave processes.

Although, the site largely functions as intended, unforeseen erosion, caused by wave action in the interior of the salt marsh, has threatened infrastructure critical to the operation of a wastewater treatment plant (WWTP) located within the project site. Addressing this erosion will allow continued function of newly restored pocket estuary habitat while greatly reducing the risk of damage to treatment plant infrastructure from storm events. In 2010, adaptive management actions were implemented in 2 locations in the eastern portion of the site: 1) elevate 300' of driveway leading the WWTP and soft-armor 100 feet to mitigate for temporarily decreased soil retention due to vegetation community shift from fresh to salt water species; 2) construct a bridge to connect the east and southwest cells of the salt marsh.

**Funders**: Puget Sound Nearshore Ecosystem Restoration Project (PSNERP)- \$417,722; SRFB - Salmon Recovery Funding Board- \$221,127; Estuary Salmon Restoration Program (ESRP)- \$183,013; DOD/US

Estuary: Skagit	Name: Fisher Slough Restoration Project, Skagit River Estuary
Type: Replacement	Total Cost: \$8 million

Summary: Located in the south fork Skagit River tidal delta near the town of Conway, WA, the Fisher Slough Restoration Project was a collaborative effort to reconnect natural freshwater tidal hydrology to approximately 50 acres of currently diked floodplain; restore historical tidal marsh vegetation communities; provide juvenile Chinook rearing habitat, remove fish passage barriers and improve fish passage to several miles of tributary spawning areas; increase watershed connectivity for coho, chum and other native fish species; and improve floodwater and sediment storage conditions for the tributary levee system. Restoration of Fisher Slough site was a priority in the Skagit Chinook Recovery Plan to help recover 6 populations of wild Chinook in the Skagit River and its natal estuary. The project broke a long-standing deadlock between agriculture and conservation interests over estuary restoration, restored critical Chinook rearing habitat and improved fish access to the 22 square mile Carpenter Creek Watershed. In 2009, NOAA awarded \$5.7 million of Recovery Act funding to The Nature Conservancy (TNC) to restore the Fisher Slough marsh site. Construction began in fall 2009, when 3 antiquated, wooden paired tide gates were replaced with aluminum self-regulating gates to improve salmon access to Fisher Slough. The new floodgates [TNC prefers this term] are managed by season: fall/winter flood control, spring salmon migration, summer irrigation. The seven-year project was completed in October 2011, with dike setback that increased marsh area from 9.8 to 55.7 acres. Additionally, Big and Little Fisher creeks were rerouted and tidal channels were excavated. Long-term benefits include reduced risk of structural failure, road damage and lost farming opportunities caused by flooding, as well as lower maintenance and operation costs. There were also human and social capital gains: conservation organizations, engineering and construction companies, tribes, and drainage and diking districts gained experience in tackling complex problems and finding win-win solutions. Long-standing social barriers and conflicts were overcome, leading to greatly improved relationships and potential for future collaborations.

Aerial Images: Fisher Slough after project (8/3/2016).

Fisher Slough, before restoration activities, (6/25/2009).

**Restoration Metrics**: Habitat area, Chinook abundance, density, size. Flood storage capacity (acre/ft). % of time tide gates are open. Acres of freshwater marsh restored. Stream-miles of improved salmon passage. Number of Blockages/Impediments/Barriers Removed

<b>Monitoring Focus</b> : Biological; Water quality Monitoring from 2009-2014 allowed researchers to distinguish the fish and environmental effects of tide gate operation from dike setback restoration. Fish were collected up and downstream of the tide gates in main channel and blind slough habitats using beach seines and fyke traps. ID'd and counted all fish, measured up to 20 of each spp. Measured water elevation, T, and/or DO, velocity.	Study Design: BACI	
<b>Parameters</b> : Chinook density, water elevations, tidal amplitudes, water temps, DO, veg cover, sediment accretion.	Species Monitored: Chinook	
Accretion. <b>Project Findings</b> : After tide gate replacement and before dike setback the Fisher Slough sites did not follow the pattern of higher abundance with increased connectivity seen at long term monitoring sites in the Skagit River delta. However, after dike set back the Fisher Slough sites demonstrated this positive relationship. Water temperature influenced Chinook abundance only in 2015. When fish abundance was expressed as a percent of carrying capacity the 2015 data was consistent with other monitored years and all years fell close to the 1:1 line between Fisher Slough and Skagit River delta with outmigrant population as a percent carrying capacity. Restoration from dike setback increased juvenile Chinook salmon abundance upstream of the floodgate approximately 10x relative to abundance during pre-dike setback. Weekly variability in floodgate operation influenced the number of juvenile Chinook salmon upstream of the floodgate by up to a factor of three (3x). Longer periods of the floodgate doors being open during the non-ebb stage of the tidal cycle resulted in more juvenile Chinook salmon upstream of the floodgate. Monitoring shows that floodgates and tide gates do have a strong influence on fish utilization of habitat and thus need to be designed and operated properly for fish if fish benefits are an important project goal. [From NOAA web page] 2014: Success for fish. Fish are benefiting even more from the restoration than expected. Ecological surveys indicate that the site can support as many as 21,800 juvenile Chinook		
<b>System Effects</b> : [Climate change & flood protection benefits] In addition to better fish passage and habitat, the Fisher Slough Project also provides flood protection, as described by the Farms, Fish and Floods Initiative (3FI), a landscape-scale effort in the Skagit Delta based on an MOU between NOAA, Skagit Conservation District, Skagit County, Skagit County Dike and Drainage Partnership, Skagitonians to Preserve Farmland, TNC, WA Dept of Fish and Wildlife and Western WA Agricultural Association. 3FI focuses on advancing mutually beneficial strategies that support the long-term viability of agriculture and salmon while reducing risks of destructive floods. 3FI complements the WA state Tidegate Fish Initiative (TFI). The Skagit Delta Hydrodynamic Model Project (SHDP) is supported by and contributes to the goals of 3FI. The SDHP Team initiated hydrodynamic modeling and alternatives analysis to identify and prioritize mutually beneficial large scale flood risk reduction and estuarine habitat restoration projects to achieve the Skagit Chinook Recovery Plan 2005 goal. The SHDP listed the Fisher Slough Project in an inventory of projects that provide these multiple benefits. A related 3FI document notes that flood protection benefits will be even more important with climate change related sea level rise and storm surges.		
Lessons Learned: [From report on entire Skagit] Project	ts using dike setback, dike breach, or fill removal	

**Lessons Learned**: [From report on entire Skagit] Projects using dike setback, dike breach, or fill removal had juv Chinook densities within the restored area consistent with the levels in nearby reference sites.

Projects using self-regulating tidegates (SRTs) had much lower juv Chinook densities than nearby reference sites. Self-regulating tidegates were better for juv Chinook salmon than the traditional flapgate they often replace (by ~2X), but SRTs averaged an order of magnitude lower in juv Chinook density compared to nearby reference sites. One combination project, at Fisher Slough (dike setback w/floodgate replacement) performed well. We detected a 10X increase in habitat use by juv Chinook salmon in Fisher Slough upstream of the tidegate, consistent with habitat use observed at other Skagit tidal delta reference sites. This increase was predominantly associated with the dike setback and current operation of the tidegate to allow fish passage during both slack and flood stages of the tide cycle.

Research on social and economic benefits of the project suggest that the \$8 million invested in restoration will save the community \$9-\$21 million over the next 50 years, reducing flooding on as many as 600 acres nearby. Project employed 300 workers.

"The success of the monitoring work at Fisher Slough is largely due to a well thought out monitoring and adaptive management plan, a hypothesis based research approach and critical funding and support from NOAA, ESRP and private funders."

**Funders**: In 2009, NOAA awarded \$5.7 million of Recovery Act funding to The Nature Conservancy (TNC) to restore the Fisher Slough marsh site.

Estuary: Skagit	Name: Wiley Slough Restoration Project, Skagit River Estuary	
Type: Removal and replacement	t <b>Total Cost</b> : \$4,623,999	
	Another source says \$4,768,975	

**Summary**: Restoration in 2008-2009 aimed at restoring tidal inundation and fish access to ~156 acres of estuarine wetlands. Included construction of 2,840 LF of set-back dikes along the pre-1956 levee footprint, and addition 2,200 LF of previously existing dikes around the site perimeter. An existing tide gate on Wiley Slough was removed, and a new, larger tide gate was constructed at the new diked perimeter. Lastly, 3,470 LF of borrow ditches were filled to promote sheet flow and drainage to historic channels. In 2009-2010, following completion of major construction activities, native plants were installed on 3.8 acres in zones adjacent to acres impacted by tidal flows. Restoration of estuarine functions to the Wiley Slough site provide significant benefits to Chinook, chum, coho, pink, sockeye, bull trout, steelhead and cutthroat by creating important rearing habitat. The Skagit Chinook Recovery Plan estimates that 2,750 acres of tidal marsh restoration are required for Chinook recovery, the highest priority habitat problem in the watershed. Wiley Slough accounts for 5.8 percent of this goal.

[WA Dept of Fish & Wildlife] Historically the site was managed to provide agricultural enhancements for winter waterfowl forage. With the ESA listing of many salmonid species such as Chinook salmon, habitat management shifted to restore estuary habitat. The restoration design which included building setback levees, relocating the Wiley Slough tide gate farther inland, and removing part of the perimeter levee allow tidal and river flows to recreate channels and provide additional natural estuary habitat.

Aerial Images: Wiley Slough tide gate relocation and tidal reconnection (8/3/2016).

Wiley Slough, before restoration activities (7/9/2009).

**Restoration Metrics**: Delta-rearing Chinook smolt production. (Each recovery action is evaluated for its potential smolt production as determined by an empirical smolt production model.) Acres of estuarine wetland habitat restored.

Monitoring Focus: Fish monitoring was conducted within restored habitat area of the Wiley Slough Restoration Project during the juvenile Chinook salmon outmigration seasons (Feb-Aug) of 2012 and 2013 in order to compare results at Wiley Slough with long term monitoring (reference) sites in the Skagit delta.	<b>Study Design</b> : The monitoring design primarily consisted of a post-treatment (i.e., after restoration) stratified random design using beach seines to capture fish.
Monitoring questions:	
<ol> <li>How does local environment vary by year, season, and lobe (Wiley, Teal) within the Wiley Slough Restoration Project?</li> </ol>	
2. What fish species are present within the restored area?	
3. How does juvenile Chinook density vary by year, season, and lobe (Wiley, Teal) within the Wiley Slough Restoration Project?	
4. How does seasonal juvenile Chinook density in the restored area compare to reference sites throughout the Skagit River estuary?	
5. What is the carrying capacity of the restored area for juvenile Chinook rearing?	

Parameters:	Species Monitored: Fish: recorded all species,
	focused on juv Chinook

**Project Findings**: Depth less in Wiley lobe and in 2013, but did not change with month. Velocity lower in Wiley and did not differ with month or year. T greater in Wiley than Teal and increased with month in both lobes and both years. Salinity increased in Wiley and in 2013. DO decreased in Wiley and decreased with month. Wiley shows more tidal influence and Teal more river influence. Depth, velocity, salinity, DO not likely influencing Chinook rearing between sites but T might be. Collected >22,000 fish (7 spp salmonids; mostly juv Chin, chum, and even yr pink). Stickleback, starry flounder, peamouth most abundant non-salmonids. Chin density greaer in Wiley, and did not vary by habitat or between channel/impoundment but did vary by year and week. Density highest Mar-Jun. Significant factors were T (positive) and salinity (negative). Landscape connectivity explained 53-85% of Chin density at longterm sites. Wiley ('12, '13) and Teal ('13) values plotted in the long term site scatter. In both years the juv Chin pop was higher than the estimated carrying capacity based on tidal channel, but lower than the estimate based on wetted area.

**System Effects**: [Climate change & flood protection benefits] In addition to better fish passage and habitat, the Wiley Slough Project also provides flood protection, as described by the Farms, Fish and Floods Initiative (3FI), a landscape-scale effort in the Skagit Delta based on an MOU between NOAA, Skagit Conservation District, Skagit County, Skagit County Dike and Drainage Partnership, Skagitonians to Preserve Farmland, TNC, WA Dept of Fish and Wildlife and Western WA Agricultural Association. 3FI focuses on advancing mutually beneficial strategies that support the long-term viability of agriculture and salmon while reducing risks of destructive floods. 3FI complements the WA state Tidegate Fish Initiative (TFI). The Skagit Delta Hydrodynamic Model Project (SHDP) is supported by and contributes to the goals of 3FI. The SDHP Team initiated hydrodynamic modeling and alternatives analysis to identify and prioritize mutually beneficial large scale flood risk reduction and estuarine habitat restoration projects to achieve the Skagit Chinook Recovery Plan 2005 goal. The SHDP listed the Wiley Slough Project in an inventory of projects that provide these multiple benefits. A related 3FI document notes that flood protection benefits will be even more important with climate change related sea level rise and storm surges.

**Lessons Learned**: From newspaper articles and some other sources, it appears there was some preproject controversy regarding conversion of habitat to wetland because the area had been managed for game bird habitat and hunting opportunities, which were reduced post-construction. Also appeared to be some increased flooding of adjacent agricultureal lands post-construction, which was mitigated via pumping.

**Funders**: Salmon Recovery Funding Board \$2,327,294; NRCS \$1,290,000; USFWS \$568,872; Puget Sound Nearshore Ecosystem Restoration Project \$52,003; and Estuary Salmon Restoration Program \$130,806

NOTE: 2008 story in Skagit Valley Herald detailing various debates about project before it was implemented.

Estuary: Skagit	Name: Swinomis Project, Skagit Riv	h Channel/Fornsby Creek/Smokehouse Floodplain er Estuary
Type: Replacement		Total Cost: \$658,666

Summary: [Skagit River System Cooperative SRSC] The Smokehouse tidelands- a network of intertidal blind and distributary channels with areas of salt marsh, mud flats, intertidal wetlands, and uplandsare located on Swinomish Indian Tribal Community reservation lands along the Swinomish Channel of the N. Fork Skagit River. Once a complex distributary for the river, the Smokehouse tidelands were significantly degraded by development of the Swinomish Navigation Channel via an Army Corps of Engineers dredging project in 1937, which converted the tidelands to a diked and drained landscape. Fish access was blocked by tide gates and dikes, and much of the intertidal habitat was buried under dredge spoils. For many years the SRSC, the Swinomish Tribe, and other project partners have worked to restore this estuarine habitat. Between 2005-2008, four top hinged "flap style" tide gates—which inhibit fish and water movement—were replaced with self-regulating tide gates (SRTs)—which restore tidal flushing—opening more than 5 miles of intertidal channel habitat to fish. Three new bridges were also installed across the tidal channels to replace non-functioning or partially blocked culverts, further improving fish access. In 2008, 3.5 acres of intertidal salt marsh habitat were restored at the mouths of the tidal channel networks through excavation and removal of dredge spoils, which buried the landscape during the maintenance of the navigation channel. Site revegetation and stewardship has been ongoing since the tidelands were reopened to tidal hydrology. Between 2006 and 2009, 16.7 acres of riparian corridors were actively replanted with native vegetation and 7 acres were passively restored to salt marsh. In 2014 and 2015, 15.9 acres of riparian corridors were planted, with plans to revegetate an additional 28.8 acres in upcoming seasons.

[WA Habitat Work Schedule website] The Fornsby Creek SRT/Smokehouse Floodplain project is located along the Swinomish Channel of the Skagit River delta, west of Mt. Vernon, WA. The site was once an expansive estuarine emergent marsh over 900 acres in size. Hydraulic modifications including installation of flap-style tide gates converted the area to arable uplands. The site still contains a significant network of remnant slough channels, simplified by decades of agriculture, with small freshwater tributary streams but isolated from tidal influence. Phase I (2003-09) restored about 50 acres of former estuarine marsh along the Swinomish Channel, with 6 distinct components: 1a) removal of wood culvert and installation of steel bridge; 1b) installation of second "Aberdeen-Style" tide gate; 2) blind channel development; 3) oxbow slough restoration (former control reach); 4) north old slough channel restoration; 5) fill removal near LaConner. The project will restore natural functions and processes within the project area. Restoration of tidal marsh, blind sloughs and distributary channels will provide important rearing habitat for Skagit basin Chinook salmon, and several other salmonid species. Replacement of a flap gate with a side-hinged SRT at South Fornsby occurred in late summer 2005.

Phase II of the Smokehouse Floodplain Project as outlined in the Chinook Recovery Plan is levee removal. With Phase I opening the floodplain to fish passage this project seeks to set back levees through key areas of the Smokehouse floodplain, allowing expression of larger emergent marsh communities and associated blind channel networks. [NOTE: Phase II does not appear to have been completed as of 7/2017.]

**Aerial Images** Smokehouse Floodplain reconnection and Fornsby Creek tide gate replacements (8/3/2016). Note image is oriented with North on the left.

Figure \_. Smokehouse Floodplain reconnection before restoration activities (7/31/2005).

**Restoration Metrics**: Annual smolt production of delta-rearing juvenile Chinook; Total Amount of Estuarine / Nearshore Acres Treated; Yards of Channel Modified/Created; Number of Tidegates

Altered/Removed To Allow Fish Passage; Acres of Estuary Created.	
Monitoring Focus:	<b>Study Design</b> : [Greene et al. ]Fornsby was monitored using a BACI design starting two years before SRT installation and for at least two years post-SRT installation. Monitored both above and below the tide gate using data loggers and a combination of beach seine and fyke trapping methods.
Parameters:	Species Monitored:

**Project Findings**: [Greene et al 2012] At S. Fornsby, replacement of a flap gate with an SRT increased connectivity measures: the percentage of time that gate doors were open increased from 28% to 40%, while the percentage of time fish could move upstream changed from 0% to 14%. Tidal muting declined from 66% to 47%, resulting in a nearly 40% increase in the effective mean higher high water (MHHW). Top hinged flap gate replacement with a side hinged SRT was followed by a 6X increase in cumulative Chinook salmon densities, but these densities were still 8X lower than its hydraulically unimpeded reference site.

**System Effects**: [Climate change & flood protection benefits] In addition to better fish passage and habitat, the Smokehouse Floodplain Project also provides flood protection, as described by the Farms, Fish and Floods Initiative (3FI), a landscape-scale effort in the Skagit Delta based on an MOU between NOAA, Skagit Conservation District, Skagit County, Skagit County Dike and Drainage Partnership, Skagitonians to Preserve Farmland, TNC, WA Dept of Fish and Wildlife and Western WA Agricultural Association. 3FI focuses on advancing mutually beneficial strategies that support the long-term viability of agriculture and salmon while reducing risks of destructive floods. 3FI complements the WA state Tidegate Fish Initiative (TFI). The Skagit Delta Hydrodynamic Model Project (SHDP) is supported by and contributes to the goals of 3FI. The SDHP Team initiated hydrodynamic modeling and alternatives analysis to identify and prioritize mutually beneficial large scale flood risk reduction and estuarine habitat restoration projects to achieve the Skagit Chinook Recovery Plan 2005 goal. The SHDP listed the Smokehouse Floodplain Project in an inventory of projects that provide these multiple benefits. A related 3FI document notes that flood protection benefits will be even more important with climate change related sea level rise and storm surges.

#### Lessons Learned:

**Funders**: WA Recreation & Conservation Office, Salmon Recovery Funding Board (SRFB)- total \$658,666. Two grants/funding instruments: Fornsby Creek SRT (02-1563) \$291,533/ and Swinomish Channel Restoration (04-1626) \$367,133. Seattle City Light Non-Flow Coordinating Committee?

Another source (Conservation Registry) has this info: WA Recreation & Conservation Office, SFRB (2003): \$291,532.86; and Swinomish Tribe (2003): \$329,700.65

NOTE: Discusses results from pre- and post project monitoring in Fornsby Slough, and compares to a reference slough in a BACI design.

Estuary: Skagit	Name: Fir Island Farms Estuary Restoration Project	
Type: Removal	Total Cost: \$16.4 million	

**Summary**: The Skagit Wildlife Area-Fir Island Farms Reserve Unit is managed agricultural land (225 acres on the south side of Fir Island Road) purchased in 1995 to create an upland snow goose reserve. This non-hunted game reserve is managed to provide a winter feeding and resting area for snow geese adjacent to the Skagit Bay estuary. Management of this site occurs through a lease agreement with a local farmer who plants a commercial agricultural crop that is harvested, and an over-wintered cover crop of winter wheat for snow goose forage. The area is part of the tidal delta of the Skagit River flanked by Dry Slough on the east and Brown's Slough on the west.

In the late 1800's, following human settlement, dikes were built and the land was converted to agricultural uses. Following the ESA listing of Chinook salmon as threatened in 1999, and subsequent development of the Skagit Chinook Recovery Plan, this site was identified as a prime location for the implementation of a restoration project to improve salmon habitat.

The Fir Island Farms Estuary Restoration project is located on the WDFW Snow Goose Reserve on Fir Island in the Skagit River Delta. Initial work on the Fir Island Farms project started in 2009; feasibility studies started in 2011; construction began in 2014 and was largely completed when the old dike was breached in fall 2016. Project goals: 1) restore the tidal processes that bring water, sediment, and nutrients to the marsh, supporting and maintaining habitat for fish and wildlife; 2) protect surrounding agricultural lands from flooding and saltwater; 3) provide parking and access for people viewing snow geese, shorebirds, and other waterfowl at the Fir Island Farms Snow Goose Reserve and provide winter forage and a reserve where hunting is prohibited.

The project set back approximately 5,800' of an existing dike and restored 131 acres of tidal marsh and tidal channels, important for juvenile Chinook salmon. Two existing 48" tide gates were removed along with the old dike, and two new 48" tide gates were built into the setback dike. In addition to habitat restoration, this project incorporates protections to reduce flooding, maintain drainage, and prevent saltwater intrusion on surrounding farmland. WDFW worked closely with Consolidated Drainage and Diking District 22 to ensure the final project meets the District's flood protection and agricultural drainage standards.

The new habitat is expected to support an additional 65,000 young Chinook a year.

Aerial Images: Restoration Metrics:		
Parameters:	Species Monitored:	
Project Findings:		
System Effects: Climate change and sea level rise project design.	predictions were also incorporated into the final	
<b>Lessons Learned</b> : The Western Washington Agricupart of the Skagit Delta Tidegates and Fish Initiative support for the project, but some farmers remain uses. "We are still losing farmlands," he said. The	ve (SFI). [WWAA director] said there is general concerned with conversion of farmland to other	

minimal impacts to neighboring farms. "Our support for salmon recovery and these projects in general is linked up with how drainage infrastructure such as tide gates are replaced," Roozen said. "When infrastructure is removed, like the dike and tide gate in this project, those have to be replaced." The Fir Island Farms project included putting in new dikes and tideg ates, we well as a pump house, at no cost to the area dike district.

Funders: Puget Sound Acquisition and Restoration Fund provided \$13.4 million.

**Partners**: Washington State Department of Fish & Wildlife; The Nature Conservancy; Salmon Recovery Funding Board; NOAA; Puget Sound Partnership; US Fish & Wildlife Service; Skagit Watershed Council

### Project Documentation:

Estuary: Skagit	Name: Deepwater Slough Restoration	
Туре:		Total Cost: \$2.3 million

**Summary**: Can't find any reference to tide gates for this project. Dike setback, dike removal, dike breach. "Dikes were removed in 2000 to reestablish valuable estuary habitat." The Deepwater Slough Project is a 204 acre estuary restoration project located on Washington Department of Fish and Wildlife land at the mouth of the South Fork of the Skagit River. The project removed dikes to restore river and tidal influence to the project area creating critical juvenile habitat for threatened Puget Sound chinook salmon. The Skagit System Cooperative is the lead on this project.

Estuary: Skagit	Name: McElroy Slough Estuary Restoration Project	
Type: Replacement		Total Cost: \$841,461

**Summary**: McElroy Slough is an independent drainage on the coast of Puget Sound in NW Skagit County adjacent to Samish Bay and the town of Blanchard. It drains and links three salmon bearing creeks (Colony, Whitehall, and Harrison) with Samish Bay. This 100-acre (historically) estuary was diked, drained and tide-gated since the early 1940s to facilitate agricultural use. The project (2006) replaced the 3 existing McElroy Slough culverts with TGs at Blanchard Road with four 6' x 6' box culverts and TGs. Three of these TGs are traditional gates with top hinges and one TG is side hinged and is self-regulating to allow saltwater into the slough at certain tide levels. The new gates have a combined total area of 144 sf; the old gates had 69 sf. The project also removed two culverts under Flinn Road (1/3 mile upstream) and replaced the crossing with a 45' bridge.

The project has improved tidal processes, fish passage and estuary rearing area for Chinook, coho, chum and cutthroat in the Colony Creek watershed. More than 26 acres along the historic slough channel have been placed under permanent easement via the Federal Wetland Reserve Program. This project re-opened 1 river mile and 4.75 acres of estuary for anadromous fish use, plus improved access to 5 miles of Colony Creek, 1 mile of Harrison Creek, and 1/2 mile of Whitehall Creek, all used by anadromous fish. The project also provided flood relief and drainage benefits to the Blanchard community. Project partners include Skagit County, US Fish and Wildlife Service and Washington Department of Fish and Wildlife. Skagit Fisheries Enhancement Group (SFEG) concluded long-term monitoring of fish use, vegetation and channel conditions at McElroy Slough in 2014. Fish sampling was led by Bruce Brown of the Skagit River System Cooperative (SRSC) under contract to SFEG. SRSC, SFEG staff, and volunteers sampled fish use upstream and downstream of the tide gates at 2-week intervals from February through the end of June. Funding for monitoring was provided by a private settlement.

Aerial Images (5/2/2015):

**Restoration Metrics**: tidal processes, fish passage and estuary rearing area for Chinook, coho, chum and cutthroat

Monitoring Focus: All	Study Design: [Beamer 2014] Fifty-four beach seine sets were made in McElroy Slough from Feb-June 2014. Sites up- and downstream of the tidegate site were sampled and are consistent with sites sampled in previous years. Sampling frequency was once in February and 2X/month in March-June. The sampling period is designed to capture the entire period when juvenile Chinook salmon use estuarine habitats in Puget Sound. In 2014, per a recommendation after 2011 beach seining, we installed data loggers up and downstream of the tidegate in order to measure variables influenced by tidegate operation: 1) water surface elevation (WSE) when the tidegate doors close, 2) WSE up and downstream of the tidegate, 3) water temperature up and downstream of the tidegate. [Thom et al. 2007] Prior to project implementation, a monitoring plan was initiated to collect baseline data related to surface and
	to collect baseline data related to surface and ground water levels, and salinity. Before

	construction commenced, the Skagit Fisheries Enhancement Group (SFEG) implemented components of the monitoring plan to collect baseline data both inside and outside of the tide gate. Other activities included documenting juvenile fish usage, channel cross sections, establishment of vegetation plots, and an aerial
Parameters: Juvenile chinook; water surface	imagery to document baseline conditions. Species Monitored: Focus on Chinook, but also
elevation (WSE) when TG doors close; WSE up- and downstream of TG; Water temp and salinity up- and downstream of TG	coho, chum, pink, cutthroat

**Project Findings**: [Beamer 2014] Juvenile Chinook appear to be able to move upstream through the tide gate and occupy tidal habitat upstream. But is unknown whether 2006-2014 results represent an improvement over the old tide gate because there are no "before tide gate replacement" fish monitoring data. Juvenile Chinook density is clearly lower upstream of the tide gate than downstream. Reference site tidal channels show the reverse relationship (i.e., more juvenile Chinook upstream than downstream) so it is reasonable to conclude the tide gate, as currently installed and operated, is a partial impediment to upstream juvenile Chinook movement. Tide gate operations that increase the time doors are open on flooding tide stage would likely improve juvenile Chinook access to habitat upstream of the tidegate. Tide gate door closure results could be used to determine whether the SRT setting could be changed so the doors closed at a higher WSE, thus leaving the doors open longer on flood tides.

NOTE: Contrary to Beamer 2014, Thom et al. 2007 state that Skagit Fisheries Enhancement Group collected pre-project fish data. JRB contacted SFEG to ask about this; no response.

**System Effects**: [SFEG 2006-2007 Annual Report] Restoring the estuary functions to McElroy Slough will greatly enhance the fish and wildlife use of this watershed as well as reduce flood hazards to the Blanchard Community.

**Lessons Learned**: By the end of 2001, the project was fully funded and permitted, and ready for construction bidding. Project partners and Blanchard residents anticipated that project implementation would commence during 2002. A solid monitoring plan had been created by the committee to look at both physical and biological changes and baseline data related to adult fish use, surface water and ground water levels were monitored. However, complications occurred which postponed project implementation. Political and engineering issues related to replacing tide gates on a Skagit County road with a tide gate that allows tidal inundation delayed the project for 4 years. Monitoring continued over this time, while project partners patiently (yet frustratingly) waited for resolution of these complicated issues through additional analysis and design review and modification. In May 2006 Skagit County finally put the project out for bid; in July 2006, the McElroy Slough Project construction bid was awarded.

[Skagit County Board of Commissioners Record of Proceedings Dec. 6, 2004] "Lynn Lennox, 3634 Legg Road, Bow, spoke of the need to move forward with the McElroy Slough Project. She explained that she personally worked very hard on this project and that much of the recent flooding in Blanchard could have been avoided if the project had been built. David Allen, 15547 Flinn Road, Blanchard, expressed concerns regarding property that he owns that is surrounded by private dikes. When he purchased the property, Mr. Allen said he was unaware that these dikes were to be maintained by the owner. However, he has obligingly done so for the past 6 years in order to keep his road passable. Approximately three years ago, adjacent property was sold to a new owner who has the mindset that if he doesn't maintain the dikes, then the government will. Mr. Allen's argument is about the right to protect his property from floodwaters without being threatened. Commissioner Dahlstedt explained to Ms. Lennox that he and others recently met with local diking district folks and the Dept of Fish and Wildlife regarding the McElroy Slough Project. He is hopeful that a proposal will be brought forth very soon that is agreeable to all parties. Chairman Anderson asked Skagit County Public Works Administrator, Dave Brookings, to have staff survey the right-of-way on Flinn Road in order to provide Mr. Allen with a straight answer as to who is responsible for dike maintenance."

Estuary: Puget Sound	Name: Shoal Bay	Tide Gate Removal Project, Lopez Island, WA	
Type: Removal		<b>Total Cost</b> : \$116,000 (Islands Weekly article says \$125,000)	
that constricted tidal flow to res utilization of the shallow water h	<b>Summary</b> : Shoal Bay lagoon, NE Lopez Island, WA. Restoration objectives: remove derelict tide gate that constricted tidal flow to restore adequate tidal flushing of the lagoon to enhance salmonid utilization of the shallow water habitat for both forage and refuge from predation, ameliorate water quality and help to maintain acceptably low water temperatures in the lagoon.		
Work (Oct. 14-16, 2009) was authorized under San Juan County, WDFW, and the US Army Corps of Engineers. concrete TG removed to restore tidal water flow and velocity, fish passage, and improve water quality. TG originally installed around 1982-83 and apparently only used for a few months to enhance conditions for an aquaculture project in the lagoon. TG comprised of a flood box, a mostly open, 13'-wide box structure and 4 additional deflecting "wing walls", all concrete. The doors were gone and the gate had not been properly functioning for years prior to removal. Four 12" corrugated plastic culverts beneath the gate drained the lagoon when water levels were slightly lower than the gate. These culverts were largely clogged or broken. Prior to removal, the tide channel measured ~12' wide (2 separate 6' openings). A scour hole was located on the landward side of the structure (maximum depth of +3.9 ft MLLW, or 1' lower than the base of the gate). Both ebb and flood tidal deltas were present on either side of the gate, indicative of impeded flushing.			
Tide channel geometry was altered by widening the tide channel as well as slightly increasing its minimum depth. This more open geometry will enhance flushing of tidal waters in and out of the lagoon, which is reflected in lower water levels during low tides. The altered channel geometry will also decrease flow velocities through the tidal channel, which will likely result in more natural rates of sedimentation in the lagoon. Prior to excavation, all large areas of saltmarsh vegetation were selected for transplanting to the finished inlet banks. Clumps of mixed patches of pickleweed (Salicornia virginica) and salt grass (Distichlis spicata) were removed by the excavator with roots intact, temporarily stored on-site, and placed into the ground by machine and hand following grading.			
[Project] removed a derelict tide habitat to San Juan County near Shoal Bay lagoon. This derelict s creating water quality problems wetland habitat. Removal of the to feed and rest. Aerial Image (5/2/2015):

**Restoration Metrics**: Reducing inflow and outflow velocity; habitat utilization by juvenile salmonids, water temperature

Monitoring Focus: Water temperature	Study Design:
Parameters: Water temp assessed post-removal	Species Monitored:

**Project Findings**: From Island Weekly article (2010) "Where fish used to get trapped in channel scour holes on either side of the structure at mid level tides, fish are now travelling in and out of the lagoon at minus tides..water temp sensors recorded a drop in summer temps within the lagoon of nearly 5 degrees (F). No fish kills were observed in summer 2010 as they had been in previous years." [FRIENDS Science Director Tina Whitman]. "This past year we have seen an astounding increase in both the number and species diversity of fish in the lagoon. This spring entire schools of juvenile pink salmon regularly prowled the lagoon on incoming tides. In six years of shell fish operations we have never seen this before. During the summer we saw large numbers of Ling cod, Tom cod and other species we have never observed in the lagoon.," [Property owner Nick Jones.]

**System Effects**: Island Weekly article: "An unanticipated outcome of the project included improved shellfish growing conditions." [Site is near a shellfish farm.]

**Lessons Learned**: Islands Weekly article: "Benefits associated with this project include...new information to inform researchers, policy-makers and other land owners, and a framework for ongoing cooperative models in our community. We were delighted to be engaged in a truly collaborative process that improved the health of the bay for fish, wildlife and shellfish growers." [Stephanie Buffum Field, Executive Director at FRIENDS.]

Estuary: Puget Sound	Name: Port Stanley Lagoon Tide Gate Retrofit, Lopez Island, WA	
Type: Replacement		Total Cost:

**Summary**: In 2006 San Juan Islands Conservation District (SJICD) completed a 3-year effort to install of a new, hydraulically-operated tide gate at the Port Stanley Lagoon outlet, restoring daily tidal flow into the lagoon for the first time in over 40 years. The SJICD and project partner San Juan County Dept of Public Works (DPW) have seen improvement in lagoon water quality, improved wildlife habitat and reduced flooding during severe winter storms.

After the original tide gate was installed in the early 1960s the lagoon gradually filled with sediment until only a shallow stagnant puddle remained each summer. At the request of the lagoon owners SJICD received a USFWS grant in 2003 to evaluate ways to restore some tidal exchange while improving the winter drainage and flooding situation. After a hydraulic modeling study and fieldtesting, SJICD presented options to the lagoon owners and neighbors. They favored allowing partial tidal exchange into the lagoon, but only up to a level that would not impact lawns, drain fields and other property. SJICD next received a WA Dept of Fish and Wildlife grant to design and implement the plan.

The project began with dredging the outlet channel and modifying the beach out-fall pipe. The DPW Lopez Island Road Crew installed the new tide gate that opens and closes at pre-set tidal elevations in June 2006. The upland portion of the beach was disturbed and compacted by heavy machinery. Beach vegetation was restored in April 2007 by planting 500 dune wild rye and 200 beach pea on the 2500 sf site. Plant choice was based on species currently present along undisturbed beach areas and suggestions by Coastal Geologic Services beach restoration specialist Jim Johannessen. Funding for this phase was provided by Ducks Unlimited, SJICD and DPW. The tide gate is managed by DPW Lopez Island Road Crew and can be viewed inside a grated vault along Port Stanley Road.

## Aerial Image (7/10/2014):

Restoration Metrics: salmonid reproduction	
Monitoring Focus: Biological	<b>Study Design</b> :2012/2013 Spawning Survey: On Dec 12 and 18, Whidbey Watershed Stewards (WWS) conducted salmonid spawning/pre-spawn mortality surveys on previously selected index reaches of mainstem Maxwelton Cr. Annual survey since 2006

before the population disappears entirely.

Fish appear very limited in ability to access the watershed. Historic reproductive population was 10's of thousands of fish for this system; population is far below sustainable levels today. The only way to assess TG functioning would be to monitor the gate itself, and assess if salmon are able to get through the outlet pipe and TG vaults. Also, outflow pipe and door function improvements may be possible without detrimental effect on flooding. At present, the only proxy available to judge TG passability is to find adult salmon in the creek, and to make assumptions about the natal population. In 2010 spawning activity was found in the Quade Cr trib, and further investigation there was recommended. A blocking culvert on Wildes Rd. was identified, and listed on the Island County replacement list. In 2011 condition of spawning habitat in Quade Cr deteriorated significantly; spawning gravels were covered by 6-8" of sand. The culvert was nearly entirely blocked by sand until county crews cleared it in fall of 2012. This culvert is undersized; a bottomless culvert should be a priority for this site. Also, the sediment problems in the system should be identified and remedied if possible. Other culverts identified as partial blockages or velocity blockages have changed since 2003 monitoring. These culverts should be reevaluated and further fish passage projects in the valley identified. This evaluation should be compared with the county structural condition report and priorities established. In particular, the mainstem Maxwelton culverts under French Rd and Erikson Rd have both deteriorated, and should be evaluated.

Estuary: Skagit	Name: Schneider Creek (Ditch) Floodgate Retrofit, Nooksak River	
<b>Type</b> : Replacement, two gates. One side-hinged, one MTR.		<b>Total Cost</b> : \$40,000 (or \$45,000)
<b>Summary</b> : Whatcom County Drainage & Irrigation District No. 2 operates a pair of 5' flood gates across the mouth of Schneider Cr, a small, lowland tributary of the Nooksack River to prevent flooding of local farm fields. The existing flap gates blocked coho from access to upstream spawning habitat. Project replaced one flap gate with a side-hinged gate and the other with a muted tidal regulated (MTR) gate. The side-hinged gate opens easily under low head. The MTR stays open until the upstream w.s.e. reaches the "ordinary high water level", then closes to prevent backflow from the Nooksack. Nehalem Marine Manufacturing fabricated and installed the gates for about \$40,000. Project funded by a NFWF grant. Installation completed January 2009. Effectiveness monitoring has begun. Permitting requirements favored retrofit of existing structure, but full-replacement of the structure would have been simpler and cheaper.		
Objective: Improve fish access to 20,000 feet of flood plain tributary channel, associated wetlands, and ponds. The targeted species and life stage are juvenile chinook expected to use the transition flood plain habitats between the Nooksack River and Schneider Ditch; adult and juvenile coho, steelhead, and cutthroat expected to use the entire Schneider ditch drainage.

NOTE: Short description, project cost and photo of	the TG (p.3)	

<b>Estuary</b> : Qwuloolt Estuary, Snohomish River	Name: Qwuloolt	Ecosystem Restoration Project	
<b>Type</b> : TG removal (Levee breach	, 3 TGs filled in)	<b>Total Cost</b> : \$3.73 million (Not including pre- and post-project monitoring)	
<b>Summary</b> : The Snohomish River drains 1,856 mi2 of the western Cascades and is the second largest river draining to Puget Sound. The river supports significant runs of coho, Chinook, chum, and pink salmon; and steelhead, cutthroat and bull trout. The Qwuloolt Estuary lies in the Snohomish River floodplain about 3 miles upstream from the Snohomish outlet to Puget Sound. Historically, the area was tidal emergent marsh and forest scrub-shrub wetland, interlaced by tidal channels and streams. In the early 1900s a levee was constructed on Ebey Slough and tide gates were installed at the mouth of Allen and Jones Creeks to convert the land to agriculture, preventing tidal access and destroying the estuary's marsh habitats. As a result, salmon and other estuarine-dependent species were unable to use the highly-productive environment. Prior to restoration the area was fallow agricultural land covered by invasive reed canary grass, thistle, and blackberries.			
The Qwuloolt project area is about 360 acres of former estuarine wetland. Restoration of the site is intended, in part, to help compensate the public for injuries to natural resources as a result of the Tulalip Landfill, a Superfund site. Restoration planning began in 1997. Since 2006, project partners worked to refine the preferred alternative to enhance ecological and biological objectives and to reduce overall project impacts and costs. Final designs were completed in 2012 through collaboration between the US Army Corps of Engineers, the Tulalip Tribes, and ESA-Adolfson.			
The US Army Corps of Engineers and Tulalip Tribes signed an agreement in 2012. The Corps awarded a \$3.73 million, two-phase construction contract to Sealaska, of Auburn, WA. Phase I involved stream channel and upland re-contouring, wave attenuation berm construction, and native vegetation restoration. Over 1.5 miles of lower Allen and Jones Creeks were restored to natural alignment. Interior site work included filling of relict agricultural drainage ditches and excavating channels to facilitate natural tidal function. A new outlet channel connecting Jones Creek with the inboard side of the Ebey Slough levee was completed in August 2013. Construction of wave attenuation berms spanned 2012-2015. Most (7.5 acres) native vegetation planting along the eastern and northern edges of project area was completed in 2012. Three stormwater filtration ponds were constructed west of the setback levee to improve the quality of stormwater runoff from the nearby industrial park.			
In October 2015, three tide gates were decommissioned and sealed at the SW end of Jones Creek, assisting in the final step of restoring natural hydrology to the site.			
Qwuloolt site. Construction of a protect Brashler Industrial Park, surrounding the area, was comp of the Ebey Slough levee was low inundation. Monitoring targeted primarily at Chinook salmon was conducted before and after the dike breach, 2013-2016. Following the breach, scientists will monitor changes including elevation, sediment			

2013-2016. Following the breach, scientists will monitor changes including elevation, sediment dynamics, water temperature and salinity, nutrient and food availability, fish population and diversity,

and wildlife abundance and diversity. There appears to be system-wide monitoring of fish and water quality for the Snohomish Estuary, with a particular focus on understanding the effects of restoration at Qwuloolt. Pre-project monitoring was initiated in 2010, and continued through at least 2016 (one year post-project). As of Sept 2017, there does not appear to be much available in the way of post-project synthesis of results.

**Restoration Metrics:** Chinook salmon access and numbers, water quality, topographic elevation, establishment of native plant communities

	T
Monitoring Focus: Juvenile Chinook	<b>Study Design</b> : [2016 monitoring]: Juvenile validation monitoring in the estuary is categorized into two different sampling bins, Estuary System- wide, and Qwuloolt Monitoring. 185 beach seine samples were taken across the estuary as part of the Estuary System-wide effort and 430 beach seine samples and 27 fyke net samples were taken at both in the Qwuloolt Restoration site and at reference sites that are part of the Qwuloolt Restoration project effectiveness monitoring effort. All monitoring data has been entered into a database and is undergoing QA/QC by NOAA Northwest Fisheries Science Center staff. The amount of monitoring was scaled back from 2015 due to reduction in funding to project partners.
Parameters:	Species Monitored: Juvenile Chinook

**Project Findings**: The project has returned natural hydrologic processes to the ecosystem and resulted in a re-inhabiting of the site by native salmon, wildlife, and plant communities.

#### System Effects:

#### Lessons Learned:

**Funders**: US Army Corps of Engineers (construction); Pacific Coast Salmon Restoration Fund (monitoring)

**Partners**: Tulalip Tribes, NOAA, U.S. Fish and Wildlife Service, Washington Department of Ecology, US Army Corps of Engineers, Natural Resource Conservation Service, City of Marysville. Other partners: Snohomish Basin Salmon Recovery Forum, Washington State Department of Fish and Wildlife, Puget Sound Partnership, Sound Transit. ESA-Adolfson (contractor)

Estuary: Humbolt Bay	Name: Rocky Gulch Habitat Restoration Project	
Type: Replacement		Total Cost:

**Summary**: Overarching goal for Rocky Gulch (6 mi N of Eureka, CA, trib to Humboldt Bay) is to restore anadromous fish access and naturally reproducing anadromous salmonid populations (coho and steelhead) from Humboldt Bay to approximately the Rock Quarry 0.9 miles upstream of Old Arcata Road. Freshwater stream, borders tidal zone, tidal inundation in first 1700'. Existing TG at 600' leaked so seawater passes but all anadromous fish passage was blocked.

Objectives: 1) provide unimpeded fish passage through the tidegate; 2) increase tidal marshes and slough channels in lower Rocky Gulch to provide juv salmonid rearing habitat and possibly tidewater goby habitat; 3) widen the creek channel and re-create a floodplain, rehabilitate dikes to better contain winter floods and protect pasture; 4) restore riparian and conifer vegetation on the newly created floodplain along Rocky Gulch; 5) freplace the barrier culvert to restore fish access to upstream habitat (Phase II of restoration).

Project Description: Replace old TG with fish friendly TG to re-establish muted tidal prism coupled with channel habitat restoration (addition of instream wood, riparian planting, cattle exclusion) in the stream-estuary ecotone upstream of tide gate. Side-hinged aluminum TG with adjustable 'guillotine' aux door mounted on existing wingwalls (reinforced w/aluminum sheets) in Dec 2004 to replace a top-hinged wooden TG. Excavated aggraded fines, reconstructed/rerouted 2,800' of channel, relocated some dikes and rehabbed others, installed riparian fencing, planted native species. Monitoring: Post project monitoring of juvenile salmonids in Rocky Gulch and limited WQ data.

#### Aerial Image (5/26/2016):

Restoration Metrics: Spawning by coho, steelhead, and anadromous cutthroat		
Monitoring Focus: N/A	Study Design:	
Parameters:	Species Monitored:	

**Project Findings**: New populations of coho salmon moved into Rocky Gulch and Gannon Slough after impassable tidegates were replaced by fish friendly tidegates.

[Project benefits, according to Mierau/McBain & Trush] 1) fish passage at tide gate at all times during tide cycle, either through main tide gate during ebb tide or through the 1'x2' auxiliary door within the main door that is permanently open (currently open 1x1 ft); 2) improved adult passage by eliminating potential for dikes to breach and flood the pasture in winter, and creating a defined channel with adequate widths and depths for upstream migration; 3) significant protection of the pasture by: (1) reducing or eliminating flooding onto it, (2) reducing or eliminating salt water intrusion onto it, (3) providing watering access for cattle at erosion-resistant hardened streambeds, (4) improving access to the pasture along Old Arcata Road via new bridge crossing; 3) a defined floodway within reconstructed dikes that will contain floods of approximately Q5 to Q10 year recurrence and a muted tidal prism; 4) greatly improved rearing habitat in the freshwater/tidal "ecotone" for high quality summer and winter rearing, and down into the brackish estuarine slough channels; 5) maintenance of pre-existing salt marsh sustained by the muted tidal prism from the tidegate; 6) long-term protection of utility infrastructure; 7) increased riparian vegetation along Old Arcata Road, existing mature conifer cover that was preserved, and improved plant species diversity; 8) better drainage of tributaries along Old Arcata Road (Halvorsen Gulch, Stevens Gulch, others) to flow directly into Rocky Gulch, improving overall drainage of rainfall runoff.

#### System Effects:

**Lessons Learned**: Side hinged door caused scour on opposing bank, requiring additional rock armoring. The tidegate fails to swing fully open, deflecting flow towards the opposite bank. This led to substantial bank erosion, which was later mitigated by placing riprap along the bank. The fabricator [Nehalem Marine?] reasoned that placing the auxiliary door in the gate reduced the forces on the gate, resulting in it not fully opening.

By working successfully with the private landowners to implement the project, clearly demonstrated the mutual benefits to both the landowners and the fishery resources. This success may encourage future cooperation with other landowners for restoration projects around Humboldt Bay. Additionally, despite a 1-year delay to the original implementation schedule, we were able to design, permit, and implement this project in a little over 2 years from completion of the CDFG Agreement .

<b>Estuary</b> : Humbolt Bay	Name: California Department of Fish and Wildlife Natural Stocks Assessment Project (Humboldt Bay Tributary Monitoring)	
Type: Replacement		Total Cost:

**Summary**: This monitoring effort focused mainly on juvenile salmonid use of estuary habitats in several small tributaries to Humboldt Bay, including restored habitats, primarily newly-constructed off-channel ponds. Some restoration projects included tide gate work, but the focus of this monitoring was not on tide gates.

[2007-2009] CDFG's Natural Stocks Assessment Project (NSA) continued sampling tidal portions of Freshwater Creek Slough, Elk River Slough, and Salmon Creek estuary to document use by juvenile salmonids. In 2007 began sampling smaller Humboldt Bay tribs- Jacoby Creek/Gannon Slough, Martin Slough, Rocky Gulch, and Wood Creek to determine if juvenile salmonids use these very small tidal streams as year round or over winter rearing habitat during high stream flow events.

[2009-2011] NSA continued sampling tidal portions of upper Freshwater Creek Slough, Wood Creek, and Salmon Creek estuary. Completed sampling in lower Freshwater Creek Slough, Elk River Slough, Hookton Slough, Jacoby Creek/Gannon Slough, Martin Slough, Rocky Gulch. Initiated sampling in Ryan Creek Slough to determine how juvenile salmonids use the Freshwater-Ryan stream-estuary ecotone as a rearing area. Installed PIT tag antennas in Wood Creek to assess performance of a newly constructed off-channel pond as over winter habitat for juvenile coho. By describing life history traits and habitat needs of juvenile coho, Chinook, steelhead, and sea-run coastal cutthroat this project provides data to help restoration planning- "snapshots" of juvenile salmonid use of these areas before and after restoration projects.

Aerial Image (Rocky Gulch, 5/26/2016):

Restoration Metrics: Presence and spawning by coho, Chinook, steelhead, and anadromous cutthroat	
Monitoring Focus: Biological	<b>Study Design</b> : Sampled fish using seine nets and minnow traps baited with frozen salmon roe
Parameters: Fish	<b>Species Monitored</b> : coho, Chinook, steelhead, cutthroat (all species caught were recorded)

**Project Findings**: New populations of coho salmon moved into Rocky Gulch and Gannon Slough after impassable tidegates were replaced by fish friendly tidegates. Juvenile salmonids sought out freshwater rather than brackish water habitat while rearing in the ecotone. Juvenile salmonids, especially coho, utilized newly constructed off channel ponds as soon as they were completed and fall/winter rains increased stream flows and converted the ponds to primarily fresh water habitat. The stream-estuary ecotone provides productive rearing habitat for juvenile salmonids, especially over winter habitat for juvenile coho.

Estuary: Humbolt Bay	Name: Salmon Creek Restoration Project			
<b>Type</b> : One tide gate replaced, one new tide gate installed.		Total Cost:		
<b>Summary</b> : Salmon Creek is Humboldt Bay's third largest tributary, draining about 5060 hectares and entering the ocean at the extreme southern end of Humboldt Bay via Hookton Slough. Historically, the Salmon Creek delta was a tidal salt marsh with a mosaic of slough channels and the drainage supported significant runs of coho, steelhead, coastal cutthroat, chinook and pacific lamprey. In the early 1900's the area was converted for grazing by construction of dikes and levees, marsh draining, straightening or relocation of stream channels, and installation of tide gates. Humboldt Bay NWR acquired the lands in 1988 and identified Salmon Creek as needing work to reestablish estuarine and off-channel habitat- sloughs, ponds and oxbows adjacent to the main channel needed by salmonids to transition to saltwater. Compared to pre-1900 conditions, almost all such rearing habitat in lower Salmon Creek had been lost. In the early 1990's, a small "fish door" was added to a tide gate flap, slightly improving fish passage				
and allowing minor tidal exchange upstream of the tide gate. In 1993, the refuge dug a new channel, re-establishing channel sinuosity and complexity. This improved habitat, but further restoration was needed to increase tidal circulation, and improve hydrology, fish access, and habitat for estuarine dependent species. In 2006-2007, an existing tide gate structure was replaced and two new gates at the mouths of Salmon Creek and adjacent Cattail Creek where they enter Hookton Slough, increasing tidal connectivity and tidal influence (Phase 1). The new tidegates have two side-hinged doors which provide better fish passage by reducing flow velocities and staying open longer through tide cycles. The middle door on the new tidegates is top-hinged but has a 2' x 4' slide door which can be kept open for constant movement of bay water into the upstream reaches of Salmon Creek, creating muted tidal conditions which improve ecosystem function.				
Phase 2 (2010-2011) focused on construction of 4,000' of new tidal slough channel with more capacity and sinuosity, mostly aligned with historic slough channels, but also maintaining connection to the former ditched channel so it could serve as backwater habitat. Four off-channel ponds totaling 2 acres were constructed and a connecting channel between Salmon Creek and Cattail Creek was excavated to provide winter freshwater rearing habitat for salmonids and improve fish movement between the two systems. Over 100 logs and rootwads, and 20 complex wood structures were added to provide cover for fish and add stream hydrology complexity. Also, twelve species of native trees and shrubs were planted adjacent to the channel and ponds. The Phase 2 design process included extensive modeling of both tidal and streamflow conditions using unsteady state hydraulic models, tidal channel geometry relationships, sediment transport analysis, and evaluation of soil properties and salinity data to predict rates of channel adjustment in response to the increased tidal prism. M. Wallace: "Here are the two subsequent reports describing our work on Salmon Creek, where an old tide gate was replaced by a newer fish friendly one (2009), and on Wood Creek where the old top hinged tide gate flap was removed. In both instances other habitat restoration measures- e.g. constructing off-channel ponds and enlarging/relocating the stream channel occurred so changes can't be attributed solely to the change in tide gates."				
Salmon Creek Project Description: (2006-07) Replace old tide gate with fish friendly tide gate to re- establish muted tidal prism coupled with channel habitat restoration (enlarging stream/tidal channel, creating off channel ponds, riparian planting) in the stream-estuary ecotone upstream of tide gate.				

Aerial Image: Salmon Creek restoration projects and locations (5/26/2016).

Restoration Metrics:	
Monitoring Focus: Biological (salmonids) Limited water quality data	<b>Study Design</b> : Pre-replacement monitoring, post- replacement 2009>. Beach seine or minnow trap to collect fish. Fish ID'd to spp, life stage, counted; salmonids examined for tags/marks, measured mm), weighed (0.1g), scale removed. Salmonids PIT tagged if size allowed.
	Monitoring: Pre and post project monitoring for salmonids in Salmon Creek and limited water quality (WQ) data. Likely other physical and biological monitoring upstream of new tide gate by project proponents.
	2011-2012: Pre-restoration sampling was conducted in the old stream channel. Post- project (after fall 2011) this became a dead end tidal channel so most sampling shifted to the new off-channel ponds. In Dec. 2011 a paired PIT tag antenna array was installed at the opening of the second-most upstream pond in Salmon Creek. Water quality (temp, salinity, conductivity, DO)
	sampled in the newly constructed ponds and adjacent slough habitat. 2013-2015: Bi-weekly sampling for juvenile salmonids in Salmon Creek, monthly sampling in Cattail Creek. A 9.1 m X 1.2 m seine net was used at two sites in Cattail

possi salma Creel off-ch detec array every DO) v pond betw collec wher wher botto 2011	tated areas where effective seining was not ble, minnow traps baited with frozen on roe were used at four sites in Cattail k and two sites in each of the constructed nannel ponds in Salmon Creek. PIT tag ctions from previously installed antenna were stored on a data logger, downloaded y 1-2 weeks. Water quality (temp, salinity, was sampled bi-weekly at the off-channel s in Salmon Creek. Due to stratification een fresh and brackish water, samples were cted at surface, mid, and bottom elevations in water depths > 0.91 m, surface and bottom in water depths were < 0.46 m (same as -2012).
Water quality: temp, salinity, DO	
Parameters: Salmonids Speci	ies Monitored: salmonids

**Project Findings**: Generally, stream-estuary ecotone (SEE) habitat restoration (off-channel pond construction; tide gate replacement/modification) in Salmon Creek appears successful at providing overwinter habitat for juvenile salmonids. Juvenile coho moved into the off-channel ponds in Salmon Creek immediately after they were built. More juvenile coho were captured in the ponds the first year post-construction than the previous 7 pre-project years combined. Most years the off-channel ponds were occupied by juvenile salmonids from December-May, but due to high water temperature and salinities and often low DO they were unsuitable for salmonids from June-November. Fish growth could be quite high in the ponds, especially in spring. In the Salmon Creek ponds we recaptured one yearling-plus coho tagged in the ponds during each of the three years of our study with growth rates of 0.79-0.87 mm/day.

**System Effects**: Summary Project Results (2003-2012). NOTE: Compiled results from several Humboldt Bay drainages, including but not limited to Salmon Creek. Juvenile salmonids, especially coho, utilize cool, freshwater tidal portion of stream-estuary ecotone (SEE). Sub yearling coho rear in the stream-ecotone up to eight months. Some may emigrate to salt water as sub yearlings while others rear in the SEE over the winter and emigrate to salt water in early spring. Yearling coho move into the SEE during fall and winter and rear there until the following spring (up to five months). By summer end, sub yearling coho rearing in the SEE are typically 15-20 mm FL longer than coho rearing in stream habitat. Coho rearing in the SEE are larger at every life stage compared to their cohorts rearing in stream habitat. The largest juvenile coho were found in tidal freshwater pond habitat. Growth rates in ponds are higher than in sloughs.

Estuary: Humbolt Bay	Name: Martin Slough Restoration Project			
Type: Replacement		Total Cost:		
<b>Summary</b> : Martin Slough, a tributary of Elk River Slough, is an important fish-bearing tributary of Humboldt Bay near Eureka, CA. In 2011, a 43-acre parcel of riparian bottomlands along the slough was purchased by North Coast Regional Land Trust (NRLT) with goals of restoring riparian and wetlands habitats, improving fish access, reducing upstream flooding, maintaining traditional agricultural production and protecting the land from further development. The Redwood Community Action Agency (RCAA) plan to address these goals includes installation of a state-of-the-art replacement tide gate, excavation of the historic Martin Slough stream channel, reinforcement of a failing levee along Swain Slough, construction of a 4-acre tidal pond complex, improvement of agricultural infrastructure and productivity on 35 acres of pastureland, installation of riparian fencing and planting of native riparian and wetland plants in restored areas. The tide gate was replaced in 2014, but due to budgeting, permitting and infrastructure issues (e.g. lowering of a gas line that crosses the property in 3 places) no further work had been completed as of January 2017. In June 2017, funds were authorized for the habitat restoration work.				
From 2007-2010 California Dept of Fish and Wildlife (CDFW) conducted monthly fish and water quality sampling in the tidal portion of Martin Slough, primarily on Eureka Municipal Golf Course property, to gather pre-restoration data on water quality (WQ) and salmonid use of the slough. After replacement of the old, failing tide gate in 2014, CDFW reinitiated monthly fish and WQ sampling to document effects of replacing the gate on juvenile salmonid use of the slough. Monitoring: Pre and post project monitoring for salmonids in Martin Slough and limited water quality (WQ) data. Likely other physical and biological monitoring upstream of new tide gate by project proponents.				

# Aerial Image (5/26/2016).

**Restoration Metrics**: Number of juvenile salmonids, with a focus on coho.

<b>Monitoring Focus</b> : Biological (salmonids); Water quality: temp, salinity, DO	<b>Study Design</b> Sampled before & after TG replacement. 2013-2015: Monthly sampling at two sites in Martin slough using a 9.1 m X 1.2 m seine net, and a 30.5 m X 1.5 m seine to sample in the off-channel pond. In heavily vegetated areas where effective seining was not possible, minnow traps baited with frozen salmon roe were used at three sites in Martin Slough.
	Field crews anaesthetized, counted, and examined all juvenile salmonids for marks or tags, and documented the life stage of each. Coho were designated "sub-yearling" or "yearling-plus" based on size differences. Yearling-plus coho, steelhead and cutthroat were also designated by development stage: parr (heavy parr marks present), presmolt (faded parr marks; silvery color), smolt (no parr marks visible; black fin edges), or adult. Fork lengths (FL) were measured to the nearest millimeter, weights to nearest 0.1 gram, and scales were collected from the left side of all juvenile salmonids >50 mm. All healthy juvenile salmonids were PIT tagged to gather residency, movement, and growth data while they were in the SEE. Fish already containing tags or marks were measured for FL, weighed, scale sampled on their

	right side, and their mark or tag number recorded.
Parameters: Salmonids	Species Monitored: coho, steelhead, cutthroat

**Project Findings**: During 2007-2010 (pre-restoration) large numbers of juvenile coho reared in Martin Slough, especially in winter-spring. In East Tributary they reared almost exclusively in the winter-spring. Juvenile coho were also captured in Martin Slough and East Tributary during 2011-2014 sampling for invasive Sacramento pikeminnow, along with cutthroat trout, tidewater goby, and a few juvenile steelhead and Chinook. After tide gate replacement, few juvenile salmonids were captured June-Dec 2015 followed by increased catches Jan-May 2016, and few were captured June-Nov 2016 followed by higher numbers in Dec. These patterns are similar to pre-restoration. Higher catches would have been likely in Nov 2016 if not for poor WQ conditions in Martin Slough and the 17th hole pond, probably at least partially caused by the new tide gate being left in a summer low flow setting, allowing little tidal exchange between Martin and Swain sloughs. WQ in Martin Slough improved shortly after the tide gate operation, and respond quickly with appropriate tide gate adjustments to maintain WQ conditions favorable for salmonids.

Growth rates of recaptured PIT tagged juvenile salmonids were quite high in 2015 (0.29-0.61 mm/day) and in 2016 (0.49-0.77 mm/day). Also, based on the increase of monthly mean FL of coho, it appears rearing conditions in Martin Slough were good for salmonids in the winter and spring of 2016, and late Nov 2016-Jan 2017. WQ conditions throughout Martin Slough were much improved Dec 2015-May 2016 over conditions found July to November 2015, and are generally much better for juvenile salmonids from late fall-spring than summer-early fall, similar to pre-restoration. Tide gate replacment has not appreciably improved conditions in Martin Slough over pre-restoration conditions, but has probably prevented them from declining- the new tide gate has preserved pre-restoration conditions that would have radically changed when the old tide gate failed completely. The new tide gate can be operated to precisely control the amount of tidal influence into Martin Slough, allowing managers to provide more stable freshwater habitat for juvenile salmonids.

#### System Effects:

Lessons Learned: "Lesson from 2016-2017 sampling: Abundant October rain increased freshwater flow and juvenile salmonid rearing conditions began to improve throughout Martin Slough. But in November, WQ became poor in mainstem Martin Slough, 17th hole pond, and North Fork while conditions were good to adequate in the East Tributary and Fairway Drive sites. With abundant Oct-Nov rain, better DO conditions were expected in the mainstem and pond. Salinity was <2 ppt at all golf course locations, indicating that the low DO was not the result of remnant trapped brackish water. CDFW noted large numbers of juvenile coho moving into the stream-estuary ecotone (SEE) of nearby Wood and Jacoby creeks, but during Nov 10 sampling of Martin Slough only 14 juvenile coho were captured, all in the East Tributary and Fairway Drive sites and none in the mainstem or 17th hole pond. These results did not fit WQ or fish capture patterns from past years, so on Nov 17 CDFW initiated a meeting with project partners and determined the new Martin Slough tide gate was likely still set for low flow (summer) operation to keep saltwater from reaching the Eureka Municipal Golf Course irrigation pond and may have been limiting water circulation in mainstem Martin Slough and 17th hole pond. The group decided to adjust the tide gate to allow greater tidal exchange between Martin and Swain sloughs. On Nov 18 CDFW collected WQ data and found modest improvement from Nov 10, likely due to continued rain and increased freshwater runoff. On Nov 21 RCAA adjusted the tide gate to increase tidal circulation and on Nov 22 CDFW found further WQ improvement. By the next regularly scheduled WQ surveys on Dec 6 (2016) and January 17 (2017), WQ conditions in Martin Slough were again similar to past years. Also, during CDFW fish sampling on Dec 6 field crews captured ~120 juvenile coho, about 50% of these in the

17th hole pond. It is likely that improved WQ in Martin Slough after tide gate adjustments resulted in large numbers of juvenile coho again using Martin Slough as non-natal rearing habitat. This lesson illustrates the need actively monitor WQ and tide gate operation, and respond quickly with appropriate tide gate adjustments to maintain WQ conditions favorable for salmonids."

From Jan-2017 Eureka Times-Standard article: "Much of our work since 1993 has been grant funded but as the decades click on there's more competition for these grants so we've had to tweak our proposals to meet the needs of the projects and missions of donor agencies."

Estuary: Humbolt Bay	Name: McDaniel Slough (Janes Creek) Tidal Restoration	
Type: Removal (four TGs)		Total Cost: "Million dollar plus"

**Summary**: The McDaniel Slough project removes 4 tide gates, deepens historic slough channels and removes failing or obsolete levees to restore 222 acres of former tidelands and 24.5 acres of freshwater wetlands. The project area was diked and drained in the early 1900's and most of the salt and brackish marsh habitats were converted to other uses. Project objectives: 1) restore a large area of tidal marsh habitat dominated by native vegetation; 2) provide unimpeded access for anadromous fish migration between Humboldt Bay, McDaniel Slough and Janes Creek; 3) create a tidal channel system maximizing estuarine fisheries habitat in large, high-order, sub-tidal channels; 4) provide connectivity of habitats using "eco-levees" with 10-to-1 slopes on bayward side to create gradation between salt marsh/mudflat habitats and uplands; 5) provide connectivity with existing habitats which also include palustrine freshwater, riparian, and brackish wetlands at Arcata Marsh and Wildlife Sanctuary and CDFW's Mad River Slough Wildlife Area; 6) alleviate rural and urban flooding due to tide gate restrictions and chronic channel aggradation; and 7) provide opportunities for public access, recreation and education.

The 2013 McDaniel Slough project created a self-sustaining estuarine tidal marsh system through restoration of natural geomorphic and biologic processes. The project removed tide gates on McDaniel slough to provide access for anadromous fish between Humboldt Bay and Janes Creek. Design features included salt marsh, mudflat, tidal channels, brackish and freshwater habitats and uplands. Excavation to create or enhance brackish and freshwater habitats provided the fill for the levees that were constructed to protect adjacent non-project lands.

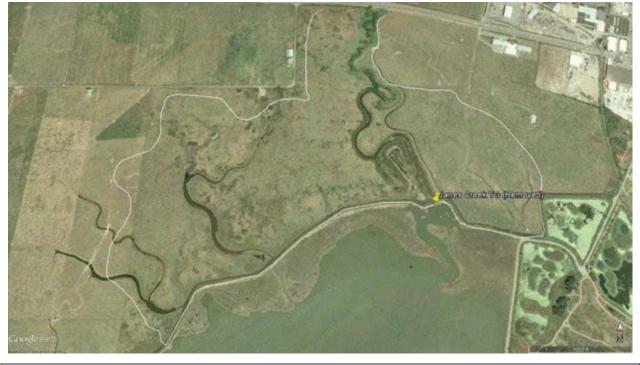

Project Description: Complete tide gate removal and levee setback to re-establish estuarine marsh habitat and allow fish passage into Janes Creek.

Monitoring: Pre and post project monitoring for salmonids in Janes Creek. Likely other physical and biological monitoring in newly established marsh by project proponents.

Aerial Images: Janes Creek tide gate removal – after project (5/26/2016)

Janes Creek before project (6/30/2004):

**Restoration Metrics**: Restore lost hydrologic function and estuarine habitat to 197 acres of Humboldt Bay's former tidelands, improve habitat for 57 acres of adjacent brackish and freshwater wetlands, restore fish passage to coho stream, improve instream habitat, improve water quality

Monitoring Focus: Biological (salmonids)

Study Design: As part of the post-project

Parameters: Salmonids	Species Monitored:
	Pre and post project monitoring for salmonids in Janes Creek. Likely other physical and biological monitoring in newly established marsh by project proponents.
	monitoring efforts, biologists continue [as of spring 2015] to sample for fish species monthly, and monitor vegetation annually for five years.

**Project Findings**: A performance standard for project success included utilization by one or more of the following species: steelhead, coho salmon, coastal cutthroat trout, and/or tidewater goby. Based on 2010-2016 monitoring, the project has met this performance standard. Monitoring resulted in frequent detections of coho, coastal cutthroat trout and tidewater goby.

**System Effects**: "Tidal inundation pushing water upstream during winter storms and high tide events has also helped to kill the invasive reed canary grass, which chokes the stream channel, causes poor water quality, impedes water flow causing flooding, and overall negatively impacts conditions for fish. Golightly said the City of Arcata and the Coastal Program have been at the forefront of battling the invasive plant for years and many who worked on the McDaniel's Slough Restoration project are hopeful that some of the salt water intrusion will benefit the eradication effort. Hydraulic modeling was used to show that the project, in addition to restoring tidal exchange to over 200 hundred acres of former tide lands and anadromy to the system, would also help improve flood flows on the creek." [https://www.fws.gov/FieldNotes/regmap.cfm?arskey=35901]

Mad River Union newspaper article quote: "'McDaniel slough fits into the sea level rise adaptation picture,' Andre said. 'The future salt marsh there will be a huge benefit in terms of buffering.' [Arcata Env. Serv. Director Mark] Andre explained that as sea level rise impacts Arcata, McDaniel slough marsh and the new taller and wider internal levees will help buffer Arcata. The salt marsh plain will slowly add elevation as silt is deposited and plants anchor the material in place. Further, Andre said, salt marshes sequester a tremendous amount of CO2 over time. HSU students are calculating the carbon-binding potential for the project."

### Lessons Learned: https://www.fws.gov/FieldNotes/regmap.cfm?arskey=35901

NOTE: This USFWS "Field Note", which appears intended to educate and inform general audiences, includes an interview with two key project members who share their experiences from the 13-years it took to complete the project. The main lesson seems to be the importance of patience and cooperation among project partners and stakeholders.

	-	monids in Wood Creek and limited water quality

Monitoring: Pre and post project monitoring for salmonids in Wood Creek and limited water quality (WQ) data. Likely other physical and biological monitoring upstream of new tide gate by project proponents.

## Aerial Image (5/26/2016):

Restoration Metrics: Over winter habitat for ju	uv coho
Rearing habitat for juv coho	
Monitoring Focus: Biological (salmonids) Limited water quality data	<b>Study Design</b> : Pre and post project monitoring for salmonids in Wood Creek and limited water quality (WQ) data.
	Sampled fish and water quality intensively in 2010-15. Sampling appears to have started in 2007.
	Starting mid-Oct. 2016 sampled 3 sites in Wood Cr with baited minnow traps and the off-channel pond with minnow traps and beach seine in the Phase 1 area and 5 sites in the Phase 2 restoration area with minnow traps and beach seine. We operated one pair of PIT tag antennas at the tide gate structure at the mouth of Wood Cr and installed 2 sets of paired antennas in the Phase 2 area to detect PIT tagged fish. Collected WQ data during highest daytime tides of the month (~ every 2 weeks) and during fish sampling effort with a YSI Professional Plus handheld WQ meter to describe juvenile salmonid rearing conditions.
	[Paraphrased from Ricker et al. 2014.] The CA Dept of Fish and Wildlife (CDFW) and NOAA Fisheries cooperatively developed the draft

**Project Findings**: [2010 case study] In winter and early spring juvenile coho likely sought out low velocity habitat in Wood Creek when water velocities in mainstem Freshwater Creek Slough were too fast to support many yearling coho. Restoration appears to have met a project goal to increase tidal prism (by removing the tide gate flap) without net loss of over winter freshwater rearing habitat for coho salmon by constructing the pond. The pond appears to replace freshwater habitat lost by the increased presence of brackish water in Wood Creek between Sites 1 and 4.

Allen, S., E. Ojerholm and M. Wallace. 2016. Juvenile salmonid use and restoration assessment of the tidal portions of selected tributaries to Humboldt Bay, California 2013-2015. NOTE: This report has extensive fish and water quality monitoring data for Wood Creek (and several other Humboldt Bay tributaries) but little in the way of interpretation specific to Wood Creek. Some clips: "Typically there is a fall redistribution of coho salmon moving from stream habitat downstream to the SEE. This year's [2013/14, a drought year] observations at...Wood Creek [i.e. few salmonid detections prior to 1st significant rainfall in Feb 2014] illustrate that a large redistribution of juvenile coho salmon occurs with the first large rain and stream flow events of the season regardless of whether they occur in the fall or later in the winter." "This and earlier studies by NSA [CDFW Natural Stock Assessment Program] (Wallace 2006; Wallace and Allen 2007, 2009, 2012, 2015; Wallace et al. 2015) showed that sub-yearling and yearling-plus coho salmon, as well as a wide size range of juvenile steelhead trout routinely reared in the stream-estuary ecotone for months." "Fish growth could be quite high in the ponds, especially in spring. In Wood Creek from Feb-April 2013 we found yearling-plus coho that were tagged and recaptured in the pond had a mean growth rate of 0.40 mm/day while those tagged and recaptured in the main channel of Wood Creek had a mean growth rate of 0.22 mm/day."

**System Effects**: [From 2010 Climate Adaptation and Knowledge Exchange (CAKE) write-up] "The Wood Creek Tidal Marsh Enhancement Project's primary climate change benefit is flood mitigation for the lower Wood Creek/Freshwater Creek area. Anticipated increases in winter precipitation will likely bring increased flooding to local watersheds. Reconnection of Wood Creek to Freshwater Creek

through removal of the tide gate and creation of a more complex wetland channel system will expand the flow capacity of the project area, thereby reducing the velocity and shear potential of flood flows."

### Lessons Learned:

Funders: Private and public partners who granted funding and in-kind assistance:

US Fish & Wildlife Service; The Nature Conservancy; NOAA Fisheries; CA Department of Fish and Game; National Fish & Wildlife Foundation; North American Wetlands Conservation Act; Natural Resources Conservation Service.

**Partners**: Restoration work was completed by Northcoast Regional Land Trust and Redwood Community Action Agency.

<b>Estuary</b> : Various, New South Wales, Australia	Name: Bringing Back the Fish	
Type: Replacement/Modification		Total Cost: \$7,792,058
		Floodgate sites only: \$2,565,965
<ul> <li>Summary: 32 of the 55 native freshwater species in NSW are considered migratory – moving between habitat types. In stream structures act as barriers to fish migration and, therefore, are considered Key Threatening Processes under the Fisheries Management Act 1994 and the Threatened Species Conservation Act 1995. Australian fish are generally poor swimmers and jumpers, making the barrier effect of instream structures even greater. New structures are now required to incorporate fish passage. However, there are many older structures that remain deleterious to fish populations by severely limiting migratory movements. As in many places, floodgates are used to reduce inundation and increase drainage to support agriculture. In this region, however, there is a high prevalence of acid sulphate soils. When these soils are exposed to the air they oxidize and acid is released. The runoff causes acidification (lower pH) in the drainage and downstream waters.</li> <li>In the 1990's I&amp;I NSW began auditing fish passage barriers in coastal NSW and prioritized the structures for remediation (modification, removal, or fishway installation). The Bringing Back the Fish Project aimed to 'enhance aquatic ecosystems across the five NSW coastal Catchment Management Authority regions by restoring stream connectivity and rehabilitating key aquatic habitats' to improve fish passage and habitat quality. Over a three year period the project removed, improved, or bypassed weirs and floodgates, redesigned or removed road crossings, and restored habitat through inundation and revegetation.</li> <li>Throughout the process I&amp;I NSW engaged the commercial and recreational fisheries, local governments, State agencies, community organizations, and landowners. Steering committees were formed in each region that included members of these groups. The committees provided regional perspective, identified overlooked barriers, and assisted in project prioritization and approval.</li> <li>Projects could only move forward with sufficient funding an</li></ul>		
Restoration Metrics:		
Monitoring Focus: The monitori determine of ecosystem process native stock integrity, primarily f been restored.	ses related to	<b>Study Design</b> : Rapid evaluation of three priority sites (1 weir, 1 double box culvert, and 1 auto-tidal floodgate). Monitoring was described in a stand-alone report, which I have not been able to locate.

Parameters:	Species Monitored:

**Project Findings**: Ten (10) weirs were improved: 4 - removed, 4 - fishway installed, 2 – structural design changes, 611 kms opened. Twenty (22) road crossings were improved: 9 – removed, 8 – fishway installed, 5 – low-flow box culverts installed, 453 kms opened, 50 ha habitat improved. Fifty-four (54) floodgates improved: 54 traditional flap gates were replaced or modified with structures allowing controlled upstream flow, 123 kms opened, 1,694 ha habitat improved. Eight (8) habitat sites were restored, resulting in 48 kms opened, 163 ha habitat improved. Restoration actions included culvert installation, bank stabilization to assist mangrove recruitment, and installation of seagrass friendly moorings. Projects were completed in 5 regions but 65% of the sites were in one region. The size of the region and the land use regulations within the area determined the number of floodgates requiring remediation. The average cost per project was: weir - \$85,000, road crossing - \$100,000, floodgate - \$35,000.

#### System Effects:

**Lessons Learned**: Most of the projects completed were in the NRCMA region. This region has more than twice the number of floodgates than the other regions. However, the disparity in projects completed is likely due to the existence of prior road crossing and floodgate programs in that area, which meant that partnerships with structural stakeholders (i.e. landowners) were already developed. Aquatic restoration requires specialized contractors. Rock-ramp fishways require specific construction expertise and many contractors are not qualified to install them. Despite the large number of projects completed, there are more than 300 high priority barriers remaining in coastal NSW. The impact of remaining barriers is a continuing threat to migratory fish populations.

**Funders**: Bringing Back the Fish funding accounted for 30% of the project cost. The Australian government provided approximately 25% of the funds. The remaining balance was comprised of inkind (cash and non-cash) contributions from local councils, water authorities, landholders, and State government sources.

**Partners**: Catchment Management Authorities; Regional Steering Committees; 34 local governments; private land owners, Office of Water; Land Property Management Agency; Department of Environment, Climate Change, and Water; National Parks and Wildlife Service; Soil Conservation Services; State Water Corporation, Fishway Consulting Services; Manly Hydraulics Lab; Department of Commerce; MidCoast Water; Streamline River Restoration; Local Aboriginal Land Councils; Landcare / RiverCare; Recreational Fishermen; Council of Freshwater Anglers; Commercial Fishermen; Wetland Care Australia; NSW Recreational Fishing Trust; and the NSW Environmental Trust, and the Federal government of Australia.

**Project Documentation**: Industry and Investment NSW (2009). Bringing back the fish – Improving Passage and Aquatic Habitat in Coastal NSW. Final Report to the Southern Rivers Catchment Management Authority. Industry and Investment NSW, Cronulla, NSW.
